                                                                                          q1,
                                                                                          q2,
                                                                                          q=1,
                                                                                          side='right')
```

Bases: `sage.misc.fast_methods.WithEqualityById`, `sage.structure.sage_object.SageObject`

A representation of an (affine) Hecke algebra given by the action of the T generators

Let F_i be a family of operators implementing an action of the operators $(T_i)_{i \in I}$ of the Hecke algebra on some vector space `domain`, given by their action on the basis of `domain`. This constructs the family of operators $(F_w)_{w \in W}$ describing the action of all elements of the basis $(T_w)_{w \in W}$ of the Hecke algebra. This is achieved by linearity on the first argument, and applying recursively the F_i along a reduced word for $w = s_{i_1} \cdots s_{i_k}$:

$$F_w(x) = F_{i_k} \circ \cdots \circ F_{i_1}(x).$$

INPUT:

- `domain` – a vector space
- `f` – a function `f(l, i)` taking a basis element l of `domain` and an index i , and returning F_i
- `cartan_type` – The Cartan type of the Hecke algebra
- `q1, q2` – The eigenvalues of the generators T of the Hecke algebra
- `side` – “left” or “right” (default: “right”) whether this is a left or right representation

EXAMPLES:

```
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(['A', 3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2); H
A representation of the (q1, q2)-Hecke algebra of type ['A', 3, 1]
on Algebra of Weyl Group of type ['A', 3]
(as a matrix group acting on the ambient space)
over Rational Field
```

Among other things, it implements the T_w operators, their inverses and compositions thereof:

```
sage: H.Tw((1,2))
Generic endomorphism of Algebra of Weyl Group of type ['A', 3]
(as a matrix group acting on the ambient space) over Rational Field
```

and the Cherednik operators Y^{λ^\vee} :

```
sage: H.Y()
Lazy family (...)_{i in Coroot lattice of the Root system of type ['A', 3, 1]}
```

REFERENCES:

- [HST2008]

Ti_inverse_on_basis(x, i)

The T_i^{-1} operators, on basis elements

INPUT:

- x – the index of a basis element
- i – the index of a generator

EXAMPLES:

```
sage: W = WeylGroup("A3")
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element()
sage: rho.Ti_inverse_on_basis(w, 1)
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
```

Ti_on_basis(x, i)

The T_i operators, on basis elements.

INPUT:

- x – the index of a basis element
- i – the index of a generator

EXAMPLES:

```
sage: W = WeylGroup("A3")
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element()
sage: rho.Ti_on_basis(w, 1)
q1*1231
```

Tw($word, signs=None, scalar=None$)

Return T_w .

INPUT:

- $word$ – a word i_1, \dots, i_k for some element w of the Weyl group. See [straighten_word\(\)](#) for how this word can be specified.
- $signs$ – a list $\epsilon_1, \dots, \epsilon_k$ of the same length as $word$ with $\epsilon_i = \pm 1$ or $None$ for $1, \dots, 1$ (default: $None$)
- $scalar$ – an element c of the base ring or $None$ for 1 (default: $None$)

OUTPUT:

a module morphism implementing

$$T_w = T_{i_k} \circ \dots \circ T_{i_1}$$

in left action notation; that is T_{i_1} is applied first, then T_{i_2} , etc.

More generally, if $scalar$ or $signs$ is specified, the morphism implements

$$cT_{i_k}^{\epsilon_k} \circ \dots \circ T_{i_1}^{\epsilon_1}.$$

EXAMPLES:

```

sage: W = WeylGroup("A3")
sage: W.element_class._repr_ = lambda x: ('e' if not x.reduced_word()
....:     else "".join(str(i) for i in x.reduced_word()))
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: x = KW.an_element(); x
123 + 3*32 + 2*3 + e

sage: T = KW.demazure_lusztig_operators(q1,q2)
sage: T12 = T.Tw( (1,2) )
sage: T12(KW.one())
q1^2*12

```

This is $T_2 \circ T_1$:

```

sage: T[2](T[1](KW.one()))
q1^2*12
sage: T[1](T[2](KW.one()))
q1^2*21
sage: T12(x) == T[2](T[1](x))
True

```

Now with signs and scalar coefficient we construct $3T_2 \circ T_1^{-1}$:

```

sage: phi = T.Tw((1,2), (-1,1), 3)
sage: phi(KW.one())
((-3*q1)/q2)*12 + ((3*q1+3*q2)/q2)*2
sage: phi(T[1](x)) == 3*T[2](x)
True

```

For debugging purposes, one can recover the input data:

```

sage: phi.word
(1, 2)
sage: phi.signs
(-1, 1)
sage: phi.scalar
3

```

Tw_inverse(word)

Return T_w^{-1} .

This is essentially a shorthand for `Tw()` with all minus signs.

Todo: Add an example where $T_i \neq T_i^{-1}$

EXAMPLES:

```

sage: W = WeylGroup(["A",3])
sage: W.element_class._repr_ = lambda x: "".join(str(i) for i in x.reduced_
↪word())
sage: KW = W.algebra(QQ)

```

(continues on next page)

(continued from previous page)

```

sage: rho = KW.demazure_lusztig_operators(1, -1)
sage: x = KW.monomial(W.an_element()); x
123
sage: word = [1,2]
sage: rho.Tw(word)(x)
12312
sage: rho.Tw_inverse(word)(x)
12321

sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1, q2)
sage: x = KW.monomial(W.an_element()); x
123
sage: rho.Tw_inverse(word)(x)
1/q2^2*12321 + ((-q1-q2)/(q1*q2^2))*1231 + ((-q1-q2)/(q1*q2^2))*1232 + ((q1^
↪ 2+2*q1*q2+q2^2)/(q1^2*q2^2))*123
sage: rho.Tw(word)(_)
123

```

Y(*base_ring=Integer Ring*)

Return the Cherednik operators Y for this representation of an affine Hecke algebra.

INPUT:

- `self` – a representation of an affine Hecke algebra
- `base_ring` – the base ring of the coroot lattice

This is a family of operators indexed by the coroot lattice for this Cartan type. In practice this is currently indexed instead by the affine coroot lattice, even if this indexing is not one to one, in order to allow for $Y[\alpha_0^\vee]$.

EXAMPLES:

```

sage: W = WeylGroup(["A",3])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: Y = rho.Y(); Y
Lazy family (...(i))_{i in Coroot lattice of the Root system of type ['A', 3,
↪ 1]}

```

Y_eigenvectors()

Return the family of eigenvectors for the Cherednik operators Y of this representation of an affine Hecke algebra.

INPUT:

- `self` – a representation of an affine Hecke algebra
- `base_ring` – the base ring of the coroot lattice

EXAMPLES:

```

sage: W = WeylGroup(["B", 2])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = rho.Y_eigenvectors()
sage: E.keys()
Weyl Group of type ['B', 2] (as a matrix group acting on the ambient space)
sage: w0 = W.long_element()

```

To set the recurrence up properly, one often needs to customize the *CherednikOperatorsEigenvectors.affine_lift()* and *CherednikOperatorsEigenvectors.affine_retract()* methods. This would usually be done by subclassing *CherednikOperatorsEigenvectors*; here we just override the methods directly.

In this particular case, we multiply by w_0 to take into account that w_0 is the seed for the recursion:

```

sage: E.affine_lift = w0._mul_
sage: E.affine_retract = w0._mul_

sage: E[w0]
2121
sage: E.eigenvalues(E[w0])
[q2^2/q1^2, q1/(-q2), q1/(-q2)]

```

This step is taken care of automatically if one instead calls the specialization `sage.coxeter_groups.CoxeterGroups.Algebras.demazure_lusztig_eigenvectors()`.

Now we can compute all eigenvectors:

```

sage: [E[w] for w in W]
[2121 - 121 - 212 + 12 + 21 - 1 - 2 + ,
 -2121 + 212,
 (q2/(q1-q2))*2121 + (q2/(-q1+q2))*121 + (q2/(-q1+q2))*212 - 12 + ((-q2)/(-
-q1+q2))*21 + 2,
 ((-q2^2)/(-q1^2+q1*q2-q2^2))*2121 - 121 + (q2^2/(-q1^2+q1*q2-q2^2))*212 + 21,
 ((-q1^2-q2^2)/(q1^2-q1*q2+q2^2))*2121 + ((-q1^2-q2^2)/(-q1^2+q1*q2-q2^2))*121,
 (-q2^2/(-q1^2+q1*q2-q2^2))*212 + (q2^2/(-q1^2+q1*q2-q2^2))*12 - 21 + 1,
 2121,
 (q2/(-q1+q2))*2121 + ((-q2)/(-q1+q2))*121 - 212 + 12,
 -2121 + 121]

```

Y_lambdacheck(*lambdacheck*)

Return the Cherednik operators Y^{λ^\vee} for this representation of an affine Hecke algebra.

INPUT:

- `lambdacheck` – an element of the coroot lattice for this Cartan type

EXAMPLES:

```

sage: W = WeylGroup(["B", 2])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()

```

(continues on next page)

(continued from previous page)

```
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
```

We take q_2 and q_1 as eigenvalues to match with the notations of [HST2008]

```
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: L = rho.Y().keys()
sage: alpha = L.simple_roots()
sage: Y0 = rho.Y_lambdacheck(alpha[0])
sage: Y1 = rho.Y_lambdacheck(alpha[1])
sage: Y2 = rho.Y_lambdacheck(alpha[2])

sage: x = KW.monomial(W.an_element()); x
12
sage: Y1(x)
((-q1^2-2*q1*q2-q2^2)/(-q2^2))*2121 + ((q1^3+q1^2*q2+q1*q2^2+q2^3)/(-q1*q2^2-
-q2))*121 + ((q1^2+q1*q2)/(-q2^2))*212 + ((-q1^2)/(-q2^2))*12
sage: Y2(x)
((-q1^4-q1^3*q2-q1*q2^3-q2^4)/(-q1^3*q2))*2121 + ((q1^3+q1^2*q2+q1*q2^2+q2^3)/(-
-q1^2*q2))*121 + (q2^3/(-q1^3))*12
sage: Y1(Y2(x))
((q1*q2+q2^2)/q1^2)*212 + ((-q2)/q1)*12
sage: Y2(Y1(x))
((q1*q2+q2^2)/q1^2)*212 + ((-q2)/q1)*12
```

The Y operators commute:

```
sage: Y0(Y1(x)) - Y1(Y0(x))
0
sage: Y2(Y1(x)) - Y1(Y2(x))
0
```

In the classical root lattice, $\alpha_0 + \alpha_1 + \alpha_2 = 0$:

```
sage: Y0(Y1(Y2(x)))
12
```

Lemma 7.2 of [HST2008]:

```
sage: w0 = KW.monomial(W.long_element())
sage: rho.Tw(0)(w0)
q2
sage: rho.Tw_inverse(1)(w0)
1/q2^212
sage: rho.Tw_inverse(2)(w0)
1/q2^121
```

Lemma 7.5 of [HST2008]:

```
sage: Y0(w0)
q1^2/q2^2*2121
sage: Y1(w0)
(q2/(-q1))*2121
```

(continues on next page)

(continued from previous page)

```
sage: Y2(w0)
(q2/(-q1))*2121
```

Todo: Add more tests

Add tests in type BC affine where the null coroot δ^\vee can have non trivial coefficient in term of α_0

See also:

- [HST2008] for the formula in terms of q_1, q_2

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```
sage: from sage.combinat.root_system.hecke_algebra_representation import _
↪ HeckeAlgebraRepresentation
sage: KW = SymmetricGroup(3).algebra(QQ)
sage: action = lambda x,i: KW.monomial(x.apply_simple_reflection(i, side="right
↪ "))
sage: H = HeckeAlgebraRepresentation(KW, action, CartanType(["A",2]), 1, -1)
sage: H.cartan_type()
['A', 2]

sage: H = WeylGroup(["A",3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.cartan_type()
['A', 3, 1]
```

domain()

Return the domain of self.

EXAMPLES:

```
sage: H = WeylGroup(["A",3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.domain()
Algebra of Weyl Group of type ['A', 3] (as a matrix group acting on the ambient_
↪ space) over Rational Field
```

on_basis(x , $word$, $signs=None$, $scalar=None$)

Action of product of T_i and T_i^{-1} on x .

INPUT:

- x – the index of a basis element
- $word$ – word of indices of generators
- $signs$ – (default: None) sequence of signs of same length as $word$; determines which operators are supposed to be taken as inverses.
- $scalar$ – (default: None) scalar to multiply the answer by

EXAMPLES:

```

sage: from sage.combinat.root_system.hecke_algebra_representation import_
↳HeckeAlgebraRepresentation
sage: W = SymmetricGroup(3)
sage: domain = W.algebra(QQ)
sage: action = lambda x,i: domain.monomial(x.apply_simple_reflection(i, side=
↳"right"))
sage: rho = HeckeAlgebraRepresentation(domain, action, CartanType(["A",2]), 1, -
↳1)

sage: rho.on_basis(W.one(), (1,2,1))
(1,3)

sage: word = (1,2)
sage: u = W.from_reduced_word(word)
sage: for w in W: assert rho.on_basis(w, word) == domain.monomial(w*u)

```

The next example tests the signs:

```

sage: W = WeylGroup("A3")
sage: W.element_class._repr_ = lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element(); w
123
sage: rho.on_basis(w, (1,), signs=(-1,))
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
sage: rho.on_basis(w, (1,), signs=( 1,))
q1*1231
sage: rho.on_basis(w, (1,1), signs=(1,-1))
123
sage: rho.on_basis(w, (1,1), signs=(-1,1))
123

```

parameters(*i*)

Return q_1, q_2 such that $(T_i - q_1)(T_i - q_2) = 0$.

EXAMPLES:

```

sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(["A",3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2)
sage: H.parameters(1)
(q1, q2)

sage: H = KW.demazure_lusztig_operators(1,-1)
sage: H.parameters(1)
(1, -1)

```

Todo: At this point, this method is constant. It's meant as a starting point for implementing parameters

depending on the node i of the Dynkin diagram.

straighten_word(*word*)

Return a tuple of indices of generators after some straightening.

INPUT:

- *word* – a list/tuple of indices of generators, the index of a generator, or an object with a reduced word method

OUTPUT: a tuple of indices of generators

EXAMPLES:

```
sage: W = WeylGroup(["A", 3])
sage: H = W.algebra(QQ).demazure_lusztig_operators(-1, 1)
sage: H.straighten_word(1)
(1,)
sage: H.straighten_word((2, 1))
(2, 1)
sage: H.straighten_word([2, 1])
(2, 1)
sage: H.straighten_word(W.an_element())
(1, 2, 3)
```

5.1.228 Integrable Representations of Affine Lie Algebras

class `sage.combinat.root_system.integrable_representations.IntegrableRepresentation`(*Lam*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.category_object.CategoryObject`

An irreducible integrable highest weight representation of an affine Lie algebra.

INPUT:

- *Lam* – a dominant weight in an extended weight lattice of affine type

REFERENCES:

- [Ka1990]

If Λ is a dominant integral weight for an affine root system, there exists a unique integrable representation $V = V_\Lambda$ of highest weight Λ . If μ is another weight, let $m(\mu)$ denote the multiplicity of the weight μ in this representation. The set $\text{supp}(V)$ of μ such that $m(\mu) > 0$ is contained in the paraboloid

$$(\Lambda + \rho | \Lambda + \rho) - (\mu + \rho | \mu + \rho) \geq 0$$

where $(|)$ is the invariant inner product on the weight lattice and ρ is the Weyl vector. Moreover if $m(\mu) > 0$ then $\mu \in \text{supp}(V)$ differs from Λ by an element of the root lattice ([Ka1990], Propositions 11.3 and 11.4).

Let δ be the nullroot, which is the lowest positive imaginary root. Then by [Ka1990], Proposition 11.3 or Corollary 11.9, for fixed μ the function $m(\mu - k\delta)$ is a monotone increasing function of k . It is useful to take μ to be such that this function is nonzero if and only if $k \geq 0$. Therefore we make the following definition. If μ is such that $m(\mu) \neq 0$ but $m(\mu + \delta) = 0$ then μ is called *maximal*.

Since δ is fixed under the action of the affine Weyl group, and since the weight multiplicities are Weyl group invariant, the function $k \mapsto m(\mu - k\delta)$ is unchanged if μ is replaced by an equivalent weight. Therefore in tabulating these functions, we may assume that μ is dominant. There are only a finite number of dominant maximal weights.

Since every nonzero weight multiplicity appears in the string $\mu - k\delta$ for one of the finite number of dominant maximal weights μ , it is important to be able to compute these. We may do this as follows.

EXAMPLES:

```
sage: Lambda = RootSystem(['A',3,1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: IntegrableRepresentation(Lambda[1]+Lambda[2]+Lambda[3]).print_strings()
2*Lambda[0] + Lambda[2]: 4 31 161 665 2380 7658 22721 63120 166085 417295 1007601_
↳2349655
Lambda[0] + 2*Lambda[1]: 2 18 99 430 1593 5274 16005 45324 121200 308829 754884_
↳1779570
Lambda[0] + 2*Lambda[3]: 2 18 99 430 1593 5274 16005 45324 121200 308829 754884_

Lambda[1] + Lambda[2] + Lambda[3]: 1 10 60 274 1056 3601 11199 32354 88009 227555_
↳563390 1343178
3*Lambda[2] - delta: 3 21 107 450 1638 5367 16194 45687 121876 310056 757056 1783324
sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: IntegrableRepresentation(Lambda[0]+Lambda[1]).print_strings()
↳
↳ # long time
Lambda[0] + Lambda[1]: 1 10 62 293 1165 4097 13120 38997 109036 289575 735870_
↳1799620
Lambda[3] + Lambda[4] - delta: 3 25 136 590 2205 7391 22780 65613 178660 463842_
↳1155717 2777795
```

In this example, we construct the extended weight lattice of Cartan type $A_3^{(1)}$, then define `Lambda` to be the fundamental weights $(\Lambda_i)_{i \in I}$. We find there are 5 maximal dominant weights in irreducible representation of highest weight $\Lambda_1 + \Lambda_2 + \Lambda_3$, and we determine their strings.

It was shown in [KacPeterson] that each string is the set of Fourier coefficients of a modular form.

Every weight μ such that the weight multiplicity $m(\mu)$ is nonzero has the form

$$\Lambda - n_0\alpha_0 - n_1\alpha_1 - \dots,$$

where the n_i are nonnegative integers. This is represented internally as a tuple (n_0, n_1, n_2, \dots) . If you want an individual multiplicity you use the method `m()` and supply it with this tuple:

```
sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(2*Lambda[0]); V
Integrable representation of ['C', 2, 1] with highest weight 2*Lambda[0]
sage: V.m((3,5,3))
18
```

The `IntegrableRepresentation` class has methods `to_weight()` and `from_weight()` to convert between this internal representation and the weight lattice:

```
sage: delta = V.weight_lattice().null_root()
sage: V.to_weight((4,3,2))
-3*Lambda[0] + 6*Lambda[1] - Lambda[2] - 4*delta
sage: V.from_weight(-3*Lambda[0] + 6*Lambda[1] - Lambda[2] - 4*delta)
(4, 3, 2)
```

To get more values, use the depth parameter:

```
sage: L0 = RootSystem(["A",1,1]).weight_lattice(extended=true).fundamental_
↳weight(0); L0
Lambda[0]
sage: IntegrableRepresentation(4*L0).print_strings(depth=20)
4*Lambda[0]: 1 1 3 6 13 23 44 75 131 215 354 561 889 1368 2097 3153 4712 6936 10151_
↳14677
2*Lambda[0] + 2*Lambda[1] - delta: 1 2 5 10 20 36 66 112 190 310 501 788 1230 1880_
↳2850 4256 6303 9222 13396 19262
4*Lambda[1] - 2*delta: 1 2 6 11 23 41 75 126 215 347 561 878 1368 2082 3153 4690_
↳6936 10121 14677 21055
```

An example in type $C_2^{(1)}$:

```
sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings() # long time
2*Lambda[0]: 1 2 9 26 77 194 477 1084 2387 5010 10227 20198
Lambda[0] + Lambda[2] - delta: 1 5 18 55 149 372 872 1941 4141 8523 17005 33019
2*Lambda[1] - delta: 1 4 15 44 122 304 721 1612 3469 7176 14414 28124
2*Lambda[2] - 2*delta: 2 7 26 72 194 467 1084 2367 5010 10191 20198 38907
```

Examples for twisted affine types:

```
sage: Lambda = RootSystem(["A",2,2]).weight_lattice(extended=True).fundamental_
↳weights()
sage: IntegrableRepresentation(Lambda[0]).strings()
{Lambda[0]: [1, 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56]}
sage: Lambda = RootSystem(['G',2,1]).dual.weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(Lambda[0]+Lambda[1]+Lambda[2])
sage: V.print_strings() # long time

```

branch(*i=None, weyl_character_ring=None, sequence=None, depth=5*)

Return the branching rule on `self`.

Removing any node from the extended Dynkin diagram of the affine Lie algebra results in the Dynkin diagram of a classical Lie algebra, which is therefore a Lie subalgebra. For example removing the 0 node from the Dynkin diagram of type $[X, r, 1]$ produces the classical Dynkin diagram of $[X, r]$.

Thus for each i in the index set, we may restrict `self` to the corresponding classical subalgebra. Of course `self` is an infinite dimensional representation, but each weight μ is assigned a grading by the number of times the simple root α_i appears in $\Lambda - \mu$. Thus the branched representation is graded and we get sequence of finite-dimensional representations which this method is able to compute.

OPTIONAL:

- `i` – (default: 0) an element of the index set
- `weyl_character_ring` – a `WeylCharacterRing`
- `sequence` – a dictionary
- `depth` – (default: 5) an upper bound for k determining how many terms to give

In the default case where $i = 0$, you do not need to specify anything else, though you may want to increase the depth if you need more terms.

EXAMPLES:

```

sage: Lambda = RootSystem(['A', 2, 1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: b = V.branch(); b
[A2(0,0),
 A2(1,1),
 A2(0,0) + 2*A2(1,1) + A2(2,2),
 2*A2(0,0) + 2*A2(0,3) + 4*A2(1,1) + 2*A2(3,0) + 2*A2(2,2),
 4*A2(0,0) + 3*A2(0,3) + 10*A2(1,1) + 3*A2(3,0) + A2(1,4) + 6*A2(2,2) + A2(4,1),
 6*A2(0,0) + 9*A2(0,3) + 20*A2(1,1) + 9*A2(3,0) + 3*A2(1,4) + 12*A2(2,2) +
↳3*A2(4,1) + A2(3,3)]

```

If the parameter `weyl_character_ring` is omitted, the ring may be recovered as the parent of one of the branched coefficients:

```

sage: A2 = b[0].parent(); A2
The Weyl Character Ring of Type A2 with Integer Ring coefficients

```

If i is not zero then you should specify the `WeylCharacterRing` that you are branching to. This is determined by the Dynkin diagram:

```

sage: Lambda = RootSystem(['B', 3, 1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type().dynkin_diagram()
  0 0
  |
  |
0---0=>=0
1  2  3
B3~

```

In this example, we observe that removing the $i = 2$ node from the Dynkin diagram produces a reducible diagram of type $A1xA1xA1$. Thus we have a branching to $\mathfrak{sl}(2) \times \mathfrak{sl}(2) \times \mathfrak{sl}(2)$:

```

sage: A1xA1xA1 = WeylCharacterRing("A1xA1xA1", style="coroots")
sage: V.branch(i=2, weyl_character_ring=A1xA1xA1)
[A1xA1xA1(1, 0, 0),
 A1xA1xA1(0, 1, 2),
 A1xA1xA1(1, 0, 0) + A1xA1xA1(1, 2, 0) + A1xA1xA1(1, 0, 2),
 A1xA1xA1(2, 1, 2) + A1xA1xA1(0, 1, 0) + 2*A1xA1xA1(0, 1, 2),
 3*A1xA1xA1(1, 0, 0) + 2*A1xA1xA1(1, 2, 0) + A1xA1xA1(1, 2, 2) + 2*A1xA1xA1(1, 0, 2) +
↳A1xA1xA1(1, 0, 4) + A1xA1xA1(3, 0, 0),
 A1xA1xA1(2, 1, 0) + 3*A1xA1xA1(2, 1, 2) + 2*A1xA1xA1(0, 1, 0) + 5*A1xA1xA1(0, 1, 2) +
↳A1xA1xA1(0, 1, 4) + A1xA1xA1(0, 3, 2)]

```

If the nodes of the two Dynkin diagrams are not in the same order, you must specify an additional parameter, sequence which gives a dictionary to the affine Dynkin diagram to the classical one.

EXAMPLES:

```

sage: Lambda = RootSystem(['F', 4, 1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type().dynkin_diagram()
0---0---0=>=0---0
0  1  2  3  4
F4~
sage: A1xC3=WeylCharacterRing("A1xC3", style="coroots")
sage: A1xC3.dynkin_diagram()
0
1
0---0=<=0
2  3  4
A1xC3

```

Observe that removing the $i = 1$ node from the $F4\sim$ Dynkin diagram gives the $A1xC3$ diagram, but the roots are in a different order. The nodes 0, 2, 3, 4 of $F4\sim$ correspond to 1, 4, 3, 2 of $A1xC3$ and so we encode this in a dictionary:

```

sage: V.branch(i=1, weyl_character_ring=A1xC3, sequence={0:1, 2:4, 3:3, 4:2}) # long_
↳time
[A1xC3(1, 0, 0, 0),
 A1xC3(0, 0, 0, 1),
 A1xC3(1, 0, 0, 0) + A1xC3(1, 2, 0, 0),

```

(continues on next page)

(continued from previous page)

```

A1xC3(2,0,0,1) + A1xC3(0,0,0,1) + A1xC3(0,1,1,0),
2*A1xC3(1,0,0,0) + A1xC3(1,0,1,0) + 2*A1xC3(1,2,0,0) + A1xC3(1,0,2,0) +
↪A1xC3(3,0,0,0),
2*A1xC3(2,0,0,1) + A1xC3(2,1,1,0) + A1xC3(0,1,0,0) + 3*A1xC3(0,0,0,1) +
↪2*A1xC3(0,1,1,0) + A1xC3(0,2,0,1)]

```

The branch method gives a way of computing the graded dimension of the integrable representation:

```

sage: Lambda = RootSystem("A1~").weight_lattice(extended=true).fundamental_
↪weights()
sage: V=IntegrableRepresentation(Lambda[0])
sage: r = [x.degree() for x in V.branch(depth=15)]; r
[1, 3, 4, 7, 13, 19, 29, 43, 62, 90, 126, 174, 239, 325, 435, 580]
sage: oeis(r) # optional_
↪-- internet
0: A029552: Expansion of phi(x) / f(-x) in powers of x where phi(), f() are_
↪Ramanujan theta functions.

```

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```

sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_
↪weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type()
['F', 4, 1]

```

coxeter_number()

Return the Coxeter number of the Cartan type of self.

The Coxeter number is defined in [Ka1990] Chapter 6, and commonly denoted h .

EXAMPLES:

```

sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_
↪weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.coxeter_number()
12

```

dominant_maximal_weights()

Return the dominant maximal weights of self.

A weight μ is *maximal* if it has nonzero multiplicity but $\mu + \delta$ has multiplicity zero. There are a finite number of dominant maximal weights. Indeed, [Ka1990] Proposition 12.6 shows that the dominant maximal weights are in bijection with the classical weights in $k \cdot F$ where F is the fundamental alcove and k is the level. The construction used in this method is based on that Proposition.

EXAMPLES:

```

sage: Lambda = RootSystem(['C',3,1]).weight_lattice(extended=true).fundamental_
↪weights()
sage: IntegrableRepresentation(2*Lambda[0]).dominant_maximal_weights()

```

(continues on next page)

(continued from previous page)

```
(2*Lambda[0],
 Lambda[0] + Lambda[2] - delta,
 2*Lambda[1] - delta,
 Lambda[1] + Lambda[3] - 2*delta,
 2*Lambda[2] - 2*delta,
 2*Lambda[3] - 3*delta)
```

dual_coxeter_number()

Return the dual Coxeter number of the Cartan type of `self`.

The dual Coxeter number is defined in [Ka1990] Chapter 6, and commonly denoted h^\vee .

EXAMPLES:

```
sage: Lambda = RootSystem(['F', 4, 1]).weight_lattice(extended=true).fundamental_
↪weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.dual_coxeter_number()
9
```

from_weight(mu)

Return the tuple (n_0, n_1, \dots) such that `mu` equals $\Lambda - \sum_{i \in I} n_i \alpha_i$ in `self`, where Λ is the highest weight of `self`.

EXAMPLES:

```
sage: Lambda = RootSystem(['A', 2, 1]).weight_lattice(extended=true).fundamental_
↪weights()
sage: V = IntegrableRepresentation(2*Lambda[2])
sage: V.to_weight((1, 0, 0))
-2*Lambda[0] + Lambda[1] + 3*Lambda[2] - delta
sage: delta = V.weight_lattice().null_root()
sage: V.from_weight(-2*Lambda[0] + Lambda[1] + 3*Lambda[2] - delta)
(1, 0, 0)
```

highest_weight()

Returns the highest weight of `self`.

EXAMPLES:

```
sage: Lambda = RootSystem(['D', 4, 1]).weight_lattice(extended=true).fundamental_
↪weights()
sage: IntegrableRepresentation(Lambda[0]+2*Lambda[2]).highest_weight()
Lambda[0] + 2*Lambda[2]
```

level()

Return the level of `self`.

The level of a highest weight representation V_Λ is defined as $(\Lambda|\delta)$ See [Ka1990] section 12.4.

EXAMPLES:

```
sage: Lambda = RootSystem(['G', 2, 1]).weight_lattice(extended=true).fundamental_
↪weights()
sage: [IntegrableRepresentation(Lambda[i]).level() for i in [0, 1, 2]]
[1, 1, 2]
```

m(*n*)Return the multiplicity of the weight μ in `self`, where $\mu = \Lambda - \sum_i n_i \alpha_i$.

INPUT:

- `n` – a tuple representing a weight μ .

EXAMPLES:

```

sage: Lambda = RootSystem(['E', 6, 1]).weight_lattice(extended=true).fundamental_
      ↪weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: u = V.highest_weight() - V.weight_lattice().null_root()
sage: V.from_weight(u)
(1, 1, 2, 2, 3, 2, 1)
sage: V.m(V.from_weight(u))
6

```

modular_characteristic(*mu=None*)Return the modular characteristic of `self`.

The modular characteristic is a rational number introduced by Kac and Peterson [KacPeterson], required to interpret the string functions as Fourier coefficients of modular forms. See [Ka1990] Section 12.7. Let k be the level, and let h^\vee be the dual Coxeter number. Then

$$m_\Lambda = \frac{|\Lambda + \rho|^2}{2(k + h^\vee)} - \frac{|\rho|^2}{2h^\vee}$$

If μ is a weight, then

$$m_{\Lambda, \mu} = m_\Lambda - \frac{|\mu|^2}{2k}.$$

OPTIONAL:

- `mu` – a weight; or alternatively:
- `n` – a tuple representing a weight μ .

If no optional parameter is specified, this returns m_Λ . If `mu` is specified, it returns $m_{\Lambda, \mu}$. You may use the tuple `n` to specify μ . If you do this, μ is $\Lambda - \sum_i n_i \alpha_i$.

EXAMPLES:

```

sage: Lambda = RootSystem(['A', 1, 1]).weight_lattice(extended=true).fundamental_
      ↪weights()
sage: V = IntegrableRepresentation(3*Lambda[0]+2*Lambda[1])
sage: [V.modular_characteristic(x) for x in V.dominant_maximal_weights()]
[11/56, -1/280, 111/280]

```

mult(*mu*)Return the weight multiplicity of `mu`.

INPUT:

- `mu` – an element of the weight lattice

EXAMPLES:

```

sage: L = RootSystem("B3~").weight_lattice(extended=True)
sage: Lambda = L.fundamental_weights()
sage: delta = L.null_root()
sage: W = L.weyl_group(prefix="s")
sage: [s0,s1,s2,s3] = W.simple_reflections()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.mult(Lambda[2]-2*delta)
3
sage: V.mult(Lambda[2]-Lambda[1])
0
sage: weights = [w.action(Lambda[1]-4*delta) for w in [s1,s2,s0*s1*s2*s3]]
sage: weights
[-Lambda[1] + Lambda[2] - 4*delta,
Lambda[1] - 4*delta,
-Lambda[1] + Lambda[2] - 4*delta]
sage: [V.mult(mu) for mu in weights]
[35, 35, 35]

```

print_strings(*depth=12*)

Print the strings of self.

See also:

[*strings\(\)*](#)

EXAMPLES:

```

sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings(depth=25)
2*Lambda[0]: 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981 2741_
↳3740 5096 6868 9233 12306 16357
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687_
↳2331 3206 4368 5922 7967 10670 14193 18803

```

root_lattice()

Return the root lattice associated to self.

EXAMPLES:

```

sage: V=IntegrableRepresentation(RootSystem(['F',4,1]).weight_
↳lattice(extended=true).fundamental_weight(0))
sage: V.root_lattice()
Root lattice of the Root system of type ['F', 4, 1]

```

s(*n, i*)

Return the action of the *i*-th simple reflection on the internal representation of weights by tuples *n* in self.

EXAMPLES:

```

sage: V = IntegrableRepresentation(RootSystem(['A',2,1]).weight_
↳lattice(extended=true).fundamental_weight(0))
sage: [V.s((0,0,0),i) for i in V._index_set]
[(1, 0, 0), (0, 0, 0), (0, 0, 0)]

```

string(*max_weight*, *depth*=12)

Return the list of multiplicities $m(\Lambda - k\delta)$ in *self*, where Λ is *max_weight* and k runs from 0 to *depth*.

INPUT:

- *max_weight* – a dominant maximal weight
- *depth* – (default: 12) the maximum value of k

EXAMPLES:

```
sage: Lambda = RootSystem(['A', 2, 1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.string(2*Lambda[0])
[1, 2, 8, 20, 52, 116, 256, 522, 1045, 1996, 3736, 6780]
sage: V.string(Lambda[1] + Lambda[2])
[0, 1, 4, 12, 32, 77, 172, 365, 740, 1445, 2736, 5041]
```

strings(*depth*=12)

Return the set of dominant maximal weights of *self*, together with the string coefficients for each.

OPTIONAL:

- *depth* – (default: 12) a parameter indicating how far to push computations

EXAMPLES:

```
sage: Lambda = RootSystem(['A', 1, 1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: S = V.strings(depth=25)
sage: for k in S:
.....:     print("{}: {}".format(k, ' '.join(str(x) for x in S[k])))
2*Lambda[0]: 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981 2741
↳3740 5096 6868 9233 12306 16357
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687
↳2331 3206 4368 5922 7967 10670 14193 18803
```

to_dominant(*n*)

Return the dominant weight in *self* equivalent to *n* under the affine Weyl group.

EXAMPLES:

```
sage: Lambda = RootSystem(['A', 2, 1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(3*Lambda[0])
sage: n = V.to_dominant((13, 11, 7)); n
(4, 3, 3)
sage: V.to_weight(n)
Lambda[0] + Lambda[1] + Lambda[2] - 4*delta
```

to_weight(*n*)

Return the weight associated to the tuple *n* in *self*.

If *n* is the tuple (n_1, n_2, \dots) , then the associated weight is $\Lambda - \sum_i n_i \alpha_i$, where Λ is the weight of the representation.

INPUT:

- `n` – a tuple representing a weight

EXAMPLES:

```
sage: Lambda = RootSystem(['A', 2, 1]).weight_lattice(extended=true).fundamental_
↳weights()
sage: V = IntegrableRepresentation(2*Lambda[2])
sage: V.to_weight((1,0,0))
-2*Lambda[0] + Lambda[1] + 3*Lambda[2] - delta
```

weight_lattice()

Return the weight lattice associated to self.

EXAMPLES:

```
sage: V=IntegrableRepresentation(RootSystem(['E', 6, 1]).weight_
↳lattice(extended=true).fundamental_weight(0))
sage: V.weight_lattice()
Extended weight lattice of the Root system of type ['E', 6, 1]
```

5.1.229 Nonsymmetric Macdonald polynomials

AUTHORS:

- Anne Schilling and Nicolas M. Thiéry (2013): initial version

ACKNOWLEDGEMENTS:

The initial version of this code (together with *root_lattice_realization_algebras.Algebras* and *hecke_algebra_representation.HeckeAlgebraRepresentation*) was written by Anne Schilling and Nicolas M. Thiery during the ICERM Semester Program on “Automorphic Forms, Combinatorial Representation Theory and Multiple Dirichlet Series” (January 28, 2013 - May 3, 2013) with the help of Dan Bump, Ben Brubaker, Bogdan Ion, Dan Orr, Arun Ram, Siddhartha Sahi, and Mark Shimozono. Special thanks go to Bogdan Ion and Mark Shimozono for their patient explanations and hand computations to check the code.

Nonsymmetric Macdonald polynomials

INPUT:

- `KL` – an affine Cartan type or the group algebra of a realization of the affine weight lattice
- `q, q1, q2` – parameters in the base ring of the group algebra (default: `q, q1, q2`)
- `normalized` – a boolean (default: `True`) whether to normalize the result to have leading coefficient 1

This implementation covers all reduced affine root systems. The polynomials are constructed recursively by the application of intertwining operators.

Todo:

- Non-reduced case (Koorwinder polynomials).
- Non-equal parameters for the affine Hecke algebra.
- Choice of convention (dominant/anti-dominant, ...).
- More uniform implementation of the T_0^\vee operator.
- Optimizations, in particular in the calculation of the eigenvalues for the recursion.

EXAMPLES:

We construct the family of nonsymmetric Macdonald polynomials in three variables in type A :

```
sage: E = NonSymmetricMacdonaldPolynomials(["A", 2, 1])
```

They are constructed as elements of the group algebra of the classical weight lattice L_0 (or one of its realizations, such as the ambient space, which is used here) and indexed by elements of L_0 :

```
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['A', 2]
```

Here is the nonsymmetric Macdonald polynomial with leading term $[2, 0, 1]$:

```
sage: E[L0([2, 0, 1])]
((-q*q1-q*q2)/(-q*q1-q2))*B[(1, 1, 1)] + ((-q1-q2)/(-q*q1-q2))*B[(2, 1, 0)] + B[(2, 0, 1)]
```

It can be seen as a polynomial (or in general a Laurent polynomial) by interpreting each term as an exponent vector. The parameter q is the exponential of the null (co)root, whereas q_1 and q_2 are the two eigenvalues of each generator T_i of the affine Hecke algebra (see the background section for details).

By setting $q_1 = t$, $q_2 = -1$ and using the `root_lattice_realization_algebras.Algebras.ElementMethods.expand()` method, we recover the nonsymmetric Macdonald polynomial as computed by [HHL06]'s combinatorial formula:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(["A", 2, 1], q=q, q1=t, q2=-1)
sage: vars = K['x0,x1,x2'].gens()
sage: E[L0([2, 0, 1]).expand(vars)
(t - 1)/(q*t - 1)*x0^2*x1 + x0^2*x2 + (q*t - q)/(q*t - 1)*x0*x1*x2

sage: from sage.combinat.sf.ns_macdonald import E
sage: E([2, 0, 1])
(t - 1)/(q*t - 1)*x0^2*x1 + x0^2*x2 + (q*t - q)/(q*t - 1)*x0*x1*x2
```

Here is a type $G_2^{(1)}$ nonsymmetric Macdonald polynomial:

```
sage: E = NonSymmetricMacdonaldPolynomials(["G", 2, 1])
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: E[omega[2]-omega[1]]
((-q*q1^3*q2-q*q1^2*q2^2)/(q*q1^4-q2^4))*B[(0, 0, 0)] + B[(1, -1, 0)] + ((-q1*q2^3-q2^4)/(q*q1^4-q2^4))*B[(1, 0, -1)]
```

Many more examples are given after the background section.

Background

The polynomial module

The nonsymmetric Macdonald polynomials are a distinguished basis of the “polynomial” module of the affine Hecke algebra. Given:

- a ground ring `K`, which contains the input parameters `q`, `q-1`, `q-2`
- an affine root system, specified by a Cartan type `C`
- a realization `L` of the weight lattice of type `C`

the polynomial module is the group algebra $K[L_0]$ of the classical weight lattice L_0 with coefficients in K . It is isomorphic to the Laurent polynomial ring over K generated by the formal exponentials of any basis of L_0 .

In our running example L is the ambient space of type $C_2^{(1)}$:

```
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q, q1, q2 = K.gens()
sage: C = CartanType(['C', 2, 1])
sage: L = RootSystem(C).ambient_space(); L
Ambient space of the Root system of type ['C', 2, 1]

sage: L.simple_roots()
Finite family {0: -2*e[0] + e['delta'], 1: e[0] - e[1], 2: 2*e[1]}
sage: omega = L.fundamental_weights(); omega
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'], 2: e[0] + e[1] + e[
->'deltacheck']}
```

```
sage: L0 = L.classical(); L0
Ambient space of the Root system of type ['C', 2]
sage: KL0 = L0.algebra(K); KL0
Algebra of the Ambient space of the Root system of type ['C', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

Affine Hecke algebra

The affine Hecke algebra is generated by elements T_i for i in the set of affine Dynkin nodes. They satisfy the same braid relations as the simple reflections s_i of the affine Weyl group. The T_i satisfy the quadratic relation

$$(T_i - q_1) \circ (T_i - q_2) = 0,$$

where q_1 and q_2 are the input parameters. Some of the representation theory requires that q_1 and q_2 satisfy additional relations; typically one uses the specializations $q_1 = u$ and $q_2 = -1/u$ or $q_1 = t$ and $q_2 = -1$. This can be achieved by constructing an appropriate field and passing q_1 and q_2 appropriately; see the examples. In principle, the parameter(s) could further depend on i ; this is not yet implemented but the code has been designed in such a way that this feature is easy to add.

Demazure-Lusztig operators

The i -th Demazure-Lusztig operator is an operator on $K[L]$ which interpolates between the reflection s_i and the Demazure operator π_i (see `root_lattice_realization.RootLatticeRealization.Algebras.ParentMethods.demazure_lusztig_operators()`):

```
sage: KL = L.algebra(K); KL
Algebra of the Ambient space of the Root system of type ['C', 2, 1]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: x = KL.monomial(omega[1]); x
B[e[0] + e['deltacheck']]
sage: T[2](x)
q1*B[e[0] + e['deltacheck']]
sage: T[1](x)
(q1+q2)*B[e[0] + e['deltacheck']] + q1*B[e[1] + e['deltacheck']]
sage: T[0](x)
q1*B[e[0] + e['deltacheck']]
```

The affine Hecke algebra acts on $K[L]$ by letting the generators T_i act by the Demazure-Lusztig operators. The class `sage.combinat.root_system.hecke_algebra_representation.HeckeAlgebraRepresentation` implements some simple generic features for representations of affine Hecke algebras defined by the action of their T -generators.:

```
sage: T
A representation of the (q1, q2)-Hecke algebra of type ['C', 2, 1] on Algebra of
↳ the Ambient space of the Root system of type ['C', 2, 1] over Fraction Field of
↳ Multivariate Polynomial Ring in q, q1, q2 over Rational Field
sage: type(T)
<class 'sage.combinat.root_system.hecke_algebra_representation.
↳ HeckeAlgebraRepresentation'>
sage: T._test_relations() # long time (1.3s)
```

Here we construct the operator $q_1 T_2^{-1} \circ T_1^{-1} T_0$ from a signed reduced word:

```
sage: T.Tw([0,1,2],[1,-1,-1], q1^2)
Generic endomorphism of Algebra of the Ambient space of the Root system of type ['C
↳ ', 2, 1]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

(note the reversal of the word). Inverses are computed using the quadratic relation.

Cherednik operators

The affine Hecke algebra contains elements Y_λ indexed by the coroot lattice. Their action on $K[L]$ is implemented in Sage:

```
sage: Y = T.Y(); Y
Lazy family (...)_{i in Coroot lattice of the Root system of type ['C', 2, 1]}
sage: alphacheck = Y.keys().simple_roots()
sage: Y1 = Y[alphacheck[1]]
sage: Y1(x)
((q1^2+2*q1*q2+q2^2)/(-q1*q2))*B[e[0] + e['deltacheck']]
```

(continues on next page)

(continued from previous page)

```

+ ((-q1^2-2*q1*q2-q2^2)/(-q2^2))*B[-e[1] + e['deltacheck']]
+ ((-q1^2-q1*q2)/(-q2^2))*B[2*e[0] - e[1] - e['delta']]
+ e['deltacheck']] + ((q1^3+q1^2*q2)/(-q2^3))*B[e[0] - e['delta']]
+ e['deltacheck']] + ((q1^3+q1^2*q2)/(-q2^3))*B[e[0] - 2*e[1] - e['delta']]
+ e['deltacheck']] + ((q1+q2)/(-q2))*B[e[1] + e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(-q2^3))*B[-e[1] - e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[2*e[0] - e[1] - 2*e['delta'] + e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(-q2^3))*B[-e[0] - e['delta'] + e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(-q2^3))*B[e[0] - 2*e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[3*e[0] - 3*e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[-e[0] - 2*e[1] - e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[e[0] - 2*e[1] - 2*e['delta'] + e['deltacheck']]
+ (q1^3/(-q2^3))*B[3*e[0] - 2*e[1] - 3*e['delta'] + e['deltacheck']]

```

The Cherednik operators span a Laurent polynomial ring inside the affine Hecke algebra; namely $\lambda \mapsto Y_\lambda$ is a group isomorphism from the classical root lattice (viewed additively) to the affine Hecke algebra (viewed multiplicatively). In practice, Y_λ is constructed by computing combinatorially its signed reduced word (and an overall scalar factor) using the periodic orientation of the alcove model in the coweight lattice (see [hecke_algebra_representation.HeckeAlgebraRepresentation.Y_lambda_check\(\)](#)):

```

sage: Lcheck = L.root_system.coweight_lattice()
sage: w = Lcheck.reduced_word_of_translation(Lcheck(alphacheck[1])); w
[0, 2, 1, 0, 2, 1]
sage: Lcheck.signs_of_alcove_walk(w)
[1, -1, 1, -1, 1, 1]

```

Level zero representation of the affine Hecke algebra

The action of the affine Hecke algebra on $K[L]$ induces an action on $K[L_0]$: the action of T_i on X^λ for λ a classical weight in L_0 is obtained by embedding the weight at level zero in the affine weight lattice (see [weight_lattice_realizations.WeightLatticeRealizations.ParentMethods.embed_at_level\(\)](#)) applying the Demazure-Lusztig operator there, and projecting from $K[L] \rightarrow K[L_0]$ mapping the exponential of δ to q (see [root_lattice_realization_algebras.Algebras.ParentMethods.q_project\(\)](#)). This is implemented in [root_lattice_realization_algebras.Algebras.ParentMethods.demazure_lusztig_operators_on_classical\(\)](#):

```

sage: T = KL.demazure_lusztig_operators_on_classical(q, q1, q2)
sage: omega = L0.fundamental_weights()
sage: x = KL0.monomial(omega[1])
sage: T[0](x)
(-q*q2)*B[(-1, 0)]

```

For classical nodes these are the usual Demazure-Lusztig operators:

```

sage: T[1](x)
(q1+q2)*B[(1, 0)] + q1*B[(0, 1)]

```

Nonsymmetric Macdonald polynomials

We can now finally define the nonsymmetric Macdonald polynomials. Because the Cherednik operators commute (and there is no radical), they can be simultaneously diagonalized; namely, $K[L_0]$ admits a K -basis of joint eigenvectors for the Y_λ . For $\mu \in L_0$, the nonsymmetric Macdonald polynomial E_μ is the unique eigenvector of the family of Cherednik operators Y_λ having μ as leading term:

```
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2); E
The family of the Macdonald polynomials of type ['C', 2, 1] with parameters q, q1,
↪q2
```

Or for short:

```
sage: E = NonSymmetricMacdonaldPolynomials(C)
```

Recursive construction of the nonsymmetric Macdonald polynomials

The generators T_i of the affine Hecke algebra almost skew commute with the Cherednik operators. More precisely, one can deform them into the so-called intertwining operators:

$$\tau_i = T_i - (q_1 + q_2) \frac{Y_i^{a-1}}{1 - Y_i^a}.$$

(where $a = 1$ except for $i = 0$ in type BC where $a = a_0 = 2$) which satisfy the following skew commutation relations:

$$\tau_i Y_\lambda = \tau_i Y_{s_i \lambda}.$$

If $s_i \mu \neq \mu$, applying τ_i on an eigenvector E_μ produces a new eigenvector (essentially $E_{s_i \mu}$) with a distinct eigenvalue. It follows that the eigenvectors indexed by an affine Weyl orbit of weights, may be recursively computed from a single weight in the orbit.

In the case at hand, there is a little complication: namely, the simple reflections s_i acting at level 0 do not act transitively on classical weights; in fact the orbits for the classical Weyl group and for the affine Weyl group are the same. Thus, one can construct the nonsymmetric Macdonald polynomials for all weights from those for the classical dominant weights, but one is lacking a creation operator to construct the nonsymmetric Macdonald polynomials for dominant weights.

Twisted Demazure-Lusztig operators

To compensate for this, one needs to consider another affinization of the action of the classical Demazure-Lusztig operators T_1, \dots, T_n , which gives rise to the double affine Hecke algebra. Following Cherednik, one adds another operator T_0^\vee implemented in: `root_lattice_realization_algebras.Algebras.ParentMethods.T0_check_on_basis()`. See also: `root_lattice_realization_algebras.Algebras.ParentMethods.twisted_demazure_lusztig_operators()`.

Depending on the type (untwisted or not), this is a representation of the affine Hecke algebra for another affinization of the classical Cartan type. The corresponding action of the affine Weyl group – which is used to compute the recursion on μ – occurs in the corresponding weight lattice realization:

```
sage: E.L()
Ambient space of the Root system of type ['C', 2, 1]
sage: E.L_prime()
```

(continues on next page)

(continued from previous page)

```

Coambient space of the Root system of type ['B', 2, 1]
sage: E.L_prime().classical()
Ambient space of the Root system of type ['C', 2]

```

See `L_prime()` and `cartan_type.CartanType_affine.other_affinization()`.

More examples

We show how to create the nonsymmetric Macdonald polynomials in two different ways and check that they are the same:

```

sage: K = QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['D',3,1], q, u, -1/u)
sage: omega = E.keys().fundamental_weights()
sage: E[omega[1]+omega[3]]
((-q*u^2+q)/(-q*u^4+1))*B[(1/2, -1/2, 1/2)] + ((-q*u^2+q)/(-q*u^4+1))*B[(1/2, 1/2, -
->1/2)] + B[(3/2, 1/2, 1/2)]

sage: KL = RootSystem(['D',3,1]).ambient_space().algebra(K)
sage: P = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
sage: E[omega[1]+omega[3]] == P[omega[1]+omega[3]]
True
sage: E[E.keys()((0,1,-1))]
((-q*u^2+q)/(-q*u^2+1))*B[(0, 0, 0)] + ((-u^2+1)/(-q*u^2+1))*B[(1, 1, 0)]
+ ((-u^2+1)/(-q*u^2+1))*B[(1, 0, -1)] + B[(0, 1, -1)]

```

In type *A*, there is also a combinatorial implementation of the nonsymmetric Macdonald polynomials in terms of augmented diagram fillings as in [HHL06]. See `sage.combinat.sf.ns_macdonald.E()`. First we check that these polynomials are indeed eigenvectors of the Cherednik operators:

```

sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t; q2 = -1
sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(K)
sage: KL0 = KL.classical()
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: omega = E.keys().fundamental_weights()
sage: w = omega[1]
sage: import sage.combinat.sf.ns_macdonald as NS
sage: p = NS.E([1,0,0]); p
x0
sage: pp = KL0.from_polynomial(p)
sage: E.eigenvalues(KL0.from_polynomial(p))
[t, (-1)/(-q*t^2), t]

sage: def eig(l): return E.eigenvalues(KL0.from_polynomial(NS.E(l)))

sage: eig([1,0,0])
[t, (-1)/(-q*t^2), t]

```

(continues on next page)

(continued from previous page)

```

sage: eig([2,0,0])
[q*t, (-1)/(-q^2*t^2), t]
sage: eig([3,0,0])
[q^2*t, (-1)/(-q^3*t^2), t]
sage: eig([2,0,4])
[(-1)/(-q^3*t), 1/(q^2*t), q^4*t^2]

```

Next we check explicitly that they agree with the current implementation:

```

sage: K = QQ['q','t'].fraction_field()
sage: q,t = K.gens()
sage: KL = RootSystem(["A",1,1]).ambient_lattice().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
sage: L0 = E.keys()
sage: KL0 = KL.classical()
sage: P = K['x0,x1']
sage: def EE(weight): return E[L0(weight)].expand(P.gens())
sage: import sage.combinat.sf.ns_macdonald as NS
sage: EE([0,0])
1
sage: NS.E([0,0])
1
sage: EE([1,0])
x0
sage: NS.E([1,0])
x0
sage: EE([0,1])
(t - 1)/(q*t - 1)*x0 + x1
sage: NS.E([0,1])
(t - 1)/(q*t - 1)*x0 + x1

sage: NS.E([2,0])
x0^2 + (q*t - q)/(q*t - 1)*x0*x1
sage: EE([2,0])
x0^2 + (q*t - q)/(q*t - 1)*x0*x1

```

The same, directly in the ambient lattice with several shifts:

```

sage: E[L0([2,0])]
((-q*t+q)/(-q*t+1))*B[(1, 1)] + B[(2, 0)]
sage: E[L0([1,-1])]
((-q*t+q)/(-q*t+1))*B[(0, 0)] + B[(1, -1)]
sage: E[L0([0,-2])]
((-q*t+q)/(-q*t+1))*B[(-1, -1)] + B[(0, -2)]

```

Systematic checks with Sage's implementation of [HHL06]:

```

sage: assert all(EE([x,y]) == NS.E([x,y]) for d in range(5) for x,y in
↳ IntegerVectors(d,2))

```

With the current implementation, we can compute nonsymmetric Macdonald polynomials for any type, for example for type $E_6^{(1)}$:

```

sage: K=QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = RootSystem(["E", 6, 1]).weight_space(extended=True).algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
sage: L0 = E.keys()

sage: E[L0.fundamental_weight(1).weyl_action([2, 4, 3, 2, 1])]
((-u^2+1)/(-q*u^16+1))*B[-Lambda[1] + Lambda[3]] + ((-u^2+1)/(-q*u^
↪ 16+1))*B[Lambda[1]]
+ B[-Lambda[2] + Lambda[5]] + ((-u^2+1)/(-q*u^16+1))*B[Lambda[2] - Lambda[4] +
↪ Lambda[5]]
+ ((-u^2+1)/(-q*u^16+1))*B[-Lambda[3] + Lambda[4]]

sage: E[L0.fundamental_weight(2).weyl_action([2, 5, 3, 4, 2])] # long time (6s)
((-q^2*u^20+q^2*u^18+q^2*u^2-q)/(-q^2*u^32+2*q*u^16-1))*B[0]
+ B[Lambda[1] - Lambda[3] + Lambda[4] - Lambda[5] + Lambda[6]]
+ ((-u^2+1)/(-q*u^16+1))*B[Lambda[1] - Lambda[3] + Lambda[5]]
+ ((-q^2*u^20+q^2*u^18+u^2-1)/(-q^2*u^32+2*q*u^16-1))*B[-Lambda[2] + Lambda[4]]
+ ((-q^2*u^20+q^2*u^18+u^2-1)/(-q^2*u^32+2*q*u^16-1))*B[Lambda[2]]
+ ((u^4-2*u^2+1)/(q^2*u^32-2*q*u^16+1))*B[Lambda[3] - Lambda[4] + Lambda[5]]
+ ((-u^2+1)/(-q*u^16+1))*B[Lambda[3] - Lambda[5] + Lambda[6]]

sage: E[L0.fundamental_weight(1)+L0.fundamental_weight(6)] # long time (13s)
((q^2*u^10-q^2*u^8-q^2*u^2+q^2)/(q^2*u^26-q*u^16-q*u^10+1))*B[0]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[1] - Lambda[2] + Lambda[6]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[1] + Lambda[2] - Lambda[4] + Lambda[6]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[1] - Lambda[3] + Lambda[4] - Lambda[5] +
↪ Lambda[6]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[1] - Lambda[3] + Lambda[5]] + B[Lambda[1] +
↪ Lambda[6]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[-Lambda[2] + Lambda[4]] + ((-q*u^2+q)/(-q*u^
↪ 10+1))*B[Lambda[2]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[3] - Lambda[4] + Lambda[5]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[3] - Lambda[5] + Lambda[6]]

```

We test various other types:

```

sage: K=QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = RootSystem(["A", 5, 2]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
sage: L0 = E.keys()
sage: E[L0.fundamental_weight(2)]
((-q*u^2+q)/(-q*u^8+1))*B[(0, 0, 0)] + B[(1, 1, 0)]
sage: E[L0((0, -1, 1))] # long time (1.5s)
((-q^2*u^10+q^2*u^8-q*u^6+q*u^4+q*u^2+u^2-q-1)/(-q^3*u^12+q^2*u^8+q*u^4-1))*B[(0, 0,
↪ 0)]
+ ((-u^2+1)/(-q*u^4+1))*B[(1, -1, 0)]
+ ((u^6-u^4-u^2+1)/(q^3*u^12-q^2*u^8-q*u^4+1))*B[(1, 1, 0)]
+ ((u^4-2*u^2+1)/(q^3*u^12-q^2*u^8-q*u^4+1))*B[(1, 0, -1)]
+ ((q^2*u^12-q^2*u^10-u^2+1)/(q^3*u^12-q^2*u^8-q*u^4+1))*B[(1, 0, 1)] + B[(0, -1,
↪ 1)]
+ ((-u^2+1)/(-q^2*u^8+1))*B[(0, 1, -1)] + ((-u^2+1)/(-q^2*u^8+1))*B[(0, 1, 1)]

```

Some tests that the T s are implemented properly by hand defining the Y s in terms of them:

```

sage: T = E._T_Y
sage: Ye1 = T.Tw((1,2,1,0), scalar = (-1/(q1*q2))^2)
sage: Ye2 = T.Tw((2,1,0,1), signs = (1,1,1,-1), scalar = (-1/(q1*q2)))
sage: Yalpha0 = T.Tw((0,1,2,1), signs = (-1,-1,-1,-1), scalar = q^-1*(-q1*q2)^2)
sage: Yalpha1 = T.Tw((1,2,0,1,2,0), signs=(1,1,-1,1,-1,1), scalar = -1/(q1*q2))
sage: Yalpha2 = T.Tw((2,1,0,1,2,1,0,1), signs = (1,1,1,-1,1,1,1,-1), scalar = (1/
↳ (q1*q2))^2)

sage: Ye1(KL0.one())
q1^2/q2^2*B[(0, 0)]
sage: Ye2(KL0.one())
((-q1)/q2)*B[(0, 0)]

sage: Yalpha0(KL0.one())
q2^2/(q*q1^2)*B[(0, 0)]
sage: Yalpha1(KL0.one())
((-q1)/q2)*B[(0, 0)]
sage: Yalpha2(KL0.one())
q1^2/q2^2*B[(0, 0)]

```

Testing the Y s directly:

```

sage: Y = E.Y()
sage: Y.keys()
Coroot lattice of the Root system of type ['BC', 2, 2]
sage: alpha = Y.keys().simple_roots()
sage: L(alpha[0])
-2*e[0] + e['deltacheck']
sage: L(alpha[1])
e[0] - e[1]
sage: L(alpha[2])
e[1]

sage: Y[alpha[0]].word
(0, 1, 2, 1)
sage: Y[alpha[0]].signs
(-1, -1, -1, -1)
sage: Y[alpha[0]].scalar # mind that Sage's q is the usual q^{1/2}
q1^2*q2^2/q
sage: Y[alpha[0]](KL0.one())
q2^2/(q*q1^2)*B((0, 0))

sage: Y[alpha[1]].word
(1, 2, 0, 1, 2, 0)
sage: Y[alpha[1]].signs
(1, 1, -1, 1, -1, 1)
sage: Y[alpha[1]].scalar
1/(-q1*q2)

sage: Y[alpha[2]].word # Bogdan says it should be the square of that; do we need
↳to take translation factors into account or not?
(2, 1, 0, 1)
sage: Y[alpha[2]].signs
(1, 1, 1, -1)
sage: Y[alpha[2]].scalar
1/(-q1*q2)

```

Checking the provided nonsymmetric Macdonald polynomial:

```

sage: E10 = KL0.monomial(L0((1,0))) + KL0( q*(1-(-q1/q2)) / (1-q^2*(-q1/q2)^4) )
sage: E10 == E[omega[1]]
True
sage: E.eigenvalues(E10) # not checked
[q*q1^2/q2^2, q2^3/(-q^2*q1^3), q1/(-q2)]

```

Checking T_0 check:

```

sage: T0check_on_basis = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: T0check_on_basis.phi # note: this is in fact a0 phi
(2, 0)
sage: T0check_on_basis.v # what to match it with?
(1,)
sage: T0check_on_basis.j # what to match it with?
2

```

(continues on next page)

(continued from previous page)

```
sage: T0check_on_basis(KL0.basis().keys().zero())
((-q1^2)/q2)*B[(1, 0)]
```

```
sage: T0check = E._T[0]
sage: T0check(KL0.one())
((-q1^2)/q2)*B[(1, 0)]
```

Systematic tests of nonsymmetric Macdonald polynomials in type $A_1^{(1)}$, in the weight lattice. Each time, we specify the eigenvalues for the action of Y_{α_0} , and Y_{α_1} :

```

↪ 3 - q^2*t^2 - q*t + 1)*x0*x1 + x1^2 + (q*t^2 - 2*q*t + q)/(q^3*t^3 - q^2*t^2 -
↪ q*t + 1)*x0*x2 + (q*t - q)/(q*t - 1)*x1*x2
```

Systematic checks with Sage's implementation of [HHL06]:

```
sage: import sage.combinat.sf.ns_macdonald as NS
sage: assert all(EE([x,y,z]) == NS.E([x,y,z]) for d in range(5) for x,y,z in
↪ IntegerVectors(d,3)) # long time (9s)
```

We check that we get eigenvectors for generic q_1, q_2 :

```
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2 = K.gens()
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: E[2*omega[2]]
((-q*q1-q*q2)/(-q*q1-q2))*B[(1, 2, 1)] + ((-q*q1-q*q2)/(-q*q1-q2))*B[(2, 1, 1)] +
→B[(2, 2, 0)]
sage: for d in range(4): # long time (9s)
.....:     for weight in IntegerVectors(d,3).map(list).map(L0):
.....:         eigenvalues = E.eigenvalues(E[L0(weight)])
```

Some type C calculations:

```

Type *BC* dual, comparison with hand calculations by Bogdan Ion:

```

sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2 = K.gens()
sage: ct = CartanType(["BC",2,2]).dual()
sage: E = NonSymmetricMacdonaldPolynomials(ct, q=q, q1=q1, q2=q2)
sage: KL = E.domain(); KL
Algebra of the Ambient space of the Root system of type ['B', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
sage: alpha = E.keys().simple_roots(); alpha
Finite family {1: (1, -1), 2: (0, 1)}
sage: omega=E.keys().fundamental_weights(); omega
Finite family {1: (1, 0), 2: (1/2, 1/2)}
sage: epsilon = E.keys().basis(); epsilon
Finite family {0: (1, 0), 1: (0, 1)}

```

Note: Sage's q is the usual q^2 :

```
sage: E.L().null_root()
e['delta']
sage: E.L().null_coroot()
2*e['deltacheck']
```

Some eigenvectors:

```
sage: E[0*omega[1]]
B[(0, 0)]
sage: E[omega[1]]
((-q^2*q1^3*q2-q^2*q1^2*q2^2)/(q^2*q1^4-q2^4))*B[(0, 0)] + B[(1, 0)]
sage: Eomega1 = KL.one() * (q^2*(-q1/q2)^2*(1-(-q1/q2))) / (1-q^2*(-q1/q2)^4) + KL.
↪monomial(omega[1])
sage: E[omega[1]] == Eomega1
True
```

Checking the Y s:

```
sage: Y = E.Y()
sage: alphacheck = Y.keys().simple_roots()
sage: Y0 = Y[alphacheck[0]]
sage: Y1 = Y[alphacheck[1]]
sage: Y2 = Y[alphacheck[2]]

sage: Y0.word, Y0.signs, Y0.scalar
((0, 1, 2, 1, 0, 1, 2, 1), (-1, -1, -1, -1, -1, -1, -1, -1), q1^4*q2^4/q^2)
sage: Y1.word, Y1.signs, Y1.scalar
((1, 2, 0, 1, 2, 0), (1, 1, -1, 1, -1, 1), 1/(-q1*q2))
sage: Y2.word, Y2.signs, Y2.scalar
((2, 1, 0, 1), (1, 1, 1, -1), 1/(-q1*q2))

sage: E.eigenvalues(0*omega[1])
[q2^4/(q^2*q1^4), q1/(-q2), q1/(-q2)]
```

Checking the T and T^{-1} s:

```
sage: T = E._T_Y
sage: Tinv0 = T.Tw_inverse([0])
sage: Tinv1 = T.Tw_inverse([1])
sage: Tinv2 = T.Tw_inverse([2])

sage: for x in [0*epsilon[0], -epsilon[0], -epsilon[1], epsilon[0], epsilon[1]]:
.....:     x = KL.monomial(x)
.....:     assert Tinv0(T[0](x)) == x and T[0](Tinv0(x)) == x
.....:     assert Tinv1(T[1](x)) == x and T[1](Tinv1(x)) == x
.....:     assert Tinv2(T[2](x)) == x and T[2](Tinv2(x)) == x

sage: start = E[omega[1]]; start
((-q^2*q1^3*q2-q^2*q1^2*q2^2)/(q^2*q1^4-q2^4))*B[(0, 0)] + B[(1, 0)]
sage: Tinv1(Tinv2(Tinv1(Tinv0(Tinv1(Tinv2(Tinv1(Tinv0(start)))))))) * (q1*q2)^4/q^2
↪== Y0(start)
True
sage: Y0(start) == q^2*q1^4/q2^4 * start
True
```

Checking the relation between the Y s:

```
sage: q^2 * Y0(Y1(Y1(Y2(Y2(start)))))) == start
True
sage: for x in [0*epsilon[0], -epsilon[0], -epsilon[1], epsilon[0], epsilon[1]]:
.....:     x = KL.monomial(x)
.....:     assert q^2 * Y0(Y1(Y1(Y2(Y2(start)))))) == start
```

KL0()

Return the group algebra where the nonsymmetric Macdonald polynomials live.

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials("B2~").KL0()
Algebra of the Ambient space of the Root system of type ['B', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational_
↳Field
sage: NonSymmetricMacdonaldPolynomials("B2~*").KL0()
Algebra of the Ambient space of the Root system of type ['C', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational_
↳Field
```

L()

Return the affinization of the classical weight space.

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L()
Ambient space of the Root system of type ['B', 2, 1]
```

L0()

Return the space indexing the monomials of the nonsymmetric Macdonald polynomials.

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials("B2~").L0()
Ambient space of the Root system of type ['B', 2]
sage: NonSymmetricMacdonaldPolynomials("B2~*").L0()
Ambient space of the Root system of type ['C', 2]
```

L_check()

Return the other affinization of the classical weight space.

Todo: should this just return L in the simply laced case?

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L_check()
Coambient space of the Root system of type ['C', 2, 1]
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L_check().classical()
Ambient space of the Root system of type ['B', 2]
```

L_prime()

The affine space where classical weights are lifted for the recursion.

Also the parent of ρ' .

EXAMPLES:

In the twisted case, this is the affinization of the classical ambient space:

```
sage: NonSymmetricMacdonaldPolynomials("B2~*").L()
Ambient space of the Root system of type ['B', 2, 1]^*
sage: NonSymmetricMacdonaldPolynomials("B2~*").L().classical()
Ambient space of the Root system of type ['C', 2]

sage: NonSymmetricMacdonaldPolynomials("B2~*").L_prime()
Ambient space of the Root system of type ['B', 2, 1]^*
sage: NonSymmetricMacdonaldPolynomials("B2~*").L_prime().classical()
Ambient space of the Root system of type ['C', 2]
```

In the untwisted case, this is the other affinization of the classical ambient space:

```
sage: NonSymmetricMacdonaldPolynomials("B2~").L()
Ambient space of the Root system of type ['B', 2, 1]
sage: NonSymmetricMacdonaldPolynomials("B2~").L().classical()
Ambient space of the Root system of type ['B', 2]

sage: NonSymmetricMacdonaldPolynomials("B2~").L_prime()
Coambient space of the Root system of type ['C', 2, 1]
sage: NonSymmetricMacdonaldPolynomials("B2~").L_prime().classical()
Ambient space of the Root system of type ['B', 2]
```

For simply laced, the two affinizations coincide:

```
sage: NonSymmetricMacdonaldPolynomials("A2~").L()
Ambient space of the Root system of type ['A', 2, 1]
sage: NonSymmetricMacdonaldPolynomials("A2~").L().classical()
Ambient space of the Root system of type ['A', 2]

sage: NonSymmetricMacdonaldPolynomials("A2~").L_prime()
Coambient space of the Root system of type ['A', 2, 1]
sage: NonSymmetricMacdonaldPolynomials("A2~").L_prime().classical()
Ambient space of the Root system of type ['A', 2]
```

Note: do we want the coambient space of type $A_2^{(1)}$ instead?

For type BC:

```
sage: NonSymmetricMacdonaldPolynomials(["BC", 3, 2]).L_prime()
Ambient space of the Root system of type ['BC', 3, 2]
```

Q_to_Qcheck()

The reindexing of the index set of the Y's by the coroot lattice.

EXAMPLES:

```
sage: E = NonSymmetricMacdonaldPolynomials("C2~")
sage: alphacheck = E.Y().keys().simple_roots()
sage: E.Q_to_Qcheck(alphacheck[0])
alphacheck[0] - alphacheck[2]
```

(continues on next page)

(continued from previous page)

```

sage: E.Q_to_Qcheck(alphacheck[1])
alphacheck[1]
sage: E.Q_to_Qcheck(alphacheck[2])
alphacheck[2]

sage: x = alphacheck[1] + 2*alphacheck[2]
sage: x.parent()
Root lattice of the Root system of type ['B', 2, 1]
sage: E.Q_to_Qcheck(x)
alphacheck[1] + 2*alphacheck[2]
sage: _.parent()
Coroot lattice of the Root system of type ['C', 2, 1]

```

Y()

Return the family of Y operators whose eigenvectors are the nonsymmetric Macdonald polynomials.

EXAMPLES:

```

sage: NonSymmetricMacdonaldPolynomials("C2~").Y()
Lazy family (<lambda>(i))_{i in Root lattice of the Root system of type ['B', 2,
↪ 1]}
sage: _.keys().classical()
Root lattice of the Root system of type ['B', 2]

sage: NonSymmetricMacdonaldPolynomials("C2~*").Y()
Lazy family (<...Y_lambdacheck...>(i))_{i in Coroot lattice of the Root system
↪ of type ['C', 2, 1]^*}
sage: _.keys().classical()
Root lattice of the Root system of type ['C', 2]

sage: NonSymmetricMacdonaldPolynomials(["BC", 3, 2]).Y()
Lazy family (<...Y_lambdacheck...>(i))_{i in Coroot lattice of the Root system
↪ of type ['BC', 3, 2]}
sage: _.keys().classical()
Root lattice of the Root system of type ['B', 3]

```

affine_lift(μ)

Return the affinization of μ in L' .

INPUT:

- μ – a classical weight μ

See also:

- [hecke_algebra_representation.CherednikOperatorsEigenvectors.affine_lift\(\)](#)
- [affine_retract\(\)](#)
- [L_prime\(\)](#)

EXAMPLES:

In the untwisted case, this is the other affinization at level 1:

```

sage: E = NonSymmetricMacdonaldPolynomials("B2~")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_lift(omega[1]).parent()
Coambient space of the Root system of type ['C', 2, 1]

```

In the twisted case, this is the usual affinization at level 1:

```

sage: E = NonSymmetricMacdonaldPolynomials("B2~*")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['C', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_lift(omega[1]).parent()
Ambient space of the Root system of type ['B', 2, 1]^*

```

affine_retract(*mu*)

Retract the affine weight μ into a classical weight.

INPUT:

- μ – an affine weight μ in L'

See also:

- `hecke_algebra_representation.HeckeAlgebraRepresentation.affine_retract()`
- `affine_lift()`
- `L_prime()`

EXAMPLES:

```

sage: E = NonSymmetricMacdonaldPolynomials("B2~")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_retract(E.affine_lift(omega[1]))
(1, 0)

```

cartan_type()

Return Cartan type of self.

EXAMPLES:

```

sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).cartan_type()
['B', 2, 1]

```

eigenvalue_experimental(*mu*, *l*)

Return the eigenvalue of Y^{λ^v} acting on the macdonald polynomial E_μ .

INPUT:

- μ – the index μ of an eigenvector
- l – an index λ^\vee of some Y

Note:

- This method is currently not used; most tests below even test the naive method. They are left here as a basis for a future implementation.
- This is actually equivariant, as long as s_i does not fix λ .
- This method is only really needed for $\lambda^\vee = \alpha_i^\vee$ with $i = 0, \dots, n$.

See Corollary 6.11 of [Haiman06].

EXAMPLES:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t
sage: q2 = -1
sage: KL = RootSystem(["A",1,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: E.eigenvalues(L0([0,0])) # Checked by hand by Mark and Arun
[1/(q*t), t]
sage: alpha = E.Y().keys().simple_roots()
sage: E.eigenvalue_experimental(L0([0,0]), alpha[0]) # todo: not implemented
1/(q*t)
sage: E.eigenvalue_experimental(L0([0,0]), alpha[1])
t
```

Some examples of eigenvalues (not mathematically checked!!!):

```
sage: E.eigenvalues(L0([1,0]))
[t, 1/(q*t)]
sage: E.eigenvalues(L0([0,1]))
[1/(q^2*t), q*t]
sage: E.eigenvalues(L0([1,1]))
[1/(q*t), t]
sage: E.eigenvalues(L0([2,1]))
[t, 1/(q*t)]
sage: E.eigenvalues(L0([-1,1]))
[(-1)/(-q^3*t), q^2*t]
sage: E.eigenvalues(L0([-2,1]))
[(-1)/(-q^4*t), q^3*t]
sage: E.eigenvalues(L0([-2,0]))
[(-1)/(-q^3*t), q^2*t]
```

Some type B examples:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t
```

(continues on next page)

(continued from previous page)

```

sage: q2 = -1
sage: L = RootSystem(["B",2,1]).ambient_space()
sage: KL = L.algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: alpha = L.simple_coroots()
sage: E.eigenvalue(L0((0,0)), alpha[0]) # not checked # not tested
q/t
sage: E.eigenvalue(L0((1,0)), alpha[1]) # What Mark got by hand # not tested
q
sage: E.eigenvalue(L0((1,0)), alpha[2]) # not checked # not tested
t
sage: E.eigenvalue(L0((1,0)), alpha[0]) # not checked # not tested
1

sage: L = RootSystem("B2~*").ambient_space()
sage: KL = L.algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: alpha = L.simple_coroots()
sage: E.eigenvalue(L0((0,0)), alpha[0]) # assuming Mark's calculation is correct,
↪ one should get # not tested
1/(q*t^2)

```

The expected value can more or less be read off from equation (37), Corollary 6.15 of [Haiman06]

Todo:

- Use proposition 6.9 of [Haiman06] to check the action of the Y s on monomials.
- Generalize to any q_1, q_2 .
- Check claim by Mark: all scalar products should occur in the finite weight lattice, with α_0 being the appropriate projection of the affine α_0 . Question: can this be emulated by being at level 0?

rho_prime()

Return the level 0 sum of the classical fundamental weights in L' .

See also:

`L_prime()`

EXAMPLES:

Untwisted case:

```

sage: NonSymmetricMacdonaldPolynomials("B2~").rho_prime() # CHECKME
3/2*e[0] + 1/2*e[1]
sage: NonSymmetricMacdonaldPolynomials("B2~").rho_prime().parent()
Coambient space of the Root system of type ['C', 2, 1]

```

Twisted case:

```

sage: NonSymmetricMacdonaldPolynomials("B2~*").rho_prime() # CHECKME
2*e[0] + e[1]

```

(continues on next page)

(continued from previous page)

```
sage: NonSymmetricMacdonaldPolynomials("B2~").rho_prime().parent()
Ambient space of the Root system of type ['B', 2, 1]^*
```

seed(μ)

Return E_μ for μ minuscule, i.e. in the fundamental alcove.

INPUT:

- μ – the index μ of an eigenvector

EXAMPLES:

```
sage: E = NonSymmetricMacdonaldPolynomials(["A", 2, 1])
sage: omega = E.keys().fundamental_weights()
sage: E.seed(omega[1])
B[(1, 0, 0)]
```

symmetric_macdonald_polynomial(μ)

Return the symmetric Macdonald polynomial indexed by μ .

INPUT:

- μ – a dominant weight μ

Warning: The result is Weyl-symmetric only for Hecke parameters of the form $q_1 = v$ and $q_2 = -1/v$. In general the value of v below, should be the square root of $-q_1/q_2$, but the use of $q_1 = t$ and $q_2 = -1$ results in nonintegral powers of t .

EXAMPLES:

```
sage: K = QQ['q,v,t'].fraction_field()
sage: q,v,t = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['A', 2, 1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(om[2])
B[(1, 1, 0)] + B[(1, 0, 1)] + B[(0, 1, 1)]
sage: E.symmetric_macdonald_polynomial(2*om[1])
((q*v^2+v^2-q-1)/(q*v^2-1))*B[(1, 1, 0)] + ((q*v^2+v^2-q-1)/(q*v^2-1))*B[(1, 0, 1)
↪1] + B[(2, 0, 0)] + ((q*v^2+v^2-q-1)/(q*v^2-1))*B[(0, 1, 1)] + B[(0, 2, 0)] ↪
↪+ B[(0, 0, 2)]
sage: f = E.symmetric_macdonald_polynomial(E.L0()((2,1,0))); f
((2*q*v^4+v^4-q*v^2+v^2-q-2)/(q*v^4-1))*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 1)
↪2] + B[(2, 1, 0)] + B[(2, 0, 1)] + B[(0, 1, 2)] + B[(0, 2, 1)]
```

We compare with the type A Macdonald polynomials coming from symmetric functions:

```
sage: P = SymmetricFunctions(K).macdonald().P()
sage: g = P[2,1].expand(3); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + (2*q*t^2 - q*t - q + t^2 + t - 2)/(q*t^2 -
↪1)*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: fe = f.expand(g.parent().gens()); fe
x0^2*x1 + x0*x1^2 + x0^2*x2 + (2*q*v^4 - q*v^2 - q + v^4 + v^2 - 2)/(q*v^4 -
↪1)*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: g.map_coefficients(lambda x: x.subs(t=v*v)) == fe
```

(continues on next page)

(continued from previous page)

True

```

sage: E = NonSymmetricMacdonaldPolynomials(['C',3,1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(om[1]+om[2])

```

twist(μ , i)

Act by s_i on the affine weight μ .

This calls `simple_reflection`; which is semantically the same as the default implementation.

EXAMPLES:

```
sage: W = WeylGroup(["B",3])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: w = W.an_element(); w
123
sage: E.twist(w,1)
1231
```

5.1.230 Pieri Factors

class `sage.combinat.root_system.pieri_factors.PieriFactors`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

An abstract class for sets of Pieri factors, used for constructing Stanley symmetric functions. The set of Pieri factors for a given type can be realized as an order ideal of the Bruhat order poset generated by a certain set of maximal elements.

See also:

- `WeylGroups.ParentMethods.pieri_factors()`
- `WeylGroups.ElementMethods.stanley_symmetric_function()`

EXAMPLES:

```
sage: W = WeylGroup(['A',4])
sage: PF = W.pieri_factors()
sage: PF.an_element().reduced_word()
[4, 3, 2, 1]
sage: Waff = WeylGroup(['A',4,1])
sage: PFaff = Waff.pieri_factors()
sage: Waff.from_reduced_word(PF.an_element().reduced_word()) in PFaff
True

sage: W = WeylGroup(['B',3,1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([2,3,2]) in PF.elements()
True
sage: PF.cardinality()
47
```

(continues on next page)

(continued from previous page)

```

sage: W = WeylGroup(['C', 3, 1])
sage: PF = W.pieri_factors()
sage: PF.generating_series()
6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
sage: sorted(w.reduced_word() for w in PF if w.length() == 2)
[[0, 1], [1, 0], [1, 2], [2, 0], [2, 1],
 [2, 3], [3, 0], [3, 1], [3, 2]]

```

REFERENCES:

- [FoSta1994]
- [BH1994]
- [Lam1996]
- [Lam2008]
- [LSS2009]
- [Pon2010]

default_weight()

Return the function $i \mapsto z^i$, where z is the generator of $\mathbb{Q}\mathbb{Q}[z]$.

EXAMPLES:

```

sage: W = WeylGroup(["A", 3, 1])
sage: weight = W.pieri_factors().default_weight()
sage: weight(1)
z
sage: weight(5)
z^5

```

elements()

Return the elements of `self`.

Those are constructed as the elements below the maximal elements of `self` in Bruhat order.

OUTPUT: a `RecursivelyEnumeratedSet_generic` object

EXAMPLES:

```

sage: PF = WeylGroup(['A', 3]).pierifactors()
sage: sorted(w.reduced_word() for w in PF.elements())
[[], [1], [2], [2, 1], [3], [3, 1], [3, 2], [3, 2, 1]]

```

See also:

`maximal_elements()`

Todo: Possibly remove this method and instead have this class inherit from `RecursivelyEnumeratedSet_generic`.

generating_series(weight=None)

Return a length generating series for the elements of `self`.

EXAMPLES:

```

sage: PF = WeylGroup(['C',3,1]).pieri_factors()
sage: PF.generating_series()
6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1

sage: PF = WeylGroup(['B',4]).pieri_factors()
sage: PF.generating_series()
z^7 + 6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1

```

max_length()

Return the maximal length of a Pieri factor.

EXAMPLES:

In type A and A affine, this is n :

```

sage: WeylGroup(['A',5]).pieri_factors().max_length()
5
sage: WeylGroup(['A',5,1]).pieri_factors().max_length()
5

```

In type B and B affine, this is $2n - 1$:

```

sage: WeylGroup(['B',5,1]).pieri_factors().max_length()
9
sage: WeylGroup(['B',5]).pieri_factors().max_length()
9

```

In type C affine this is $2n$:

```

sage: WeylGroup(['C',5,1]).pieri_factors().max_length()
10

```

In type D affine this is $2n - 2$:

```

sage: WeylGroup(['D',5,1]).pieri_factors().max_length()
8

```

class sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

Bases: *sage.combinat.root_system.pieri_factors.PieriFactors*

maximal_elements()

Return the maximal elements of `self` with respect to Bruhat order.

The current implementation is via a conjectural type-free formula. Use `maximal_elements_combinatorial()` for proven type-specific implementations. To compare type-free and type-specific (combinatorial) implementations, use `method_test_maximal_elements()`.

EXAMPLES:

```

sage: W = WeylGroup(['A',4,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 4, 3, 2], [1, 0, 4, 3], [2, 1, 0, 4], [3, 2, 1, 0], [4, 3, 2, 1]]

sage: W = WeylGroup(RootSystem(["C",3,1]).weight_space())
sage: PF = W.pieri_factors()

```

(continues on next page)

(continued from previous page)

```

sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
 [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]

sage: W = WeylGroup(RootSystem(["B",3,1]).weight_space())
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 2, 3, 2, 0], [1, 0, 2, 3, 2], [1, 2, 3, 2, 1],
 [2, 1, 0, 2, 3], [2, 3, 2, 1, 0], [3, 2, 1, 0, 2]]

sage: W = WeylGroup(['D',4,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 2, 4, 3, 2, 0], [1, 0, 2, 4, 3, 2], [1, 2, 4, 3, 2, 1],
 [2, 1, 0, 2, 4, 3], [2, 4, 3, 2, 1, 0], [3, 2, 1, 0, 2, 3],
 [4, 2, 1, 0, 2, 4], [4, 3, 2, 1, 0, 2]]

```

class sage.combinat.root_system.pieri_factors.PieriFactors_finite_type

Bases: *sage.combinat.root_system.pieri_factors.PieriFactors*

The Pieri factors of finite type A are the restriction of the Pieri factors of affine type A to finite permutations (under the canonical embedding of finite type A into the affine Weyl group), and the Pieri factors of finite type B are the restriction of the Pieri factors of affine type C. The finite type D Pieri factors are (weakly) conjectured to be the restriction of the Pieri factors of affine type D.

maximal_elements()

The current algorithm uses the fact that the maximal Pieri factors of affine type A,B,C, or D either contain a finite Weyl group element, or contain an affine Weyl group element whose reflection by s_0 gets a finite Weyl group element, and that either of these finite group elements will serve as a maximal element for finite Pieri factors. A better algorithm is desirable.

EXAMPLES:

```

sage: PF = WeylGroup(['A',5]).pieri_factors()
sage: [v.reduced_word() for v in PF.maximal_elements()]
[[5, 4, 3, 2, 1]]

sage: WeylGroup(['B',4]).pieri_factors().maximal_elements()
[
[-1  0  0  0]
[ 0  1  0  0]
[ 0  0  1  0]
[ 0  0  0  1]
]

```

class sage.combinat.root_system.pieri_factors.PieriFactors_type_A(W)

Bases: *sage.combinat.root_system.pieri_factors.PieriFactors_finite_type*

The set of Pieri factors for finite type A.

This is the set of elements of the Weyl group that have a reduced word that is strictly decreasing. This may also be viewed as the restriction of affine type A Pieri factors to finite Weyl group elements.

maximal_elements_combinatorial()

Return the maximal Pieri factors, using the type A combinatorial description.

EXAMPLES:

```
sage: W = WeylGroup(['A', 4])
sage: PF = W.pieri_factors()
sage: PF.maximal_elements_combinatorial()[0].reduced_word()
[4, 3, 2, 1]
```

stanley_symm_poly_weight(*w*)

EXAMPLES:

```
sage: W = WeylGroup(['A', 4])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3, 1]))
0
```

```
class sage.combinat.root_system.pieri_factors.PieriFactors_type_A_affine(W, min_length,
                                                                    max_length,
                                                                    min_support,
                                                                    max_support)
```

Bases: *sage.combinat.root_system.pieri_factors.PieriFactors_affine_type*

The set of Pieri factors for type A affine, that is the set of elements of the Weyl Group which are cyclically decreasing.

Those are used for constructing (affine) Stanley symmetric functions.

The Pieri factors are in bijection with the proper subsets of the `index_set`. The bijection is given by the support. Namely, let f be a Pieri factor, and red a reduced word for f . No simple reflection appears twice in red , and the support S of red (that is the i such that s_i appears in red) does not depend on the reduced word).

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: WeylGroup(["A", 3, 1]).pier_factors().cardinality()
15
```

generating_series(*weight=None*)

Return a length generating series for the elements of `self`.

EXAMPLES:

```
sage: W = WeylGroup(["A", 3, 1])
sage: W.pieri_factors().cardinality()
15
sage: W.pieri_factors().generating_series()
4*z^3 + 6*z^2 + 4*z + 1
```

maximal_elements_combinatorial()

Return the maximal Pieri factors, using the affine type A combinatorial description.

EXAMPLES:

```
sage: W = WeylGroup(['A', 4, 1])
sage: PF = W.pieri_factors()
sage: [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
[[3, 2, 1, 0], [2, 1, 0, 4], [1, 0, 4, 3], [0, 4, 3, 2], [4, 3, 2, 1]]
```

stanley_symm_poly_weight(w)

Weight used in computing (affine) Stanley symmetric polynomials for affine type A.

EXAMPLES:

```
sage: W = WeylGroup(['A', 5, 1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.one())
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5, 4, 2, 1, 0]))
0
```

subset($length$)

Return the subset of the elements of `self` of length `length`.

INPUT:

- `length` – a non-negative integer

EXAMPLES:

```
sage: PF = WeylGroup(["A", 3, 1]).pierifactors(); PF
Pieri factors for Weyl Group of type ['A', 3, 1] (as a matrix group acting on
↳ the root space)
sage: PF3 = PF.subset(length = 2)
sage: PF3.cardinality()
6
```

class `sage.combinat.root_system.pieri_factors.PieriFactors_type_B`(W)

Bases: `sage.combinat.root_system.pieri_factors.PieriFactors_finite_type`

The type B finite Pieri factors are realized as the set of elements that have a reduced word that is a subword of $12\dots(n-1)n(n-1)\dots 21$. They are the restriction of the type C affine Pieri factors to the set of finite Weyl group elements under the usual embedding.

maximal_elements_combinatorial()

Return the maximal Pieri factors, using the type B combinatorial description.

EXAMPLES:

```
sage: PF = WeylGroup(['B', 4]).pierifactors()
sage: PF.maximal_elements_combinatorial()[0].reduced_word()
[1, 2, 3, 4, 3, 2, 1]
```

stanley_symm_poly_weight(w)

Weight used in computing Stanley symmetric polynomials of type B.

The weight for finite type B is the number of components of the support of an element minus the number of occurrences of n in a reduced word.

EXAMPLES:

```
sage: W = WeylGroup(['B', 5])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3, 1, 5]))
2
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3, 4, 5]))
0
```

(continues on next page)

(continued from previous page)

```
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1,2,3,4,5,4]))
0
```

class `sage.combinat.root_system.pieri_factors.PieriFactors_type_B_affine(W)`

Bases: `sage.combinat.root_system.pieri_factors.PieriFactors_affine_type`

The type B affine Pieri factors are realized as the order ideal (in Bruhat order) generated by the following elements:

- cyclic rotations of the element with reduced word $234\dots(n-1)n(n-1)\dots 3210$, except for $123\dots n\dots 320$ and $023\dots n\dots 321$.
- $123\dots(n-1)n(n-1)\dots 321$
- $023\dots(n-1)n(n-1)\dots 320$

EXAMPLES:

```
sage: W = WeylGroup(['B',4,1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([2,3,4,3,2,1,0]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,3,4,3,2,1]) in PF.maximal_elements()
False
sage: W.from_reduced_word([1,0,2,3,4,3,2]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,3,4,3,2,0]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,0]) in PF
True
```

maximal_elements_combinatorial()

Return the maximal Pieri factors, using the affine type B combinatorial description.

EXAMPLES:

```
sage: W = WeylGroup(['B',4,1])
sage: [u.reduced_word() for u in W.pieri_factors().maximal_elements_
↳combinatorial()]
[[1, 0, 2, 3, 4, 3, 2], [2, 1, 0, 2, 3, 4, 3], [3, 2, 1, 0, 2, 3, 4], [4, 3, 2,
↳1, 0, 2, 3], [3, 4, 3, 2, 1, 0, 2], [2, 3, 4, 3, 2, 1, 0], [1, 2, 3, 4, 3, 2,
↳1], [0, 2, 3, 4, 3, 2, 0]]
```

stanley_symm_poly_weight(w)

Return the weight of a Pieri factor to be used in the definition of Stanley symmetric functions.

For type B, this weight involves the number of components of the complement of the support of an element, where we consider 0 and 1 to be one node – if 1 is in the support, then we pretend 0 in the support, and vice versa. We also consider 0 and 1 to be one node for the purpose of counting components of the complement (as if the Dynkin diagram were that of type C). Let n be the rank of the affine Weyl group in question (if type `['B',k,1]` then we have $n = k+1$). Let $\chi(v.length() < n-1)$ be the indicator function that is 1 if the length of v is smaller than $n-1$, and 0 if the length of v is greater than or equal to $n-1$. If we call $c'(v)$ the number of components of the complement of the support of v , then the type B weight is given by $\text{weight} = c'(v) - \chi(v.length() < n-1)$.

EXAMPLES:

```

sage: W = WeylGroup(['B', 5, 1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0, 3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0, 1, 3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2, 3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2, 3, 4, 5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0, 5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2, 4, 5, 4, 3, 0]))
-1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([4, 5, 4, 3, 0]))
0

```

class sage.combinat.root_system.pieri_factors.PieriFactors_type_C_affine(W)

Bases: *sage.combinat.root_system.pieri_factors.PieriFactors_affine_type*

The type C affine Pieri factors are realized as the order ideal (in Bruhat order) generated by cyclic rotations of the element with unique reduced word $123\dots(n-1)n(n-1)\dots 3210$.

EXAMPLES:

```

sage: W = WeylGroup(['C', 3, 1])
sage: PF = W.pieri_factors()
sage: sorted([u.reduced_word() for u in PF.maximal_elements()], key=str)
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
 [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]

```

maximal_elements_combinatorial()

Return the maximal Pieri factors, using the affine type C combinatorial description.

EXAMPLES:

```

sage: PF = WeylGroup(['C', 3, 1]).pier_factors()
sage: [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [2, 1, 0, 1, 2, 3], [3, 2, 1, 0, 1, 2],
 ↪ [2, 3, 2, 1, 0, 1], [1, 2, 3, 2, 1, 0]]

```

stanley_symm_poly_weight(w)

Return the weight of a Pieri factor to be used in the definition of Stanley symmetric functions.

For type C, this weight is the number of connected components of the support (the indices appearing in a reduced word) of an element.

EXAMPLES:

```

sage: W = WeylGroup(['C', 5, 1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1, 3]))
2
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1, 3, 2, 0]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5, 3, 0]))

```

(continues on next page)

(continued from previous page)

```

3
sage: PF.stanley_symm_poly_weight(W.one())
0

```

class `sage.combinat.root_system.pieri_factors.PieriFactors_type_D_affine(W)`

Bases: `sage.combinat.root_system.pieri_factors.PieriFactors_affine_type`

The type D affine Pieri factors are realized as the order ideal (in Bruhat order) generated by the following elements:

- cyclic rotations of the element with reduced word $234\dots(n-2)n(n-1)(n-2)\dots 3210$ such that 1 and 0 are always adjacent and $(n-1)$ and n are always adjacent.
- $123\dots(n-2)n(n-1)(n-2)\dots 321$
- $023\dots(n-2)n(n-1)(n-2)\dots 320$
- $n(n-2)\dots 2102\dots(n-2)n$
- $(n-1)(n-2)\dots 2102\dots(n-2)(n-1)$

EXAMPLES:

```

sage: W = WeylGroup(['D', 5, 1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([3, 2, 1, 0]) in PF
True
sage: W.from_reduced_word([0, 3, 2, 1]) in PF
False
sage: W.from_reduced_word([0, 1, 3, 2]) in PF
True
sage: W.from_reduced_word([2, 0, 1, 3]) in PF
True
sage: sorted([u.reduced_word() for u in PF.maximal_elements()], key=str)
[[0, 2, 3, 5, 4, 3, 2, 0], [1, 0, 2, 3, 5, 4, 3, 2], [1, 2, 3, 5, 4, 3, 2, 1],
 [2, 1, 0, 2, 3, 5, 4, 3], [2, 3, 5, 4, 3, 2, 1, 0], [3, 2, 1, 0, 2, 3, 5, 4],
 [3, 5, 4, 3, 2, 1, 0, 2], [4, 3, 2, 1, 0, 2, 3, 4], [5, 3, 2, 1, 0, 2, 3, 5],
 [5, 4, 3, 2, 1, 0, 2, 3]]

```

maximal_elements_combinatorial()

Return the maximal Pieri factors, using the affine type D combinatorial description.

EXAMPLES:

```

sage: W = WeylGroup(['D', 5, 1])
sage: PF = W.pieri_factors()
sage: set(PF.maximal_elements_combinatorial()) == set(PF.maximal_elements())
True

```

stanley_symm_poly_weight(w)

Return the weight of w , to be used in the definition of Stanley symmetric functions.

INPUT:

- w – a Pieri factor for this type

For type D , this weight involves the number of components of the complement of the support of an element, where we consider 0 and 1 to be one node – if 1 is in the support, then we pretend 0 in the support, and vice

versa. Similarly with $n - 1$ and n . We also consider 0 and 1, $n - 1$ and n to be one node for the purpose of counting components of the complement (as if the Dynkin diagram were that of type C).

Type D Stanley symmetric polynomial weights are still conjectural. The given weight comes from conditions on elements of the affine Fomin-Stanley subalgebra, but work is needed to show this weight is correct for affine Stanley symmetric functions – see [LSS2009, Pon2010]_ for details.

EXAMPLES:

```
sage: W = WeylGroup(['D', 5, 1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2, 1]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2, 1, 0]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([]))
0

sage: W = WeylGroup(['D', 7, 1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2, 4, 6]))
2
```

5.1.231 Tutorial: visualizing root systems

Root systems encode the positions of collections of hyperplanes in space, and form the fundamental combinatorial data underlying Coxeter and Weyl groups, Lie algebras and groups, etc. The theory can be a bit intimidating at first because of the many technical gadgets (roots, coroots, weights, ...). Visualizing them goes a long way toward building a geometric intuition.

This tutorial starts from simple plots and guides you all the way to advanced plots with your own combinatorial data drawn on top of it.

See also:

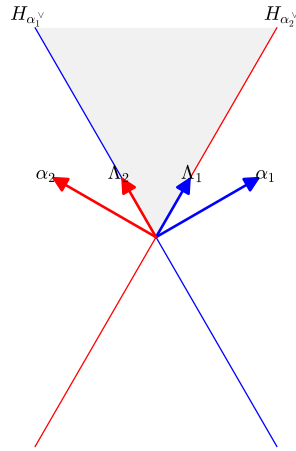

- [Root systems](#) – An overview of root systems in Sage
- [RootLatticeRealizations.ParentMethods.plot\(\)](#) – the main plotting function, with pointers to all the subroutines

First plots

In this first plot, we draw the root system for type A_2 in the ambient space. It is generated from two hyperplanes at a 120 degree angle:

```
sage: L = RootSystem(["A", 2]).ambient_space()
sage: L.plot()
Graphics object consisting of 13 graphics primitives
```

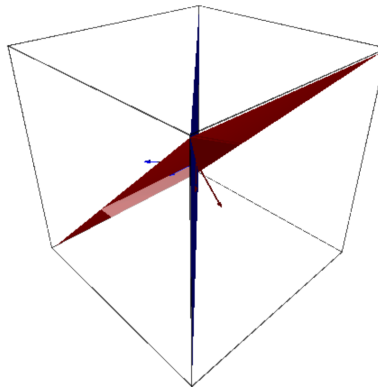

Each of those hyperplane $H_{\alpha_i^V}$ is described by a linear form α_i^V called simple coroot. To each such hyperplane corresponds a reflection along a vector called root. In this picture, the reflections are orthogonal and the two simple roots α_1 and α_2 are vectors which are normal to the reflection hyperplanes. The same color code is used uniformly: blue for

1, red for 2, green for 3, ... (see `CartanType.color()`). The fundamental weights, Λ_1 and Λ_2 form the dual basis of the coroots.

The two reflections generate a group of order six which is nothing but the usual symmetric group S_3 , in its natural action by permutations of the coordinates of the ambient space. Wait, but the ambient space should be of dimension 3 then? That's perfectly right. Here is the full picture in 3D:

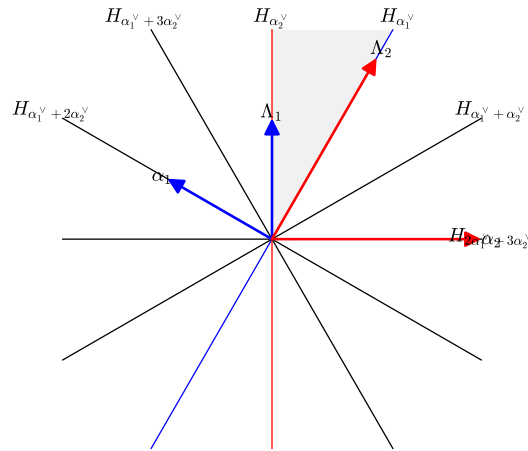

```
sage: L = RootSystem(["A", 2]).ambient_space()
sage: L.plot(projection=False)
Graphics3d Object
```

However in this space, the line $(1, 1, 1)$ is fixed by the action of the group. Therefore, the so called barycentric projection orthogonal to $(1, 1, 1)$ gives a convenient 2D picture which contains all the essential information. The same projection is used by default in type G_2 :

```
sage: L = RootSystem(["G", 2]).ambient_space()
sage: L.plot(reflection_hyperplanes="all")
Graphics object consisting of 21 graphics primitives
```

The group is now the dihedral group of order 12, generated by the two reflections s_1 and s_2 . The picture displays the hyperplanes for all 12 reflections of the group. Those reflections delimit 12 chambers which are in one to one correspondence with the elements of the group. The fundamental chamber, which is grayed out, is associated with the identity of the group.

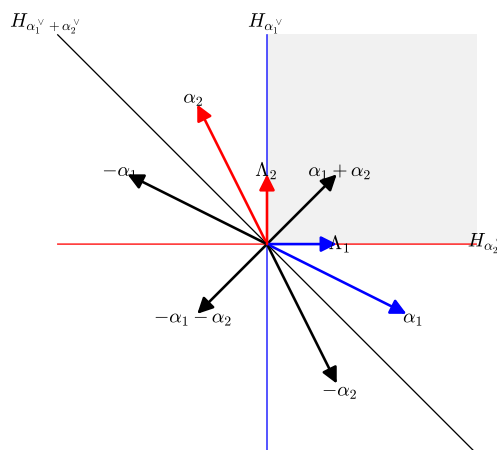

Warning: The fundamental chamber is currently plotted as the cone generated by the fundamental weights. As can be seen on the previous 3D picture this is not quite correct if the fundamental weights do not span the space.

Another caveat is that some plotting features may require manipulating elements with rational coordinates which will fail if one is working in, say, the weight lattice. It is therefore recommended to use the root, weight, or ambient spaces for plotting purposes rather than their lattice counterparts.

Coming back to the symmetric group, here is the picture in the weight space, with all roots and all reflection hyperplanes; remark that, unlike in the ambient space, a root is not necessarily orthogonal to its corresponding reflection hyperplane:

```
sage: L = RootSystem(["A",2]).weight_space()
sage: L.plot(roots="all", reflection_hyperplanes="all").show(figsize=15)
```

Note: Setting a larger figure size as above can help reduce the overlap between the text labels when the figure gets crowded.

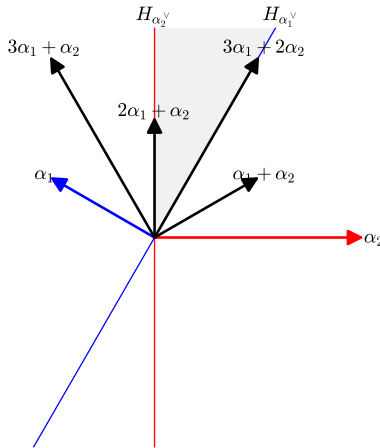

One can further customize which roots to display, as in the following example showing the positive roots in the weight space for type $[G',2]$, labelled by their coordinates in the root lattice:

```

sage: Q = RootSystem(["G",2]).root_space()
sage: L = RootSystem(["G",2]).ambient_space()
sage: L.plot(roots=list(Q.positive_roots()), fundamental_weights=False)
Graphics object consisting of 17 graphics primitives

```

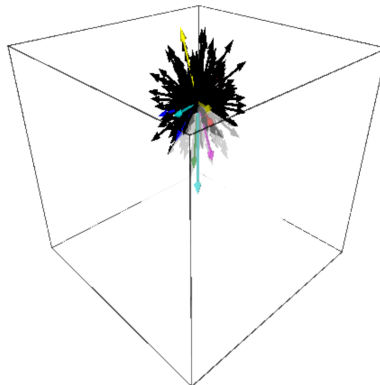

One can also customize the projection by specifying a function. Here, we display all the roots for type E_8 using the projection from its eight dimensional ambient space onto 3D described on [Wikipedia%27s E8 3D picture](#):

```

sage: M = matrix([[0., -0.556793440452, 0.19694925177, -0.19694925177, 0.0805477263944, -
↪ 0.385290876171, 0., 0.385290876171],
.....: [0.180913155536, 0., 0.160212955043, 0.160212955043, 0., 0.
↪ 0.990170516545, 0.766360424875, 0.0990170516545],
.....: [0.338261212718, 0, 0, -0.338261212718, 0.672816364803, 0.171502564281,
↪ 0, -0.171502564281]])
sage: L = RootSystem(["E",8]).ambient_space()
sage: L.dimension()
8
sage: L.plot(roots="all", reflection_hyperplanes=False, projection=lambda v: M*vector(v),
↪ labels=False) # long time
Graphics3d Object

```

The projection function should be linear or affine, and return a vector with rational coordinates. The rationale for the later constraint is to allow for using the PPL exact library for manipulating polytopes. Indeed exact calculations give

cleaner pictures (adjacent objects, intersection with the bounding box, ...). Besides the interface to PPL is indeed currently faster than that for CDD, and it is likely to become even more so.

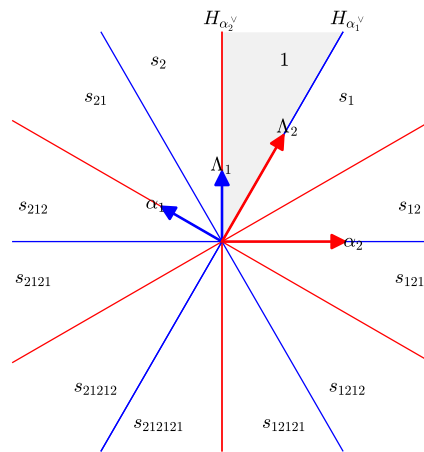

Exercise

Draw all finite root systems in 2D, using the canonical projection onto their Coxeter plane. See [Stembridge's page](#).

Alcoves and chambers

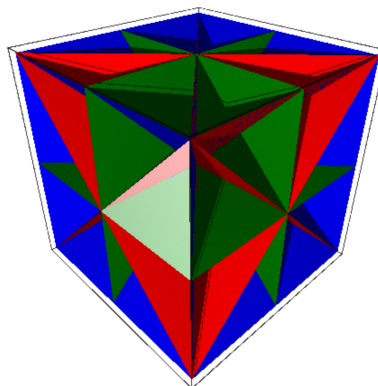

We now draw the root system for type G_2 , with its alcoves (in finite type, those really are the chambers) and the corresponding elements of the Weyl group. We enlarge a bit the bounding box to make sure everything fits in the picture:

```
sage: RootSystem(["G",2]).ambient_space().plot(alcoves=True, alcove_labels=True,
↪ bounding_box=5)
Graphics object consisting of 37 graphics primitives
```

The same picture in 3D, for type B_3 :

```
sage: RootSystem(["B",3]).ambient_space().plot(alcoves=True, alcove_labels=True)
Graphics3d Object
```

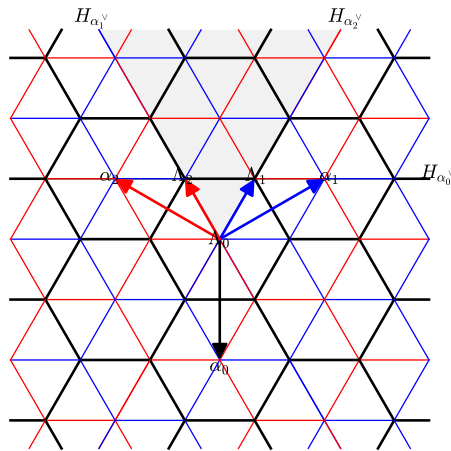

Exercise

Can you spot the fundamental chamber? The fundamental weights? The simple roots? The longest element of the Weyl group?

Alcove pictures for affine types

We now draw the usual alcove picture for affine type $A_2^{(1)}$:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot() # long time
Graphics object consisting of 160 graphics primitives
```

This picture is convenient because it is low dimensional and contains most of the relevant information. Beside, by choosing the ambient space, the elements of the Weyl group act as orthogonal affine maps. In particular, reflections are usual (affine) orthogonal reflections. However this is in fact only a slice of the real picture: the Weyl group actually acts by linear maps on the full ambient space. Those maps stabilize the so-called level l hyperplanes, and we are visualizing here what's happening at level 1. Here is the full picture in 3D:

```
sage: L.plot(bounding_box=[[-3,3],[-3,3],[-1,1]], affine=False) # long time
Graphics3d Object
```

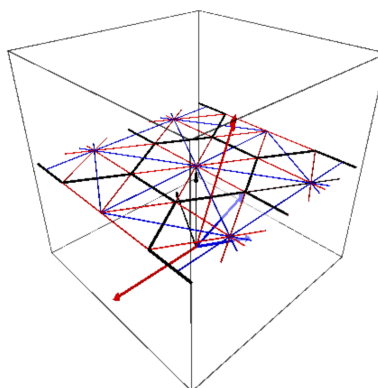

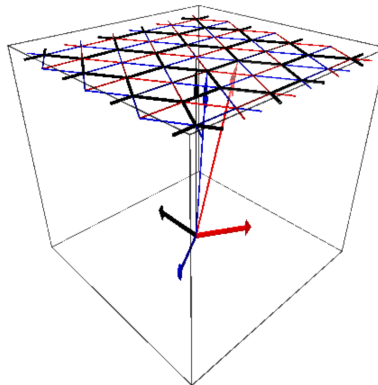

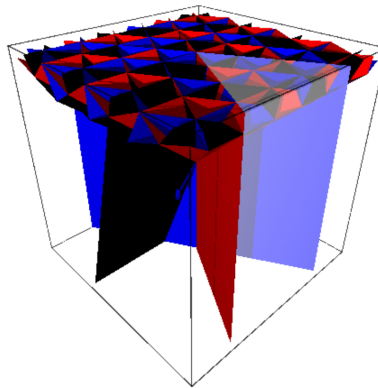

In fact, in type A , this really is a picture in 4D, but as usual the barycentric projection kills the boring extra dimension for us.

It's usually more readable to only draw the intersection of the reflection hyperplanes with the level 1 hyperplane:

```
sage: L.plot(affine=False, level=1) # long time
Graphics3d Object
```

Such 3D pictures are useful to better understand technicalities, like the fact that the fundamental weights do not necessarily all live at level 1:

```
sage: L = RootSystem(["G",2,1]).ambient_space()
sage: L.plot(affine=False, level=1)
Graphics3d Object
```

Note: Such pictures may tend to be a bit flat, and it may be helpful to play with the `aspect_ratio` and more generally with the various options of the `show()` method:

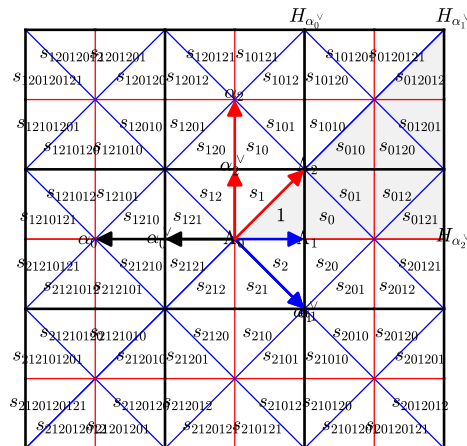

```
sage: p = L.plot(affine=False, level=1)
sage: p.show(aspect_ratio=[1,1,2], frame=False)
```

Exercise

Draw the alcove picture at level 1, and compare the position of the fundamental weights and the vertices of the fundamental alcove.

As for finite root systems, the alcoves are indexed by the elements of the Weyl group W . Two alcoves indexed by u and v respectively share a wall if u and v are neighbors in the right Cayley graph: $u = vs_i$; the color of that wall is given by i :

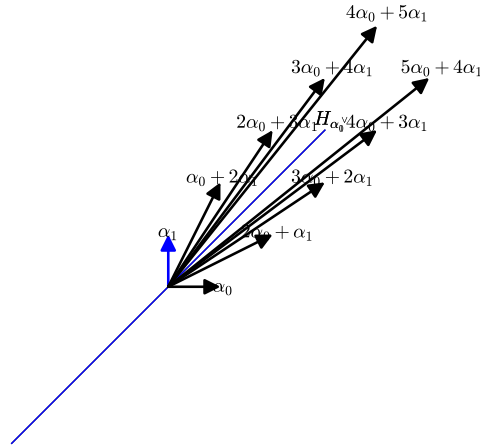

```
sage: L = RootSystem(["C",2,1]).ambient_space()
sage: L.plot(coroots="simple", alcove_labels=True) # long time
Graphics object consisting of 216 graphics primitives
```

Even 2D pictures of the rank $1 + 1$ cases can give some food for thought. Here, we draw the root lattice, with the positive roots of small height in the root poset:

```
sage: L = RootSystem(["A",1,1]).root_lattice()
sage: seed = L.simple_roots()
sage: succ = attrcall("pred")
sage: positive_roots = RecursivelyEnumeratedSet(seed, succ, structure='graded')
sage: it = iter(positive_roots)
sage: first_positive_roots = [next(it) for i in range(10)]
sage: L.plot(roots=first_positive_roots, affine=False, alcoves=False)
Graphics object consisting of 24 graphics primitives
```

Exercises

1. Use the same trick to draw the reflection hyperplanes in the weight lattice for the coroots of small height. Add the indexing of the alcoves by elements of the Weyl group. See below for a solution.
2. Draw the positive roots in the weight lattice and in the extended weight lattice.
3. Draw the reflection hyperplanes in the root lattice
4. Recreate John Stembridge's "Sandwich" arrangement pictures by choosing appropriate coroots for the reflection hyperplanes.

Here is a polished solution for the first exercise:

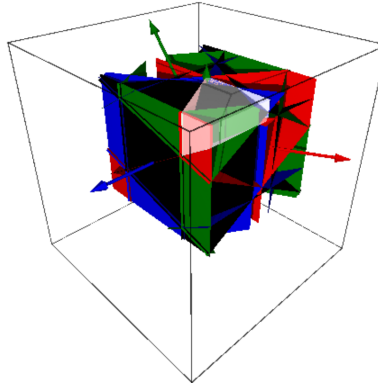

```
sage: L = RootSystem(["A", 1, 1]).weight_space()
sage: seed = L.simple_coroots()
sage: succ = attrcall("pred")
sage: positive_coroots = RecursivelyEnumeratedSet(seed, succ, structure='graded')
sage: it = iter(positive_coroots)
sage: first_positive_coroots = [next(it) for i in range(20)]
sage: p = L.plot(fundamental_chamber=True, reflection_hyperplanes=first_positive_coroots,
.....:         affine=False, alcove_labels=1,
.....:         bounding_box=[[-9, 9], [-1, 2]],
.....:         projection=lambda x: matrix([[1, -1], [1, 1]])*vector(x))
sage: p.show(figsize=20) # long time
```

Higher dimension affine pictures

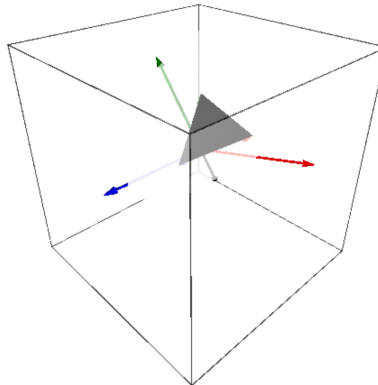

We now do some plots for rank 4 affine types, at level 1. The space is tiled by the alcoves, each of which is a 3D simplex:

```
sage: L = RootSystem(["A", 3, 1]).ambient_space()
sage: L.plot(reflection_hyperplanes=False, bounding_box=85/100) # long time
Graphics3d Object
```

It is recommended to use a small bounding box here, for otherwise the number of simplices grows quicker than what Sage can handle smoothly. It can help to specify explicitly which alcoves to visualize. Here is the fundamental alcove, specified by an element of the Weyl group:

```
sage: W = L.weyl_group()
sage: L.plot(reflection_hyperplanes=False, alcoves=[W.one()], bounding_box=2)
Graphics3d Object
```

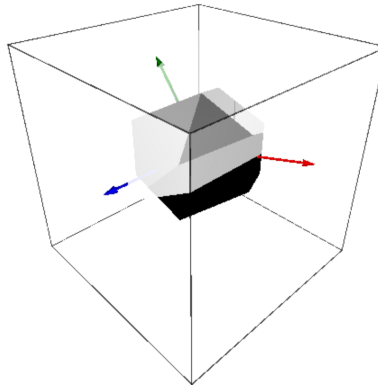

and the fundamental polygon, specified by the coordinates of its center in the root lattice:

```
sage: W = L.weyl_group()
sage: L.plot(reflection_hyperplanes=False, alcoves=[[0,0]], bounding_box=2)
Graphics3d Object
```

Finally, we draw the alcoves in the classical fundamental chambers, using that those are indexed by the elements of the Weyl group having no other left descent than 0. In order to see the inner structure, we only draw the wireframe of the facets of the alcoves. Specifying the `wireframe` option requires a more flexible syntax for plots which will be explained later on in this tutorial:

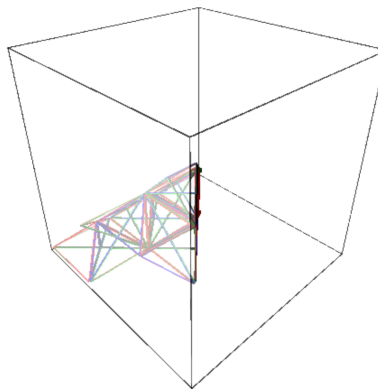

```
sage: L = RootSystem(["B", 3, 1]).ambient_space()
sage: W = L.weyl_group()
sage: alcoves = [~w for d in range(12) for w in W.affine_grassmannian_elements_of_given_
↪ length(d)]
sage: p = L.plot_fundamental_chamber("classical")
sage: p += L.plot_alcoves(alcoves=alcoves, wireframe=True)
sage: p += L.plot_fundamental_weights()
```

(continues on next page)

(continued from previous page)

```
sage: p.show(frame=False)
```

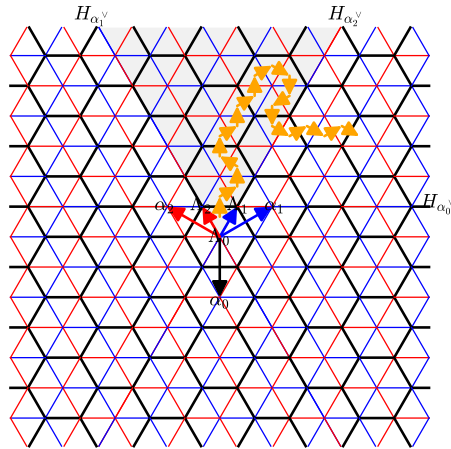

Exercises

1. Draw the fundamental alcove in the ambient space, just by itself (no reflection hyperplane, root, ...). The automorphism group of the Dynkin diagram for $A_3^{(1)}$ (a cycle of length 4) is the dihedral group. Visualize the corresponding symmetries of the fundamental alcove.
2. Draw the fundamental alcoves for the other rank 4 affine types, and recover the automorphism groups of their Dynkin diagram from the pictures.

Drawing on top of a root system plot

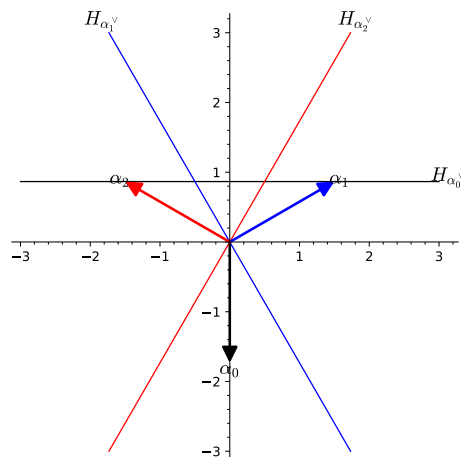

The root system plots have been designed to be used as wallpaper on top of which to draw more information. In the following example, we draw an alcove walk, specified by a word of indices of simple reflections, on top of the weight lattice in affine type $A_{2,1}$:

```
sage: L = RootSystem(["A", 2, 1]).ambient_space()
sage: w1 = [0, 2, 1, 2, 0, 2, 1, 0, 2, 1, 2, 1, 2, 0, 2, 0, 1, 2, 0]
sage: L.plot(alcove_walk=w1, bounding_box=6) # long time
Graphics object consisting of 535 graphics primitives
```

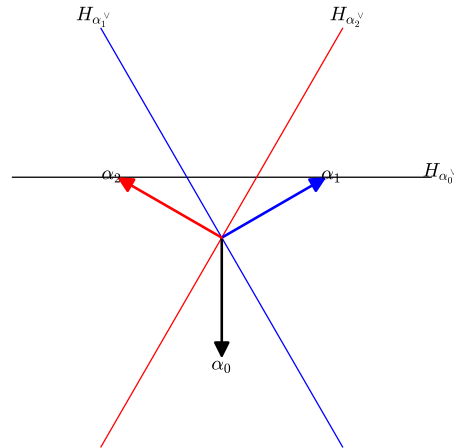

Now, what about drawing several alcove walks, and specifying some colors? A single do-it-all plot method would be cumbersome; so instead, it is actually built on top of many methods (see the list below) that can be called independently and combined at will:

```
sage: L.plot_roots() + L.plot_reflection_hyperplanes()
Graphics object consisting of 12 graphics primitives
```

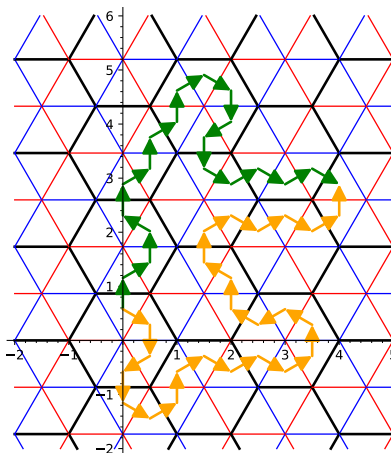

Note: By default the axes are disabled in root system plots since they tend to pollute the picture. Annoyingly they come back when combining them. Here is a workaround:

```
sage: p = L.plot_roots() + L.plot_reflection_hyperplanes()
sage: p.axes(False)
sage: p
Graphics object consisting of 12 graphics primitives
```

In order to specify common information for all the pieces of a root system plot (choice of projection, bounding box, color code for the index set, ...), the easiest is to create an option object using `plot_parse_options()`, and pass it down to each piece. We use this to plot our two walks:

```
sage: plot_options = L.plot_parse_options(bounding_box=[[-2,5],[2,6]])
sage: w2 = [2,1,2,0,2,0,2,1,2,0,1,2,1,2,1,0,1,2,0,2,0,1,2,0,2]
sage: p = L.plot_alcoves(plot_options=plot_options) # long time
sage: p += L.plot_alcove_walk(w1, color="green", plot_options=plot_options) # long time
sage: p += L.plot_alcove_walk(w2, color="orange", plot_options=plot_options) # long time
sage: p # long time
Graphics object consisting of ... graphics primitives
```

And another with some foldings:

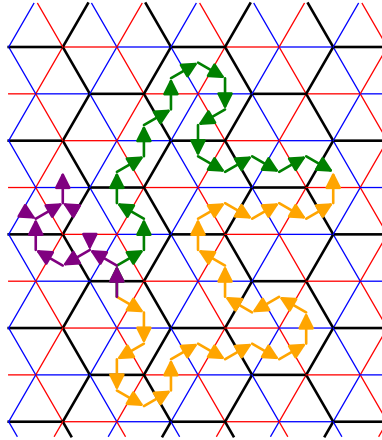

```
sage: p += L.plot_alcove_walk([0,1,2,0,2,0,1,2,0,1],
.....:                        foldings=[False, False, True, False, False, False, True,
↪ False, True, False],
                                         (continues on next page)
```

(continued from previous page)

```

.....:                                     color="purple")
sage: p.axes(False)
sage: p.show(figsize=20)

```

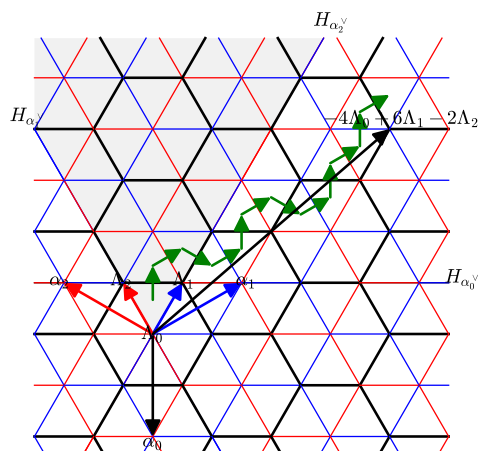

Here we show a weight at level 0 and the reduced word implementing the translation by this weight:

```

sage: L = RootSystem(["A", 2, 1]).ambient_space()
sage: P = RootSystem(["A", 2, 1]).weight_space(extended=True)
sage: Lambda = P.fundamental_weights()
sage: t = 6*Lambda[1] - 2*Lambda[2] - 4*Lambda[0]
sage: walk = L.reduced_word_of_translation(L(t))
sage: plot_options = L.plot_parse_options(bounding_box=[[-2, 5], [-2, 5]])
sage: p = L.plot(plot_options=plot_options) # long time
sage: p += L.plot_alcove_walk(walk, color="green", plot_options=plot_options) # long time
sage: p += plot_options.family_of_vectors({t: L(t)}) # long time
sage: plot_options.finalize(p) # long time
Graphics object consisting of ... graphics primitives
sage: p # long time
Graphics object consisting of ... graphics primitives

```

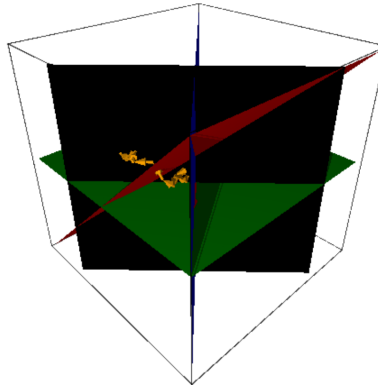

Note that the coloring of the translated alcove does not match with that of the fundamental alcove: the translation actually lives in the extended Weyl group and is the composition of the simple reflections indexed by the alcove walk

together with a rotation implementing an automorphism of the Dynkin diagram.

We conclude with a rank $3 + 1$ alcove walk:

```
sage: L = RootSystem(["B", 3, 1]).ambient_space()
sage: w3 = [0, 2, 1, 3, 2, 0, 2, 1, 0, 2, 3, 1, 2, 1, 3, 2, 0, 2, 0, 1, 2, 0]
sage: L.plot_fundamental_weights() + L.plot_reflection_hyperplanes(bounding_box=2) + L.
↳plot_alcove_walk(w3)
Graphics3d Object
```

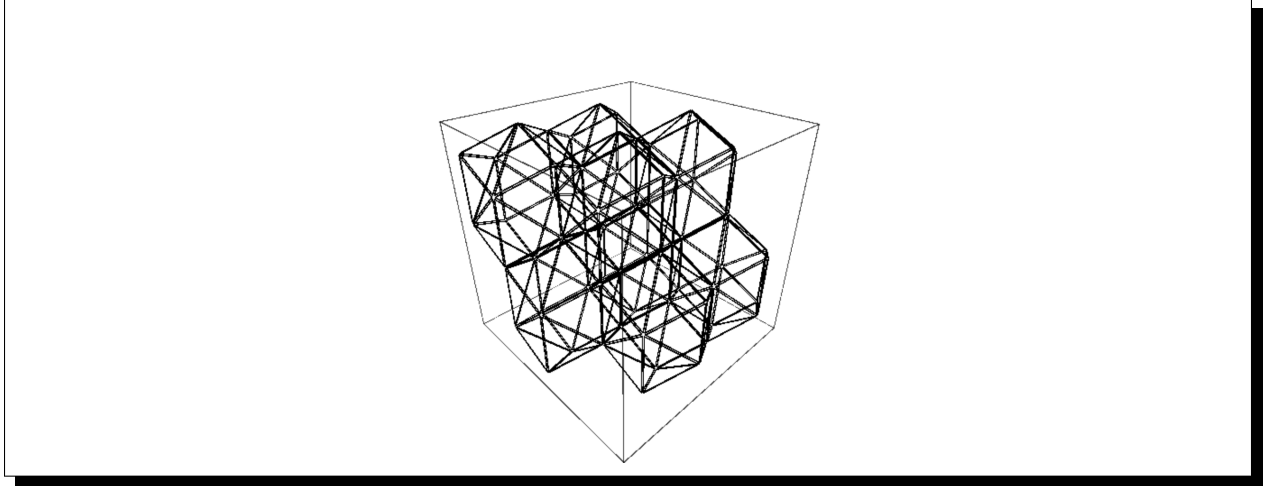

Exercise

1. Draw the tiling of 3D space by the fundamental polygons for types A,B,C,D. Hints: use the `wireframe` option of `RootLatticeRealizations.ParentMethods.plot_alcoves()` and the `color` option of `plot()` to only draw the alcove facets indexed by 0.

Solution

```
sage: L = RootSystem(["A", 3, 1]).ambient_space()
sage: alcoves = cartesian_product([[0, 1], [0, 1], [0, 1]])
sage: color = lambda i: "black" if i==0 else None
sage: L.plot_alcoves(alcoves=alcoves, color=color, bounding_box=10, wireframe=True).
↳show(frame=False) # long time
```

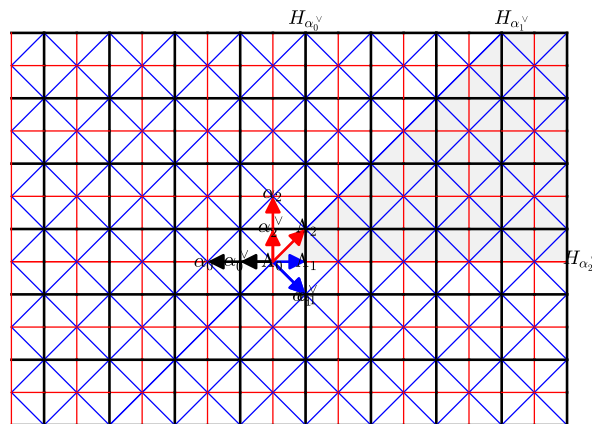

Hand drawing on top of a root system plot (aka Coxeter graph paper)

Taken from John Stembridge's excellent [data archive](#):

"If you've ever worked with affine reflection groups, you've probably wasted lots of time drawing the reflecting hyperplanes of the rank 2 groups on scraps of paper. You may also have wished you had pads of graph paper with these lines drawn in for you. If so, you've come to the right place. Behold! Coxeter graph paper!"

Now you can create your own customized color Coxeter graph paper:

```
sage: L = RootSystem(["C", 2, 1]).ambient_space()
sage: p = L.plot(bounding_box=[[-8,9],[-5,7]], coroots="simple") # long time (10 s)
sage: p # long time
Graphics object consisting of ... graphics primitives
```

By default Sage's plot are bitmap pictures which would come out ugly if printed on paper. Instead, we recommend saving the picture in postscript or svg before printing it:

```
sage: p.save("C21paper.eps") # not tested
```

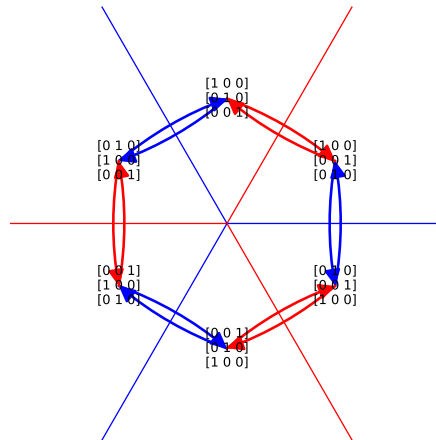

Note: Drawing pictures with a large number of alcoves is currently somewhat ridiculously slow. This is due to the use of generic code that works uniformly in all dimension rather than taylor-made code for 2D. Things should improve

with the fast interface to the PPL library (see e.g. [trac ticket #12553](#)).

Drawing custom objects on top of a root system plot

So far so good. Now, what if one wants to draw, on top of a root system plot, some object for which there is no preexisting plot method? Again, the `plot_options` object come in handy, as it can be used to compute appropriate coordinates. Here we draw the permutohedron, that is the Cayley graph of the symmetric group W , by positioning each element w at $w(\rho)$, where ρ is in the fundamental alcove:

```
sage: L = RootSystem(["A", 2]).ambient_space()
sage: rho = L.rho()
sage: plot_options = L.plot_parse_options()
sage: W = L.weyl_group()
sage: g = W.cayley_graph(side="right")
sage: positions = {w: plot_options.projection(w.action(rho)) for w in W}
sage: p = L.plot_alcoves()
sage: p += g.plot(pos = positions, vertex_size=0,
.....:           color_by_label=plot_options.color)
sage: p.axes(False)
sage: p
Graphics object consisting of 30 graphics primitives
```

Todo: Could we have nice \LaTeX labels in this graph?

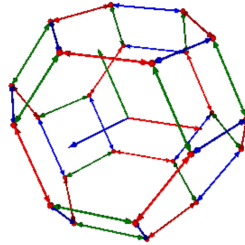

The same picture for A_3 gives a nice 3D permutohedron:

```
sage: L = RootSystem(["A", 3]).ambient_space()
sage: rho = L.rho()
sage: plot_options = L.plot_parse_options()
sage: W = L.weyl_group()
sage: g = W.cayley_graph(side="right")
sage: positions = {w: plot_options.projection(w.action(rho)) for w in W}
sage: p = L.plot_roots()
sage: p += g.plot3d(pos3d=positions, color_by_label=plot_options.color)
```

(continues on next page)

(continued from previous page)

```
sage: p
Graphics3d Object
```

Exercises

1. Locate the identity element of W in the previous picture
2. Rotate the picture appropriately to highlight the various symmetries of the permutohedron.
3. Make a function out of the previous example, and explore the Cayley graphs of all rank 2 and 3 Weyl groups.
4. Draw the root poset for type B_2 and B_3
5. Draw the root poset for type E_8 to recover the picture from [Wikipedia article File:E8_3D.png](#)

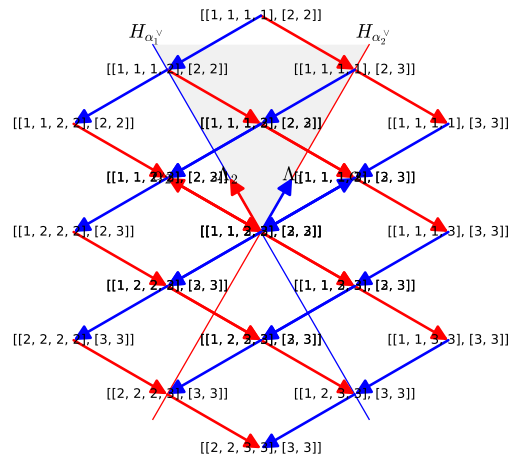

Similarly, we display a crystal graph by positioning each element according to its weight:

```
sage: C = crystals.Tableaux(["A", 2], shape=[4, 2])
sage: L = C.weight_lattice_realization()
sage: plot_options = L.plot_parse_options()

sage: g = C.digraph()
sage: positions = {x: plot_options.projection(x.weight()) for x in C}
sage: p = L.plot()
sage: p += g.plot(pos=positions,
.....:             color_by_label=plot_options.color, vertex_size=0)
sage: p.axes(False)
sage: p.show(figsize=15)
```

Note: In the above picture, many pairs of tableaux have the same weight and are thus superposed (look for example near the center). Some more layout logic would be needed to separate those nodes properly, but the foundations are laid firmly and uniformly across all types of root systems for writing such extensions.

Here is an analogue picture in 3D:

```

sage: C = crystals.Tableaux(["A",3], shape=[3,2,1])
sage: L = C.weight_lattice_realization()
sage: plot_options = L.plot_parse_options()
sage: g = C.digraph()
sage: positions = {x:plot_options.projection(x.weight()) for x in C}
sage: p = L.plot(reflection_hyperplanes=False, fundamental_weights=False)
sage: p += g.plot3d(pos3d=positions, vertex_labels=True,
.....:               color_by_label=plot_options.color, edge_labels=True)
sage: p
Graphics3d Object

```

Exercise

Explore the previous picture and notice how the edges of the crystal graph are parallel to the simple roots.

Enjoy and please post your best pictures on the [Sage-Combinat wiki](#).

```

class sage.combinat.root_system.plot.PlotOptions(space, projection=True, bounding_box=3,
color=<bound method CartanTypeFactory.color of
<class
'sage.combinat.root_system.cartan_type.CartanTypeFactory'>>,
labels=True, level=None, affine=None,
arrowsize=5)

```

Bases: object

A class for plotting options for root lattice realizations.

See also:

- [RootLatticeRealizations.ParentMethods.plot\(\)](#) for a description of the plotting options
- [Tutorial: visualizing root systems](#) for a tutorial on root system plotting

color(*i*)

Return the color to be used for objects indexed by *i*.

INPUT:

- *i* – an index

See also:

[`index_of_object\(\)`](#)

EXAMPLES:

```
sage: L = RootSystem(["A", 2]).root_lattice()
sage: options = L.plot_parse_options(labels=False)
sage: alpha = L.simple_roots()
sage: options.color(1)
'blue'
sage: options.color(2)
'red'
sage: for alpha in L.roots():
.....:     print("{} {}".format(alpha, options.color(alpha)))
alpha[1]          blue
alpha[2]          red
alpha[1] + alpha[2] black
-alpha[1]         black
-alpha[2]         black
-alpha[1] - alpha[2] black
```

cone(rays=[], lines=[], color='black', thickness=1, alpha=1, wireframe=False, label=None, draw_degenerate=True, as_polyhedron=False)

Return the cone generated by the given rays and lines.

INPUT:

- rays, lines – lists of elements of the root lattice realization (default: [])
- color – a color (default: "black")
- alpha – a number in the interval [0, 1] (default: 1) the desired transparency
- label – an object to be used as for this cone. The label itself will be constructed by calling `latex()` or `repr()` on the object depending on the graphics backend.
- draw_degenerate – a boolean (default: True) whether to draw cones with a degenerate intersection with the bounding box
- as_polyhedron – a boolean (default: False) whether to return the result as a polyhedron, without clipping it to the bounding box, and without making a plot out of it (for testing purposes)

OUTPUT:

A graphic object, a polyhedron, or \emptyset .

EXAMPLES:

```
sage: L = RootSystem(["A", 2]).root_lattice()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: p = options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green',
↳ label=2)
sage: p
Graphics object consisting of 2 graphics primitives
sage: list(p)
[Polygon defined by 4 points,
Text '$2$' at the point (3.15..., 3.15...)]
```

(continues on next page)

(continued from previous page)

```
sage: options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2,
↳ as_polyhedron=True)
A 2-dimensional polyhedron in ZZ^2 defined as the convex hull of 1 vertex, 1
↳ ray, 1 line
```

An empty result, being outside of the bounding box:

```
sage: options = L.plot_parse_options(labels=True, bounding_box=[[-10,-9]]*2)
sage: options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2)
0
```

Test that the options are properly passed down:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
sage: p = options.cone(rays=[alpha[1]+alpha[2]], color='green', label=2,
↳ thickness=4, alpha=.5)
sage: list(p)
[Line defined by 2 points, Text '$2$' at the point (3.15...,3.15...)]
sage: sorted(p[0].options().items())
[('alpha', 0.5000000000000000), ('legend_color', None),
 ('legend_label', None), ('rgbcolor', 'green'), ('thickness', 4),
 ('zorder', 1)]
```

This method is tested indirectly but extensively by the various plot methods of root lattice realizations.

empty(*args)

Return an empty plot.

EXAMPLES:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options(labels=True)
```

This currently returns `int(0)`:

```
sage: options.empty()
0
```

This is not a plot, so may cause some corner cases. On the other hand, `0` behaves as a fast neutral element, which is important given the typical idioms used in the plotting code:

```
sage: p = point([0,0])
sage: p + options.empty() is p
True
```

family_of_vectors(vectors)

Return a plot of a family of vectors.

INPUT:

- `vectors` – family or vectors in `self`

The vectors are labelled by their index.

EXAMPLES:

```

sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: p = options.family_of_vectors(alpha); p
Graphics object consisting of 4 graphics primitives
sage: list(p)
[Arrow from (0.0,0.0) to (1.0,0.0),
 Text '$1$' at the point (1.05,0.0),
 Arrow from (0.0,0.0) to (0.0,1.0),
 Text '$2$' at the point (0.0,1.05)]

```

Handling of colors and labels:

```

sage: color=lambda i: "purple" if i==1 else None
sage: options = L.plot_parse_options(labels=False, color=color)
sage: p = options.family_of_vectors(alpha)
sage: list(p)
[Arrow from (0.0,0.0) to (1.0,0.0)]
sage: p[0].options()['rgbcolor']
'purple'

```

Matplotlib emits a warning for arrows of length 0 and draws nothing anyway. So we do not draw them at all:

```

sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: Lambda = L.fundamental_weights()
sage: p = options.family_of_vectors(Lambda); p
Graphics object consisting of 5 graphics primitives
sage: list(p)
[Text '$0$' at the point (0.0,0.0),
 Arrow from (0.0,0.0) to (0.5,0.86602451838...),
 Text '$1$' at the point (0.525,0.909325744308...),
 Arrow from (0.0,0.0) to (-0.5,0.86602451838...),
 Text '$2$' at the point (-0.525,0.909325744308...)]

```

finalize(G)

Finalize a root system plot.

INPUT:

- G – a root system plot or \emptyset

This sets the aspect ratio to 1 and remove the axes. This should be called by all the user-level plotting methods of root systems. This will become mostly obsolete when customization options won't be lost anymore upon addition of graphics objects and there will be a proper empty object for 2D and 3D plots.

EXAMPLES:

```

sage: L = RootSystem(["B",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: p = L.plot_roots(plot_options=options)
sage: p += L.plot_coroots(plot_options=options)
sage: p.axes()
True

```

(continues on next page)

(continued from previous page)

```

sage: p = options.finalize(p)
sage: p.axes()
False
sage: p.aspect_ratio()
1.0

sage: options = L.plot_parse_options(affine=False)
sage: p = L.plot_roots(plot_options=options)
sage: p += point([[1,1,0]])
sage: p = options.finalize(p)
sage: p.aspect_ratio()
[1.0, 1.0, 1.0]

```

If the input is \emptyset , this returns an empty graphics object:

```

sage: type(options.finalize(0))
<class 'sage.plot.plot3d.base.Graphics3dGroup'>

sage: options = L.plot_parse_options()
sage: type(options.finalize(0))
<class 'sage.plot.graphics.Graphics'>
sage: list(options.finalize(0))
[]

```

in_bounding_box(*x*)

Return whether *x* is in the bounding box.

INPUT:

- *x* – an element of the root lattice realization

This method is currently one of the bottlenecks, and therefore cached.

EXAMPLES:

```

sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: options.in_bounding_box(alpha[1])
True
sage: options.in_bounding_box(3*alpha[1])
False

```

index_of_object(*i*)

Try to return the node of the Dynkin diagram indexing the object *i*.

OUTPUT: a node of the Dynkin diagram or None

EXAMPLES:

```

sage: L = RootSystem(["A",3]).root_lattice()
sage: alpha = L.simple_roots()
sage: omega = RootSystem(["A",3]).weight_lattice().fundamental_weights()
sage: options = L.plot_parse_options(labels=False)
sage: options.index_of_object(3)

```

(continues on next page)

(continued from previous page)

```

3
sage: options.index_of_object(alpha[1])
1
sage: options.index_of_object(omega[2])
2
sage: options.index_of_object(omega[2]+omega[3])
sage: options.index_of_object(30)
sage: options.index_of_object("bla")

```

intersection_at_level_1(*x*)Return *x* scaled at the appropriate level, if level is set; otherwise return *x*.

INPUT:

- *x* – an element of the root lattice realization

EXAMPLES:

```

sage: L = RootSystem(["A", 2, 1]).weight_space()
sage: options = L.plot_parse_options()
sage: options.intersection_at_level_1(L.rho())
1/3*Lambda[0] + 1/3*Lambda[1] + 1/3*Lambda[2]

sage: options = L.plot_parse_options(affine=False, level=2)
sage: options.intersection_at_level_1(L.rho())
2/3*Lambda[0] + 2/3*Lambda[1] + 2/3*Lambda[2]

```

When level is not set, *x* is returned:

```

sage: options = L.plot_parse_options(affine=False)
sage: options.intersection_at_level_1(L.rho())
Lambda[0] + Lambda[1] + Lambda[2]

```

projection(*v*)Return the projection of *v*.

INPUT:

- *x* – an element of the root lattice realization

OUTPUT:

An immutable vector with integer or rational coefficients.

EXAMPLES:

```

sage: L = RootSystem(["A", 2, 1]).ambient_space()
sage: options = L.plot_parse_options()
sage: options.projection(L.rho())
(0, 989/571)

sage: options = L.plot_parse_options(projection=False)
sage: options.projection(L.rho())
(2, 1, 0)

```

reflection_hyperplane(*coroot*, *as_polyhedron=False*)

Return a plot of the reflection hyperplane indexed by this coroot.

- `coroot` – a coroot

EXAMPLES:

```
sage: L = RootSystem(["B", 2]).weight_space()
sage: alphacheck = L.simple_coroots()
sage: options = L.plot_parse_options()
sage: H = options.reflection_hyperplane(alphacheck[1]); H
Graphics object consisting of 2 graphics primitives
```

Todo: Display the periodic orientation by adding a + and a – sign close to the label. Typically by using the associated root to shift a bit from the vertex upon which the hyperplane label is attached.

text(*label*, *position*, *rgbcolor*=(0, 0, 0))

Return text widget with label *label* at position *position*

INPUT:

- *label* – a string, or a Sage object upon which latex will be called
- *position* – a position
- *rgbcolor* – the color as an RGB tuple

EXAMPLES:

```
sage: L = RootSystem(["A", 2]).root_lattice()
sage: options = L.plot_parse_options()
sage: list(options.text("coucou", [0, 1]))
[Text 'coucou' at the point (0.0, 1.0)]
sage: list(options.text(L.simple_root(1), [0, 1]))
[Text '$\alpha_{1}$' at the point (0.0, 1.0)]
sage: list(options.text(L.simple_root(2), [1, 0], rgbcolor=(1, 0.5, 0)))
[Text '$\alpha_{2}$' at the point (1.0, 0.0)]

sage: options = RootSystem(["A", 2]).root_lattice().plot_parse_
↪options(labels=False)
sage: options.text("coucou", [0, 1])
0

sage: options = RootSystem(["B", 3]).root_lattice().plot_parse_options()
sage: print(options.text("coucou", [0, 1, 2]).x3d_str())
<Transform translation='0 1 2'>
<Shape><Text string='coucou' solid='true'/><Appearance><Material diffuseColor=
↪'0.0 0.0 0.0' shininess='1.0' specularColor='0.0 0.0 0.0'/></Appearance></
↪Shape>
</Transform>
```

thickness(*i*)

Return the thickness to be used for lines indexed by *i*.

INPUT:

- *i* – an index

See also:

`index_of_object()`

EXAMPLES:

```
sage: L = RootSystem(["A", 2, 1]).root_lattice()
sage: options = L.plot_parse_options(labels=False)
sage: alpha = L.simple_roots()
sage: options.thickness(0)
2
sage: options.thickness(1)
1
sage: options.thickness(2)
1
sage: for alpha in L.simple_roots():
.....:     print("{} {}".format(alpha, options.thickness(alpha)))
alpha[0] 2
alpha[1] 1
alpha[2] 1
```

`sage.combinat.root_system.plot.barycentric_projection_matrix(n, angle=0)`

Returns a family of $n + 1$ vectors evenly spaced in a real vector space of dimension n

Those vectors are of norm 1, the scalar product between any two vector is $1/n$, thus the distance between two tips is constant.

The family is built recursively and uniquely determined by the following property: the last vector is $(0, \dots, 0, -1)$, and the projection of the first n vectors in dimension $n - 1$, after appropriate rescaling to norm 1, retrieves the family for $n - 1$.

OUTPUT:

A matrix with $n + 1$ columns of height n with rational or symbolic coefficients.

EXAMPLES:

One vector in dimension 0:

```
sage: from sage.combinat.root_system.root_lattice_realizations import barycentric_
->projection_matrix
sage: m = barycentric_projection_matrix(0); m
[]
sage: matrix(QQ, 0, 1).nrows()
0
sage: matrix(QQ, 0, 1).ncols()
1
```

Two vectors in dimension 1:

```
sage: barycentric_projection_matrix(1)
[ 1 -1]
```

Three vectors in dimension 2:

```
sage: barycentric_projection_matrix(2)
[ 1/2*sqrt(3) -1/2*sqrt(3) 0]
[ 1/2 1/2 -1]
```

Four vectors in dimension 3:

```
sage: m = barycentric_projection_matrix(3); m
[ 1/3*sqrt(3)*sqrt(2) -1/3*sqrt(3)*sqrt(2) 0
↪0]
[          1/3*sqrt(2)          1/3*sqrt(2) -2/3*sqrt(2)
↪0]
[          1/3          1/3          1/3
↪1]
```

The columns give four vectors that sum up to zero:

```
sage: sum(m.columns())
(0, 0, 0)
```

and have regular mutual angles:

```
sage: m.transpose()*m
[ 1 -1/3 -1/3 -1/3]
[-1/3 1 -1/3 -1/3]
[-1/3 -1/3 1 -1/3]
[-1/3 -1/3 -1/3 1]
```

Here is a plot of them:

```
sage: sum(arrow((0,0,0),x) for x in m.columns())
Graphics3d Object
```

For 2D drawings of root systems, it is desirable to rotate the result to match with the usual conventions:

```
sage: barycentric_projection_matrix(2, angle=2*pi/3)
[ 1/2 -1 1/2]
[ 1/2*sqrt(3) 0 -1/2*sqrt(3)]
```

5.1.232 Finite complex reflection groups

Let V be a finite-dimensional complex vector space. A reflection of V is an operator $r \in GL(V)$ that has finite order and fixes pointwise a hyperplane in V .

For more definitions and classification types of finite complex reflection groups, see [Wikipedia article Complex_reflection_group](#).

The point of entry to work with reflection groups is `ReflectionGroup()` which can be used with finite Cartan-Killing types:

```
sage: ReflectionGroup(['A',2]) # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup(['F',4]) # optional - gap3
Irreducible real reflection group of rank 4 and type F4
sage: ReflectionGroup(['H',3]) # optional - gap3
Irreducible real reflection group of rank 3 and type H3
```

or with Shephard-Todd types:

```

sage: ReflectionGroup((1,1,3)) # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup((2,1,3)) # optional - gap3
Irreducible real reflection group of rank 3 and type B3
sage: ReflectionGroup((3,1,3)) # optional - gap3
Irreducible complex reflection group of rank 3 and type G(3,1,3)
sage: ReflectionGroup((4,2,3)) # optional - gap3
Irreducible complex reflection group of rank 3 and type G(4,2,3)
sage: ReflectionGroup(4) # optional - gap3
Irreducible complex reflection group of rank 2 and type ST4
sage: ReflectionGroup(31) # optional - gap3
Irreducible complex reflection group of rank 4 and type ST31

```

Also reducible types are allowed using concatenation:

```

sage: ReflectionGroup(['A',3],(4,2,3)) # optional - gap3
Reducible complex reflection group of rank 6 and type A3 x G(4,2,3)

```

Some special cases also occur, among them are:

```

sage: W = ReflectionGroup((2,2,2)); W # optional - gap3
Reducible real reflection group of rank 2 and type A1 x A1
sage: W = ReflectionGroup((2,2,3)); W # optional - gap3
Irreducible real reflection group of rank 3 and type A3

```

Warning: Uses the GAP3 package *Chevie* which is available as an experimental package (installed by `sage -i gap3`) or to download by hand from [Jean Michel's website](#).

A guided tour

We start with the example type B_2 :

```

sage: W = ReflectionGroup(['B',2]); W # optional - gap3
Irreducible real reflection group of rank 2 and type B2

```

Most importantly, observe that the group elements are usually represented by permutations of the roots:

```

sage: for w in W: print(w) # optional - gap3
()
(1,3)(2,6)(5,7)
(1,5)(2,4)(6,8)
(1,7,5,3)(2,4,6,8)
(1,3,5,7)(2,8,6,4)
(2,8)(3,7)(4,6)
(1,7)(3,5)(4,8)
(1,5)(2,6)(3,7)(4,8)

```

This has the drawback that one can hardly see anything. Usually, one would look at elements with either of the following methods:

```

sage: for w in W: w.reduced_word()                                # optional - gap3
[]
[2]
[1]
[1, 2]
[2, 1]
[2, 1, 2]
[1, 2, 1]
[1, 2, 1, 2]

sage: for w in W: w.reduced_word_in_reflections()                # optional - gap3
[]
[2]
[1]
[1, 2]
[1, 4]
[3]
[4]
[1, 3]

sage: for w in W: w.reduced_word(); w.to_matrix(); print("")    # optional - gap3
[]
[1 0]
[0 1]

[2]
[ 1  1]
[ 0 -1]

[1]
[-1 0]
[ 2  1]

[1, 2]
[-1 -1]
[ 2  1]

[2, 1]
[ 1  1]
[-2 -1]

[2, 1, 2]
[ 1  0]
[-2 -1]

[1, 2, 1]
[-1 -1]
[ 0  1]

[1, 2, 1, 2]
[-1  0]
[ 0 -1]

```

The standard references for actions of complex reflection groups have the matrices acting on the right, so:

```
sage: W.simple_reflection(1).to_matrix()           # optional - gap3
[-1  0]
[ 2  1]
```

sends the simple root α_0 , or $(1, 0)$ in vector notation, to its negative, while sending α_1 to $2\alpha_0 + \alpha_1$.

Todo:

- properly provide root systems for real reflection groups
- element class should be unique to be able to work with large groups without creating elements multiple times
- `is_shephard_group`, `is_generalized_coxeter_group`
- exponents and coexponents
- coinvariant ring:
 - fake degrees from Torsten Hoge
 - operation of linear characters on all characters
 - harmonic polynomials
- linear forms for hyperplanes
- field of definition
- intersection lattice and characteristic polynomial:

```
X = [ alpha(t) for t in W.distinguished_reflections() ]
X = Matrix(CF, X).transpose()
Y = Matroid(X)
```

- linear characters
- permutation π on irreducibles
- hyperplane orbits (76.13 in Gap Manual)
- improve `invariant_form` with a code similar to the one in `reflection_group_real.py`
- add a method `reflection_to_root` or `distinguished_reflection_to_positive_root`
- diagrams in ASCII-art (76.15)
- standard (BMR) presentations
- character table directly from Chevie
- `GenericOrder` (76.20), `TorusOrder` (76.21)
- correct fundamental invariants for G_{34} , check the others
- copy hardcoded data (degrees, invariants, braid relations...) into sage
- add other hardcoded data from the tables in chevie (location is `SAGEDIR/local/gap3/gap-jm5-2015-02-01/gap3/pkg/chevie/tbl`): basic derivations, discriminant, ...
- transfer code for `reduced_word_in_reflections` into Gap4 or Sage
- list of reduced words for an element
- list of reduced words in reflections for an element

- Hurwitz action?
- `is_crystallographic()` should be hardcoded

                                                                    dex_set=None,
                                                                    hyper-
                                                                    plane_index_set=None,
                                                                    reflec-
                                                                    tion_index_set=None)
```

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.groups.perm_gps.permgroup.PermutationGroup_generic`

A complex reflection group given as a permutation group.

See also:

[ReflectionGroup\(\)](#)

class `Element`

Bases: `sage.combinat.root_system.reflection_group_element.ComplexReflectionGroupElement`

conjugacy_class()

Return the conjugacy class of `self`.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for w in W: sorted(w.conjugacy_class()) # optional - gap3
[()]
[(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)]
[(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)]
[(1,2,6)(3,4,5), (1,6,2)(3,5,4)]
[(1,2,6)(3,4,5), (1,6,2)(3,5,4)]
[(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)]
```

conjugacy_class_representative()

Return a representative of the conjugacy class of `self`.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for w in W: # optional - gap3
.....:     print('%s %s'%(w.reduced_word(), w.conjugacy_class_
↪representative().reduced_word())) # optional - gap3
[] []
[2] [1]
[1] [1]
[1, 2] [1, 2]
[2, 1] [1, 2]
[1, 2, 1] [1]
```

reflection_length(*in_unitary_group=False*)

Return the reflection length of `self`.

This is the minimal numbers of reflections needed to obtain `self`.

INPUT:

- `in_unitary_group` – (default: `False`) if `True`, the reflection length is computed in the unitary group which is the dimension of the move space of `self`

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: sorted([t.reflection_length() for t in W]) # optional - gap3
[0, 1, 1, 1, 2, 2]

sage: W = ReflectionGroup((2,1,2)) # optional - gap3
sage: sorted([t.reflection_length() for t in W]) # optional - gap3
[0, 1, 1, 1, 1, 2, 2, 2]

sage: W = ReflectionGroup((2,2,2)) # optional - gap3
sage: sorted([t.reflection_length() for t in W]) # optional - gap3
[0, 1, 1, 2]

sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: sorted([t.reflection_length() for t in W]) # optional - gap3
[0, 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 2]
```

apply_vector_field(*f*, *vf*=None)

Returns a rational function obtained by applying the vector field `vf` to the rational function `f`.

If `vf` is not given, the primitive vector field is used.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: for x in W.primitive_vector_field()[0].parent().gens(): # optional - gap3
.....:     print(W.apply_vector_field(x))
3*x1/(6*x0^2 - 6*x0*x1 - 12*x1^2)
1/(6*x0^2 - 6*x0*x1 - 12*x1^2)
```

braid_relations()

Return the braid relations of `self`.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.braid_relations() # optional - gap3
[[[1, 2, 1], [2, 1, 2]]]

sage: W = ReflectionGroup((2,1,3)) # optional - gap3
sage: W.braid_relations() # optional - gap3
[[[1, 2, 1, 2], [2, 1, 2, 1]], [[1, 3], [3, 1]], [[2, 3, 2], [3, 2, 3]]]

sage: W = ReflectionGroup((2,2,3)) # optional - gap3
sage: W.braid_relations() # optional - gap3
[[[1, 2, 1], [2, 1, 2]], [[1, 3], [3, 1]], [[2, 3, 2], [3, 2, 3]]]
```

cartan_matrix()

Return the Cartan matrix associated with `self`.

If `self` is crystallographic, the returned Cartan matrix is an instance of `CartanMatrix`, and a normal matrix otherwise.

Let s_1, \dots, s_n be a set of reflections which generate `self` with associated simple roots s_1, \dots, s_n and simple coroots s_i^\vee . Then the Cartan matrix $C = (c_{ij})$ is given by $s_i^\vee(s_j)$. The Cartan matrix completely determines the reflection representation if the s_i are linearly independent.

EXAMPLES:

```

sage: ReflectionGroup(['A',4]).cartan_matrix()           # optional - gap3
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]

sage: ReflectionGroup(['H',4]).cartan_matrix()         # optional - gap3
[          2 E(5)^2 + E(5)^3          0          0]
[E(5)^2 + E(5)^3          2          -1          0]
[          0          -1          2          -1]
[          0          0          -1          2]

sage: ReflectionGroup(4).cartan_matrix()              # optional - gap3
[-2*E(3) - E(3)^2          E(3)^2]
[          -E(3)^2 -2*E(3) - E(3)^2]

sage: ReflectionGroup((4,2,2)).cartan_matrix()       # optional - gap3
[  2  -2*E(4)  -2]
[ E(4)      2 1 - E(4)]
[-1 1 + E(4)  2]

```

codedegrees()

Return the codegrees of `self` ordered within each irreducible component of `self`.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,4))                   # optional - gap3
sage: W.codedegrees()                                # optional - gap3
(2, 1, 0)

sage: W = ReflectionGroup((2,1,4))                   # optional - gap3
sage: W.codedegrees()                                # optional - gap3
(6, 4, 2, 0)

sage: W = ReflectionGroup((4,1,4))                   # optional - gap3
sage: W.codedegrees()                                # optional - gap3
(12, 8, 4, 0)

sage: W = ReflectionGroup((4,2,4))                   # optional - gap3
sage: W.codedegrees()                                # optional - gap3
(12, 8, 4, 0)

sage: W = ReflectionGroup((4,4,4))                   # optional - gap3
sage: W.codedegrees()                                # optional - gap3
(8, 8, 4, 0)

```

(continues on next page)

(continued from previous page)

```

sage: W = ReflectionGroup((1,1,4), (3,1,2)) # optional - gap3
sage: W.codedegrees() # optional - gap3
(2, 1, 0, 3, 0)

sage: W = ReflectionGroup((1,1,4), (6,1,12), 23) # optional - gap3 #_
↪ fails in GAP3
sage: W.codedegrees() # optional - gap3
(2, 1, 0, 66, 60, 54, 48, 42, 36, 30, 24, 18, 12, 6, 0, 8, 4, 0)

```

conjugacy_classes()

Return the conjugacy classes of self.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for C in W.conjugacy_classes(): sorted(C) # optional - gap3
[()]
[(1,3)(2,5)(4,6), (1,4)(2,3)(5,6), (1,5)(2,4)(3,6)]
[(1,2,6)(3,4,5), (1,6,2)(3,5,4)]

sage: W = ReflectionGroup((1,1,4)) # optional - gap3
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality() # optional -
↪ gap3
True

sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality() # optional -
↪ gap3
True

sage: W = ReflectionGroup(23) # optional - gap3
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality() # optional -
↪ gap3
True

```

conjugacy_classes_representatives()

Return the shortest representatives of the conjugacy classes of self.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()] #_
↪ optional - gap3
[[], [1], [1, 2]]

sage: W = ReflectionGroup((1,1,4)) # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()] #_
↪ optional - gap3
[[], [1], [1, 3], [1, 2], [1, 3, 2]]

sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()] #_
↪ optional - gap3

```

(continues on next page)

(continued from previous page)

```

[[], [1], [1, 1], [2, 1, 2, 1], [2, 1, 2, 1, 1],
 [2, 1, 1, 2, 1, 1], [2], [1, 2], [1, 1, 2]]

sage: W = ReflectionGroup(23) # optional - gap3
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()] #_
↳ optional - gap3
[[],
 [1],
 [1, 2],
 [1, 3],
 [2, 3],
 [1, 2, 3],
 [1, 2, 1, 2],
 [1, 2, 1, 2, 3],
 [1, 2, 1, 2, 3, 2, 1, 2, 3],
 [1, 2, 1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]]

```

coxeter_number(chi=None)

Return the Coxeter number associated to the irreducible character *chi* of the reflection group *self*.

The *Coxeter number* of a complex reflection group *W* is the trace in a character χ of $\sum_t (Id - t)$, where *t* runs over all reflections. The result is always an integer.

When χ is the reflection representation, the Coxeter number is equal to $\frac{N+N^*}{n}$ where *N* is the number of reflections, *N** is the number of reflection hyperplanes, and *n* is the rank of *W*. If *W* is further well-generated, the Coxeter number is equal to the highest degree *d_n* and to the order of a Coxeter element *c* of *W*.

EXAMPLES:

```

sage: W = ReflectionGroup(["H",4]) # optional - gap3
sage: W.coxeter_number() # optional - gap3
30
sage: all(W.coxeter_number(chi).is_integer() # optional - gap3
.....: for chi in W.irreducible_characters())
True
sage: W = ReflectionGroup(14) # optional - gap3
sage: W.coxeter_number() # optional - gap3
24

```

degrees()

Return the degrees of *self* ordered within each irreducible component of *self*.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,4)) # optional - gap3
sage: W.degrees() # optional - gap3
(2, 3, 4)

sage: W = ReflectionGroup((2,1,4)) # optional - gap3
sage: W.degrees() # optional - gap3
(2, 4, 6, 8)

sage: W = ReflectionGroup((4,1,4)) # optional - gap3

```

(continues on next page)

(continued from previous page)

```

sage: W.degrees() # optional - gap3
(4, 8, 12, 16)

sage: W = ReflectionGroup((4,2,4)) # optional - gap3
sage: W.degrees() # optional - gap3
(4, 8, 8, 12)

sage: W = ReflectionGroup((4,4,4)) # optional - gap3
sage: W.degrees() # optional - gap3
(4, 4, 8, 12)

```

Examples of reducible types:

```

sage: W = ReflectionGroup((1,1,4), (3,1,2)); W # optional - gap3
Reducible complex reflection group of rank 5 and type A3 x G(3,1,2)
sage: W.degrees() # optional - gap3
(2, 3, 4, 3, 6)

sage: W = ReflectionGroup((1,1,4), (6,1,12), 23) # optional - gap3 #_
↪ fails in GAP3
sage: W.degrees() # optional - gap3
(2, 3, 4, 6, 12, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 2, 6, 10)

```

discriminant()Return the discriminant of `self` in the polynomial ring on which the group acts.

This is the product

$$\prod_H \alpha_H^{e_H},$$

where α_H is the linear form of the hyperplane H and e_H is its stabilizer order.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: W.discriminant() # optional - gap3
x0^6 - 3*x0^5*x1 - 3/4*x0^4*x1^2 + 13/2*x0^3*x1^3
- 3/4*x0^2*x1^4 - 3*x0*x1^5 + x1^6

sage: W = ReflectionGroup(['B',2]) # optional - gap3
sage: W.discriminant() # optional - gap3
x0^6*x1^2 - 6*x0^5*x1^3 + 13*x0^4*x1^4 - 12*x0^3*x1^5 + 4*x0^2*x1^6

```

discriminant_in_invariant_ring(invariants=None)Return the discriminant of `self` in the invariant ring.This is the function f in the invariants such that $f(F_1(x), \dots, F_n(x))$ is the discriminant.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',3]) # optional - gap3
sage: W.discriminant_in_invariant_ring() # optional - gap3
6*t0^3*t1^2 - 18*t0^4*t2 + 9*t1^4 - 36*t0*t1^2*t2 + 24*t0^2*t2^2 - 8*t2^3

```

(continues on next page)

(continued from previous page)

```

sage: W = ReflectionGroup(['B',3]) # optional - gap3
sage: W.discriminant_invariant_ring() # optional - gap3
-t0^2*t1^2*t2 + 16*t0^3*t2^2 + 2*t1^3*t2 - 36*t0*t1*t2^2 + 108*t2^3

sage: W = ReflectionGroup(['H',3]) # optional - gap3

```

distinguished_reflection(*i*)

Return the *i*-th distinguished reflection of self.

These are the reflections in self acting on the complement of the fixed hyperplane H as $\exp(2\pi i/n)$, where n is the order of the reflection subgroup fixing H .

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.distinguished_reflection(1) # optional - gap3
(1,4)(2,3)(5,6)
sage: W.distinguished_reflection(2) # optional - gap3
(1,3)(2,5)(4,6)
sage: W.distinguished_reflection(3) # optional - gap3
(1,5)(2,4)(3,6)

sage: W = ReflectionGroup((3,1,1),hyperplane_index_set=['a']) # optional -
↪gap3
sage: W.distinguished_reflection('a') # optional - gap3
(1,2,3)

sage: W = ReflectionGroup((1,1,3),(3,1,2)) # optional - gap3
sage: for i in range(W.number_of_reflection_hyperplanes()): # optional - gap3

```

(continues on next page)

(continued from previous page)

```

.....:      W.distinguished_reflection(i+1)          # optional - gap3
(1,6)(2,5)(7,8)
(1,5)(2,7)(6,8)
(3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,28,30)
(3,11)(4,12)(9,13)(10,14)(15,19)(16,20)(17,21)(18,22)(23,27)(24,28)(25,26)(29,
↪30)
(1,7)(2,6)(5,8)

(4,21,27)(10,22,28)(11,13,19)(12,14,20)(16,26,30)(17,18,25)(23,24,29)
(3,13)(4,24)(9,19)(10,29)(11,15)(12,26)(14,21)(16,23)(17,30)(18,27)(20,22)(25,
↪28)

```

distinguished_reflections()

Return a finite family containing the distinguished reflections of `self` indexed by `hyperplane_index_set()`.

These are the reflections in `self` acting on the complement of the fixed hyperplane H as $\exp(2\pi i/n)$, where n is the order of the reflection subgroup fixing H .

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3))                    # optional - gap3
sage: W.distinguished_reflections()                  # optional - gap3
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((1,1,3),hyperplane_index_set=['a','b','c']) #_
↪optional - gap3
sage: W.distinguished_reflections()                  # optional - gap3
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((3,1,1))                    # optional - gap3
sage: W.distinguished_reflections()                  # optional - gap3
Finite family {1: (1,2,3)}

sage: W = ReflectionGroup((1,1,3),(3,1,2))            # optional - gap3
sage: W.distinguished_reflections()                  # optional - gap3
Finite family {1: (1,6)(2,5)(7,8), 2: (1,5)(2,7)(6,8),
3: (3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,28,30),
4: (3,11)(4,12)(9,13)(10,14)(15,19)(16,20)(17,21)(18,22)(23,27)(24,28)(25,
↪26)(29,30),
5: (1,7)(2,6)(5,8),
6: (3,19)(4,25)(9,11)(10,17)(12,28)(13,15)(14,30)(16,18)(20,27)(21,29)(22,
↪23)(24,26),
7: (4,21,27)(10,22,28)(11,13,19)(12,14,20)(16,26,30)(17,18,25)(23,24,29),
8: (3,13)(4,24)(9,19)(10,29)(11,15)(12,26)(14,21)(16,23)(17,30)(18,27)(20,
↪22)(25,28)}

```

fake_degrees()

Return the list of the fake degrees associated to `self`.

The fake degrees are q -versions of the degree of the character. In particular, they sum to Hilbert series of the coinvariant algebra of `self`.

Note: The ordering follows the one in Chevie and is not compatible with the current implementation of `irreducible_characters()`.

EXAMPLES:

```
sage: W = ReflectionGroup(12) # optional - gap3
sage: W.fake_degrees() # optional - gap3
[1, q^12, q^11 + q, q^8 + q^4, q^7 + q^5, q^6 + q^4 + q^2,
 q^10 + q^8 + q^6, q^9 + q^7 + q^5 + q^3]

sage: W = ReflectionGroup(["H",4]) # optional - gap3
sage: W.cardinality() # optional - gap3
14400
sage: sum(fdeg.subs(q=1)**2 for fdeg in W.fake_degrees()) # optional - gap3
14400
```

`fundamental_invariants()`

Return the fundamental invariants of `self`.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.fundamental_invariants() # optional - gap3
(-2*x0^2 + 2*x0*x1 - 2*x1^2, 6*x0^2*x1 - 6*x0*x1^2)

sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: W.fundamental_invariants() # optional - gap3
(x0^3 + x1^3, x0^3*x1^3)
```

`hyperplane_index_set()`

Return the index set of the hyperplanes of `self`.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,4)) # optional - gap3
sage: W.hyperplane_index_set() # optional - gap3
(1, 2, 3, 4, 5, 6)
sage: W = ReflectionGroup((1,1,4), hyperplane_index_set=[1,3,'asdf',7,9,11])
↪ # optional - gap3
sage: W.hyperplane_index_set() # optional - gap3
(1, 3, 'asdf', 7, 9, 11)
sage: W = ReflectionGroup((1,1,4), hyperplane_index_set=('a','b','c','d','e','f'
↪)) # optional - gap3
sage: W.hyperplane_index_set() # optional - gap3
('a', 'b', 'c', 'd', 'e', 'f')
```

`independent_roots()`

Return a collection of simple roots generating the underlying vector space of `self`.

For well-generated groups, these are all simple roots. Otherwise, a linearly independent subset of the simple roots is chosen.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.independent_roots() # optional - gap3
Finite family {1: (1, 0), 2: (0, 1)}

sage: W = ReflectionGroup((4,2,3)) # optional - gap3
sage: W.simple_roots() # optional - gap3
Finite family {1: (1, 0, 0), 2: (-E(4), 1, 0), 3: (-1, 1, 0), 4: (0, -1, 1)}
sage: W.independent_roots() # optional - gap3
Finite family {1: (1, 0, 0), 2: (-E(4), 1, 0), 4: (0, -1, 1)}

```

index_set()

Return the index set of the simple reflections of `self`.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,4)) # optional - gap3
sage: W.index_set() # optional - gap3
(1, 2, 3)
sage: W = ReflectionGroup((1,1,4), index_set=[1,3,'asdf']) # optional - gap3
sage: W.index_set() # optional - gap3
(1, 3, 'asdf')
sage: W = ReflectionGroup((1,1,4), index_set=('a', 'b', 'c')) # optional - gap3
↪gap3
sage: W.index_set() # optional - gap3
('a', 'b', 'c')

```

invariant_form(*brute_force=False*)

Return the form that is invariant under the action of `self`.

This is unique only up to a global scalar on the irreducible components.

INPUT:

- `brute_force` – if `True`, the computation is done by applying the Reynolds operator; this is, the invariant form of e_i and e_j is computed as the sum $\langle w(e_i), w(e_j) \rangle$, where $\langle \cdot, \cdot \rangle$ is the standard scalar product

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3]) # optional - gap3
sage: F = W.invariant_form(); F # optional - gap3
[ 1 -1/2  0]
[-1/2  1 -1/2]
[  0 -1/2  1]

```

To check that this is indeed the invariant form, see:

```

sage: S = W.simple_reflections() # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose() for i in W.index_
↪set() ) # optional - gap3
True

sage: W = ReflectionGroup(['B', 3]) # optional - gap3
sage: F = W.invariant_form(); F # optional - gap3
[ 1 -1  0]
[-1  2 -1]

```

(continues on next page)

(continued from previous page)

```

[ 0 -1 2]
sage: w = W.an_element().to_matrix() # optional - gap3
sage: w * F * w.transpose().conjugate() == F # optional - gap3
True

sage: S = W.simple_reflections() # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose() for i in W.index_
↳set() ) # optional - gap3
True

sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: F = W.invariant_form(); F # optional - gap3
[1 0]
[0 1]

sage: S = W.simple_reflections() # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in_
↳W.index_set() ) # optional - gap3
True

```

It also worked for badly generated groups:

```

sage: W = ReflectionGroup(7) # optional - gap3
sage: W.is_well_generated() # optional - gap3
False

sage: F = W.invariant_form(); F # optional - gap3
[1 0]
[0 1]

sage: S = W.simple_reflections() # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in_
↳W.index_set() ) # optional - gap3
True

```

And also for reducible types:

```

sage: W = ReflectionGroup(['B',3],(4,2,3),4,7); W # optional - gap3
Reducible complex reflection group of rank 10 and type B3 x G(4,2,3) x ST4 x ST7
sage: F = W.invariant_form(); S = W.simple_reflections() # optional - gap3
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in_
↳W.index_set() ) # optional - gap3
True

```

`invariant_form_standardization()`

Return the transformation of the space that turns the invariant form of `self` into the standard scalar product.

Let I be the invariant form of a complex reflection group, and let A be the Hermitian matrix such that $A^2 = I$. The matrix A defines a change of basis such that the identity matrix is the invariant form. Indeed, we have

$$(A^{-1}xA)\mathcal{I}(A^{-1}yA)^* = A^{-1}xIy^*A^{-1} = A^{-1}IA^{-1} = \mathcal{I},$$

where \mathcal{I} is the identity matrix.

EXAMPLES:

```

sage: W = ReflectionGroup((4,2,5))           # optional - gap3
sage: I = W.invariant_form()                # optional - gap3
sage: A = W.invariant_form_standardization() # optional - gap3
sage: A^2 == I                              # optional - gap3
True

```

irreducible_components()

Return a list containing the irreducible components of `self` as finite reflection groups.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3))           # optional - gap3
sage: W.irreducible_components()            # optional - gap3
[Irreducible real reflection group of rank 2 and type A2]

sage: W = ReflectionGroup((1,1,3),(2,1,3))  # optional - gap3
sage: W.irreducible_components()            # optional - gap3
[Irreducible real reflection group of rank 2 and type A2,
Irreducible real reflection group of rank 3 and type B3]

```

is_crystallographic()

Return True if `self` is crystallographic.

This is, if the field of definition is the rational field.

Todo: Make this more robust and do not use the matrix representation of the simple reflections.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)); W       # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: W.is_crystallographic()               # optional - gap3
True

sage: W = ReflectionGroup((2,1,3)); W       # optional - gap3
Irreducible real reflection group of rank 3 and type B3
sage: W.is_crystallographic()               # optional - gap3
True

sage: W = ReflectionGroup(23); W            # optional - gap3
Irreducible real reflection group of rank 3 and type H3
sage: W.is_crystallographic()               # optional - gap3
False

sage: W = ReflectionGroup((3,1,3)); W       # optional - gap3
Irreducible complex reflection group of rank 3 and type G(3,1,3)
sage: W.is_crystallographic()               # optional - gap3
False

sage: W = ReflectionGroup((4,2,2)); W       # optional - gap3
Irreducible complex reflection group of rank 2 and type G(4,2,2)
sage: W.is_crystallographic()               # optional - gap3
False

```

jacobian_of_fundamental_invariants(*invs=None*)

Return the matrix $[\partial_{x_i} F_j]$, where *invs* are any polynomials F_1, \dots, F_n in x_1, \dots, x_n .

INPUT:

- *invs* – (default: the fundamental invariants) the polynomials F_1, \dots, F_n

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])           # optional - gap3
sage: W.fundamental_invariants()           # optional - gap3
(-2*x0^2 + 2*x0*x1 - 2*x1^2, 6*x0^2*x1 - 6*x0*x1^2)

sage: W.jacobian_of_fundamental_invariants() # optional - gap3
[      -4*x0 + 2*x1      2*x0 - 4*x1]
[12*x0*x1 - 6*x1^2 6*x0^2 - 12*x0*x1]
```

number_of_irreducible_components()

Return the number of irreducible components of *self*.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))         # optional - gap3
sage: W.number_of_irreducible_components() # optional - gap3
1

sage: W = ReflectionGroup((1,1,3),(2,1,3)) # optional - gap3
sage: W.number_of_irreducible_components() # optional - gap3
2
```

primitive_vector_field(*invs=None*)

Return the primitive vector field of *self* if irreducible and well-generated.

The primitive vector field is given as the coefficients (being rational functions) in the basis $\partial_{x_1}, \dots, \partial_{x_n}$.

This is the partial derivation along the unique invariant of degree given by the Coxeter number. It can be computed as the row of the inverse of the Jacobian given by the highest degree.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])         # optional - gap3
sage: W.primitive_vector_field()           # optional - gap3
(3*x1/(6*x0^2 - 6*x0*x1 - 12*x1^2), 1/(6*x0^2 - 6*x0*x1 - 12*x1^2))
```

rank()

Return the rank of *self*.

This is the dimension of the underlying vector space.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))         # optional - gap3
sage: W.rank()                             # optional - gap3
2

sage: W = ReflectionGroup((2,1,3))         # optional - gap3
sage: W.rank()                             # optional - gap3
3

sage: W = ReflectionGroup((4,1,3))         # optional - gap3
```

(continues on next page)

(continued from previous page)

```

sage: W.rank() # optional - gap3
3
sage: W = ReflectionGroup((4,2,3)) # optional - gap3
sage: W.rank() # optional - gap3
3

```

reflection(*i*)Return the *i*-th reflection of self.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.reflection(1) # optional - gap3
(1,4)(2,3)(5,6)
sage: W.reflection(2) # optional - gap3
(1,3)(2,5)(4,6)
sage: W.reflection(3) # optional - gap3
(1,5)(2,4)(3,6)

sage: W = ReflectionGroup((3,1,1),reflection_index_set=['a','b']) # optional -
↳ gap3
sage: W.reflection('a') # optional - gap3
(1,2,3)
sage: W.reflection('b') # optional - gap3
(1,3,2)

```

reflection_character()

Return the reflection characters of self.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.reflection_character() # optional - gap3
[2, 0, -1]

```

reflection_eigenvalues(*w*, *is_class_representative=False*)Return the reflection eigenvalue of *w* in self.

INPUT:

- *is_class_representative* – boolean (default True) whether to compute instead on the conjugacy class representative.

See also:

[*reflection_eigenvalues_family\(\)*](#)

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for w in W: # optional - gap3
.....:     print('%s %s'%(w.reduced_word(), W.reflection_eigenvalues(w))) #
↳ optional - gap3
[] [0, 0]
[2] [1/2, 0]
[1] [1/2, 0]

```

(continues on next page)

(continued from previous page)

```
[1, 2] [1/3, 2/3]
[2, 1] [1/3, 2/3]
[1, 2, 1] [1/2, 0]
```

reflection_eigenvalues_family()

Return the reflection eigenvalues of `self` as a finite family indexed by the class representatives of `self`.

OUTPUT:

- list with entries k/n representing the eigenvalue ζ_n^k .

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.reflection_eigenvalues_family() # optional - gap3
Finite family {(): [0, 0], (1,4)(2,3)(5,6): [1/2, 0], (1,6,2)(3,5,4): [1/3, 2/
↪3]}
```

```
sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: reflection_eigenvalues = W.reflection_eigenvalues_family() # optional -
↪ gap3
sage: for elt in sorted(reflection_eigenvalues.keys()): # optional - gap3
.....:     print('%s %s'%(elt, reflection_eigenvalues[elt])) # optional - gap3
() [0, 0]
(1,3,9)(2,4,10)(6,11,17)(8,12,18)(14,19,23)(15,16,20)(21,22,24) [1/3, 0]
(1,3,9)(2,16,24)(4,20,21)(5,7,13)(6,12,23)(8,19,17)(10,15,22)(11,18,14) [1/3, 1/

```

reflection_hyperplane(*i*, *as_linear_functional*=False, *with_order*=False)

Return the *i*-th reflection hyperplane of *self*.

The *i*-th reflection hyperplane corresponds to the *i* distinguished reflection.

INPUT:

- *i* – an index in the index set
- *as_linear_functionals* – (default:False) flag whether to return the hyperplane or its linear functional in the basis dual to the given root basis

EXAMPLES:

```
sage: W = ReflectionGroup((2,1,2)) # optional - gap3
sage: W.reflection_hyperplane(3) # optional - gap3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
```

One can ask for the result as a linear form:

```
sage: W.reflection_hyperplane(3, True) # optional - gap3
(0, 1)
```

reflection_hyperplanes(*as_linear_functionals*=False, *with_order*=False)

Return the list of all reflection hyperplanes of *self*, either as a codimension 1 space, or as its linear functional.

INPUT:

- *as_linear_functionals* – (default:False) flag whether to return the hyperplane or its linear functional in the basis dual to the given root basis

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for H in W.reflection_hyperplanes(): H # optional - gap3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 1/2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1]

sage: for H in W.reflection_hyperplanes(as_linear_functionals=True): H #_
↪optional - gap3
```

(continues on next page)

((1, -2), 2)
((0, 1), 2)
((1, 0), 2)

```

reflection_index_set()

Return the index set of the reflections of self.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,4)) # optional - gap3
sage: W.reflection_index_set() # optional - gap3
(1, 2, 3, 4, 5, 6)
sage: W = ReflectionGroup((1,1,4), reflection_index_set=[1,3,'asdf',7,9,11])
↳ # optional - gap3
sage: W.reflection_index_set() # optional - gap3
(1, 3, 'asdf', 7, 9, 11)
sage: W = ReflectionGroup((1,1,4), reflection_index_set=('a','b','c','d','e','f'
↳ )) # optional - gap3
sage: W.reflection_index_set() # optional - gap3
('a', 'b', 'c', 'd', 'e', 'f')

```

reflections()

Return a finite family containing the reflections of self, indexed by self.reflection_index_set().

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.reflections() # optional - gap3
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((1,1,3),reflection_index_set=['a','b','c']) #
↳ optional - gap3
sage: W.reflections() # optional - gap3
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}

sage: W = ReflectionGroup((3,1,1)) # optional - gap3
sage: W.reflections() # optional - gap3
Finite family {1: (1,2,3), 2: (1,3,2)}

sage: W = ReflectionGroup((1,1,3),(3,1,2)) # optional - gap3
sage: W.reflections() # optional - gap3
Finite family {1: (1,6)(2,5)(7,8), 2: (1,5)(2,7)(6,8),
3: (3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,
↳28,30),
4: (3,11)(4,12)(9,13)(10,14)(15,19)(16,20)(17,21)(18,22)(23,
↳27)(24,28)(25,26)(29,30),
5: (1,7)(2,6)(5,8),

↳18)(23,29,24)}

```

roots()Return all roots corresponding to all reflections of *self*.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.roots() # optional - gap3
[(1, 0), (0, 1), (1, 1), (-1, 0), (0, -1), (-1, -1)]

sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: W.roots() # optional - gap3
[(1, 0), (-1, 1), (E(3), 0), (-E(3), 1), (0, 1), (1, -1),
(0, E(3)), (1, -E(3)), (E(3)^2, 0), (-E(3)^2, 1),
(E(3), -1), (E(3), -E(3)), (0, E(3)^2), (1, -E(3)^2),
(-1, E(3)), (-E(3), E(3)), (E(3)^2, -1), (E(3)^2, -E(3)),
(E(3), -E(3)^2), (-E(3)^2, E(3)), (-1, E(3)^2),
(-E(3), E(3)^2), (E(3)^2, -E(3)^2), (-E(3)^2, E(3)^2)]

sage: W = ReflectionGroup((4,2,2)) # optional - gap3
sage: W.roots() # optional - gap3

```

(continues on next page)

sage: W = ReflectionGroup((1,1,4), (3,1,2))           # optional - gap3
sage: W.roots()                                     # optional - gap3
[(1, 0, 0, 0, 0), (0, 1, 0, 0, 0), (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0), (0, 0, 0, -1, 1), (1, 1, 0, 0, 0),
 (0, 1, 1, 0, 0), (1, 1, 1, 0, 0), (-1, 0, 0, 0, 0),
 (0, -1, 0, 0, 0), (0, 0, -1, 0, 0), (-1, -1, 0, 0, 0),
 (0, -1, -1, 0, 0), (-1, -1, -1, 0, 0), (0, 0, 0, E(3), 0),
 (0, 0, 0, -E(3), 1), (0, 0, 0, 0, 1), (0, 0, 0, 1, -1),
 (0, 0, 0, 0, E(3)), (0, 0, 0, 1, -E(3)), (0, 0, 0, E(3)^2, 0),
 (0, 0, 0, -E(3)^2, 1), (0, 0, 0, E(3), -1), (0, 0, 0, E(3), -E(3)),
 (0, 0, 0, 0, E(3)^2), (0, 0, 0, 1, -E(3)^2), (0, 0, 0, -1, E(3)),
 (0, 0, 0, -E(3), E(3)), (0, 0, 0, E(3)^2, -1),
 (0, 0, 0, E(3)^2, -E(3)), (0, 0, 0, E(3), -E(3)^2),
 (0, 0, 0, -E(3)^2, E(3)), (0, 0, 0, -1, E(3)^2),
 (0, 0, 0, -E(3), E(3)^2), (0, 0, 0, E(3)^2, -E(3)^2),
 (0, 0, 0, -E(3)^2, E(3)^2)]

```

series()

Return the series of the classification type to which `self` belongs.

For real reflection groups, these are the Cartan-Killing classification types “A”, “B”, “C”, “D”, “E”, “F”, “G”, “H”, “I”, and for complex non-real reflection groups these are the Shephard-Todd classification type “ST”.

EXAMPLES:

```

sage: ReflectionGroup((1,1,3)).series()           # optional - gap3
['A']
sage: ReflectionGroup((3,1,3)).series()           # optional - gap3
['ST']

```

set_reflection_representation(refl_repr=None)

Set the reflection representation of `self`.

INPUT:

- `refl_repr` – a dictionary representing the matrices of the generators of `self` with keys given by the index set, or `None` to reset to the default reflection representation

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3))               # optional - gap3
sage: for w in W: w.to_matrix(); print("-----") # optional - gap3
[1 0]
[0 1]
-----
[ 1  1]
[ 0 -1]
-----

```

[1 0 0]
-----
sage: W.set_reflection_representation() # optional - gap3

```

simple_coroot(*i*)Return the simple root with index *i*.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',3]) # optional - gap3
sage: W.simple_coroot(1) # optional - gap3
(2, -1, 0)

```

simple_coroots()

Return the simple coroots of self.

These are the coroots corresponding to the simple reflections.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.simple_coroots() # optional - gap3
Finite family {1: (2, -1), 2: (-1, 2)}

sage: W = ReflectionGroup((1,1,4), (2,1,2)) # optional - gap3
sage: W.simple_coroots() # optional - gap3
Finite family {1: (2, -1, 0, 0, 0), 2: (-1, 2, -1, 0, 0), 3: (0, -1, 2, 0, 0),
↪4: (0, 0, 0, 2, -2), 5: (0, 0, 0, -1, 2)}

sage: W = ReflectionGroup((3,1,2)) # optional - gap3
sage: W.simple_coroots() # optional - gap3
Finite family {1: (-2*E(3) - E(3)^2, 0), 2: (-1, 1)}

sage: W = ReflectionGroup((1,1,4), (3,1,2)) # optional - gap3
sage: W.simple_coroots() # optional - gap3
Finite family {1: (2, -1, 0, 0, 0), 2: (-1, 2, -1, 0, 0), 3: (0, -1, 2, 0, 0),
↪4: (0, 0, 0, -2*E(3) - E(3)^2, 0), 5: (0, 0, 0, -1, 1)}

```

simple_reflection(*i*)

Return the *i*-th simple reflection of self.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.simple_reflection(1) # optional - gap3
(1,4)(2,3)(5,6)
sage: W.simple_reflections() # optional - gap3
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6)}

```

simple_root(*i*)

Return the simple root with index *i*.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',3]) # optional - gap3
sage: W.simple_root(1) # optional - gap3
(1, 0, 0)
sage: W.simple_root(2) # optional - gap3
(0, 1, 0)
sage: W.simple_root(3) # optional - gap3
(0, 0, 1)

```

simple_roots()

Return the simple roots of self.

These are the roots corresponding to the simple reflections.

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: W.simple_roots() # optional - gap3
Finite family {1: (1, 0), 2: (0, 1)}

```

(continues on next page)

(continued from previous page)

```

sage: W = ReflectionGroup((1,1,4), (2,1,2))           # optional - gap3
sage: W.simple_roots()                               # optional - gap3
Finite family {1: (1, 0, 0, 0, 0), 2: (0, 1, 0, 0, 0), 3: (0, 0, 1, 0, 0), 4: ↵
↵(0, 0, 0, 1, 0), 5: (0, 0, 0, 0, 1)}

sage: W = ReflectionGroup((3,1,2))                   # optional - gap3
sage: W.simple_roots()                               # optional - gap3
Finite family {1: (1, 0), 2: (-1, 1)}

sage: W = ReflectionGroup((1,1,4), (3,1,2))           # optional - gap3
sage: W.simple_roots()                               # optional - gap3
Finite family {1: (1, 0, 0, 0, 0), 2: (0, 1, 0, 0, 0), 3: (0, 0, 1, 0, 0), 4: ↵
↵(0, 0, 0, 1, 0), 5: (0, 0, 0, -1, 1)}

```

```

class sage.combinat.root_system.reflection_group_complex.IrreducibleComplexReflectionGroup(W_types,
in-
dex_set=None,
hy-
per-
plane_index_set=
re-
flec-
tion_index_set=

```

Bases: `sage.combinat.root_system.reflection_group_complex.ComplexReflectionGroup`

class Element

Bases: `sage.combinat.root_system.reflection_group_complex.ComplexReflectionGroup.Element`

is_coxeter_element(*which_primitive=1, is_class_representative=False*)

Return True if self is a Coxeter element.

This is, whether self has an eigenvalue that is a primitive *h*-th root of unity.

INPUT:

- *which_primitive* – (default:1) for which power of the first primitive *h*-th root of unity to look as a reflection eigenvalue for a regular element
- *is_class_representative* – boolean (default True) whether to compute instead on the conjugacy class representative

See also:

`coxeter_element()` `coxeter_elements()`

EXAMPLES:

```

sage: W = ReflectionGroup((1,1,3))                   # optional - gap3
sage: for w in W:                                     # optional - gap3
.....:     print('%s %s'%(w.reduced_word(), w.is_coxeter_element())) ↵
↵optional - gap3
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True

```

(continues on next page)

(continued from previous page)

```
[1, 2, 1] False
```

is_h_regular(*is_class_representative=False*)

Return whether *self* is regular.

This is if *self* has an eigenvector with eigenvalue h and which does not lie in any reflection hyperplane. Here, h denotes the Coxeter number.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: for w in W: # optional - gap3
.....:     print('%s %s'%(w.reduced_word(), w.is_h_regular())) # optional -
↳ gap3
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False
```

is_regular(*h, is_class_representative=False*)

Return whether *self* is regular.

This is, if *self* has an eigenvector with eigenvalue of order h and which does not lie in any reflection hyperplane.

INPUT:

- h – the order of the eigenvalue
- *is_class_representative* – boolean (default True) whether to compute instead on the conjugacy class representative

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3)) # optional - gap3
sage: h = W.coxeter_number() # optional - gap3
sage: for w in W: # optional - gap3
.....:     print("{} {}".format(w.reduced_word(), w.is_regular(h)))
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False

sage: W = ReflectionGroup(23); h = W.coxeter_number() # optional - gap3
sage: for w in W: # optional - gap3
.....:     if w.is_regular(h): # optional - gap3
.....:         w.reduced_word() # optional - gap3

[1, 2, 1, 2, 3, 2, 1, 2, 1, 3, 2]
[1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]

```

Check that [trac ticket #25478](#) is fixed:

```

sage: W = ReflectionGroup(["A",5]) # optional - gap3
sage: w = W.from_reduced_word([1,2,3,5]) # optional - gap3
sage: w.is_regular(4) # optional - gap3
False
sage: W = ReflectionGroup(["A",3]) # optional - gap3
sage: len([w for w in W if w.is_regular(w.order())]) # optional - gap3
18

```

`sage.combinat.root_system.reflection_group_complex.multi_partitions(n, S, i=None)`
 Return all vectors as lists of the same length as S whose standard inner product with S equals n.

EXAMPLES:

```

sage: from sage.combinat.root_system.reflection_group_complex import multi_
↪partitions
sage: multi_partitions(10, [2,3,3,4])
[[5, 0, 0, 0],
 [3, 0, 0, 1],
 [2, 2, 0, 0],
 [2, 1, 1, 0],
 [2, 0, 2, 0],
 [1, 0, 0, 2],
 [0, 2, 0, 1],
 [0, 1, 1, 1],
 [0, 0, 2, 1]]

```

`sage.combinat.root_system.reflection_group_complex.power(f, k)`
 Return f^k and caching all intermediate results.

Speeds the computation if one has to compute f^k 's for many values of k .

EXAMPLES:

```

sage: P.<x,y,z> = PolynomialRing(QQ)
sage: f = -2*x^2 + 2*x*y - 2*y^2 + 2*y*z - 2*z^2
sage: all( f^k == power(f,k) for k in range(20) )
True

```

5.1.233 Finite real reflection groups

Let V be a finite-dimensional real vector space. A reflection of V is an operator $r \in \text{GL}(V)$ that has order 2 and fixes pointwise a hyperplane in V . In the present implementation, finite real reflection groups are tied with a root system.

Finite real reflection groups with root systems have been classified according to finite Cartan-Killing types. For more definitions and classification types of finite complex reflection groups, see [Wikipedia article Complex_reflection_group](#).

The point of entry to work with reflection groups is `ReflectionGroup()` which can be used with finite Cartan-Killing types:

```

sage: ReflectionGroup(['A',2]) # optional - gap3
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup(['F',4]) # optional - gap3
Irreducible real reflection group of rank 4 and type F4
sage: ReflectionGroup(['H',3]) # optional - gap3
Irreducible real reflection group of rank 3 and type H3

```

AUTHORS:

- Christian Stump (initial version 2011–2015)

Warning: Uses the GAP3 package *Chevie* which is available as an experimental package (installed by `sage -i gap3`) or to download by hand from [Jean Michel's website](#).

```

class sage.combinat.root_system.reflection_group_real.IrreducibleRealReflectionGroup(W_types,
                                                                                      in-
                                                                                      dex_set=None,
                                                                                      hy-
                                                                                      per-

                                                                           tion_index_set=None)
```

Bases: `sage.combinat.root_system.reflection_group_complex.ComplexReflectionGroup`

A real reflection group given as a permutation group.

See also:

`ReflectionGroup()`

class Element

```
Bases: sage.combinat.root_system.reflection_group_element.
RealReflectionGroupElement, sage.combinat.root_system.reflection_group_complex.
ComplexReflectionGroup.Element
```

left_coset_representatives()

Return the left coset representatives of self.

See also:

`right_coset_representatives()`

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: for w in W: # optional - gap3
.....:     lcr = w.left_coset_representatives() # optional - gap3
.....:     print("%s %s"%(w.reduced_word(), # optional - gap3
.....:                    [v.reduced_word() for v in lcr])) # optional -
↳gap3
[] [[], [2], [1], [1, 2], [2, 1], [1, 2, 1]]
[2] [[], [2], [1]]
[1] [[], [1], [2, 1]]
[1, 2] [[]]
[2, 1] [[]]
[1, 2, 1] [[], [2], [1, 2]]
```

right_coset_representatives()

Return the right coset representatives of self.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: for w in W: # optional - gap3
.....:     rcr = w.right_coset_representatives() # optional - gap3
.....:     print("%s %s"%(w.reduced_word(), # optional - gap3
.....:                    [v.reduced_word() for v in rcr])) # optional -
↳gap3
[] [[], [2], [1], [2, 1], [1, 2], [1, 2, 1]]
[2] [[], [2], [1]]
[1] [[], [1], [1, 2]]
[1, 2] [[]]
[2, 1] [[]]
[1, 2, 1] [[], [2], [2, 1]]
```

almost_positive_roots()

Return the almost positive roots of self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',3], ['B',2]) # optional - gap3
sage: W.almost_positive_roots() # optional - gap3
[(-1, 0, 0, 0, 0),
 (0, -1, 0, 0, 0),
 (0, 0, -1, 0, 0),
 (0, 0, 0, -1, 0),
 (0, 0, 0, 0, -1),
 (1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0),
 (0, 0, 0, 0, 1),
 (1, 1, 0, 0, 0),
 (0, 1, 1, 0, 0),
 (0, 0, 0, 1, 1),
 (1, 1, 1, 0, 0),
 (0, 0, 0, 2, 1)]

sage: W = ReflectionGroup(['A',3]) # optional - gap3
sage: W.almost_positive_roots() # optional - gap3
[(-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (1, 1, 1)]

```

bipartite_index_set()

Return the bipartite index set of a real reflection group.

EXAMPLES:

```

sage: W = ReflectionGroup(["A",5]) # optional - gap3
sage: W.bipartite_index_set() # optional - gap3
[[1, 3, 5], [2, 4]]

sage: W = ReflectionGroup(["A",5],index_set=['a','b','c','d','e']) # optional -
↪ gap3
sage: W.bipartite_index_set() # optional - gap3
[['a', 'c', 'e'], ['b', 'd']]

```

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3]) # optional - gap3
sage: W.cartan_type() # optional - gap3
['A', 3]

sage: W = ReflectionGroup(['A', 3], ['B', 3]) # optional - gap3
sage: W.cartan_type() # optional - gap3
A3xB3 relabelled by {1: 3, 2: 2, 3: 1}

```

coxeter_diagram()

Return the Coxeter diagram associated to `self`.

EXAMPLES:

```

sage: G = ReflectionGroup(['B', 3]) # optional - gap3
sage: sorted(G.coxeter_diagram().edges(labels=True)) # optional - gap3
[(1, 2, 4), (2, 3, 3)]

```

coxeter_matrix()

Return the Coxeter matrix associated to `self`.

EXAMPLES:

```

sage: G = ReflectionGroup(['A', 3]) # optional - gap3
sage: G.coxeter_matrix() # optional - gap3
[1 3 2]
[3 1 3]
[2 3 1]

```

fundamental_weight(*i*)

Return the fundamental weight with index `i`.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3]) # optional - gap3
sage: [ W.fundamental_weight(i) for i in W.index_set() ] # optional - gap3
[(3/4, 1/2, 1/4), (1/2, 1, 1/2), (1/4, 1/2, 3/4)]

```

fundamental_weights()

Return the fundamental weights of `self` in terms of the simple roots.

The fundamental weights are defined by $s_j(\omega_i) = \omega_i - \delta_{i=j}\alpha_j$ for the simple reflection s_j with corresponding simple roots α_j .

In other words, the transpose Cartan matrix sends the weight basis to the root basis. Observe again that the action here is defined as a right action, see the example below.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3], ['B', 2]) # optional - gap3
sage: W.fundamental_weights() # optional - gap3
Finite family {1: (3/4, 1/2, 1/4, 0, 0), 2: (1/2, 1, 1/2, 0, 0), 3: (1/4, 1/2, 3/4, 0, 0), 4: (0, 0, 0, 1, 1/2), 5: (0, 0, 0, 1, 1)}

sage: W = ReflectionGroup(['A', 3]) # optional - gap3
sage: W.fundamental_weights() # optional - gap3
Finite family {1: (3/4, 1/2, 1/4), 2: (1/2, 1, 1/2), 3: (1/4, 1/2, 3/4)}

```

(continues on next page)

(continued from previous page)

```

sage: W = ReflectionGroup(['A',3])           # optional - gap3
sage: S = W.simple_reflections()          # optional - gap3
sage: N = W.fundamental_weights()         # optional - gap3
sage: for i in W.index_set():              # optional - gap3
.....:     for j in W.index_set():         # optional - gap3
.....:         print("{} {} {} {}".format(i, j, N[i], N[i]*S[j].to_matrix()))
1 1 (3/4, 1/2, 1/4) (-1/4, 1/2, 1/4)
1 2 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
1 3 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
2 1 (1/2, 1, 1/2) (1/2, 1, 1/2)
2 2 (1/2, 1, 1/2) (1/2, 0, 1/2)
2 3 (1/2, 1, 1/2) (1/2, 1, 1/2)
3 1 (1/4, 1/2, 3/4) (1/4, 1/2, 3/4)
3 2 (1/4, 1/2, 3/4) (1/4, 1/2, 3/4)
3 3 (1/4, 1/2, 3/4) (1/4, 1/2, -1/4)

```

iteration(*algorithm*='breadth', *tracking_words*=True)

Return an iterator going through all elements in self.

INPUT:

- *algorithm* (default: 'breadth') – must be one of the following:
 - 'breadth' - iterate over in a linear extension of the weak order
 - 'depth' - iterate by a depth-first-search
 - 'parabolic' - iterate by using parabolic subgroups
- *tracking_words* (default: True) – whether or not to keep track of the reduced words and store them in `_reduced_word`

Note: The fastest iteration is the parabolic iteration and the depth first algorithm without tracking words is second. In particular, 'depth' is ~1.5x faster than 'breadth'.

Note: The 'parabolic' iteration does not track words and requires keeping the subgroup corresponding to $I \setminus \{i\}$ in memory (for each i individually).

EXAMPLES:

```

sage: W = ReflectionGroup(["B",2])           # optional - gap3
sage: for w in W.iteration("breadth",True):  # optional - gap3
.....:     print("%s %s"%(w, w._reduced_word)) # optional - gap3
() []
(1,3)(2,6)(5,7) [1]
(1,5)(2,4)(6,8) [0]
(1,7,5,3)(2,4,6,8) [0, 1]
(1,3,5,7)(2,8,6,4) [1, 0]
(2,8)(3,7)(4,6) [1, 0, 1]
(1,7)(3,5)(4,8) [0, 1, 0]
(1,5)(2,6)(3,7)(4,8) [0, 1, 0, 1]

```

(continues on next page)

(continued from previous page)

```

sage: for w in W.iteration("depth", False): w           # optional - gap3
()
(1,3)(2,6)(5,7)
(1,5)(2,4)(6,8)
(1,3,5,7)(2,8,6,4)
(1,7)(3,5)(4,8)
(1,7,5,3)(2,4,6,8)
(2,8)(3,7)(4,6)
(1,5)(2,6)(3,7)(4,8)

```

positive_roots()

Return the positive roots of self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',3], ['B',2])           # optional - gap3
sage: W.positive_roots()                             # optional - gap3
[(1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0),
 (0, 0, 0, 0, 1),
 (1, 1, 0, 0, 0),
 (0, 1, 1, 0, 0),
 (0, 0, 0, 1, 1),
 (1, 1, 1, 0, 0),
 (0, 0, 0, 2, 1)]

sage: W = ReflectionGroup(['A',3])                   # optional - gap3
sage: W.positive_roots()                             # optional - gap3
[(1, 0, 0), (0, 1, 0), (0, 0, 1), (1, 1, 0), (0, 1, 1), (1, 1, 1)]

```

reflection_to_positive_root(r)

Return the positive root orthogonal to the given reflection.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: for r in W.reflections(): # optional - gap3
.....:     print(W.reflection_to_positive_root(r))
(1, 0)
(0, 1)
(1, 1)

```

right_coset_representatives(J)

Return the right coset representatives of self for the parabolic subgroup generated by the simple reflections in J.

EXAMPLES:

```

sage: W = ReflectionGroup(["A",3]) # optional - gap3
sage: for J in Subsets([1,2,3]): W.right_coset_representatives(J) # optional -
↪ gap3

```

[()]
```

root_to_reflection(*root*)

Return the reflection along the given root.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: for beta in W.roots(): W.root_to_reflection(beta) # optional - gap3
(1,4)(2,3)(5,6)
(1,3)(2,5)(4,6)
(1,5)(2,4)(3,6)
(1,4)(2,3)(5,6)
(1,3)(2,5)(4,6)
(1,5)(2,4)(3,6)
```

simple_root_index(*i*)

Return the index of the simple root α_i .

This is the position of α_i in the list of simple roots.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',3]) # optional - gap3
sage: [W.simple_root_index(i) for i in W.index_set()] # optional - gap3
[0, 1, 2]
```

`sage.combinat.root_system.reflection_group_real.ReflectionGroup(*args, **kws)`

Construct a finite (complex or real) reflection group as a Sage permutation group by fetching the permutation representation of the generators from chevie's database.

INPUT:

can be one or multiple of the following:

- a triple (r, p, n) with p divides r , which denotes the group $G(r, p, n)$
- an integer between 4 and 37, which denotes an exceptional irreducible complex reflection group
- a finite Cartan-Killing type

EXAMPLES:

Finite reflection groups can be constructed from

Cartan-Killing classification types:

```
sage: W = ReflectionGroup(['A',3]); W # optional - gap3
Irreducible real reflection group of rank 3 and type A3

sage: W = ReflectionGroup(['H',4]); W # optional - gap3
Irreducible real reflection group of rank 4 and type H4

sage: W = ReflectionGroup(['I',5]); W # optional - gap3
Irreducible real reflection group of rank 2 and type I2(5)
```

the complex infinite family $G(r, p, n)$ with p divides r :

```
sage: W = ReflectionGroup((1,1,4)); W # optional - gap3
Irreducible real reflection group of rank 3 and type A3

sage: W = ReflectionGroup((2,1,3)); W # optional - gap3
Irreducible real reflection group of rank 3 and type B3
```

Chevalley-Shepard-Todd exceptional classification types:

```
sage: W = ReflectionGroup(23); W # optional - gap3
Irreducible real reflection group of rank 3 and type H3
```

Cartan types and matrices:

```
sage: ReflectionGroup(CartanType(['A',2])) # optional - gap3
Irreducible real reflection group of rank 2 and type A2

sage: ReflectionGroup(CartanType((['A',2],['A',2]))) # optional - gap3
```

(continues on next page)

(continued from previous page)

```

Reducible real reflection group of rank 4 and type A2 x A2
sage: C = CartanMatrix(['A',2]) # optional - gap3
sage: ReflectionGroup(C) # optional - gap3
Irreducible real reflection group of rank 2 and type A2

```

multiples of the above:

```

sage: W = ReflectionGroup(['A',2],['B',2]); W # optional - gap3
Reducible real reflection group of rank 4 and type A2 x B2

sage: W = ReflectionGroup(['A',2],4); W # optional - gap3
Reducible complex reflection group of rank 4 and type A2 x ST4

sage: W = ReflectionGroup((4,2,2),4); W # optional - gap3
Reducible complex reflection group of rank 4 and type G(4,2,2) x ST4

```

`sage.combinat.root_system.reflection_group_real.is_chevie_available()`
 Test whether the GAP3 Chevie package is available.

EXAMPLES:

```

sage: from sage.combinat.root_system.reflection_group_real import is_chevie_
↪available
sage: is_chevie_available() # random
False
sage: is_chevie_available() in [True, False]
True

```

5.1.234 Group algebras of root lattice realizations

class `sage.combinat.root_system.root_lattice_realization_algebras.Algebras`(*category*, *args)
 Bases: `sage.categories.algebra_functor.AlgebrasCategory`

The category of group algebras of root lattice realizations.

This includes typically weight rings (group algebras of weight lattices).

class `ElementMethods`

Bases: `object`

acted_upon(*w*)

Implements the action of *w* on self.

INPUT:

- *w* – an element of the Weyl group acting on the underlying weight lattice realization

EXAMPLES:

```

sage: L = RootSystem(["A",3]).ambient_space()
sage: W = L.weyl_group()
sage: M = L.algebra(QQ['q','t'])
sage: m = M.an_element(); m # TODO: investigate why we don't get something_
↪more interesting
B[(2, 2, 3, 0)]

```

(continues on next page)

(continued from previous page)

```

sage: m = (m+1)^2; m
B[(0, 0, 0, 0)] + 2*B[(2, 2, 3, 0)] + B[(4, 4, 6, 0)]
sage: w = W.an_element(); w.reduced_word()
[1, 2, 3]
sage: m.acted_upon(w)
B[(0, 0, 0, 0)] + 2*B[(0, 2, 2, 3)] + B[(0, 4, 4, 6)]

```

expand(*alphabet*)

Expand self into variables in the alphabet.

INPUT:

- *alphabet* – a non empty list/tuple of (invertible) variables in a ring to expand in

EXAMPLES:

```

sage: L = RootSystem(["A",2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: p = KL.an_element() + KL.sum_of_monomials(L.some_elements()); p
B[(1, 0, 0)] + B[(1, -1, 0)] + B[(1, 1, 0)] + 2*B[(2, 2, 3)] + B[(0, 1, -1)]
sage: F = LaurentPolynomialRing(QQ, 'x,y,z')
sage: p.expand(F.gens())
2*x^2*y^2*z^3 + x*y + x + y*z^-1 + x*y^-1

```

class ParentMethods

Bases: object

T0_check_on_basis(*q1, q2, convention='antidominant'*)Return the T_0^V operator acting on the basis.This implements the formula for T_0^V in Section 6.12 of [Haiman06].

REFERENCES:

Warning: The current implementation probably returns just nonsense, if the convention is not “dominant”.

EXAMPLES:

```

sage: K = QQ['q1,q2'].fraction_field()
sage: q1,q2 = K.gens()

sage: L = RootSystem(["A",1,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L.fundamental_weights()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: f(L0.zero())
(q1+q2)*B[(0, 0)] + q1*B[(1, -1)]

sage: L = RootSystem(["A",3,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L0.fundamental_weights()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")

```

(continues on next page)

(continued from previous page)

```
sage: f(L0.zero())          # not checked
(q1+q2)*B[(0, 0, 0, 0)] + q1^3/q2^2*B[(1, 0, 0, -1)]
```

The following results have not been checked:

```
sage: for x in some_weights:
.....:     print("{} : {}".format(x, f(x)))
(1, 0, 0, 0) : q1*B[(1, 0, 0, 0)]
(1, 1, 0, 0) : q1*B[(1, 1, 0, 0)]
(1, 1, 1, 0) : q1*B[(1, 1, 1, 0)]
```

Some examples for type $B_2^{(1)}$ dual:

```
sage: L = RootSystem("B2~*").ambient_space()
sage: L0 = L.classical()
sage: e = L.basis()
sage: K = QQ['q,u'].fraction_field()
sage: q,u = K.gens()
sage: q1 = u
sage: q2 = -1/u
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant
↪")
```

Direct calculation:

```
sage: T.Tw(0)(KL0.monomial(L0([0,0])))
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
sage: KL.T0_check_on_basis(q1,q2, convention="dominant")(L0([0,0]))
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
```

Step by step calculation, comparing by hand with Mark Shimozono:

```
sage: res = T.Tw(2)(KL0.monomial(L0([0,0]))); res
u*B[(0, 0)]
sage: res = res * KL0.monomial(L0([-1,1])); res
u*B[-1, 1]
sage: res = T.Tw_inverse(1)(res); res
(u^2-1)*B[(0, 0)] + u^2*B[(1, -1)]
sage: res = T.Tw_inverse(2)(res); res
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
```

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```
sage: A = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: A.cartan_type()
['A', 2, 1]
sage: A = RootSystem(["B",2]).weight_space().algebra(QQ)
```

(continues on next page)

(continued from previous page)

```
sage: A.cartan_type()
['B', 2]
```

classical()

Return the group algebra of the corresponding classical lattice.

EXAMPLES:

```
sage: KL = RootSystem(["A", 2, 1]).ambient_space().algebra(QQ)
sage: KL.classical()
Algebra of the Ambient space of the Root system of type ['A', 2] over
↪Rational Field
```

demazure_lusztig_operator_on_basis(*weight*, *i*, *q1*, *q2*, *convention*='antidominant')

Return the result of applying the *i*-th Demazure-Lusztig operator on *weight*.

INPUT:

- *weight* – an element λ of the weight lattice
- *i* – an element of the index set
- *q1*, *q2* – two elements of the ground ring
- *convention* – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

See [demazure_lusztig_operators\(\)](#) for the details.

EXAMPLES:

```
sage: L = RootSystem(["A", 1]).ambient_space()
sage: K = QQ['q1, q2']
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL.demazure_lusztig_operator_on_basis(L((2, 2)), 1, q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3, 0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0, 3)), 1, q1, q2)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(3, 0)]
```

At $q_1 = 1$ and $q_2 = 0$ we recover the action of the isobaric divided differences π_i :

```
sage: KL.demazure_lusztig_operator_on_basis(L((2, 2)), 1, 1, 0)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3, 0)), 1, 1, 0)
B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0, 3)), 1, 1, 0)
-B[(1, 2)] - B[(2, 1)]
```

Or $1 - \pi_i$ for *bar*=True:

```
sage: KL.demazure_lusztig_operator_on_basis(L((2, 2)), 1, 1, 0, convention=
↪"bar")
0
sage: KL.demazure_lusztig_operator_on_basis(L((3, 0)), 1, 1, 0, convention=
↪"bar")
-B[(1, 2)] - B[(2, 1)] - B[(0, 3)]
```

(continues on next page)

(continued from previous page)

```
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0, convention=
↪"bar")
B[(1, 2)] + B[(2, 1)] + B[(0, 3)]
```

At $q_1 = 1$ and $q_2 = -1$ we recover the action of the simple reflection s_i :

```
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, -1)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, -1)
B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, -1)
B[(3, 0)]
```

demazure_lusztig_operator_on_classical_on_basis(*weight*, *i*, *q*, *q1*, *q2*,
convention='antidominant')

Return the result of applying the i -th Demazure-Lusztig operator on the classical weight *weight* embedded at level 0.

INPUT:

- *weight* – a classical weight λ
- *i* – an element of the index set
- *q1*, *q2* – two elements of the ground ring
- *convention* – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

See [demazure_lusztig_operators\(\)](#) for the details.

Todo:

- Optimize the code to only do the embedding/projection for T_0
- Add an option to specify at which level one wants to work. Currently this is level 0.

EXAMPLES:

```
sage: L = RootSystem(["A", 1, 1]).ambient_space()
sage: L0 = L.classical()
sage: K = QQ['q,q1,q2']
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = L0.algebra(K)
```

These operators coincide with the usual Demazure-Lusztig operators:

```
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((2,2)), 1, q, ↵
↪q1, q2)
q1*B[(2, 2)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((2,2)), 1, q1, q2)
q1*B[(2, 2)]

sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((3,0)), 1, q, ↵
↪q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
```

except that we now have an action of T_0 , which introduces some q s:

```

sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((2,2)), 0, q, ↵
↵q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((3,0)), 0, q, ↵
↵q1, q2)
(-q^2*q1-q^2*q2)*B[(1, 2)] + (-q*q1-q*q2)*B[(2, 1)] + (-q^3*q2)*B[(0, 3)]

```

demazure_lusztig_operators(*q1, q2, convention='antidominant'*)

Return the Demazure-Lusztig operators acting on self.

INPUT:

- *q1, q2* – two elements of the ground ring
- *convention* – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

If R is the parent weight ring, the Demazure-Lusztig operator T_i is the linear map $R \rightarrow R$ obtained by interpolating between the isobaric divided difference operator π_i (see [isobaric_divided_difference_on_basis\(\)](#)) and the simple reflection s_i .

$$(q_1 + q_2)\pi_i - q_2s_i$$

The Demazure-Lusztig operators give the usual representation of the operator T_i of the (affine) Hecke algebra with eigenvalues q_1 and q_2 associated to the Weyl group.

Several variants are available to match with various conventions used in the literature:

- “bar” replaces π_i in the formula above by $\bar{\pi}_i = (1 - \pi_i)$.
- “dominant” conjugates the operator by $x^\lambda \mapsto x^{-\lambda}$.

The names dominant and antidominant for the conventions were chosen with regards to the nonsymmetric Macdonald polynomials. The Y operators for the Macdonald polynomials in the “dominant” convention satisfy $Y_\lambda = T_{t_\lambda}$ for λ dominant. This is also the convention used in [Haiman06]. For the “antidominant” convention, $Y_\lambda = T_{t_\lambda}$ with λ antidominant.

See also:

- [demazure_lusztig_operator_on_basis\(\)](#).
- [NonSymmetricMacdonaldPolynomials](#).

REFERENCES:

EXAMPLES:

```

sage: L = RootSystem(["A", 1]).ambient_space()
sage: K = QQ['q1, q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention="bar")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, convention="dominant
↵")
sage: x = KL.monomial(L((3,0)))
sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: Tbar[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q1-2*q2)*B[(0, 3)]
sage: Tbar[1](x) + T[1](x)
(q1+q2)*B[(3, 0)] + (-2*q2)*B[(0, 3)]
sage: Tdominant[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(0, 3)]

```

(continues on next page)

(continued from previous page)

```
sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[(0, 0)] - 1/q2*B[(1, -1)]
```

We repeat similar computation in the affine setting:

```
sage: L = RootSystem(["A", 2, 1]).ambient_space()
sage: K = QQ['q1, q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention="bar")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, convention="dominant
↪")
sage: e = L.basis()
sage: x = KL.monomial(3*e[0])
sage: T[1](x)
(q1+q2)*B[e[0] + 2*e[1]] + (q1+q2)*B[2*e[0] + e[1]] + (q1+q2)*B[3*e[0]] + ↪
↪q1*B[3*e[1]]
sage: Tbar[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]] + (-q1-2*q2)*B[3*e[1]]
sage: Tbar[1](x) + T[1](x)
(q1+q2)*B[3*e[0]] + (-2*q2)*B[3*e[1]]
sage: Tdominant[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]] + (-q2)*B[3*e[1]]
sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[0] - 1/q2*B[e[0] - e[1]]
```

One can obtain iterated operators by passing a reduced word or an element of the Weyl group:

```
sage: T[1, 2](x)
(q1^2+2*q1*q2+q2^2)*B[e[0] + e[1] + e[2]] +
(q1^2+2*q1*q2+q2^2)*B[e[0] + 2*e[1]] +
(q1^2+q1*q2)*B[e[0] + 2*e[2]] + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + e[1]] +
(q1^2+q1*q2)*B[2*e[0] + e[2]] + (q1^2+q1*q2)*B[3*e[0]] +
(q1^2+q1*q2)*B[e[1] + 2*e[2]] + (q1^2+q1*q2)*B[2*e[1] + e[2]] +
(q1^2+q1*q2)*B[3*e[1]] + q1^2*B[3*e[2]]
```

and use that to check, for example, the braid relations:

```
sage: T[1, 2, 1](x) - T[2, 1, 2](x)
0
```

The operators satisfy the relations of the affine Hecke algebra with parameters q_1, q_2 :

```
sage: T._test_relations()
sage: Tdominant._test_relations()
sage: Tbar._test_relations() #-q2, q1+2*q2 # todo: not implemented: set ↪
↪the appropriate eigenvalues!
```

And the \bar{T} are basically the inverses of the T s:

```
sage: Tinv = KL.demazure_lusztig_operators(2/q1+1/q2,-1/q1,convention="bar")
sage: [Tinv[1](T[1](x))-x for x in KL.some_elements()]
[0, 0, 0, 0, 0, 0, 0]
```

We check that $\Lambda_1 - \Lambda_0$ is an eigenvector for the Y s in affine type:

```
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2=K.gens()
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L0 = L.classical()
sage: Lambda = L.fundamental_weights()
sage: alphacheck = L0.simple_coroots()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2, convention="dominant")
sage: Y = T.Y()
sage: alphacheck = Y.keys().alpha() # alpha of coroot lattice is alphacheck
sage: alphacheck
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}
sage: x = KL.monomial(Lambda[1]-Lambda[0]); x
B[e[0]]
```

In fact it is not exactly an eigenvector, but the extra 'delta' term is to be interpreted as a q parameter:

```
sage: Y[alphacheck[0]](KL.one())
q2^2/q1^2*B[0]
sage: Y[alphacheck[1]](x)
((-q2^2)/(-q1^2))*B[e[0] - e['delta']]
sage: Y[alphacheck[2]](x)
(q1/(-q2))*B[e[0]]
sage: KL.q_project(Y[alphacheck[1]](x),q)
((-q2^2)/(-q*q1^2))*B[(1, 0, 0)]

sage: KL.q_project(x, q)
B[(1, 0, 0)]
sage: KL.q_project(Y[alphacheck[0]](x),q)
((-q*q1)/q2)*B[(1, 0, 0)]
sage: KL.q_project(Y[alphacheck[1]](x),q)
((-q2^2)/(-q*q1^2))*B[(1, 0, 0)]
sage: KL.q_project(Y[alphacheck[2]](x),q)
(q1/(-q2))*B[(1, 0, 0)]
```

We now check systematically that the Demazure-Lusztig operators satisfy the relations of the Iwahori-Hecke algebra:

```
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(crystallographic=True): # long_
↪time 12s
.....: L = RootSystem(cartan_type).root_lattice()
.....: KL = L.algebra(K)
.....: T = KL.demazure_lusztig_operators(q1,q2)
.....: T._test_relations()
```

(continues on next page)

(continued from previous page)

```

sage: for cartan_type in CartanType.samples(crystallographic=True): # long_
↳time 12s
.....: L = RootSystem(cartan_type).weight_lattice()
.....: KL = L.algebra(K)
.....: T = KL.demazure_lusztig_operators(q1,q2)
.....: T._test_relations()

```

Recall that the Demazure-Lusztig operators are only defined when all monomials belong to the weight lattice. Thus, in the group algebra of the ambient space, we need to specify explicitly the elements on which to run the tests:

```

sage: for cartan_type in CartanType.samples(crystallographic=True): # long_
↳time 12s
.....: L = RootSystem(cartan_type).ambient_space()
.....: KL = L.algebra(K)
.....: weight_lattice = RootSystem(cartan_type).weight_lattice(extended=L.
↳is_extended())
.....: elements = [ KL.monomial(L(weight)) for weight in weight_lattice.
↳some_elements() ]
.....: T = KL.demazure_lusztig_operators(q1,q2)
.....: T._test_relations(elements=elements)

```

demazure_lusztig_operators_on_classical($q, q1, q2, convention='antidominant'$)

Return the Demazure-Lusztig operators acting at level 1 on `self.classical()`.

INPUT:

- $q, q1, q2$ – three elements of the ground ring
- `convention` – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

Let KL be the group algebra of an affine weight lattice realization L . The Demazure-Lusztig operators for KL act on the group algebra of the corresponding classical weight lattice by embedding it at level 1, and projecting back.

See also:

- `demazure_lusztig_operators()`.
- `demazure_lusztig_operator_on_classical_on_basis()`.
- `q_project()`

EXAMPLES:

```

sage: L = RootSystem(["A", 1, 1]).ambient_space()
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: L0 = KL0.basis().keys()
sage: T = KL.demazure_lusztig_operators_on_classical(q, q1, q2)

sage: x = KL0.monomial(L0((3,0))); x
B[(3, 0)]

```

For T_1, \dots we recover the usual Demazure-Lusztig operators:

```

sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]

```

For T_0 , we can note that, in the projection, δ is mapped to q :

```
sage: T[0](x)
(-q^2*q1-q^2*q2)*B[(1, 2)] + (-q*q1-q*q2)*B[(2, 1)] + (-q^3*q2)*B[(0, 3)]
```

Note that there is no translation part, and in particular 1 is an eigenvector for all T_i 's:

```
sage: T[0](KL0.one())
q1*B[(0, 0)]
sage: T[1](KL0.one())
q1*B[(0, 0)]

sage: Y = T.Y()
sage: alphacheck=Y.keys().simple_roots()
sage: Y[alphacheck[0]](KL0.one())
((-q2)/(q*q1))*B[(0, 0)]
```

Matching with Ion Bogdan's hand calculations from 3/15/2013:

```
sage: L = RootSystem(["A", 1, 1]).weight_space(extended=True)
sage: K = QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: L0 = KL0.basis().keys()
sage: omega = L0.fundamental_weights()
sage: T = KL.demazure_lusztig_operators_on_classical(q, u, -1/u, convention=
->"dominant")
sage: Y = T.Y()
sage: alphacheck = Y.keys().simple_roots()

sage: Ydelta = Y[Y.keys().null_root()]
sage: Ydelta.word, Ydelta.signs, Ydelta.scalar
((), (), 1/q)

sage: Y1 = Y[alphacheck[1]]
sage: Y1.word, Y1.signs, Y1.scalar # This is T_0 T_1 (T_1 acts first, then
->T_0); Ion gets T_1 T_0
((1, 0), (1, 1), 1)

sage: Y0 = Y[alphacheck[0]]
sage: Y0.word, Y0.signs, Y0.scalar # This is 1/q T_1^-1 T_0^-1
((0, 1), (-1, -1), 1/q)
```

Note that the following computations use the "dominant" convention:

```
sage: T0 = T.Tw(0)
sage: T0(KL0.monomial(omega[1]))
q*u*B[-Lambda[1]] + ((u^2-1)/u)*B[Lambda[1]]
sage: T0(KL0.monomial(2*omega[1]))
((q*u^2-q)/u)*B[0] + q^2*u*B[-2*Lambda[1]] + ((u^2-1)/u)*B[2*Lambda[1]]

sage: T0(KL0.monomial(-omega[1]))
1/(q*u)*B[Lambda[1]]
```

(continues on next page)

(continued from previous page)

```
sage: T0(KL0.monomial(-2*omega[1]))
((-u^2+1)/(q*u))*B[0] + 1/(q^2*u)*B[2*Lambda[1]]
```

demazure_operators()

Return the Demazure operators acting on `self`.

The i -th Demazure operator is defined by:

$$\pi_i = \frac{1 - e^{-\alpha_i} s_i}{1 - e^{-\alpha_i}}$$

It acts on e^λ , for λ a weight, by:

$$\pi_i e^\lambda = \frac{e^\lambda - e^{-\alpha_i + s_i \lambda}}{1 - e^{-\alpha_i}}$$

This matches with Lascoux' definition [Lascoux2003] of π_i , and with the i -th Demazure operator of [Kumar1987], which also works for general Kac-Moody types.

REFERENCES:

EXAMPLES:

We compute some Schur functions, as images of dominant monomials under the action of the maximal isobaric divided difference Δ_{w_0} :

```
sage: L = RootSystem(["A", 2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: w0 = tuple(L.weyl_group().long_element().reduced_word())
sage: pi = KL.demazure_operators()
sage: pi0 = pi[w0]
sage: pi0(KL.monomial(L((2, 1))))
2*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 2)] + B[(2, 1, 0)] + B[(2, 0, 1)]
↪ + B[(0, 1, 2)] + B[(0, 2, 1)]
```

Let us make the result into an actual polynomial:

```
sage: P = QQ['x, y, z']
sage: pi0(KL.monomial(L((2, 1)))) .expand(P.gens())
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

This is indeed a Schur function:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s[2, 1].expand(3, P.variable_names())
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

Let us check this systematically on Schur functions of degree 6:

```
sage: for p in Partitions(6, max_length=3).list():
.....:     assert s.monomial(p).expand(3, P.variable_names()) == pi0(KL.
↪ monomial(L(tuple(p))).expand(P.gens()))
```

We check systematically that these operators satisfy the Iwahori-Hecke algebra relations:

```

sage: for cartan_type in CartanType.samples(crystallographic=True): # long
↳time 12s
.....: L = RootSystem(cartan_type).weight_lattice()
.....: KL = L.algebra(QQ)
.....: T = KL.demazure_operators()
.....: T._test_relations()

sage: L = RootSystem(['A',1,1]).weight_lattice()
sage: KL = L.algebra(QQ)
sage: T = KL.demazure_operators()
sage: T._test_relations()

```

Warning: The Demazure operators are only defined if all the elements in the support have integral scalar products with the coroots (basically, they are in the weight lattice). Otherwise an error is raised:

```

sage: L = RootSystem(CartanType(["G",2]).dual()).ambient_space()
sage: KL = L.algebra(QQ)
sage: pi = KL.demazure_operators()
sage: pi[1](KL.monomial(L([0,0,1])))
Traceback (most recent call last):
...
ValueError: the weight does not have an integral scalar product with the
↳coroot

```

divided_difference_on_basis(*weight*, *i*)

Return the result of applying the *i*-th divided difference on *weight*.

INPUT:

- *weight* – a weight
- *i* – an element of the index set

Todo: type free definition (Viviane's definition uses that we are in the ambient space)

EXAMPLES:

```

sage: L = RootSystem(["A",1]).ambient_space()
sage: KL = L.algebra(QQ)
sage: KL.divided_difference_on_basis(L((2,2)), 1) # todo: not implemented
0
sage: KL.divided_difference_on_basis(L((3,0)), 1) # todo: not implemented
B[(2, 0)] + B[(1, 1)] + B[(0, 2)]
sage: KL.divided_difference_on_basis(L((0,3)), 1) # todo: not implemented
-B[(2, 0)] - B[(1, 1)] - B[(0, 2)]

```

In type *A* and in the ambient lattice, we recover the usual action of divided differences polynomials:

```

sage: x,y = QQ['x,y'].gens()
sage: d = lambda p: (p - p(y,x)) / (x-y)
sage: d(x^2*y^2)
0

```

(continues on next page)

(continued from previous page)

```
sage: d(x^3)
x^2 + x*y + y^2
sage: d(y^3)
-x^2 - x*y - y^2
```

from_polynomial(*p*)Construct an element of `self` from a polynomial *p*.

INPUT:

- *p* – a polynomial

EXAMPLES:

```
sage: L = RootSystem(["A",2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: x,y,z = QQ['x,y,z'].gens()
sage: KL.from_polynomial(x)
B[(1, 0, 0)]
sage: KL.from_polynomial(x^2*y + 2*y - z)
B[(2, 1, 0)] + 2*B[(0, 1, 0)] - B[(0, 0, 1)]
```

Todo: make this work for Laurent polynomials too**isobaric_divided_difference_on_basis**(*weight*, *i*)Return the result of applying the *i*-th isobaric divided difference on *weight*.

INPUT:

- *weight* – a weight
- *i* – an element of the index set

See also:[*demazure_operators\(\)*](#)

EXAMPLES:

```
sage: L = RootSystem(["A",1]).ambient_space()
sage: KL = L.algebra(QQ)
sage: KL.isobaric_divided_difference_on_basis(L((2,2)), 1)
B[(2, 2)]
sage: KL.isobaric_divided_difference_on_basis(L((3,0)), 1)
B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]
sage: KL.isobaric_divided_difference_on_basis(L((0,3)), 1)
-B[(1, 2)] - B[(2, 1)]
```

In type *A* and in the ambient lattice, we recover the usual action of divided differences on polynomials:

```
sage: x,y = QQ['x,y'].gens()
sage: d = lambda p: (x*p - (x*p)(y,x)) / (x-y)
sage: d(x^2*y^2)
x^2*y^2
sage: d(x^3)
x^3 + x^2*y + x*y^2 + y^3
sage: d(y^3)
-x^2*y - x*y^2
```

REFERENCES:

q_project(*x*, *q*)

Implement the q -projection morphism from `self` to the group algebra of the classical space.

INPUT:

- x – an element of the group algebra of `self`
- q – an element of the ground ring

This is an algebra morphism mapping δ to q and X^b to its classical counterpart for the other elements b of the basis of the realization.

EXAMPLES:

```
sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: x = KL.an_element() + KL.monomial(4*e[1] + 3*e[2] + e['deltacheck'] -
↪ 2*e['delta']); x
B[2*e[0] + 2*e[1] + 3*e[2]] + B[4*e[1] + 3*e[2] - 2*e['delta'] + e[
↪ 'deltacheck']]
sage: KL.q_project(x, q)
B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]

sage: KL = RootSystem(["BC",3,2]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: x = KL.an_element() + KL.monomial(4*e[1] + 3*e[2] + e['deltacheck'] -
↪ 2*e['delta']); x
B[2*e[0] + 2*e[1] + 3*e[2]] + B[4*e[1] + 3*e[2] - 2*e['delta'] + e[
↪ 'deltacheck']]
sage: KL.q_project(x, q)
B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]
```

Warning: Recall that the null root, usually denoted δ , is in fact `a[0]\delta` in Sage's notation, in order to avoid half integer coefficients (this only makes a difference in type BC). Similarly, what's usually denoted q is in fact `q^a[0]` in Sage's notations, to avoid manipulating square roots:

```
sage: KL.q_project(KL.monomial(L.null_root()), q)
q^2*B[(0, 0, 0)]
```

q_project_on_basis(*l*, *q*)

Return the monomial $c * cl(l)$ in the group algebra of the classical lattice.

INPUT:

- l – an element of the root lattice realization
- q – an element of the ground ring

Here, $cl(l)$ is the projection of l in the classical lattice, and c is the coefficient of l in δ .

See also:

[`q_project_on_basis\(\)`](#)

EXAMPLES:

```

sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: KL.q_project_on_basis( 4*e[1] + 3*e[2] + e['deltacheck'] - 2*e['delta
↪'], q)
1/q^2*B[(0, 4, 3)]

```

some_elements()

Return some elements of the algebra self.

EXAMPLES:

```

sage: A = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: A.some_elements()
[B[2*e[0] + 2*e[1] + 3*e[2]],
B[-e[0] + e[2] + e['delta']],
B[e[0] - e[1]],
B[e[1] - e[2]],
B[e['deltacheck']],
B[e[0] + e['deltacheck']],
B[e[0] + e[1] + e['deltacheck']]]

sage: A = RootSystem(["B",2]).weight_space().algebra(QQ)
sage: A.some_elements()
[B[2*Lambda[1] + 2*Lambda[2]],
B[2*Lambda[1] - 2*Lambda[2]],
B[-Lambda[1] + 2*Lambda[2]],
B[Lambda[1]],
B[Lambda[2]]]

```

twisted_demazure_lusztig_operator_on_basis(weight, i, q1, q2, convention='antidominant')

Return the twisted Demazure-Lusztig operator acting on the basis.

INPUT:

- weight – an element λ of the weight lattice
- i – an element of the index set
- q1, q2 – two elements of the ground ring
- convention – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

See also:

[twisted_demazure_lusztig_operators\(\)](#)

EXAMPLES:

```

sage: L = RootSystem(["A",3,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: Lambda = L.classical().fundamental_weights()
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], ↪
↪1, q1, q2, convention="dominant")
(-q2)*B[(2, 3, 0, 0)]

```

(continues on next page)

(continued from previous page)

```

sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2],
↳2, q1, q2, convention="dominant")
(-q1-q2)*B[(3, 1, 1, 0)] + (-q2)*B[(3, 0, 2, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2],
↳3, q1, q2, convention="dominant")
q1*B[(3, 2, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2],
↳0, q1, q2, convention="dominant")
((q1*q2+q2^2)/q1)*B[(1, 2, 1, 1)] + ((q1*q2+q2^2)/q1)*B[(1, 2, 2, 0)] + q2^
↳2/q1*B[(1, 2, 0, 2)]
+ ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 1, 1, 1)] + ((q1^2+2*q1*q2+q2^2)/q1)*B[(2,
↳1, 2, 0)]
+ ((q1*q2+q2^2)/q1)*B[(2, 1, 0, 2)] + ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 2, 1,
↳0)] + ((q1*q2+q2^2)/q1)*B[(2, 2, 0, 1)]

```

twisted_demazure_lusztig_operators($q1, q2, convention='antidominant'$)

Return the twisted Demazure-Lusztig operators acting on self.

INPUT:

- $q1, q2$ – two elements of the ground ring
- `convention` – “antidominant”, “bar”, or “dominant” (default: “antidominant”)

Warning:

- the code is currently only tested for $q_1 q_2 = -1$
- only the “dominant” convention is functional for $i = 0$

For T_1, \dots, T_n , these operators are the usual Demazure-Lusztig operators. On the other hand, the operator T_0 is twisted:

```

sage: L = RootSystem(["A", 3, 1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1, q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1, q2, convention="dominant
↳")
sage: T._test_relations()

```

Todo: Choose a good set of Cartan Type to run on. Rank >4 is too big. But C_1 and B_1 are boring.

We now check systematically that those operators satisfy the relations of the Iwahori-Hecke algebra:

```

sage: K = QQ['q1, q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(affine=True,
↳crystallographic=True): # long time 12s
.....:     if cartan_type.rank() > 4: continue
.....:     if cartan_type.type() == 'BC': continue
.....:     KL = RootSystem(cartan_type).weight_lattice().algebra(K)

```

(continues on next page)

(continued from previous page)

```

.....: T = KL.twisted_demazure_lusztig_operators(q1, q2, convention=
↪ "dominant")
.....: T._test_relations()

```

Todo: Investigate why T_0^\vee currently does not satisfy the quadratic relation in type BC . This should hopefully be fixed when T_0^\vee will have a more uniform implementation:

```

sage: cartan_type = CartanType(["BC",1,2])
sage: KL = RootSystem(cartan_type).weight_lattice().algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant
↪ ")
sage: T._test_relations()
Traceback (most recent call last):
... tester.assertTrue(Ti(Ti(x,i,-q2),i,-q1).is_zero()) ...
AssertionError: False is not true

```

Comparison with T_0 :

```

sage: L = RootSystem(["A",2,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['t,q'].fraction_field()
sage: t,q = K.gens()
sage: q1 = t
sage: q2 = -1
sage: KL = L.algebra(K)
sage: L0 = L.classical()
sage: T = KL.demazure_lusztig_operators(q1,q2, convention="dominant")
sage: def T0(*l0): return KL.q_project(T[0].on_basis()(L.embed_at_
↪ level(L0(l0), 1)), q)
sage: T0_check_on_basis = KL.T0_check_on_basis(q1, q2, convention="dominant
↪ ")
sage: def T0c(*l0): return T0_check_on_basis(L0(l0))

sage: T0(0,0,1) # not double checked
((-t+1)/q)*B[(1, 0, 0)] + 1/q^2*B[(2, 0, -1)]
sage: T0c(0,0,1)
(t^2-t)*B[(1, 0, 0)] + (t^2-t)*B[(1, 1, -1)] + t^2*B[(2, 0, -1)] + (t-
↪ 1)*B[(0, 0, 1)]

```

5.1.235 Root lattice realizations

```

class sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations(base,
name=None)

```

Bases: `sage.categories.category_types.Category_over_base_ring`

The category of root lattice realizations over a given base ring

A *root lattice realization* L over a base ring R is a free module (or vector space if R is a field) endowed with an embedding of the root lattice of some root system.

Typical root lattice realizations over \mathbf{Z} include the root lattice, weight lattice, and ambient lattice. Typical root lattice realizations over \mathbf{Q} include the root space, weight space, and ambient space.

To describe the embedding, a root lattice realization must implement a method `simple_root()` returning for each i in the index set the image of the simple root α_i under the embedding.

A root lattice realization must further implement a method on elements `scalar()`, computing the scalar product with elements of the coroot lattice or coroot space.

Using those, this category provides tools for reflections, roots, the Weyl group and its action, ...

See also:

- [RootSystem](#)
- [WeightLatticeRealizations](#)
- [RootSpace](#)
- [WeightSpace](#)
- [AmbientSpace](#)

EXAMPLES:

Here, we consider the root system of type A_7 , and embed the root lattice element $x = \alpha_2 + 2\alpha_6$ in several root lattice realizations:

```
sage: R = RootSystem(["A", 7])
sage: alpha = R.root_lattice().simple_roots()
sage: x = alpha[2] + 2 * alpha[5]

sage: L = R.root_space()
sage: L(x)
alpha[2] + 2*alpha[5]

sage: L = R.weight_lattice()
sage: L(x)
-Lambda[1] + 2*Lambda[2] - Lambda[3] - 2*Lambda[4] + 4*Lambda[5] - 2*Lambda[6]

sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 2, -2, 0, 0)
```

We embed the root space element $x = \alpha_2 + 1/2\alpha_6$ in several root lattice realizations:

```
sage: alpha = R.root_space().simple_roots()
sage: x = alpha[2] + 1/2 * alpha[5]

sage: L = R.weight_space()
sage: L(x)
-Lambda[1] + 2*Lambda[2] - Lambda[3] - 1/2*Lambda[4] + Lambda[5] - 1/2*Lambda[6]

sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 1/2, -1/2, 0, 0)
```

Of course, one can't embed the root space in the weight lattice:

```

sage: L = R.weight_lattice()
sage: L(x)
Traceback (most recent call last):
...
TypeError: do not know how to make x (= alpha[2] + 1/2*alpha[5]) an element of self.
↳(=Weight lattice of the Root system of type ['A', 7])

```

If K_1 is a subring of K_2 , then one could in theory have an embedding from the root space over K_1 to any root lattice realization over K_2 ; this is not implemented:

```

sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.weight_space(K2)

sage: alpha = R.root_space(K2).simple_roots()
sage: L(alpha[1])
2*Lambda[1] - Lambda[2]

sage: alpha = R.root_space(K1).simple_roots()
sage: L(alpha[1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= alpha[1]) an element of self (=Weight space
↳over the Univariate Polynomial Ring in q over Rational Field of the Root system
↳of type ['A', 7])

```

By a slight abuse, the embedding of the root lattice is not actually required to be faithful. Typically for an affine root system, the null root of the root lattice is killed in the non extended weight lattice:

```

sage: R = RootSystem(["A", 3, 1])
sage: delta = R.root_lattice().null_root()
sage: L = R.weight_lattice()
sage: L(delta)
0

```

Algebras

alias of `sage.combinat.root_system.root_lattice_realization_algebras.Algebras`

class ElementMethods

Bases: object

affine_orbit()

The orbit of self under the dot or affine action of the Weyl group.

EXAMPLES:

```

sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().dot_orbit())           # the output order is not
↳specified
[(-2, 1, 4), (-2, 3, 2), (2, -1, 2),
 (2, 1, 0), (0, -1, 4), (0, 3, 0)]

sage: L = RootSystem(['B', 2]).weight_lattice()
sage: sorted(L.fundamental_weights()[1].dot_orbit()) # the output order
↳is not specified

```

(continues on next page)

(continued from previous page)

```
[-4*Lambda[1], -4*Lambda[1] + 4*Lambda[2],
 -3*Lambda[1] - 2*Lambda[2], -3*Lambda[1] + 4*Lambda[2],
 Lambda[1], Lambda[1] - 6*Lambda[2],
 2*Lambda[1] - 6*Lambda[2], 2*Lambda[1] - 2*Lambda[2]]
```

We compare the dot action orbit to the regular orbit:

```
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().dot_orbit())
24
sage: len((-L.rho()).dot_orbit())
1
sage: La = L.fundamental_weights()
sage: len(La[1].dot_orbit())
24
sage: len(La[1].orbit())
4
sage: len((-L.rho() + La[1]).dot_orbit())
4
sage: len(La[2].dot_orbit())
24
sage: len(La[2].orbit())
6
sage: len((-L.rho() + La[2]).dot_orbit())
6
```

associated_coroot()

Returns the coroot associated to this root

EXAMPLES:

```
sage: alpha = RootSystem(["A", 3]).root_space().simple_roots()
sage: alpha[1].associated_coroot()
alphacheck[1]
```

associated_reflection()

Given a positive root `self`, returns a reduced word for the reflection orthogonal to `self`.

Since the answer is cached, it is a tuple instead of a list.

EXAMPLES:

```
sage: RootSystem(['C', 3]).root_lattice().simple_root(3).weyl_action([1, 2]).
↪ associated_reflection()
(1, 2, 3, 2, 1)
sage: RootSystem(['C', 3]).root_lattice().simple_root(2).associated_
↪ reflection()
(2,)
```

descents (*index_set=None, positive=False*)

Returns the descents of `pt`

EXAMPLES:

```
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=space.simple_roots()
sage: (alpha[1]+alpha[2]+alpha[4]).descents()
[3, 5]
```

dot_action(*w*, *inverse=False*)

Act on `self` by `w` using the dot or affine action.

Let w be an element of the Weyl group. The *dot action* or *affine action* is given by:

$$w \bullet \lambda = w(\lambda + \rho) - \rho,$$

where ρ is the sum of the fundamental weights.

INPUT:

- `w` – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list (such as a reduced word) of elements from the index set
- `inverse` – a boolean (default: `False`); whether to act by the inverse element

EXAMPLES:

```
sage: P = RootSystem(['B',3]).weight_lattice()
sage: La = P.fundamental_weights()
sage: mu = La[1] + 2*La[2] - 3*La[3]
sage: mu.dot_action([1])
-3*Lambda[1] + 4*Lambda[2] - 3*Lambda[3]
sage: mu.dot_action([3])
Lambda[1] + Lambda[3]
sage: mu.dot_action([1,2,3])
-4*Lambda[1] + Lambda[2] + 3*Lambda[3]
```

We check that the origin of this action is at $-\rho$:

```
sage: all((-P.rho()).dot_action([i]) == -P.rho()
.....:      for i in P.index_set())
True
```

REFERENCES:

- [Wikipedia article Affine_action](#)

dot_orbit()

The orbit of `self` under the dot or affine action of the Weyl group.

EXAMPLES:

```
sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().dot_orbit())           # the output order is not
↳specified
[(-2, 1, 4), (-2, 3, 2), (2, -1, 2),
 (2, 1, 0), (0, -1, 4), (0, 3, 0)]

sage: L = RootSystem(['B',2]).weight_lattice()
sage: sorted(L.fundamental_weights()[1].dot_orbit()) # the output order
↳is not specified
[-4*Lambda[1], -4*Lambda[1] + 4*Lambda[2],
 -3*Lambda[1] - 2*Lambda[2], -3*Lambda[1] + 4*Lambda[2],
```

(continues on next page)

(continued from previous page)

```
Lambda[1], Lambda[1] - 6*Lambda[2],
2*Lambda[1] - 6*Lambda[2], 2*Lambda[1] - 2*Lambda[2]]
```

We compare the dot action orbit to the regular orbit:

```
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().dot_orbit())
24
sage: len((-L.rho()).dot_orbit())
1
sage: La = L.fundamental_weights()
sage: len(La[1].dot_orbit())
24
sage: len(La[1].orbit())
4
sage: len((-L.rho() + La[1]).dot_orbit())
4
sage: len(La[2].dot_orbit())
24
sage: len(La[2].orbit())
6
sage: len((-L.rho() + La[2]).dot_orbit())
6
```

extraspecial_pair()

Return the extraspecial pair of `self` under the ordering defined by `positive_roots_by_height()`.

The *extraspecial pair* of a positive root γ with some total ordering $<$ of the root lattice that respects height is the pair of positive roots (α, β) such that $\gamma = \alpha + \beta$ and α is as small as possible.

EXAMPLES:

```
sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().extraspecial_pair()
(alpha[2], 3*alpha[1] + alpha[2])
```

first_descent(index_set=None, positive=False)

Returns the first descent of `pt`

One can use the `index_set` option to restrict to the parabolic subgroup indexed by `index_set`.

EXAMPLES:

```
sage: space=RootSystem(['A', 5]).weight_space()
sage: alpha=space.simple_roots()
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent()
3
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1, 2, 5])
5
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1, 2, 5, 3, 4])
5
```

greater()

Returns the elements in the orbit of `self` which are greater than `self` in the weak order.

EXAMPLES:

```

sage: L = RootSystem(['A', 3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].greater()
[(0, 0, 1, 0), (0, 0, 0, 1)]
sage: len(L.rho().greater())
24
sage: len((-L.rho()).greater())
1
sage: sorted([len(x.greater()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, 24]

```

has_descent(*i*, *positive=False*)

Test if self has a descent at position *i*, that is if self is on the strict negative side of the i^{th} simple reflection hyperplane.

If positive if True, tests if it is on the strict positive side instead.

EXAMPLES:

```

sage: space=RootSystem(['A', 5]).weight_space()
sage: alpha=RootSystem(['A', 5]).weight_space().simple_roots()
sage: [alpha[i].has_descent(1) for i in space.index_set()]
[False, True, False, False]
sage: [(-alpha[i]).has_descent(1) for i in space.index_set()]
[True, False, False, False]
sage: [alpha[i].has_descent(1, True) for i in space.index_set()]
[True, False, False, False]
sage: [(-alpha[i]).has_descent(1, True) for i in space.index_set()]
[False, True, False, False]
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(3)
True
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(1)
False
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(1, True)
True

```

height()

Return the height of self.

The height of a root $\alpha = \sum_i a_i \alpha_i$ is defined to be $h(\alpha) := \sum_i a_i$.

EXAMPLES:

```

sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().height()
5

```

is_dominant(*index_set=None*, *positive=True*)

Returns whether self is dominant.

This is done with respect to the subroot system indicated by the subset of Dynkin nodes *index_set*. If *index_set* is None then the entire Dynkin node set is used. If *positive* is False then the dominance condition is replaced by antidominance.

EXAMPLES:

```

sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: [x.is_dominant(positive=False) for x in Lambda]
[False, False]
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False
sage: (Lambda[1]-Lambda[2]).is_dominant([1])
True
sage: (Lambda[1]-Lambda[2]).is_dominant([2])
False
sage: [x.is_dominant() for x in L.roots()]
[False, True, False, False, False, False]
sage: [x.is_dominant(positive=False) for x in L.roots()]
[False, False, False, False, True, False]

```

is_dominant_weight()

Test whether self is a dominant element of the weight lattice.

EXAMPLES:

```

sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: (3*Lambda[1]+Lambda[2]).is_dominant()
True
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False

```

Tests that the scalar products with the coroots are all nonnegative integers. For example, if x is the sum of a dominant element of the weight lattice plus some other element orthogonal to all coroots, then the implementation correctly reports x to be a dominant weight:

```

sage: x = Lambda[1] + L([-1,-1,-1])
sage: x.is_dominant_weight()
True

```

is_imaginary_root()

Return True if self is an imaginary root.

A root α is imaginary if it is not W conjugate to a simple root where W is the corresponding Weyl group.

EXAMPLES:

```

sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_imaginary_root()
False

```

(continues on next page)

(continued from previous page)

```
sage: elt = alpha[0] + alpha[1] + 2*alpha[2]
sage: elt.is_imaginary_root()
True
```

is_long_root()

Return True if self is a long (real) root.

EXAMPLES:

```
sage: Q = RootSystem(['B', 2, 1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_long_root()
True
sage: alpha[1].is_long_root()
True
sage: alpha[2].is_long_root()
False
```

is_parabolic_root(index_set)

Supposing that self is a root, is it in the parabolic subsystem with Dynkin nodes `index_set`?

INPUT:

- `index_set` – the Dynkin node set of the parabolic subsystem.

Todo: This implementation is only valid in the root or weight lattice

EXAMPLES:

```
sage: alpha = RootSystem(['A', 3]).root_lattice().from_vector(vector([1, 1,
↪0]))
sage: alpha.is_parabolic_root([1, 3])
False
sage: alpha.is_parabolic_root([1, 2])
True
sage: alpha.is_parabolic_root([2])
False
```

is_real_root()

Return True if self is a real root.

A root α is real if it is W conjugate to a simple root where W is the corresponding Weyl group.

EXAMPLES:

```
sage: Q = RootSystem(['B', 2, 1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_real_root()
True
sage: elt = alpha[0] + alpha[1] + 2*alpha[2]
sage: elt.is_real_root()
False
```

is_short_root()

Return True if self is a short (real) root.

Returns False unless the parent is an irreducible root system of finite type having two root lengths and self is of the shorter length. There is no check of whether self is actually a root.

EXAMPLES:

```
sage: Q = RootSystem(['C', 2]).root_lattice()
sage: al = Q.simple_root(1).weyl_action([1, 2]); al
alpha[1] + alpha[2]
sage: al.is_short_root()
True
sage: bt = Q.simple_root(2).weyl_action([2, 1, 2]); bt
-2*alpha[1] - alpha[2]
sage: bt.is_short_root()
False
sage: RootSystem(['A', 2]).root_lattice().simple_root(1).is_short_root()
False
```

An example in affine type:

```
sage: Q = RootSystem(['B', 2, 1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_short_root()
False
sage: alpha[1].is_short_root()
False
sage: alpha[2].is_short_root()
True
```

level()

EXAMPLES:

```
sage: L = RootSystem(['A', 2, 1]).weight_lattice()
sage: L.rho().level()
3
```

norm_squared()

Return the norm squared of self with respect to the symmetric form.

EXAMPLES:

```
sage: Q = RootSystem(['B', 2, 1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].norm_squared()
4
sage: alpha[2].norm_squared()
2
sage: elt = alpha[0] - 3*alpha[1] + alpha[2]
sage: elt.norm_squared()
50
sage: elt = alpha[0] + alpha[1] + 2*alpha[2]
sage: elt.norm_squared()
0
sage: Q = RootSystem(CartanType(['A', 4, 2]).dual()).root_lattice()
sage: Qc = RootSystem(['A', 4, 2]).coroot_lattice()
sage: alpha = Q.simple_roots()
```

(continues on next page)

(continued from previous page)

```

sage: alphac = Qc.simple_roots()
sage: elt = alpha[0] + 2*alpha[1] + 2*alpha[2]
sage: eltc = alphac[0] + 2*alphac[1] + 2*alphac[2]
sage: elt.norm_squared()
0
sage: eltc.norm_squared()
0

```

orbit()

The orbit of `self` under the action of the Weyl group.

EXAMPLES:

ρ is a regular element whose orbit is in bijection with the Weyl group. In particular, it has 6 elements for the symmetric group S_3 :

```

sage: L = RootSystem(["A", 2]).ambient_lattice()
sage: sorted(L.rho().orbit())           # the output order is not
↳ specified
[(1, 2, 0), (1, 0, 2), (2, 1, 0),
 (2, 0, 1), (0, 1, 2), (0, 2, 1)]

sage: L = RootSystem(["A", 3]).weight_lattice()
sage: len(L.rho().orbit())
24
sage: len(L.fundamental_weights()[1].orbit())
4
sage: len(L.fundamental_weights()[2].orbit())
6

```

pred(index_set=None)

Return the immediate predecessors of `self` for the weak order.

INPUT:

- `index_set` - a subset (as a list or iterable) of the nodes of the Dynkin diagram; (default: `None` for all of them)

If `index_set` is specified, the successors for the corresponding parabolic subsystem are returned.

EXAMPLES:

```

sage: L = RootSystem(['A', 3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].pred()
[]
sage: L.rho().pred()
[]
sage: (-L.rho()).pred()
[Lambda[1] - 2*Lambda[2] - Lambda[3], -2*Lambda[1] + Lambda[2] -
↳ 2*Lambda[3], -Lambda[1] - 2*Lambda[2] + Lambda[3]]
sage: (-L.rho()).pred(index_set=[1])
[Lambda[1] - 2*Lambda[2] - Lambda[3]]

```

reduced_word(index_set=None, positive=True)

Returns a reduced word for the inverse of the shortest Weyl group element that sends the vector `self` into the dominant chamber.

With the `index_set` optional parameter, this is done with respect to the corresponding parabolic subgroup.

If `positive` is `False`, use the antidominant chamber instead.

EXAMPLES:

```
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: alpha[1].reduced_word()
[2, 3, 4, 5]
sage: alpha[1].reduced_word([1,2])
[2]
```

reflection(*root*, *use_coroot=False*)

Reflects `self` across the hyperplane orthogonal to `root`.

If `use_coroot` is `True`, `root` is interpreted as a coroot.

EXAMPLES:

```
sage: R = RootSystem(['C',4])
sage: weight_lattice = R.weight_lattice()
sage: mu = weight_lattice.from_vector(vector([0,0,1,2]))
sage: coroot_lattice = R.coroot_lattice()
sage: alphavee = coroot_lattice.from_vector(vector([0,0,1,1]))
sage: mu.reflection(alphavee, use_coroot=True)
6*Lambda[2] - 5*Lambda[3] + 2*Lambda[4]
sage: root_lattice = R.root_lattice()
sage: beta = root_lattice.from_vector(vector([0,1,1,0]))
sage: mu.reflection(beta)
Lambda[1] - Lambda[2] + 3*Lambda[4]
```

scalar(*lambdacheck*)

Implement the natural pairing with the coroot lattice.

INPUT:

- `self` – an element of a root lattice realization
- `lambdacheck` – an element of the coroot lattice or coroot space

OUTPUT: the scalar product of `self` and `lambdacheck`

EXAMPLES:

```
sage: L = RootSystem(['A',4]).root_lattice()
sage: alpha      = L.simple_roots()
sage: alphacheck = L.simple_coroots()
sage: alpha[1].scalar(alphacheck[1])
2
sage: alpha[1].scalar(alphacheck[2])
-1
sage: matrix([ [ alpha[i].scalar(alphacheck[j])
.....:          for i in L.index_set() ]
.....:          for j in L.index_set() ])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
```

simple_reflection(*i*)

Returns the image of `self` by the *i*-th simple reflection.

EXAMPLES:

```
sage: alpha = RootSystem(["A", 3]).root_lattice().alpha()
sage: alpha[1].simple_reflection(2)
alpha[1] + alpha[2]

sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended = True)
sage: Lambda = Q.fundamental_weights()
sage: L = Lambda[0] + Q.null_root()
sage: L.simple_reflection(0)
-Lambda[0] + Lambda[1] + Lambda[3]
```

simple_reflections()

The images of `self` by all the simple reflections

EXAMPLES:

```
sage: alpha = RootSystem(["A", 3]).root_lattice().alpha()
sage: alpha[1].simple_reflections()
[-alpha[1], alpha[1] + alpha[2], alpha[1]]
```

smaller()

Returns the elements in the orbit of `self` which are smaller than `self` in the weak order.

EXAMPLES:

```
sage: L = RootSystem(['A', 3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].smaller()
[(0, 0, 1, 0), (0, 1, 0, 0), (1, 0, 0, 0)]
sage: len(L.rho().smaller())
1
sage: len((-L.rho()).smaller())
24
sage: sorted([len(x.smaller()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, 24]
```

succ(*index_set=None*)

Return the immediate successors of `self` for the weak order.

INPUT:

- `index_set` - a subset (as a list or iterable) of the nodes of the Dynkin diagram; (default: `None` for all of them)

If `index_set` is specified, the successors for the corresponding parabolic subsystem are returned.

EXAMPLES:

```
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].succ()
[-Lambda[1] + Lambda[2]]
sage: L.rho().succ()
[-Lambda[1] + 2*Lambda[2] + Lambda[3], 2*Lambda[1] - Lambda[2] +
 2*Lambda[3], Lambda[1] + 2*Lambda[2] - Lambda[3]]
```

(continues on next page)

(continued from previous page)

```

sage: (-L.rho()).succ()
[]
sage: L.rho().succ(index_set=[1])
[-Lambda[1] + 2*Lambda[2] + Lambda[3]]
sage: L.rho().succ(index_set=[2])
[2*Lambda[1] - Lambda[2] + 2*Lambda[3]]

```

symmetric_form(alpha)

Return the symmetric form of self with alpha.

Consider the simple roots α_i and let $(b_{ij})_{ij}$ denote the symmetrized Cartan matrix $(a_{ij})_{ij}$, we have

$$(\alpha_i | \alpha_j) = b_{ij}$$

and extended bilinearly. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

EXAMPLES:

```

sage: Q = RootSystem(['B', 2, 1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].symmetric_form(alpha[0])
0
sage: alpha[1].symmetric_form(alpha[1])
4
sage: elt = alpha[0] - 3*alpha[1] + alpha[2]
sage: elt.symmetric_form(alpha[1])
-14
sage: elt.symmetric_form(alpha[0]+2*alpha[2])
14
sage: Q = RootSystem(CartanType(['A', 4, 2]).dual()).root_lattice()
sage: Qc = RootSystem(['A', 4, 2]).coroot_lattice()
sage: alpha = Q.simple_roots()
sage: alphac = Qc.simple_roots()
sage: elt = alpha[0] + 2*alpha[1] + 2*alpha[2]
sage: eltc = alphac[0] + 2*alphac[1] + 2*alphac[2]
sage: elt.symmetric_form(alpha[1])
0
sage: eltc.symmetric_form(alphac[1])
0

```

to_ambient()

Map self to the ambient space.

EXAMPLES:

```

sage: alpha = CartanType(['B', 4]).root_system().root_lattice().an_element();
↪ alpha
2*alpha[1] + 2*alpha[2] + 3*alpha[3]
sage: alpha.to_ambient()
(2, 0, 1, -3)
sage: mu = CartanType(['B', 4]).root_system().weight_lattice().an_element(); ↪
↪ mu
2*Lambda[1] + 2*Lambda[2] + 3*Lambda[3]
sage: mu.to_ambient()

```

(continues on next page)

(continued from previous page)

```
(7, 5, 3, 0)
sage: v = CartanType(['B',4]).root_system().ambient_space().an_element(); v
(2, 2, 3, 0)
sage: v.to_ambient()
(2, 2, 3, 0)
sage: alphavee = CartanType(['B',4]).root_system().coroot_lattice().an_
↪element(); alphavee
2*alphacheck[1] + 2*alphacheck[2] + 3*alphacheck[3]
sage: alphavee.to_ambient()
(2, 0, 1, -3)
```

to_classical()

Map self to the classical lattice/space.

Only makes sense for affine type.

EXAMPLES:

```
sage: R = CartanType(['A',3,1]).root_system()
sage: alpha = R.root_lattice().an_element(); alpha
2*alpha[0] + 2*alpha[1] + 3*alpha[2]
sage: alb = alpha.to_classical(); alb
alpha[2] - 2*alpha[3]
sage: alb.parent()
Root lattice of the Root system of type ['A', 3]
sage: v = R.ambient_space().an_element(); v
2*e[0] + 2*e[1] + 3*e[2]
sage: v.to_classical()
(2, 2, 3, 0)
```

to_dominant_chamber(*index_set=None, positive=True, reduced_word=False*)

Returns the unique dominant element in the Weyl group orbit of the vector self.

If *positive* is False, returns the antidominant orbit element.

With the *index_set* optional parameter, this is done with respect to the corresponding parabolic subgroup.

If *reduced_word* is True, returns the 2-tuple (*weight*, *direction*) where *weight* is the (anti)dominant orbit element and *direction* is a reduced word for the Weyl group element sending *weight* to self.

Warning: In infinite type, an orbit may not contain a dominant element. In this case the function may go into an infinite loop.

For affine root systems, errors are generated if the orbit does not contain the requested kind of representative. If the input vector is of positive (resp. negative) level, then there is a dominant (resp. antidominant) element in its orbit but not an antidominant (resp. dominant) one. If the vector is of level zero, then there are neither dominant nor antidominant orbit representatives, except for multiples of the null root, which are themselves both dominant and antidominant orbit representatives.

EXAMPLES:

```

sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: alpha[1].to_dominant_chamber()
Lambda[1] + Lambda[5]
sage: alpha[1].to_dominant_chamber([1,2])
Lambda[1] + Lambda[2] - Lambda[3]
sage: wl=RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: mu=wl.from_vector(vector([1,-3,0]))
sage: mu.to_dominant_chamber(positive=False, reduced_word = True)
(-Lambda[1] - Lambda[2] - delta, [0, 2])

sage: R = RootSystem(['A',1,1])
sage: rl = R.root_lattice()
sage: nu = rl.zero()
sage: nu.to_dominant_chamber()
0
sage: nu.to_dominant_chamber(positive=False)
0
sage: mu = rl.from_vector(vector([0,1]))
sage: mu.to_dominant_chamber()
Traceback (most recent call last):
...
ValueError: alpha[1] is not in the orbit of the fundamental chamber
sage: mu.to_dominant_chamber(positive=False)
Traceback (most recent call last):
...
ValueError: alpha[1] is not in the orbit of the negative of the fundamental_
↪chamber

```

to_dual_type_cospace()

Map self to the dual type cospace.

For example, if self is in the root lattice of type $[B', 2]$, send it to the coroot lattice of type $[C', 2]$.

EXAMPLES:

```

sage: v = CartanType(['C',3]).root_system().weight_lattice().an_element(); v
2*Lambda[1] + 2*Lambda[2] + 3*Lambda[3]
sage: w = v.to_dual_type_cospace(); w
2*Lambdacheck[1] + 2*Lambdacheck[2] + 3*Lambdacheck[3]
sage: w.parent()
Coweight lattice of the Root system of type ['B', 3]

```

to_simple_root(reduced_word=False)

Return (the index of) a simple root in the orbit of the positive root self.

INPUT:

- self – a positive root
- reduced_word – a boolean (default: False)

OUTPUT:

- The index i of a simple root α_i . If reduced_word is True, this returns instead a pair (i, word) , where word is a sequence of reflections mapping α_i up the root poset to self.

EXAMPLES:

```

sage: L = RootSystem(["A",3]).root_lattice()
sage: positive_roots = L.positive_roots()
sage: for alpha in sorted(positive_roots):
.....:     print("{} {}".format(alpha, alpha.to_simple_root()))
alpha[1] 1
alpha[1] + alpha[2] 2
alpha[1] + alpha[2] + alpha[3] 3
alpha[2] 2
alpha[2] + alpha[3] 3
alpha[3] 3
sage: for alpha in sorted(positive_roots):
.....:     print("{} {}".format(alpha, alpha.to_simple_root(reduced_
↳word=True)))
alpha[1] (1, ())
alpha[1] + alpha[2] (2, (1,))
alpha[1] + alpha[2] + alpha[3] (3, (1, 2))
alpha[2] (2, ())
alpha[2] + alpha[3] (3, (2,))
alpha[3] (3, ())

```

ALGORITHM:

This method walks from `self` down to the antidominant chamber by applying successively the simple reflection given by the first descent. Since `self` is a positive root, each step goes down the root poset, and one must eventually cross a simple root α_i .

See also:

- `first_descent()`
- `to_dominant_chamber()`

Warning: The behavior is not specified if the input is not a positive root. For a finite root system, this is currently caught (albeit with a not perfect message):

```

sage: alpha = L.simple_roots()
sage: (2*alpha[1]).to_simple_root()
Traceback (most recent call last):
...
ValueError: -2*alpha[1] - 2*alpha[2] - 2*alpha[3] is not a positive root

```

For an infinite root system, this method may run into an infinite recursion if the input is not a positive root.

translation(*x*)**INPUT:**

- `self` - an element t at level 0
- `x` - an element of the same space

Returns x translated by t , that is $x + level(x)t$

EXAMPLES:

```

sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: alpha = L.simple_roots()

```

(continues on next page)

(continued from previous page)

```
sage: Lambda = L.fundamental_weights()
sage: t = alpha[2]
```

Let us look at the translation of an element of level 1:

```
sage: Lambda[1].level()
1
sage: t.translation(Lambda[1])
-Lambda[0] + 2*Lambda[2]
sage: Lambda[1] + t
-Lambda[0] + 2*Lambda[2]
```

and of an element of level 0:

```
sage: alpha [1].level()
0
sage: t.translation(alpha [1])
-Lambda[0] + 2*Lambda[1] - Lambda[2]
sage: alpha[1] + 0*t
-Lambda[0] + 2*Lambda[1] - Lambda[2]
```

The arguments are given in this seemingly unnatural order to make it easy to construct the translation function:

```
sage: f = t.translation
sage: f(Lambda[1])
-Lambda[0] + 2*Lambda[2]
```

weyl_action(*element*, *inverse=False*)

Act on `self` by an element of the Coxeter or Weyl group.

INPUT:

- `element` – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list (such as a reduced word) of elements from the index set
- `inverse` – a boolean (default: `False`); whether to act by the inverse element

EXAMPLES:

```
sage: wl = RootSystem(['A', 3]).weight_lattice()
sage: mu = wl.from_vector(vector([1, 0, -2]))
sage: mu
Lambda[1] - 2*Lambda[3]
sage: mudom, rw = mu.to_dominant_chamber(positive=False, reduced_word =
↪ True)
sage: mudom, rw
(-Lambda[2] - Lambda[3], [1, 2])
```

Acting by a (reduced) word:

```
sage: mudom.weyl_action(rw)
Lambda[1] - 2*Lambda[3]
sage: mu.weyl_action(rw, inverse = True)
-Lambda[2] - Lambda[3]
```

Acting by an element of the Coxeter or Weyl group on a vector in its own lattice of definition (implemented by matrix multiplication on a vector):

```
sage: w = wl.weyl_group().from_reduced_word([1, 2])
sage: mudom.weyl_action(w)
Lambda[1] - 2*Lambda[3]
```

Acting by an element of an isomorphic Coxeter or Weyl group (implemented by the action of a corresponding reduced word):

```
sage: W = WeylGroup(['A', 3], prefix="s")
sage: w = W.from_reduced_word([1, 2])
sage: wl.weyl_group() == W
False
sage: mudom.weyl_action(w)
Lambda[1] - 2*Lambda[3]
```

weyl_stabilizer(*index_set=None*)

Returns the subset of Dynkin nodes whose reflections fix *self*.

If *index_set* is not *None*, only consider nodes in this set. Note that if *self* is dominant or antidominant, then its stabilizer is the parabolic subgroup defined by the returned node set.

EXAMPLES:

```
sage: wl = RootSystem(['A', 2, 1]).weight_lattice(extended = True)
sage: al = wl.null_root()
sage: al.weyl_stabilizer()
[0, 1, 2]
sage: wl = RootSystem(['A', 4]).weight_lattice()
sage: mu = wl.from_vector(vector([1, 1, 0, 0]))
sage: mu.weyl_stabilizer()
[3, 4]
sage: mu.weyl_stabilizer(index_set = [1, 2, 3])
[3]
```

class ParentMethods

Bases: object

a_long_simple_root()

Returns a long simple root, corresponding to the highest outgoing edge in the Dynkin diagram.

Caveat: this may break in affine type $A_{2n}^{(2)}$

Caveat: meaningful/broken for non irreducible?

TODO: implement `CartanType.nodes_by_length` as in `MuPAD-Combinat` (using `CartanType.symmetrizer`), and use it here.

almost_positive_roots()

Returns the almost positive roots of *self*

These are the positive roots together with the simple negative roots.

See also:

`almost_positive_root_decomposition()`, `tau_plus_minus()`

EXAMPLES:

```
sage: L = RootSystem(['A',2]).root_lattice()
sage: L.almost_positive_roots()
[-alpha[1], alpha[1], alpha[1] + alpha[2], -alpha[2], alpha[2]]
```

almost_positive_roots_decomposition()

Returns the decomposition of the almost positive roots of `self`

This is the list of the orbits of the almost positive roots under the action of the dihedral group generated by the operators τ_+ and τ_- .

See also:

- `almost_positive_roots()`
- `tau_plus_minus()`

EXAMPLES:

```
sage: RootSystem(['A',2]).root_lattice().almost_positive_roots_
↪decomposition()
[-alpha[1], alpha[1], alpha[1] + alpha[2], alpha[2], -alpha[2]]

sage: RootSystem(['B',2]).root_lattice().almost_positive_roots_
↪decomposition()
[-alpha[1], alpha[1], alpha[1] + 2*alpha[2]], [-alpha[2], alpha[2],
↪alpha[1] + alpha[2]]

sage: RootSystem(['D',4]).root_lattice().almost_positive_roots_
↪decomposition()
[-alpha[1], alpha[1], alpha[1] + alpha[2], alpha[2] + alpha[3] + alpha[4]],
[-alpha[2], alpha[2], alpha[1] + alpha[2] + alpha[3] + alpha[4], alpha[1]
↪+ 2*alpha[2] + alpha[3] + alpha[4]],
[-alpha[3], alpha[3], alpha[2] + alpha[3], alpha[1] + alpha[2] + alpha[4]],
[-alpha[4], alpha[4], alpha[2] + alpha[4], alpha[1] + alpha[2] + alpha[3]]
```

alpha()

Returns the family $(\alpha_i)_{i \in I}$ of the simple roots, with the extra feature that, for simple irreducible root systems, α_0 yields the opposite of the highest root.

EXAMPLES:

```
sage: alpha = RootSystem(["A",2]).root_lattice().alpha()
sage: alpha[1]
alpha[1]
sage: alpha[0]
-alpha[1] - alpha[2]
```

alphacheck()

Return the family $(\alpha_i^\vee)_{i \in I}$ of the simple coroots, with the extra feature that, for simple irreducible root systems, α_0^\vee yields the coroot associated to the opposite of the highest root (caveat: for non-simply-laced root systems, this is not the opposite of the highest coroot!).

EXAMPLES:

```
sage: alphacheck = RootSystem(["A",2]).ambient_space().alphacheck()
sage: alphacheck
Finite family {1: (1, -1, 0), 2: (0, 1, -1)}
```

Here is now α_0^\vee :
 (-1, 0, 1)

Todo: add a non simply laced example

Finally, here is an affine example:

```
sage: RootSystem(["A",2,1]).weight_space().alphacheck()
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}

sage: RootSystem(["A",3]).ambient_space().alphacheck()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

basic_imaginary_roots()

Return the basic imaginary roots of self.

The basic imaginary roots δ are the set of imaginary roots in $-C^\vee$ where C is the dominant chamber (i.e., $\langle \beta, \alpha_i^\vee \rangle \leq 0$ for all $i \in I$). All imaginary roots are W -conjugate to a simple imaginary root.

EXAMPLES:

```
sage: RootSystem(['A', 2]).root_lattice().basic_imaginary_roots()
()
sage: Q = RootSystem(['A', 2, 1]).root_lattice()
sage: Q.basic_imaginary_roots()
(alpha[0] + alpha[1] + alpha[2],)
sage: delta = Q.basic_imaginary_roots()[0]
sage: all(delta.scalar(Q.simple_coroot(i)) <= 0 for i in Q.index_set())
True
```

cartan_type()

EXAMPLES:

```
sage: r = RootSystem(['A',4]).root_space()
sage: r.cartan_type()
['A', 4]
```

classical()

Return the corresponding root/weight/ambient lattice/space.

EXAMPLES:

```
sage: RootSystem(["A",4,1]).root_lattice().classical()
Root lattice of the Root system of type ['A', 4]
sage: RootSystem(["A",4,1]).weight_lattice().classical()
Weight lattice of the Root system of type ['A', 4]
sage: RootSystem(["A",4,1]).ambient_space().classical()
Ambient space of the Root system of type ['A', 4]
```

cohighest_root()

Returns the associated coroot of the highest root.

Note: this is usually not the highest coroot.

EXAMPLES:

```
sage: RootSystem(['A', 3]).ambient_space().cohighest_root()
(1, 0, 0, -1)
```

coroot_lattice()

Returns the coroot lattice.

EXAMPLES:

```
sage: RootSystem(['A', 2]).root_lattice().coroot_lattice()
Coroot lattice of the Root system of type ['A', 2]
```

coroot_space(*base_ring=Rational Field*)

Return the coroot space over *base_ring*.

INPUT:

- *base_ring* – a ring (default: \mathbb{Q})

EXAMPLES:

```
sage: RootSystem(['A', 2]).root_lattice().coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 2]
```

```
sage: RootSystem(['A', 2]).root_lattice().coroot_space(QQ['q'])
Coroot space over the Univariate Polynomial Ring in q over Rational Field
↳ of the Root system of type ['A', 2]
```

dual_type_cospace()

Returns the cospace of dual type.

For example, if invoked on the root lattice of type $[B', 2]$, returns the coroot lattice of type $[C', 2]$.

Warning: Not implemented for ambient spaces.

EXAMPLES:

```
sage: CartanType(['B', 2]).root_system().root_lattice().dual_type_cospace()
Coroot lattice of the Root system of type ['C', 2]
sage: CartanType(['F', 4]).root_system().coweight_lattice().dual_type_
↳ cospace()
Weight lattice of the Root system of type ['F', 4] relabelled by {1: 4, 2: 3,
↳ 3: 2, 4: 1}
```

dynkin_diagram()

EXAMPLES:

```
sage: r = RootSystem(['A', 4]).root_space()
sage: r.dynkin_diagram()
0---0---0---0
1  2  3  4
A4
```

fundamental_weights_from_simple_roots()

Return the fundamental weights.

This is computed from the simple roots by using the inverse of the Cartan matrix. This method is therefore only valid for finite types and if this realization of the root lattice is large enough to contain

them.

EXAMPLES:

In the root space, we retrieve the inverse of the Cartan matrix:

```
sage: L = RootSystem(["B",3]).root_space()
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: alpha[1] + alpha[2] + alpha[3],
               2: alpha[1] + 2*alpha[2] + 2*alpha[3],
               3: 1/2*alpha[1] + alpha[2] + 3/2*alpha[3]}
sage: ~L.cartan_type().cartan_matrix()
[ 1  1 1/2]
[ 1  2  1]
[ 1  2 3/2]
```

In the weight lattice and the ambient space, we retrieve the fundamental weights:

```
sage: L = RootSystem(["B",3]).weight_lattice()
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}

sage: L = RootSystem(["B",3]).ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

However the fundamental weights do not belong to the root lattice:

```
sage: L = RootSystem(["B",3]).root_lattice()
sage: L.fundamental_weights_from_simple_roots()
Traceback (most recent call last):
...
ValueError: The fundamental weights do not live in this realization of the
↪root lattice
```

Beware of the usual GL_n vs SL_n catch in type A :

```
sage: L = RootSystem(["A",3]).ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: (3/4, -1/4, -1/4, -1/4), 2: (1/2, 1/2, -1/2, -1/2), 3: (1/
↪4, 1/4, 1/4, -3/4)}

sage: L = RootSystem(["A",3]).ambient_lattice()
sage: L.fundamental_weights_from_simple_roots()
Traceback (most recent call last):
...
ValueError: The fundamental weights do not live in this realization of the
↪root lattice
```

generalized_nonnesting_partition_lattice(*m*, *facade=False*)

Return the lattice of m -nonnesting partitions

This has been defined by Athanasiadis, see chapter 5 of [Arm06].

INPUT:

- m – integer

See also:

`nonnesting_partition_lattice()`

EXAMPLES:

```
sage: R = RootSystem(['A', 2])
sage: RS = R.root_lattice()
sage: P = RS.generalized_nonnesting_partition_lattice(2); P
Finite lattice containing 12 elements
sage: P.coxeter_transformation()**20 == 1
True
```

highest_root()

Returns the highest root (for an irreducible finite root system)

EXAMPLES:

```
sage: RootSystem(['A', 4]).ambient_space().highest_root()
(1, 0, 0, 0, -1)

sage: RootSystem(['E', 6]).weight_space().highest_root()
Lambda[2]
```

index_set()

EXAMPLES:

```
sage: r = RootSystem(['A', 4]).root_space()
sage: r.index_set()
(1, 2, 3, 4)
```

long_roots()

Return a list of the long roots of self.

EXAMPLES:

```
sage: L = RootSystem(['B', 3]).root_lattice()
sage: sorted(L.long_roots())
[-alpha[1], -alpha[1] - 2*alpha[2] - 2*alpha[3],
 -alpha[1] - alpha[2], -alpha[1] - alpha[2] - 2*alpha[3],
 alpha[1], alpha[1] + alpha[2],
 alpha[1] + alpha[2] + 2*alpha[3],
 alpha[1] + 2*alpha[2] + 2*alpha[3], -alpha[2],
 -alpha[2] - 2*alpha[3], alpha[2], alpha[2] + 2*alpha[3]]
```

negative_roots()

Returns the negative roots of self.

EXAMPLES:

```
sage: L = RootSystem(['A', 2]).weight_lattice()
sage: sorted(L.negative_roots())
[-2*Lambda[1] + Lambda[2], -Lambda[1] - Lambda[2], Lambda[1] - 2*Lambda[2]]
```

Algorithm: negate the positive roots

nonnesting_partition_lattice(*facade=False*)

Return the lattice of nonnesting partitions

This is the lattice of order ideals of the root poset.

This has been defined by Postnikov, see Remark 2 in [Reiner97].

See also:

[generalized_nonnesting_partition_lattice\(\)](#), [root_poset\(\)](#)

EXAMPLES:

```
sage: R = RootSystem(['A', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 14 elements
sage: P.coxeter_transformation()**10 == 1
True

sage: R = RootSystem(['B', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 20 elements
sage: P.coxeter_transformation()**7 == 1
True
```

REFERENCES:

nonparabolic_positive_root_sum(*index_set=None*)

Return the sum of positive roots not in a parabolic subsystem.

The conventions for *index_set* are as in [nonparabolic_positive_roots\(\)](#).

EXAMPLES:

```
sage: Q = RootSystem(['A', 3]).root_lattice()
sage: Q.nonparabolic_positive_root_sum((1, 2))
alpha[1] + 2*alpha[2] + 3*alpha[3]
sage: Q.nonparabolic_positive_root_sum()
0
sage: Q.nonparabolic_positive_root_sum(())
3*alpha[1] + 4*alpha[2] + 3*alpha[3]
```

nonparabolic_positive_roots(*index_set=None*)

Return the positive roots of *self* that are not in the parabolic subsystem indicated by *index_set*.

If *index_set* is *None*, as in [positive_roots\(\)](#) it is assumed to be the entire Dynkin node set. Then the parabolic subsystem consists of all positive roots and the empty list is returned.

EXAMPLES:

```
sage: L = RootSystem(['A', 3]).root_lattice()
sage: L.nonparabolic_positive_roots()
[]
sage: sorted(L.nonparabolic_positive_roots((1, 2)))
[alpha[1] + alpha[2] + alpha[3], alpha[2] + alpha[3], alpha[3]]
```

(continues on next page)

(continued from previous page)

```
sage: sorted(L.nonparabolic_positive_roots())
[alpha[1], alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3], alpha[2], ↵
↵alpha[2] + alpha[3], alpha[3]]
```

null_coroot()

Returns the null coroot of self.

The null coroot is the smallest non trivial positive coroot which is orthogonal to all simple roots. It exists for any affine root system.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).root_lattice().null_coroot()
alphacheck[0] + alphacheck[1] + alphacheck[2]
sage: RootSystem(['D',4,1]).root_lattice().null_coroot()
alphacheck[0] + alphacheck[1] + 2*alphacheck[2] + alphacheck[3] + ↵
↵alphacheck[4]
sage: RootSystem(['F',4,1]).root_lattice().null_coroot()
alphacheck[0] + 2*alphacheck[1] + 3*alphacheck[2] + 2*alphacheck[3] + ↵
↵alphacheck[4]
```

null_root()

Returns the null root of self. The null root is the smallest non trivial positive root which is orthogonal to all simple coroots. It exists for any affine root system.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).root_lattice().null_root()
alpha[0] + 2*alpha[1] + alpha[2]
sage: RootSystem(['D',4,1]).root_lattice().null_root()
alpha[0] + alpha[1] + 2*alpha[2] + alpha[3] + alpha[4]
sage: RootSystem(['F',4,1]).root_lattice().null_root()
alpha[0] + 2*alpha[1] + 3*alpha[2] + 4*alpha[3] + 2*alpha[4]
```

plot(*roots='simple', coroots=False, reflection_hyperplanes='simple', fundamental_weights=None, fundamental_chamber=None, alcoves=None, alcove_labels=False, alcove_walk=None, **options*)

Return a picture of this root lattice realization.

INPUT:

- **roots** – which roots to display, if any. Can be one of the following:
 - "simple" – The simple roots (the default)
 - "classical" – Not yet implemented
 - "all" – Only works in the finite case
 - A list or tuple of roots
 - False
- **coroots** – which coroots to display, if any. Can be one of the following:
 - "simple" – The simple coroots (the default)
 - "classical" – Not yet implemented
 - "all" – Only works in the finite case
 - A list or tuple of coroots
 - False
- **fundamental_weights** – a boolean or None (default: None) whether to display the fundamental weights. If None, the fundamental weights are drawn if available.

- `reflection_hyperplanes` – which reflection hyperplanes to display, if any. Can be one of the following:
 - "simple" – The simple roots
 - "classical" – Not yet implemented
 - "all" – Only works in the finite case
 - A list or tuple of roots
 - False (the default)
- `fundamental_chamber` – whether and how to draw the fundamental chamber. Can be one of the following:
 - A boolean – Set to True to draw the fundamental chamber
 - "classical" – Draw the classical fundamental chamber
 - None – (the default) The fundamental chamber is drawn except in the root lattice where this is not yet implemented. For affine types the classical fundamental chamber is drawn instead.
- `alcoves` – one of the following (default: True):
 - A boolean – Whether to display the alcoves
 - A list of alcoves – The alcoves to be drawn. Each alcove is specified by the coordinates of its center in the root lattice (affine type only). Otherwise the alcoves that intersect the bounding box are drawn.
- `alcove_labels` – one of the following (default: False):
 - A boolean – Whether to display the elements of the Weyl group indexing the alcoves. This currently requires to also set the `alcoves` option.
 - A number l – The label is drawn at level l (affine type only), which only makes sense if `affine` is False.
- `bounding_box` – a rational number or a list of pairs thereof (default: 3)

Specifies a bounding box, in the coordinate system for this plot, in which to plot alcoves and other infinite objects. If the bounding box is a number a , then the bounding box is of the form $[-a, a]$ in all directions. Beware that there can be some border effects and the returned graphic is not necessarily strictly contained in the bounding box.

- `alcove_walk` – an alcove walk or None (default: None)

The alcove walk is described by a list (or iterable) of vertices of the Dynkin diagram which specifies which wall is crossed at each step, starting from the fundamental alcove.

- `projection` – one of the following (default: True):
 - True – The default projection for the root lattice realization is used.
 - False – No projection is used.
 - `barycentric` – A barycentric projection is used.
 - A function – If a function is specified, it should implement a linear (or affine) map taking as input an element of this root lattice realization and returning its desired coordinates in the plot, as a vector with rational coordinates.
- `color` – a function mapping vertices of the Dynkin diagram to colors (default: "black" for 0, "blue" for 1, "red" for 2, "green" for 3)

This is used to set the color for the simple roots, fundamental weights, reflection hyperplanes, alcove facets, etc. If the color is None, the object is not drawn.

- `labels` – a boolean (default: True) whether to display labels on the simple roots, fundamental weights, etc.

EXAMPLES:

```
sage: L = RootSystem(["A", 2, 1]).ambient_space().plot() # long time
```

See also:

- `plot_parse_options()`
- `plot_roots()`, `plot_coroots()`
- `plot_fundamental_weights()`

- `plot_fundamental_chamber()`
- `plot_reflection_hyperplanes()`
- `plot_alcoves()`
- `plot_alcove_walk()`
- `plot_ls_paths()`
- `plot_mv_polytope()`
- `plot_crystal()`

plot_alcove_walk(*word*, *start*=None, *foldings*=None, *color*='orange', ***options*)

Plot an alcove walk.

INPUT:

- *word* – a list of elements of the index set
- *foldings* – a list of booleans or None (default: None)
- *start* – an element of this space (default: None for ρ)
- ***options* – plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

An alcove walk of type $A_2^{(1)}$:

```
sage: L = RootSystem(["A", 2, 1]).ambient_space()
sage: w1 = [0, 2, 1, 2, 0, 2, 1, 0, 2, 1, 2, 1, 2, 0, 2, 0, 1, 2, 0]
sage: p = L.plot_alcoves(bounding_box=5) # long time (5s)
sage: p += L.plot_alcove_walk(w1) # long time
sage: p # long time
Graphics object consisting of 375 graphics primitives
```

The same plot with another alcove walk:

```
sage: w2 = [2, 1, 2, 0, 2, 0, 2, 1, 2, 0, 1, 2, 1, 2, 1, 0, 1, 2, 0, 2, 0, 1, 2, 0, 2]
sage: p += L.plot_alcove_walk(w2, color="orange") # long time
```

And another with some foldings:

```
sage: pic = L.plot_alcoves(bounding_box=3) # long time
sage: pic += L.plot_alcove_walk([0, 1, 2, 0, 2, 0, 1, 2, 0, 1], # long time (3s)
....: foldings = [False, False, True, False, False,
←False, True, False, True, False],
....: color="green"); pic
Graphics object consisting of 155 graphics primitives
```

plot_alcoves(*alcoves*=True, *alcove_labels*=False, *wireframe*=False, ***options*)

Plot the alcoves and optionally their labels.

INPUT:

- *alcoves* – a list of alcoves or True (default: True)
- *alcove_labels* – a boolean or a number specifying at which level to put the label (default: False)
- ***options* – Plotting options

See also:

- `plot()` for a description of the plotting options

- *Tutorial: visualizing root systems* for a tutorial on root system plotting, and in particular how the alcoves can be specified.

EXAMPLES:

2D plots:

```
sage: RootSystem(["B",2,1]).ambient_space().plot_alcoves()
↳ # long time (3s)
Graphics object consisting of 228 graphics primitives
```

3D plots:

```
sage: RootSystem(["A",2,1]).weight_space().plot_alcoves(affine=False)
↳ # long time (3s)
Graphics3d Object
sage: RootSystem(["G",2,1]).ambient_space().plot_alcoves(affine=False,
↳ level=1) # long time (3s)
Graphics3d Object
```

Here we plot a single alcove:

```
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: W = L.weyl_group()
sage: L.plot(alcoves=[W.one()], reflection_hyperplanes=False, bounding_
↳ box=2)
Graphics3d Object
```

plot_bounding_box(**options)

Plot the bounding box.

INPUT:

- **options – Plotting options

This is mostly for testing purposes.

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot_bounding_box()
Graphics object consisting of 1 graphics primitive
```

plot_coroots(collection='simple', **options)

Plot the (simple/classical) coroots of this root lattice.

INPUT:

- collection – which coroots to display. Can be one of the following:
 - "simple" (the default)
 - "classical"
 - "all"
- **options – Plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(['B',3]).ambient_space().plot_coroots()
Graphics3d Object
```

plot_crystal(*crystal*, *plot_labels=True*, *label_color='black'*, *edge_labels=False*, *circle_size=0.06*, *circle_thickness=1.6*, ***options*)

Plot a finite crystal.

INPUT:

- *crystal* – the finite crystal to plot
- *plot_labels* – (default: True) can be one of the following:
 - True - use the latex labels
 - 'circles' - use circles for multiplicity up to 4; if the multiplicity is larger, then it uses the multiplicity
 - 'multiplicities' - use the multiplicities
- *label_color* – (default: 'black') the color of the labels
- *edge_labels* – (default: False) if True, then draw in the edge label
- *circle_size* – (default: 0.06) the size of the circles
- *circle_thickness* – (default: 1.6) the thickness of the extra rings of circles
- ***options* – plotting options

See also:

- [plot\(\)](#) for a description of the plotting options
- [Tutorial: visualizing root systems](#) for a tutorial on root system plotting

EXAMPLES:

```
sage: L = RootSystem(['A',2]).ambient_space()
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
sage: L.plot_crystal(C, plot_labels='multiplicities')
Graphics object consisting of 15 graphics primitives
sage: C = crystals.Tableaux(['A',2], shape=[8,4])
sage: p = L.plot_crystal(C, plot_labels='circles')
sage: p.show(figsize=15)
```

A 3-dimensional example:

```
sage: L = RootSystem(['B',3]).ambient_space()
sage: C = crystals.Tableaux(['B',3], shape=[2,1])
sage: L.plot_crystal(C, plot_labels='circles', edge_labels=True) # long time
Graphics3d Object
```

plot_fundamental_chamber(*style='normal'*, ***options*)

Plot the (classical) fundamental chamber.

INPUT:

- *style* – "normal" or "classical" (default: "normal")
- ***options* – Plotting options

See also:

- [plot\(\)](#) for a description of the plotting options
- [Tutorial: visualizing root systems](#) for a tutorial on root system plotting

EXAMPLES:

2D plots:

```
sage: RootSystem(["B",2]).ambient_space().plot_fundamental_chamber()
Graphics object consisting of 1 graphics primitive
sage: RootSystem(["B",2,1]).ambient_space().plot_fundamental_chamber()
Graphics object consisting of 1 graphics primitive
sage: RootSystem(["B",2,1]).ambient_space().plot_fundamental_chamber(
↪"classical")
Graphics object consisting of 1 graphics primitive
```

3D plots:

```
sage: RootSystem(["A",3,1]).weight_space().plot_fundamental_chamber()
Graphics3d Object
sage: RootSystem(["B",3,1]).ambient_space().plot_fundamental_chamber()
Graphics3d Object
```

This feature is currently not available in the root lattice/space:

```
sage: list(RootSystem(["A",2]).root_lattice().plot_fundamental_chamber())
Traceback (most recent call last):
...
TypeError: classical fundamental chamber not yet available in the root_
↪lattice
```

plot_fundamental_weights(**options)

Plot the fundamental weights of this root lattice.

INPUT:

- **options – Plotting options

See also:

- [plot\(\)](#) for a description of the plotting options
- [Tutorial: visualizing root systems](#) for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["B",3]).ambient_space().plot_fundamental_weights()
Graphics3d Object
```

plot_hedron(**options)

Plot the polyhedron whose vertices are given by the orbit of ρ .

In type A , this is the usual permutohedron.

See also:

- [plot\(\)](#) for a description of the plotting options
- [Tutorial: visualizing root systems](#) for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["A",2]).ambient_space().plot_hedron()
Graphics object consisting of 8 graphics primitives
sage: RootSystem(["A",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["C",3]).ambient_space().plot_hedron()
```

(continues on next page)

(continued from previous page)

```
Graphics3d Object
sage: RootSystem(["D",3]).ambient_space().plot_hedron()
Graphics3d Object
```

Surprise: polyhedra of large dimension know how to project themselves nicely:

```
sage: RootSystem(["F",4]).ambient_space().plot_hedron() # long time
Graphics3d Object
```

plot_ls_paths(*paths*, *plot_labels=None*, *colored_labels=True*, ***options*)
Plot LS paths.

INPUT:

- *paths* – a finite crystal or list of LS paths
- *plot_labels* – (default: `None`) the distance to plot the LS labels from the endpoint of the path; set to `None` to not display the labels
- *colored_labels* – (default: `True`) if `True`, then color the labels the same color as the LS path
- ***options* – plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: B = crystals.LSPaths(['A',2], [1,1])
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot_fundamental_weights() + L.plot_ls_paths(B)
Graphics object consisting of 14 graphics primitives
```

This also works in 3 dimensions:

```
sage: B = crystals.LSPaths(['B',3], [2,0,0])
sage: L = RootSystem(['B',3]).ambient_space()
sage: L.plot_ls_paths(B)
Graphics3d Object
```

plot_mv_polytope(*mv_polytope*, *mark_endpoints=True*, *circle_size=0.06*, *circle_thickness=1.6*,
wireframe='blue', *fill='green'*, *alpha=1*, ***options*)

Plot an MV polytope.

INPUT:

- *mv_polytope* – an MV polytope
- *mark_endpoints* – (default: `True`) mark the endpoints of the MV polytope
- *circle_size* – (default: `0.06`) the size of the circles
- *circle_thickness* – (default: `1.6`) the thickness of the extra rings of circles
- *wireframe* – (default: `'blue'`) color to draw the wireframe of the polytope with
- *fill* – (default: `'green'`) color to fill the polytope with
- *alpha* – (default: `1`) the alpha value (opacity) of the fill
- ***options* – plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: B = crystals.infinity.MVPolytopes(['C',2])
sage: L = RootSystem(['C',2]).ambient_space()
sage: p = B.highest_weight_vector().f_string([1,2,1,2])
sage: L.plot_fundamental_weights() + L.plot_mv_polytope(p)
Graphics object consisting of 14 graphics primitives
```

This also works in 3 dimensions:

```
sage: B = crystals.infinity.MVPolytopes(['A',3])
sage: L = RootSystem(['A',3]).ambient_space()
sage: p = B.highest_weight_vector().f_string([2,1,3,2])
sage: L.plot_mv_polytope(p)
Graphics3d Object
```

plot_parse_options(args)**

Return an option object to be used for root system plotting.

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: options
<sage.combinat.root_system.plot.PlotOptions object at ...>
```

See also:

- [plot\(\)](#) for a description of the plotting options
- [Tutorial: visualizing root systems](#) for a tutorial on root system plotting

plot_reflection_hyperplanes(collection='simple', **options)

Plot the simple reflection hyperplanes.

INPUT:

- `collection` – which reflection hyperplanes to display. Can be one of the following:
 - "simple" (the default)
 - "classical"
 - "all"
- `**options` – Plotting options

See also:

- [plot\(\)](#) for a description of the plotting options
- [Tutorial: visualizing root systems](#) for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["A",2,1]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
sage: RootSystem(["G",2,1]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
sage: RootSystem(["A",3]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(["A",3,1]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(["B",3,1]).ambient_space().plot_reflection_hyperplanes()
```

(continues on next page)

(continued from previous page)

```
Graphics3d Object
sage: RootSystem(["A",2,1]).weight_space().plot_reflection_
↳hyperplanes(affine=False, level=1)
Graphics3d Object
sage: RootSystem(["A",2]).root_lattice().plot_reflection_hyperplanes()
Graphics object consisting of 4 graphics primitives
```

Todo: Provide an option for transparency?

plot_roots(*collection='simple', **options*)

Plot the (simple/classical) roots of this root lattice.

INPUT:

- *collection* – which roots to display can be one of the following:
 - "simple" (the default)
 - "classical"
 - "all"
- ***options* – Plotting options

See also:

- *plot()* for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["B",3]).ambient_space().plot_roots()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_roots("all")
Graphics3d Object
```

positive_imaginary_roots()

Return the positive imaginary roots of *self*.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).root_lattice()
sage: L.positive_imaginary_roots()
()

sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PIR = L.positive_imaginary_roots(); PIR
Positive imaginary roots of type ['A', 3, 1]
sage: [PIR.unrank(i) for i in range(5)]
[alpha[0] + alpha[1] + alpha[2] + alpha[3],
 2*alpha[0] + 2*alpha[1] + 2*alpha[2] + 2*alpha[3],
 3*alpha[0] + 3*alpha[1] + 3*alpha[2] + 3*alpha[3],
 4*alpha[0] + 4*alpha[1] + 4*alpha[2] + 4*alpha[3],
 5*alpha[0] + 5*alpha[1] + 5*alpha[2] + 5*alpha[3]]
```

positive_real_roots()

Return the positive real roots of *self*.

EXAMPLES:

```

sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_real_roots())
[alpha[1], alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3],
 alpha[2], alpha[2] + alpha[3], alpha[3]]

sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PRR = L.positive_real_roots(); PRR
Positive real roots of type ['A', 3, 1]
sage: [PRR.unrank(i) for i in range(10)]
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],
 alpha[1] + alpha[2] + alpha[3],
 alpha[0] + 2*alpha[1] + alpha[2] + alpha[3],
 alpha[0] + alpha[1] + 2*alpha[2] + alpha[3],
 alpha[0] + alpha[1] + alpha[2] + 2*alpha[3],
 alpha[0] + 2*alpha[1] + 2*alpha[2] + alpha[3]]

sage: Q = RootSystem(['A',4,2]).root_lattice()
sage: PR = Q.positive_roots()
sage: [PR.unrank(i) for i in range(5)]
[alpha[1],
 alpha[2],
 alpha[1] + alpha[2],
 2*alpha[1] + alpha[2],
 alpha[0] + alpha[1] + alpha[2]]

sage: Q = RootSystem(['D',3,2]).root_lattice()
sage: PR = Q.positive_roots()
sage: [PR.unrank(i) for i in range(5)]
[alpha[1],
 alpha[2],
 alpha[1] + 2*alpha[2],
 alpha[1] + alpha[2],
 alpha[0] + alpha[1] + 2*alpha[2]]

```

positive_roots(*index_set=None*)

Return the positive roots of *self*.

If *index_set* is not *None*, returns the positive roots of the parabolic subsystem with simple roots in *index_set*.

Algorithm for finite type: generate them from the simple roots by applying successive reflections toward the positive chamber.

EXAMPLES:

```

sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_roots())
[alpha[1], alpha[1] + alpha[2],
 alpha[1] + alpha[2] + alpha[3], alpha[2],
 alpha[2] + alpha[3], alpha[3]]

```

(continues on next page)

(continued from previous page)

```

sage: sorted(L.positive_roots((1,2)))
[alpha[1], alpha[1] + alpha[2], alpha[2]]
sage: sorted(L.positive_roots())
[]

sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PR = L.positive_roots(); PR
Disjoint union of Family (Positive real roots of type ['A', 3, 1],
    Positive imaginary roots of type ['A', 3, 1])
sage: [PR.unrank(i) for i in range(10)]
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],
 alpha[1] + alpha[2] + alpha[3],
 alpha[0] + 2*alpha[1] + alpha[2] + alpha[3],
 alpha[0] + alpha[1] + 2*alpha[2] + alpha[3],
 alpha[0] + alpha[1] + alpha[2] + 2*alpha[3],
 alpha[0] + 2*alpha[1] + 2*alpha[2] + alpha[3]]

```

positive_roots_by_height(*increasing=True*)

Returns a list of positive roots in increasing order by height.

If *increasing* is False, returns them in decreasing order.**Warning:** Raise an error if the Cartan type is not finite.

EXAMPLES:

```

sage: L = RootSystem(['C',2]).root_lattice()
sage: L.positive_roots_by_height()
[alpha[2], alpha[1], alpha[1] + alpha[2], 2*alpha[1] + alpha[2]]
sage: L.positive_roots_by_height(increasing = False)
[2*alpha[1] + alpha[2], alpha[1] + alpha[2], alpha[2], alpha[1]]

sage: L = RootSystem(['A',2,1]).root_lattice()
sage: L.positive_roots_by_height()
Traceback (most recent call last):
...
NotImplementedError: Only implemented for finite Cartan type

```

positive_roots_nonparabolic(*index_set=None*)Returns the set of positive roots outside the parabolic subsystem with Dynkin node set *index_set*.

INPUT:

- *index_set* – (default:None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

```

sage: lattice = RootSystem(['A',3]).root_lattice()
sage: sorted(lattice.positive_roots_nonparabolic((1,3)), key=str)

```

(continues on next page)

(continued from previous page)

```
[alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3], alpha[2], alpha[2] +
↪alpha[3]]
sage: sorted(lattice.positive_roots_nonparabolic((2,3)), key=str)
[alpha[1], alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3]]
sage: lattice.positive_roots_nonparabolic()
[]
sage: lattice.positive_roots_nonparabolic((1,2,3))
[]
```

Warning: This returns an error if the Cartan type is not finite.

`positive_roots_nonparabolic_sum(index_set=None)`

Returns the sum of positive roots outside the parabolic subsystem with Dynkin node set `index_set`.

INPUT:

- `index_set` – (default:None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

```
sage: lattice = RootSystem(['A',3]).root_lattice()
sage: lattice.positive_roots_nonparabolic_sum((1,3))
2*alpha[1] + 4*alpha[2] + 2*alpha[3]
sage: lattice.positive_roots_nonparabolic_sum((2,3))
3*alpha[1] + 2*alpha[2] + alpha[3]
sage: lattice.positive_roots_nonparabolic_sum()
3*alpha[1] + 4*alpha[2] + 3*alpha[3]
sage: lattice.positive_roots_nonparabolic_sum()
0
sage: lattice.positive_roots_nonparabolic_sum((1,2,3))
0
```

Warning: This returns an error if the Cartan type is not finite.

`positive_roots_parabolic(index_set=None)`

Return the set of positive roots for the parabolic subsystem with Dynkin node set `index_set`.

INPUT:

- `index_set` – (default:None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

```
sage: lattice = RootSystem(['A',3]).root_lattice()
sage: sorted(lattice.positive_roots_parabolic((1,3)), key=str)
[alpha[1], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic((2,3)), key=str)
[alpha[2], alpha[2] + alpha[3], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic(), key=str)
[alpha[1], alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3], alpha[2],
↪alpha[2] + alpha[3], alpha[3]]
```

Warning: This returns an error if the Cartan type is not finite.

projection(*root*, *coroot=None*, *to_negative=True*)

Returns the projection along the root, and across the hyperplane define by coroot, as a function π from self to self. π is a half-linear map which stabilizes the negative half space, and acts by reflection on the positive half space.

If *to_negative* is False, then this project onto the positive half space instead.

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x=space.simple_roots()[1]
sage: y=space.simple_coroots()[1]
sage: pi = space.projection(x,y)
sage: x
2*Lambda[1] - Lambda[2]
sage: pi(x)
-2*Lambda[1] + Lambda[2]
sage: pi(-x)
-2*Lambda[1] + Lambda[2]
sage: pi = space.projection(x,y,False)
sage: pi(-x)
2*Lambda[1] - Lambda[2]
```

reflection(*root*, *coroot=None*)

Returns the reflection along the root, and across the hyperplane define by coroot, as a function from self to self.

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x=space.simple_roots()[1]
sage: y=space.simple_coroots()[1]
sage: s = space.reflection(x,y)
sage: x
2*Lambda[1] - Lambda[2]
sage: s(x)
-2*Lambda[1] + Lambda[2]
sage: s(-x)
2*Lambda[1] - Lambda[2]
```

root_poset(*restricted=False*, *facade=False*)

Returns the (restricted) root poset associated to self.

The elements are given by the positive roots (resp. non-simple, positive roots), and $\alpha \leq \beta$ iff $\beta - \alpha$ is a non-negative linear combination of simple roots.

INPUT:

- *restricted* – (default:False) if True, only non-simple roots are considered.
- *facade* – (default:False) passes facade option to the poset generator.

EXAMPLES:

```
sage: Phi = RootSystem(['A',1]).root_poset(); Phi
Finite poset containing 1 elements
```

(continues on next page)

(continued from previous page)

```

sage: Phi.cover_relations()
[]

sage: Phi = RootSystem(['A',2]).root_poset(); Phi
Finite poset containing 3 elements

sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1], alpha[1] + alpha[2]], [alpha[2], alpha[1] + alpha[2]]]

sage: Phi = RootSystem(['A',3]).root_poset(restricted=True); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3]], [alpha[2] +
↪alpha[3], alpha[1] + alpha[2] + alpha[3]]]

sage: Phi = RootSystem(['B',2]).root_poset(); Phi
Finite poset containing 4 elements
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1] + alpha[2], alpha[1] + 2*alpha[2]],
 [alpha[1], alpha[1] + alpha[2]],
 [alpha[2], alpha[1] + alpha[2]]]

```

roots()

Return the roots of self.

EXAMPLES:

```

sage: RootSystem(['A',2]).ambient_lattice().roots()
((1, -1, 0), (1, 0, -1), (0, 1, -1), (-1, 1, 0), (-1, 0, 1), (0, -1, 1))

```

This matches with [Wikipedia article Root systems](#):

```

sage: for T in CartanType.samples(finite = True, crystallographic = True):
....:     print("%s %3s %3s"%(T, len(RootSystem(T).root_lattice().roots()),
↪len(RootSystem(T).weight_lattice().roots())))
['A', 1]  2  2
['A', 5] 30 30
['B', 1]  2  2
['B', 5] 50 50
['C', 1]  2  2
['C', 5] 50 50
['D', 2]  4  4
['D', 3] 12 12
['D', 5] 40 40
['E', 6] 72 72
['E', 7]126 126
['E', 8]240 240
['F', 4] 48 48
['G', 2] 12 12

```

Todo: The result should be an enumerated set, and handle infinite root systems.

s()Return the family $(s_i)_{i \in I}$ of the simple reflections of this root system.

EXAMPLES:

```
sage: r = RootSystem(["A", 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )
-alpha[1]
```

short_roots()

Return a list of the short roots of self.

EXAMPLES:

```
sage: L = RootSystem(['B', 3]).root_lattice()
sage: sorted(L.short_roots())
[-alpha[1] - alpha[2] - alpha[3],
 alpha[1] + alpha[2] + alpha[3],
 -alpha[2] - alpha[3],
 alpha[2] + alpha[3],
 -alpha[3],
 alpha[3]]
```

simple_coroot(i)Returns the i^{th} simple coroot.

EXAMPLES:

```
sage: RootSystem(['A', 2]).root_lattice().simple_coroot(1)
alphacheck[1]
```

simple_coroots()Returns the family $(\alpha_i^\vee)_{i \in I}$ of the simple coroots.

EXAMPLES:

```
sage: alphacheck = RootSystem(['A', 3]).root_lattice().simple_coroots()
sage: [alphacheck[i] for i in [1, 2, 3]]
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

simple_projection(i, to_negative=True)Returns the projection along the i^{th} simple root, and across the hyperplane define by the i^{th} simple coroot, as a function from self to self.

INPUT:

- i - i is in self's index set

EXAMPLES:

```
sage: space = RootSystem(['A', 2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: pi = space.simple_projection(1)
sage: x
2*Lambda[1] - Lambda[2]
sage: pi(x)
-2*Lambda[1] + Lambda[2]
```

(continues on next page)

(continued from previous page)

```

sage: pi(-x)
-2*Lambda[1] + Lambda[2]
sage: pi = space.simple_projection(1,False)
sage: pi(-x)
2*Lambda[1] - Lambda[2]

```

simple_projections(*to_negative=True*)Returns the family $(s_i)_{i \in I}$ of the simple projections of this root system

EXAMPLES:

```

sage: space = RootSystem(['A',2]).weight_lattice()
sage: pi = space.simple_projections()
sage: x = space.simple_roots()
sage: pi[1](x[2])
-Lambda[1] + 2*Lambda[2]

```

simple_reflection(*i*)Returns the i^{th} simple reflection, as a function from self to self.

INPUT:

- *i* - *i* is in self's index set

EXAMPLES:

```

sage: space = RootSystem(['A',2]).ambient_lattice()
sage: s = space.simple_reflection(1)
sage: x = space.simple_roots()[1]
sage: x
(1, -1, 0)
sage: s(x)
(-1, 1, 0)

```

simple_reflections()Return the family $(s_i)_{i \in I}$ of the simple reflections of this root system.

EXAMPLES:

```

sage: r = RootSystem(["A", 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )
-alpha[1]

```

simple_root(*i*)Returns the i^{th} simple root.

This should be overridden by any subclass, and typically implemented as a cached method for efficiency.

EXAMPLES:

```

sage: r = RootSystem(["A",3]).root_lattice()
sage: r.simple_root(1)
alpha[1]

```

simple_roots()Returns the family $(\alpha_i)_{i \in I}$ of the simple roots.

EXAMPLES:

```
sage: alpha = RootSystem(["A",3]).root_lattice().simple_roots()
sage: [alpha[i] for i in [1,2,3]]
[alpha[1], alpha[2], alpha[3]]
```

simple_roots_tilde()

Return the family $(\tilde{\alpha}_i)_{i \in I}$ of the simple roots.

INPUT:

- `self` – an affine root lattice realization

The $\tilde{\alpha}_i$ give the embedding of the root lattice of the other affinization of the same classical root lattice into this root lattice (space?).

This uses the fact that $\alpha_i = \tilde{\alpha}_i$ for i not a special node, and that

$$\delta = \sum a_i \alpha_i = \sum b_i \tilde{\alpha}_i$$

EXAMPLES:

In simply laced cases, this is boring:

```
sage: RootSystem(["A",3,1]).root_lattice().simple_roots_tilde()
Finite family {0: alpha[0], 1: alpha[1], 2: alpha[2], 3: alpha[3]}
```

This was checked by hand:

```
sage: RootSystem(["C",2,1]).coroot_lattice().simple_roots_tilde()
Finite family {0: alphacheck[0] - alphacheck[2], 1: alphacheck[1], 2: ↵
↵ alphacheck[2]}
sage: RootSystem(["B",2,1]).coroot_lattice().simple_roots_tilde()
Finite family {0: alphacheck[0] - alphacheck[1], 1: alphacheck[1], 2: ↵
↵ alphacheck[2]}
```

What about type BC?

some_elements()

Return some elements of this root lattice realization

EXAMPLES:

```
sage: L = RootSystem(["A",2]).weight_lattice()
sage: L.some_elements()
[2*Lambda[1] + 2*Lambda[2], 2*Lambda[1] - Lambda[2], -Lambda[1] + ↵
↵ 2*Lambda[2], Lambda[1], Lambda[2]]
sage: L = RootSystem(["A",2]).root_lattice()
sage: L.some_elements()
[2*alpha[1] + 2*alpha[2], alpha[1], alpha[2]]
```

tau_epsilon_operator_on_almost_positive_roots(J)

The τ_ϵ operator on almost positive roots

Given a subset J of non adjacent vertices of the Dynkin diagram, this constructs the operator on the almost positive roots which fixes the negative simple roots α_i for i not in J , and acts otherwise by:

$$\tau_+(\beta) = \left(\prod_{i \in J} s_i \right) (\beta)$$

See Equation (1.2) of [CFZ2002].

EXAMPLES:

```
sage: L = RootSystem(['A',4]).root_lattice()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])
sage: alpha = L.simple_roots()
```

The action on a negative simple root not in J :

```
sage: tau(-alpha[2])
-alpha[2]
```

The action on a negative simple root in J :

```
sage: tau(-alpha[1])
alpha[1]
```

The action on all almost positive roots:

```
sage: for root in L.almost_positive_roots():
.....:     print('tau({:<41}) = {}'.format(str(root), tau(root)))
tau(-alpha[1]                                ) = alpha[1]
tau(alpha[1]                                  ) = -alpha[1]
tau(alpha[1] + alpha[2]                       ) = alpha[2] + alpha[3]
tau(alpha[1] + alpha[2] + alpha[3]            ) = alpha[2]
tau(alpha[1] + alpha[2] + alpha[3] + alpha[4]) = alpha[2] + alpha[3] +
↪alpha[4]
tau(-alpha[2]                                  ) = -alpha[2]
tau(alpha[2]                                  ) = alpha[1] + alpha[2] +
↪alpha[3]
tau(alpha[2] + alpha[3]                       ) = alpha[1] + alpha[2]
tau(alpha[2] + alpha[3] + alpha[4]            ) = alpha[1] + alpha[2] +
↪alpha[3] + alpha[4]
tau(-alpha[3]                                  ) = alpha[3]
tau(alpha[3]                                  ) = -alpha[3]
tau(alpha[3] + alpha[4]                       ) = alpha[4]
tau(-alpha[4]                                  ) = -alpha[4]
tau(alpha[4]                                  ) = alpha[3] + alpha[4]
```

This method works on any root lattice realization:

```
sage: L = RootSystem(['B',3]).ambient_space()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])
sage: for root in L.almost_positive_roots():
.....:     print('tau({:<41}) = {}'.format(str(root), tau(root)))
tau((-1, 1, 0)                                ) = (1, -1, 0)
tau((1, 0, 0)                                  ) = (0, 1, 0)
tau((1, -1, 0)                                 ) = (-1, 1, 0)
tau((1, 1, 0)                                  ) = (1, 1, 0)
tau((1, 0, -1)                                 ) = (0, 1, 1)
tau((1, 0, 1)                                  ) = (0, 1, -1)
tau((0, -1, 1)                                 ) = (0, -1, 1)
tau((0, 1, 0)                                  ) = (1, 0, 0)
tau((0, 1, -1)                                 ) = (1, 0, 1)
tau((0, 1, 1)                                  ) = (1, 0, -1)
```

(continues on next page)

(continued from previous page)

<code>tau((0, 0, -1)</code>	<code>) = (0, 0, 1)</code>
<code>tau((0, 0, 1)</code>	<code>) = (0, 0, -1)</code>

See also:`tau_plus_minus()`**tau_plus_minus()**Returns the τ^+ and τ^- piecewise linear operators on `self`Those operators are induced by the bipartition $\{L, R\}$ of the simple roots of `self`, and stabilize the almost positive roots. Namely, τ_+ fixes the negative simple roots α_i for i in R , and acts otherwise by:

$$\tau_+(\beta) = \left(\prod_{i \in L} s_i \right) (\beta)$$

 τ_- acts analogously, with L and R interchanged.Those operators are used to construct the associahedron, a polytopal realization of the cluster complex (see `Associahedron`).**See also:**`tau_epsilon_operator_on_almost_positive_roots()`

EXAMPLES:

We explore the example of [CFZ2002] Eq.(1.3):

```
sage: S = RootSystem(['A', 2]).root_lattice()
sage: taup, taum = S.tau_plus_minus()
sage: for beta in S.almost_positive_roots(): print("{} , {} , {}".
↪format(beta, taup(beta), taum(beta)))
-alpha[1] , alpha[1] , -alpha[1]
alpha[1] , -alpha[1] , alpha[1] + alpha[2]
alpha[1] + alpha[2] , alpha[2] , alpha[1]
-alpha[2] , -alpha[2] , alpha[2]
alpha[2] , alpha[1] + alpha[2] , -alpha[2]
```

to_ambient_space_morphism()

Return the morphism to the ambient space.

EXAMPLES:

```
sage: CartanType(['B', 2]).root_system().root_lattice().to_ambient_space_
↪morphism()
Generic morphism:
From: Root lattice of the Root system of type ['B', 2]
To: Ambient space of the Root system of type ['B', 2]
sage: CartanType(['B', 2]).root_system().coroot_lattice().to_ambient_space_
↪morphism()
Generic morphism:
From: Coroot lattice of the Root system of type ['B', 2]
To: Ambient space of the Root system of type ['B', 2]
sage: CartanType(['B', 2]).root_system().weight_lattice().to_ambient_space_
↪morphism()
Generic morphism:
```

(continues on next page)

(continued from previous page)

```
From: Weight lattice of the Root system of type ['B', 2]
To:   Ambient space of the Root system of type ['B', 2]
```

weyl_group(*prefix=None*)

Returns the Weyl group associated to self.

EXAMPLES:

```
sage: RootSystem(['F', 4]).ambient_space().weyl_group()
Weyl Group of type ['F', 4] (as a matrix group acting on the ambient space)
sage: RootSystem(['F', 4]).root_space().weyl_group()
Weyl Group of type ['F', 4] (as a matrix group acting on the root space)
```

super_categories()

EXAMPLES:

```
sage: from sage.combinat.root_system.root_lattice_realizations import _
      ↪ RootLatticeRealizations
sage: RootLatticeRealizations(QQ).super_categories()
[Category of vector spaces with basis over Rational Field]
```

5.1.236 Root lattices and root spaces

class `sage.combinat.root_system.root_space.RootSpace`(*root_system, base_ring*)Bases: `sage.combinat.free_module.CombinatorialFreeModule`

The root space of a root system over a given base ring

INPUT:

- *root_system* - a root system
- *base_ring*: a ring R

The *root space* (or lattice if *base_ring* is \mathbf{Z}) of a root system is the formal free module $\bigoplus_i R\alpha_i$ generated by the simple roots $(\alpha_i)_{i \in I}$ of the root system.

This class is also used for coroot spaces (or lattices).

See also:

- `RootSystem()`
- `RootSystem.root_lattice()` and `RootSystem.root_space()`
- `RootLatticeRealizations()`

Todo: standardize the variable used for the root space in the examples (P?)

Elementalias of `RootSpaceElement`**simple_root**()Return the basis element indexed by *i*.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.monomial('a')
B['a']
```

F.monomial is in fact (almost) a map:

```
sage: F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'} over
↳Rational Field
```

to_ambient_space_morphism()

The morphism from self to its associated ambient space.

EXAMPLES:

```
sage: CartanType(['A', 2]).root_system().root_lattice().to_ambient_space_
↳morphism()
Generic morphism:
From: Root lattice of the Root system of type ['A', 2]
To: Ambient space of the Root system of type ['A', 2]
```

to_coroot_space_morphism()

Returns the nu map to the coroot space over the same base ring, using the symmetrizer of the Cartan matrix

It does not map the root lattice to the coroot lattice, but has the property that any root is mapped to some scalar multiple of its associated coroot.

EXAMPLES:

```
sage: R = RootSystem(['A', 3]).root_space()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
alphacheck[1] + alphacheck[2]

sage: R = RootSystem(['A', 3]).root_lattice()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
alphacheck[1] + alphacheck[2]

sage: S = RootSystem(['G', 2]).root_space()
sage: alpha = S.simple_roots()
sage: f = S.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
alphacheck[1] + 3*alphacheck[2]
```

class sage.combinat.root_system.root_space.RootSpaceElement

Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

associated_coroot()

Returns the coroot associated to this root

OUTPUT:

An element of the coroot space over the same base ring; in particular the result is in the coroot lattice whenever `self` is in the root lattice.

EXAMPLES:

```
sage: L = RootSystem(["B", 3]).root_space()
sage: alpha = L.simple_roots()
sage: alpha[1].associated_coroot()
alphacheck[1]
sage: alpha[1].associated_coroot().parent()
Coroot space over the Rational Field of the Root system of type ['B', 3]

sage: L.highest_root()
alpha[1] + 2*alpha[2] + 2*alpha[3]
sage: L.highest_root().associated_coroot()
alphacheck[1] + 2*alphacheck[2] + alphacheck[3]

sage: alpha = RootSystem(["B", 3]).root_lattice().simple_roots()
sage: alpha[1].associated_coroot()
alphacheck[1]
sage: alpha[1].associated_coroot().parent()
Coroot lattice of the Root system of type ['B', 3]
```

is_positive_root()

Checks whether an element in the root space lies in the nonnegative cone spanned by the simple roots.

EXAMPLES:

```
sage: R=RootSystem(['A', 3, 1]).root_space()
sage: B=R.basis()
sage: w=B[0]+B[3]
sage: w.is_positive_root()
True
sage: w=B[1]-B[2]
sage: w.is_positive_root()
False
```

max_coroot_le()

Returns the highest positive coroot whose associated root is less than or equal to `self`.

INPUT:

- `self` – an element of the nonnegative integer span of simple roots.

Returns `None` for the zero element.

Really `self` is an element of a coroot lattice and this method returns the highest root whose associated coroot is \leq `self`.

Warning: This implementation only handles finite Cartan types

EXAMPLES:

```
sage: root_lattice = RootSystem(['C',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
alphacheck[1] + 2*alphacheck[2]
sage: root_lattice.from_vector(vector([2,1])).max_coroot_le()
alphacheck[1] + 2*alphacheck[2]
sage: root_lattice = RootSystem(['B',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
2*alphacheck[1] + alphacheck[2]
sage: root_lattice.from_vector(vector([1,2])).max_coroot_le()
2*alphacheck[1] + alphacheck[2]

sage: root_lattice.zero().max_coroot_le() is None
True
sage: root_lattice.from_vector(vector([-1,0])).max_coroot_le()
Traceback (most recent call last):
...
ValueError: -alpha[1] is not in the positive cone of roots
sage: root_lattice = RootSystem(['A',2,1]).root_lattice()
sage: root_lattice.simple_root(1).max_coroot_le()
Traceback (most recent call last):
...
NotImplementedError: Only implemented for finite Cartan type
```

`max_quantum_element()`

Returns a reduced word for the longest element of the Weyl group whose shortest path in the quantum Bruhat graph to the identity, has sum of quantum coroots at most `self`.

INPUT:

- `self` – an element of the nonnegative integer span of simple roots.

Really `self` is an element of a coroot lattice.

Warning: This implementation only handles finite Cartan types

EXAMPLES:

```
sage: Qvee = RootSystem(['C',2]).coroot_lattice()
sage: Qvee.from_vector(vector([1,2])).max_quantum_element()
[2, 1, 2, 1]
sage: Qvee.from_vector(vector([1,1])).max_quantum_element()
[1, 2, 1]
sage: Qvee.from_vector(vector([0,2])).max_quantum_element()
[2]
```

`quantum_root()`

Returns True if `self` is a quantum root and False otherwise.

INPUT:

- `self` – an element of the nonnegative integer span of simple roots.

A root α is a quantum root if $\ell(s_\alpha) = \langle 2\rho, \alpha^\vee \rangle - 1$ where ℓ is the length function, s_α is the reflection across the hyperplane orthogonal to α , and 2ρ is the sum of positive roots.

Warning: This implementation only handles finite Cartan types and assumes that `self` is a root.

Todo: Rename to `is_quantum_root`

EXAMPLES:

```
sage: Q = RootSystem(['C',2]).root_lattice()
sage: positive_roots = Q.positive_roots()
sage: for x in sorted(positive_roots):
....:     print("{} {}".format(x, x.quantum_root()))
alpha[1] True
alpha[1] + alpha[2] False
2*alpha[1] + alpha[2] True
alpha[2] True
```

scalar(*lambdacheck*)

The scalar product between the root lattice and the coroot lattice.

EXAMPLES:

```
sage: L = RootSystem(['B',4]).root_lattice()
sage: alpha      = L.simple_roots()
sage: alphacheck = L.simple_coroots()
sage: alpha[1].scalar(alphacheck[1])
2
sage: alpha[1].scalar(alphacheck[2])
-1
```

The scalar products between the roots and coroots are given by the Cartan matrix:

```
sage: matrix([ [ alpha[i].scalar(alphacheck[j])
....:           for i in L.index_set() ]
....:         for j in L.index_set() ])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -2  2]

sage: L.cartan_type().cartan_matrix()
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -2  2]
```

to_ambient()

Map `self` to the ambient space.

EXAMPLES:

```

sage: alpha = CartanType(['B',2]).root_system().root_lattice().an_element();
↪ alpha
2*alpha[1] + 2*alpha[2]
sage: alpha.to_ambient()
(2, 0)
sage: alphavee = CartanType(['B',2]).root_system().coroot_lattice().an_
↪ element(); alphavee
2*alphacheck[1] + 2*alphacheck[2]
sage: alphavee.to_ambient()
(2, 2)

```

5.1.237 Root systems

See *Root Systems* for an overview.

```

class sage.combinat.root_system.root_system.RootSystem(cartan_type, as_dual_of=None)
  Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.
  sage_object.SageObject

```

A class for root systems.

EXAMPLES:

We construct the root system for type B_3 :

```

sage: R=RootSystem(['B',3]); R
Root system of type ['B', 3]

```

R models the root system abstractly. It comes equipped with various realizations of the root and weight lattices, where all computations take place. Let us play first with the root lattice:

```

sage: space = R.root_lattice()
sage: space
Root lattice of the Root system of type ['B', 3]

```

This is the free \mathbf{Z} -module $\bigoplus_i \mathbf{Z}.\alpha_i$ spanned by the simple roots:

```

sage: space.base_ring()
Integer Ring
sage: list(space.basis())
[alpha[1], alpha[2], alpha[3]]

```

Let us do some computations with the simple roots:

```

sage: alpha = space.simple_roots()
sage: alpha[1] + alpha[2]
alpha[1] + alpha[2]

```

There is a canonical pairing between the root lattice and the coroot lattice:

```

sage: R.coroot_lattice()
Coroot lattice of the Root system of type ['B', 3]

```

We construct the simple coroots, and do some computations (see comments about duality below for some caveat):

```
sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

We can carry over the same computations in any of the other realizations of the root lattice, like the root space $\bigoplus_i \mathbb{Q}.\alpha_i$, the weight lattice $\bigoplus_i \mathbb{Z}.\Lambda_i$, the weight space $\bigoplus_i \mathbb{Q}.\Lambda_i$. For example:

```
sage: space = R.weight_space()
sage: space
Weight space over the Rational Field of the Root system of type ['B', 3]
```

```
sage: space.base_ring()
Rational Field
sage: list(space.basis())
[Lambda[1], Lambda[2], Lambda[3]]
```

```
sage: alpha = space.simple_roots()
sage: alpha[1] + alpha[2]
Lambda[1] + Lambda[2] - 2*Lambda[3]
```

The fundamental weights are the dual basis of the coroots:

```
sage: Lambda = space.fundamental_weights()
sage: Lambda[1]
Lambda[1]
```

```
sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

```
sage: [Lambda[i].scalar(alphacheck[1]) for i in space.index_set()]
[1, 0, 0]
sage: [Lambda[i].scalar(alphacheck[2]) for i in space.index_set()]
[0, 1, 0]
sage: [Lambda[i].scalar(alphacheck[3]) for i in space.index_set()]
[0, 0, 1]
```

Let us use the simple reflections. In the weight space, they work as in the *number game*: firing the node i on an element x adds c times the simple root α_i , where c is the coefficient of i in x :

```
sage: s = space.simple_reflections()
sage: Lambda[1].simple_reflection(1)
-Lambda[1] + Lambda[2]
sage: Lambda[2].simple_reflection(1)
Lambda[2]
sage: Lambda[3].simple_reflection(1)
Lambda[3]
sage: (-2*Lambda[1] + Lambda[2] + Lambda[3]).simple_reflection(1)
2*Lambda[1] - Lambda[2] + Lambda[3]
```

It can be convenient to manipulate the simple reflections themselves:

```

sage: s = space.simple_reflections()
sage: s[1](Lambda[1])
-Lambda[1] + Lambda[2]
sage: s[1](Lambda[2])
Lambda[2]
sage: s[1](Lambda[3])
Lambda[3]

```

Ambient spaces

The root system may also come equipped with an ambient space. This is a \mathbb{Q} -module, endowed with its canonical Euclidean scalar product, which admits simultaneous embeddings of the (extended) weight and the (extended) coweight lattice, and therefore the root and the coroot lattice. This is implemented on a type by type basis for the finite crystallographic root systems following Bourbaki's conventions and is extended to the affine cases. Coefficients permitting, this is also available as an ambient lattice.

See also:

[`ambient_space\(\)`](#) and [`ambient_lattice\(\)`](#) for details

In finite type A , we recover the natural representation of the symmetric group as group of permutation matrices:

```

sage: RootSystem(["A",2]).ambient_space().weyl_group().simple_reflections()
Finite family {1: [0 1 0]
                  [1 0 0]
                  [0 0 1],
                2: [1 0 0]
                  [0 0 1]
                  [0 1 0]}

```

In type B , C , and D , we recover the natural representation of the Weyl group as groups of signed permutation matrices:

```

sage: RootSystem(["B",3]).ambient_space().weyl_group().simple_reflections()
Finite family {1: [0 1 0]
                  [1 0 0]
                  [0 0 1],
                2: [1 0 0]
                  [0 0 1]
                  [0 1 0],
                3: [ 1  0  0]
                  [ 0  1  0]
                  [ 0  0 -1]}

```

In (untwisted) affine types A, \dots, D , one can recover from the ambient space the affine permutation representation, in window notation. Let us consider the ambient space for affine type A :

```

sage: L = RootSystem(["A",2,1]).ambient_space(); L
Ambient space of the Root system of type ['A', 2, 1]

```

Define the “identity” by an appropriate vector at level -3 :

```

sage: e = L.basis(); Lambda = L.fundamental_weights()
sage: id = e[0] + 2*e[1] + 3*e[2] - 3*Lambda[0]

```

The corresponding permutation is obtained by projecting it onto the classical ambient space:

```
sage: L.classical()
Ambient space of the Root system of type ['A', 2]
sage: L.classical()(id)
(1, 2, 3)
```

Here is the orbit of the identity under the action of the finite group:

```
sage: W = L.weak_group()
sage: S3 = [ w.action(id) for w in W.classical() ]
sage: [L.classical()(x) for x in S3]
[(1, 2, 3), (3, 1, 2), (2, 3, 1), (2, 1, 3), (1, 3, 2), (3, 2, 1)]
```

And the action of s_0 on these yields:

```
sage: s = W.simple_reflections()
sage: [L.classical()(s[0].action(x)) for x in S3]
[(0, 2, 4), (-1, 1, 6), (-2, 3, 5), (0, 1, 5), (-1, 3, 4), (-2, 2, 6)]
```

We can also plot various components of the ambient spaces:

```
sage: L = RootSystem(['A', 2]).ambient_space()
sage: L.plot()
Graphics object consisting of 13 graphics primitives
```

For more on plotting, see *Tutorial: visualizing root systems*.

Dual root systems

The root system is aware of its dual root system:

```
sage: R.dual
Dual of root system of type ['B', 3]
```

`R.dual` is really the root system of type C_3 :

```
sage: R.dual.cartan_type()
['C', 3]
```

And the coroot lattice that we have been manipulating before is really implemented as the root lattice of the dual root system:

```
sage: R.dual.root_lattice()
Coroot lattice of the Root system of type ['B', 3]
```

In particular, the coroots for the root lattice are in fact the roots of the coroot lattice:

```
sage: list(R.root_lattice().simple_coroots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: list(R.coroot_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: list(R.dual.root_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

The coweight lattice and space are defined similarly. Note that, to limit confusion, all the output have been tweaked appropriately.

See also:

- `sage.combinat.root_system`
- [RootSpace](#)
- [WeightSpace](#)
- `AmbientSpace`
- [RootLatticeRealizations](#)
- [WeightLatticeRealizations](#)

ambient_lattice()

Return the ambient lattice for this `root_system`.

This is the ambient space, over \mathbf{Z} .

See also:

- [ambient_space\(\)](#)
- [root_lattice\(\)](#)
- [weight_lattice\(\)](#)

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4]
sage: RootSystem(['A',4,1]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4, 1]
```

Except in type A, only an ambient space can be realized:

```
sage: RootSystem(['B',4]).ambient_lattice()
sage: RootSystem(['C',4]).ambient_lattice()
sage: RootSystem(['D',4]).ambient_lattice()
sage: RootSystem(['E',6]).ambient_lattice()
sage: RootSystem(['F',4]).ambient_lattice()
sage: RootSystem(['G',2]).ambient_lattice()
```

ambient_space(*base_ring=Rational Field*)

Return the usual ambient space for this `root_system`.

INPUT:

- `base_ring` – a base ring (default: \mathbf{Q})

This is a `base_ring`-module, endowed with its canonical Euclidean scalar product, which admits simultaneous embeddings into the weight and the coweight lattice, and therefore the root and the coroot lattice, and preserves scalar products between elements of the coroot lattice and elements of the root or weight lattice (and dually).

There is no mechanical way to define the ambient space just from the Cartan matrix. Instead it is constructed from hard coded type by type data, according to the usual Bourbaki conventions. Such data is provided for all the finite (crystallographic) types. From this data, ambient spaces can be built as well for dual types,

reducible types and affine types. When no data is available, or if the base ring is not large enough, None is returned.

Warning: for affine types

See also:

- The section on ambient spaces in *RootSystem*
- `ambient_lattice()`
- *AmbientSpace*
- `AmbientSpace`
- `root_space()`
- `weight:space()`

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_space()
Ambient space of the Root system of type ['A', 4]
```

```
sage: RootSystem(['B',4]).ambient_space()
Ambient space of the Root system of type ['B', 4]
```

```
sage: RootSystem(['C',4]).ambient_space()
Ambient space of the Root system of type ['C', 4]
```

```
sage: RootSystem(['D',4]).ambient_space()
Ambient space of the Root system of type ['D', 4]
```

```
sage: RootSystem(['E',6]).ambient_space()
Ambient space of the Root system of type ['E', 6]
```

```
sage: RootSystem(['F',4]).ambient_space()
Ambient space of the Root system of type ['F', 4]
```

```
sage: RootSystem(['G',2]).ambient_space()
Ambient space of the Root system of type ['G', 2]
```

An alternative base ring can be provided as an option:

```
sage: e = RootSystem(['B',3]).ambient_space(RR)
sage: TestSuite(e).run()
```

It should contain the smallest ring over which the ambient space can be defined (\mathbf{Z} in type A or \mathbf{Q} otherwise). Otherwise None is returned:

```
sage: RootSystem(['B',2]).ambient_space(ZZ)
```

The base ring should also be totally ordered. In practice, only \mathbf{Z} and \mathbf{Q} are really supported at this point, but you are welcome to experiment:

```

sage: e = RootSystem(['G',2]).ambient_space(RR)
sage: TestSuite(e).run()
Failure in _test_root_lattice_realization:
Traceback (most recent call last):
...
AssertionError: 2.0000000000000000 != 2.0000000000000000
-----
The following tests failed: _test_root_lattice_realization

```

cartan_matrix()

EXAMPLES:

```

sage: RootSystem(['A',3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -1]
[ 0 -1  2]

```

cartan_type()

Returns the Cartan type of the root system.

EXAMPLES:

```

sage: R = RootSystem(['A',3])
sage: R.cartan_type()
['A', 3]

```

coambient_space(*base_ring=Rational Field*)

Return the coambient space for this root system.

This is the ambient space of the dual root system.

See also:

- [ambient_space\(\)](#)

EXAMPLES:

```

sage: L = RootSystem(["B",2]).ambient_space(); L
Ambient space of the Root system of type ['B', 2]
sage: coL = RootSystem(["B",2]).coambient_space(); coL
Coambient space of the Root system of type ['B', 2]

```

The roots and coroots are interchanged:

```

sage: coL.simple_roots()
Finite family {1: (1, -1), 2: (0, 2)}
sage: L.simple_coroots()
Finite family {1: (1, -1), 2: (0, 2)}

sage: coL.simple_coroots()
Finite family {1: (1, -1), 2: (0, 1)}
sage: L.simple_roots()
Finite family {1: (1, -1), 2: (0, 1)}

```

coroot_lattice()

Returns the coroot lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A', 3]).coroot_lattice()
Coroot lattice of the Root system of type ['A', 3]
```

coroot_space(*base_ring=Rational Field*)

Returns the coroot space associated to self.

EXAMPLES:

```
sage: RootSystem(['A', 3]).coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 3]
```

coweight_lattice(*extended=False*)

Returns the coweight lattice associated to self.

This is the weight lattice of the dual root system.

See also:

- [coweight_space\(\)](#)
- [weight_space\(\)](#), [weight_lattice\(\)](#)
- [WeightSpace](#)

EXAMPLES:

```
sage: RootSystem(['A', 3]).coweight_lattice()
Coweight lattice of the Root system of type ['A', 3]

sage: RootSystem(['A', 3, 1]).coweight_lattice(extended = True)
Extended coweight lattice of the Root system of type ['A', 3, 1]
```

coweight_space(*base_ring=Rational Field, extended=False*)

Returns the coweight space associated to self.

This is the weight space of the dual root system.

See also:

- [coweight_lattice\(\)](#)
- [weight_space\(\)](#), [weight_lattice\(\)](#)
- [WeightSpace](#)

EXAMPLES:

```
sage: RootSystem(['A', 3]).coweight_space()
Coweight space over the Rational Field of the Root system of type ['A', 3]

sage: RootSystem(['A', 3, 1]).coweight_space(extended=True)
Extended coweight space over the Rational Field of the Root system of type ['A',
↪ 3, 1]
```

dynkin_diagram()

Returns the Dynkin diagram of the root system.

EXAMPLES:

```
sage: R = RootSystem(['A', 3])
sage: R.dynkin_diagram()
0---0---0
1  2  3
A3
```

index_set()

EXAMPLES:

```
sage: RootSystem(['A', 3]).index_set()
(1, 2, 3)
```

is_finite()

Returns True if self is a finite root system.

EXAMPLES:

```
sage: RootSystem(["A", 3]).is_finite()
True
sage: RootSystem(["A", 3, 1]).is_finite()
False
```

is_irreducible()

Returns True if self is an irreducible root system.

EXAMPLES:

```
sage: RootSystem(['A', 3]).is_irreducible()
True
sage: RootSystem("A2xB2").is_irreducible()
False
```

root_lattice()

Returns the root lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A', 3]).root_lattice()
Root lattice of the Root system of type ['A', 3]
```

root_poset(*restricted=False, facade=False*)

Returns the (restricted) root poset associated to self.

The elements are given by the positive roots (resp. non-simple, positive roots), and $\alpha \leq \beta$ iff $\beta - \alpha$ is a non-negative linear combination of simple roots.

INPUT:

- **restricted** – (default:False) if True, only non-simple roots are considered.
- **facade** – (default:False) passes facade option to the poset generator.

EXAMPLES:

```
sage: Phi = RootSystem(['A', 2]).root_poset(); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1], alpha[1] + alpha[2]], [alpha[2], alpha[1] + alpha[2]]]
```

(continues on next page)

(continued from previous page)

```

sage: Phi = RootSystem(['A',3]).root_poset(restricted=True); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3]], [alpha[2] + alpha[3],
↪alpha[1] + alpha[2] + alpha[3]]]

sage: Phi = RootSystem(['B',2]).root_poset(); Phi
Finite poset containing 4 elements
sage: Phi.cover_relations()
[[alpha[2], alpha[1] + alpha[2]], [alpha[1], alpha[1] + alpha[2]], [alpha[1] +
↪alpha[2], alpha[1] + 2*alpha[2]]]

```

root_space(*base_ring=Rational Field*)

Returns the root space associated to self.

EXAMPLES:

```

sage: RootSystem(['A',3]).root_space()
Root space over the Rational Field of the Root system of type ['A', 3]

```

weight_lattice(*extended=False*)

Returns the weight lattice associated to self.

See also:

- [weight_space\(\)](#)
- [coweight_space\(\)](#), [coweight_lattice\(\)](#)
- [WeightSpace](#)

EXAMPLES:

```

sage: RootSystem(['A',3]).weight_lattice()
Weight lattice of the Root system of type ['A', 3]

sage: RootSystem(['A',3,1]).weight_space(extended = True)
Extended weight space over the Rational Field of the Root system of type ['A',
↪3, 1]

```

weight_space(*base_ring=Rational Field, extended=False*)

Returns the weight space associated to self.

See also:

- [weight_lattice\(\)](#)
- [coweight_space\(\)](#), [coweight_lattice\(\)](#)
- [WeightSpace](#)

EXAMPLES:

```
sage: RootSystem(['A',3]).weight_space()
Weight space over the Rational Field of the Root system of type ['A', 3]

sage: RootSystem(['A',3,1]).weight_space(extended = True)
Extended weight space over the Rational Field of the Root system of type ['A', 3, 1]
```

sage.combinat.root_system.root_system.WeylDim(ct, coeffs)

The Weyl Dimension Formula.

INPUT:

- type - a Cartan type
- coeffs - a list of nonnegative integers

The length of the list must equal the rank type[1]. A dominant weight hwt is constructed by summing the fundamental weights with coefficients from this list. The dimension of the irreducible representation of the semisimple complex Lie algebra with highest weight vector hwt is returned.

EXAMPLES:

For $SO(7)$, the Cartan type is B_3 , so:

```
sage: WeylDim(['B',3],[1,0,0]) # standard representation of SO(7)
7
sage: WeylDim(['B',3],[0,1,0]) # exterior square
21
sage: WeylDim(['B',3],[0,0,1]) # spin representation of spin(7)
8
sage: WeylDim(['B',3],[1,0,1]) # sum of the first and third fundamental weights
48
sage: [WeylDim(['F',4],x) for x in ([1,0,0,0],[0,1,0,0],[0,0,1,0],[0,0,0,1])]
[52, 1274, 273, 26]
sage: [WeylDim(['E',6],x) for x in ([0,0,0,0,0,0],[0,1,0,0,0,0],[0,0,0,0,1,0],
↪ [0,0,0,0,0,1],[0,0,0,0,0,2],[0,0,0,0,1,0],[0,0,1,0,0,0],[1,0,0,0,0,0],
↪ [0,0,0,0,0,1],[2,0,0,0,0,0])]
[1, 78, 27, 351, 351, 351, 27, 650, 351]
```

5.1.238 Root system data for super type A

class sage.combinat.root_system.type_super_A.AmbientSpace(root_system, base_ring, index_set=None)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

The ambient space for (super) type $A(m|n)$.

EXAMPLES:

```
sage: R = RootSystem(['A', [2,1]])
sage: AL = R.ambient_space(); AL
Ambient space of the Root system of type ['A', [2, 1]]
sage: AL.basis()
Finite family {-3: (1, 0, 0, 0, 0),
-2: (0, 1, 0, 0, 0),
```

(continues on next page)

(continued from previous page)

```
-1: (0, 0, 1, 0, 0),
1: (0, 0, 0, 1, 0),
2: (0, 0, 0, 0, 1)}
```

class ElementBases: `sage.combinat.root_system.ambient_space.AmbientSpaceElement`**associated_coroot()**Return the coroot associated to `self`.

EXAMPLES:

```
sage: L = RootSystem(['A', [3,2]]).ambient_space()
sage: al = L.simple_roots()
sage: al[-1].associated_coroot()
(0, 0, 1, -1, 0, 0, 0)
sage: al[0].associated_coroot()
(0, 0, 0, 1, -1, 0, 0)
sage: al[1].associated_coroot()
(0, 0, 0, 0, -1, 1, 0)

sage: a = al[-1] + al[0] + al[1]; a
(0, 0, 1, 0, 0, -1, 0)
sage: a.associated_coroot()
(0, 0, 1, 0, -2, 1, 0)
sage: h = L.simple_coroots()
sage: h[-1] + h[0] + h[1]
(0, 0, 1, 0, -2, 1, 0)

sage: (al[-1] + al[0] + al[2]).associated_coroot()
(0, 0, 1, 0, -1, -1, 1)
```

dot_product(*lambda*check)

The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

```
sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: a = L.simple_roots()
sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.
↪index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
```

has_descent(*i*, *positive=False*)Test if `self` has a descent at position `i`, that is if `self` is on the strict negative side of the i^{th} simple reflection hyperplane.If `positive` is `True`, tests if it is on the strict positive side instead.

EXAMPLES:

```

sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: al = L.simple_roots()
sage: [al[i].has_descent(1) for i in L.index_set()]
[False, False, True, False]
sage: [(-al[i]).has_descent(1) for i in L.index_set()]
[False, False, False, True]
sage: [al[i].has_descent(1, True) for i in L.index_set()]
[False, False, False, True]
sage: [(-al[i]).has_descent(1, True) for i in L.index_set()]
[False, False, True, False]
sage: (al[-2] + al[0] + al[1]).has_descent(-1)
True
sage: (al[-2] + al[0] + al[1]).has_descent(1)
False
sage: (al[-2] + al[0] + al[1]).has_descent(1, positive=True)
True
sage: all(all(not la.has_descent(i) for i in L.index_set())
.....:        for la in L.fundamental_weights())
True

```

inner_product (*lambdacheck*)

The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

```

sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: a = L.simple_roots()
sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.
↪index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]

```

is_dominant_weight()

Test whether self is a dominant element of the weight lattice.

EXAMPLES:

```

sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: (3*Lambda[1]+Lambda[2]).is_dominant()
True
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False

```

Tests that the scalar products with the coroots are all nonnegative integers. For example, if x is the sum of a dominant element of the weight lattice plus some other element orthogonal to all coroots, then the implementation correctly reports x to be a dominant weight:

```
sage: x = Lambda[1] + L([-1,-1,-1])
sage: x.is_dominant_weight()
True
```

scalar(*lambdacheck*)

The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

```
sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: a = L.simple_roots()
sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.
↪index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
```

dimension()

Return the dimension of this ambient space.

EXAMPLES:

```
sage: e = RootSystem(['A', [4,2]]).ambient_space()
sage: e.dimension()
8
```

fundamental_weight(*i*)

Return the fundamental weight Λ_i of self.

EXAMPLES:

```
sage: L = RootSystem(['A', [3,2]]).ambient_space()
sage: L.fundamental_weight(-1)
(1, 1, 1, 0, 0, 0, 0)
sage: L.fundamental_weight(0)
(1, 1, 1, 1, 0, 0, 0)
sage: L.fundamental_weight(2)
(1, 1, 1, 1, -1, -1, -2)
sage: list(L.fundamental_weights())
[(1, 0, 0, 0, 0, 0, 0),
 (1, 1, 0, 0, 0, 0, 0),
 (1, 1, 1, 0, 0, 0, 0),
 (1, 1, 1, 1, 0, 0, 0),
 (1, 1, 1, 1, -1, -1, -2),
 (1, 1, 1, 1, -1, -1, -2)]
```

```
sage: L = RootSystem(['A', [2,3]]).ambient_space()
sage: La = L.fundamental_weights()
sage: al = L.simple_roots()
sage: I = L.index_set()
sage: matrix([[al[i].scalar(La[j]) for i in I] for j in I])
[ 1  0  0  0  0  0]
[ 0  1  0  0  0  0]
```

(continues on next page)

(continued from previous page)

```
[ 0 0 1 0 0 0]
[ 0 0 0 -1 0 0]
[ 0 0 0 0 -1 0]
[ 0 0 0 0 0 -1]
```

highest_root()Return the highest root of `self`.

EXAMPLES:

```
sage: e = RootSystem(['A', [4,2]]).ambient_lattice()
sage: e.highest_root()
(1, 0, 0, 0, 0, 0, -1)
```

negative_even_roots()Return the negative even roots of `self`.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_even_roots()
[(0, -1, 1, 0, 0), (-1, 0, 1, 0, 0),
 (-1, 1, 0, 0, 0), (0, 0, 0, -1, 1)]
```

negative_odd_roots()Return the negative odd roots of `self`.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_odd_roots()
[(0, 0, -1, 1, 0),
 (0, 0, -1, 0, 1),
 (0, -1, 0, 1, 0),
 (0, -1, 0, 0, 1),
 (-1, 0, 0, 1, 0),
 (-1, 0, 0, 0, 1)]
```

negative_roots()Return the negative roots of `self`.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_roots()
[(0, -1, 1, 0, 0),
 (-1, 0, 1, 0, 0),
 (-1, 1, 0, 0, 0),
 (0, 0, 0, -1, 1),
 (0, 0, -1, 1, 0),
 (0, 0, -1, 0, 1),
 (0, -1, 0, 1, 0),
 (0, -1, 0, 0, 1),
 (-1, 0, 0, 1, 0),
 (-1, 0, 0, 0, 1)]
```

positive_even_roots()

Return the positive even roots of `self`.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_even_roots()
[(0, 1, -1, 0, 0), (1, 0, -1, 0, 0),
 (1, -1, 0, 0, 0), (0, 0, 0, 1, -1)]
```

positive_odd_roots()

Return the positive odd roots of `self`.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_odd_roots()
[(0, 0, 1, -1, 0),
 (0, 0, 1, 0, -1),
 (0, 1, 0, -1, 0),
 (0, 1, 0, 0, -1),
 (1, 0, 0, -1, 0),
 (1, 0, 0, 0, -1)]
```

positive_roots()

Return the positive roots of `self`.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_roots()
[(0, 1, -1, 0, 0),
 (1, 0, -1, 0, 0),
 (1, -1, 0, 0, 0),
 (0, 0, 0, 1, -1),
 (0, 0, 1, -1, 0),
 (0, 0, 1, 0, -1),
 (0, 1, 0, -1, 0),
 (0, 1, 0, 0, -1),
 (1, 0, 0, -1, 0),
 (1, 0, 0, 0, -1)]
```

simple_coroot(*i*)

Return the simple coroot h_i of `self`.

EXAMPLES:

```
sage: L = RootSystem(['A', [3,2]]).ambient_space()
sage: L.simple_coroot(-2)
(0, 1, -1, 0, 0, 0, 0)
sage: L.simple_coroot(0)
(0, 0, 0, 1, -1, 0, 0)
sage: L.simple_coroot(2)
(0, 0, 0, 0, 0, -1, 1)
sage: list(L.simple_coroots())
[(1, -1, 0, 0, 0, 0, 0),
```

(continues on next page)

(continued from previous page)

```
(0, 1, -1, 0, 0, 0, 0),
(0, 0, 1, -1, 0, 0, 0),
(0, 0, 0, 1, -1, 0, 0),
(0, 0, 0, 0, -1, 1, 0),
(0, 0, 0, 0, 0, -1, 1)]
```

simple_root(*i*)Return the *i*-th simple root of self.

EXAMPLES:

```
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: list(e.simple_roots())
[(1, -1, 0, 0, 0), (0, 1, -1, 0, 0),
(0, 0, 1, -1, 0), (0, 0, 0, 1, -1)]
```

classmethod smallest_base_ring(*cartan_type=None*)

Return the smallest base ring the ambient space can be defined upon.

See also:

[*smallest_base_ring\(\)*](#)

EXAMPLES:

```
sage: e = RootSystem(['A', [3,1]]).ambient_space()
sage: e.smallest_base_ring()
Integer Ring
```

class sage.combinat.root_system.type_super_A.CartanType(*m, n*)Bases: [*sage.combinat.root_system.cartan_type.SuperCartanType_standard*](#)Cartan Type $A(m|n)$.

See also:

[CartanType\(\)](#)**AmbientSpace**alias of [*AmbientSpace*](#)**ascii_art(*label=<function CartanType.<lambda> at 0x7f874983b940>, node=None*)**

Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```
sage: t = CartanType(['A', [3,2]])
sage: print(t.ascii_art())
0---0---0---X---0---0
-3  -2  -1  0   1   2
sage: t = CartanType(['A', [3,7]])
sage: print(t.ascii_art())
0---0---0---X---0---0---0---0---0---0---0
-3  -2  -1  0   1   2   3   4   5   6   7
sage: t = CartanType(['A', [0,7]])
sage: print(t.ascii_art())
```

(continues on next page)

(continued from previous page)

```

X---0---0---0---0---0---0---0
0  1  2  3  4  5  6  7
sage: t = CartanType(['A', [0,0]])
sage: print(t.ascii_art())
X
0
sage: t = CartanType(['A', [5,0]])
sage: print(t.ascii_art())
0---0---0---0---0---X
-5  -4  -3  -2  -1  0

```

cartan_matrix()

Return the Cartan matrix associated to self.

EXAMPLES:

```

sage: ct = CartanType(['A', [2,3]])
sage: ct.cartan_matrix()
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  0  1  0  0]
[ 0  0 -1  2 -1  0]
[ 0  0  0 -1  2 -1]
[ 0  0  0  0 -1  2]

```

dual()

Return dual of self.

EXAMPLES:

```

sage: CartanType(['A', [2,3])).dual()
['A', [2, 3]]

```

dynkin_diagram()

Return the Dynkin diagram of super type A.

EXAMPLES:

```

sage: a = CartanType(['A', [4,2])).dynkin_diagram()
sage: a
0---0---0---0---X---0---0
-4  -3  -2  -1  0  1  2
A4|2
sage: a.edges(sort=True)
[(-4, -3, 1), (-3, -4, 1), (-3, -2, 1), (-2, -3, 1),
 (-2, -1, 1), (-1, -2, 1), (-1, 0, 1), (0, -1, 1),
 (0, 1, 1), (1, 0, -1), (1, 2, 1), (2, 1, 1)]

```

index_set()

Return the index set of self.

EXAMPLES:

```

sage: CartanType(['A', [2,3])).index_set()
(-2, -1, 0, 1, 2, 3)

```

is_affine()

Return whether `self` is affine or not.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).is_affine()
False
```

is_finite()

Return whether `self` is finite or not.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).is_finite()
True
```

is_irreducible()

Return whether `self` is irreducible, which is True.

EXAMPLES:

```
sage: CartanType(['A', [3,4]]).is_irreducible()
True
```

relabel (*relabelling*)

Return a relabelled copy of this Cartan type.

INPUT:

- `relabelling` – a function (or a list or dictionary)

OUTPUT:

an isomorphic Cartan type obtained by relabelling the nodes of the Dynkin diagram. Namely, the node with label `i` is relabelled `f(i)` (or, by `f[i]` if `f` is a list or dictionary).

EXAMPLES:

```
sage: ct = CartanType(['A', [1,2]])
sage: ct.dynkin_diagram()
0---X---0---0
-1  0   1   2
A1|2
sage: f={1:2,2:1,0:0,-1:-1}
sage: ct.relabel(f)
['A', [1, 2]] relabelled by {-1: -1, 0: 0, 1: 2, 2: 1}
sage: ct.relabel(f).dynkin_diagram()
0---X---0---0
-1  0   2   1
A1|2 relabelled by {-1: -1, 0: 0, 1: 2, 2: 1}
```

root_system()

Return root system of `self`.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).root_system()
Root system of type ['A', [2, 3]]
```

symmetrizer()

Return symmetrizing matrix for self.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).symmetrizer()
Finite family {-2: 1, -1: 1, 0: 1, 1: -1, 2: -1, 3: -1}
```

type()

Return type of self.

EXAMPLES:

```
sage: CartanType(['A', [2,3]]).type()
'A'
```

5.1.239 Root system data for type A

class `sage.combinat.root_system.type_A.AmbientSpace`(*root_system*, *base_ring*, *index_set=None*)

Bases: `sage.combinat.root_system.ambient_space.AmbientSpace`

EXAMPLES:

```
sage: R = RootSystem(["A", 3])
sage: e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3]
sage: TestSuite(e).run()
```

By default, this ambient space uses the barycentric projection for plotting:

```
sage: L = RootSystem(["A", 2]).ambient_space()
sage: e = L.basis()
sage: L._plot_projection(e[0])
(1/2, 989/1142)
sage: L._plot_projection(e[1])
(-1, 0)
sage: L._plot_projection(e[2])
(1/2, -989/1142)
sage: L = RootSystem(["A", 3]).ambient_space()
sage: l = L.an_element(); l
(2, 2, 3, 0)
sage: L._plot_projection(l)
(0, -1121/1189, 7/3)
```

See also:

- `sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations.ParentMethods._plot_projection()`

det(*k=1*)

returns the vector $(1, \dots, 1)$ which in the $['A', r]$ weight lattice, interpreted as a weight of $GL(r+1, \mathbb{C})$ is the determinant. If the optional parameter *k* is given, returns (k, \dots, k) , the *k*-th power of the determinant.

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_space()
sage: e.det(1/2)
(1/2, 1/2, 1/2, 1/2)
```

dimension()

EXAMPLES:

```
sage: e = RootSystem(["A",3]).ambient_space()
sage: e.dimension()
4
```

fundamental_weight(*i*)

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
```

highest_root()

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.highest_root()
(1, 0, 0, -1)
```

negative_roots()

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 1, 0),
 (0, -1, 0, 1),
 (0, 0, -1, 1)]
```

positive_roots()

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.positive_roots()
[(1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]
```

root(*i*,*j*)

Note that indexing starts at 0.

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.root(0,1)
(1, -1, 0, 0)
```

simple_root(*i*)

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

classmethod smallest_base_ring(*cartan_type=None*)

Returns the smallest base ring the ambient space can be defined upon

See also:

[*smallest_base_ring\(\)*](#)

EXAMPLES:

```
sage: e = RootSystem(["A",3]).ambient_space()
sage: e.smallest_base_ring()
Integer Ring
```

class sage.combinat.root_system.type_A.**CartanType**(*n*)

Bases: [*sage.combinat.root_system.cartan_type.CartanType_standard_finite*](#), [*sage.combinat.root_system.cartan_type.CartanType_simply_laced*](#), [*sage.combinat.root_system.cartan_type.CartanType_simple*](#)

Cartan Type A_n

See also:

[CartanType\(\)](#)

AmbientSpace

alias of [*AmbientSpace*](#)

PieriFactors

alias of [*sage.combinat.root_system.pieri_factors.PieriFactors_type_A*](#)

ascii_art(*label=<function CartanType.<lambda> at 0x7f8749826a60>*, *node=None*)

Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['A',0]).ascii_art())
sage: print(CartanType(['A',1]).ascii_art())
0
1
sage: print(CartanType(['A',3]).ascii_art())
0---0---0
1  2  3
sage: print(CartanType(['A',12]).ascii_art())
0---0---0---0---0---0---0---0---0---0---0---0---0---0---0---0
1  2  3  4  5  6  7  8  9  10 11 12
sage: print(CartanType(['A',5]).ascii_art(label = lambda x: x+2))
0---0---0---0---0
```

(continues on next page)

(continued from previous page)

```

3   4   5   6   7
sage: print(CartanType(['A',5]).ascii_art(label = lambda x: x-2))
0---0---0---0---0
-1  0   1   2   3

```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```

sage: CartanType(['A',4]).coxeter_number()
5

```

dual_coxeter_number()

Return the dual Coxeter number associated with self.

EXAMPLES:

```

sage: CartanType(['A',4]).dual_coxeter_number()
5

```

dynkin_diagram()

Returns the Dynkin diagram of type A.

EXAMPLES:

```

sage: a = CartanType(['A',3]).dynkin_diagram()
sage: a
0---0---0
1   2   3
A3
sage: a.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 1)]

```

5.1.240 Root system data for (untwisted) type A affine**class** sage.combinat.root_system.type_A_affine.CartanType(*n*)Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine*

EXAMPLES:

```

sage: ct = CartanType(['A',4,1])
sage: ct
['A', 4, 1]
sage: ct._repr_(compact = True)
'A4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True

```

(continues on next page)

(continued from previous page)

```

sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['A', 4]
sage: ct.dual()
['A', 4, 1]

sage: ct = CartanType(['A', 1, 1])
sage: ct.is_simply_laced()
False
sage: ct.dual()
['A', 1, 1]

```

PieriFactors

alias of `sage.combinat.root_system.pieri_factors.PieriFactors_type_A_affine`

ascii_art(label=<function CartanType.<lambda> at 0x7f874989bdc0>, node=None)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```

sage: print(CartanType(['A', 3, 1]).ascii_art())
0
0-----+
|         |
|         |
0---0---0
1  2  3

sage: print(CartanType(['A', 5, 1]).ascii_art(label = lambda x: x+2))
2
0-----+
|         |
|         |
0---0---0---0---0
3  4  5  6  7

sage: print(CartanType(['A', 1, 1]).ascii_art())
0<=>0
0  1

sage: print(CartanType(['A', 1, 1]).ascii_art(label = lambda x: x+2))
0<=>0
2  3

```

dual()

Type A_1^1 is self dual despite not being simply laced.

EXAMPLES:

```
sage: CartanType(['A', 1, 1]).dual()
['A', 1, 1]
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type A.

EXAMPLES:

```
sage: a = CartanType(['A', 3, 1]).dynkin_diagram()
sage: a
0
0-----+
|       |
|       |
0---0---0
1   2   3
A3~
sage: a.edges(sort=True)
[(0, 1, 1),
 (0, 3, 1),
 (1, 0, 1),
 (1, 2, 1),
 (2, 1, 1),
 (2, 3, 1),
 (3, 0, 1),
 (3, 2, 1)]

sage: a = DynkinDiagram(['A', 1, 1])
sage: a
0<=>0
0   1
A1~
sage: a.edges(sort=True)
[(0, 1, 2), (1, 0, 2)]
```

5.1.241 Root system data for type A infinity

class `sage.combinat.root_system.type_A_infinity.CartanType(index_set)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard`, `sage.combinat.root_system.cartan_type.CartanType_simple`

The Cartan type A_∞ .

We use NN and ZZ to explicitly differentiate between the $A_{+\infty}$ and A_∞ root systems, respectively. While oo is the same as +Infinity in Sage, it is used as an alias for ZZ.

ascii_art(*label=<function CartanType.<lambda> at 0x7f874983bca0>*, *node=None*)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['A', ZZ]).ascii_art())
..---0---0---0---0---0---0---0---..
   -3  -2  -1   0   1   2   3
```

(continues on next page)

(continued from previous page)

```
sage: print(CartanType(['A', NN]).ascii_art())
0---0---0---0---0---0---0---..
0  1  2  3  4  5  6
```

dual()

Simply laced Cartan types are self-dual, so return self.

EXAMPLES:

```
sage: CartanType(['A', NN]).dual()
['A', NN]
sage: CartanType(['A', ZZ]).dual()
['A', ZZ]
```

index_set()

Return the index set for the Cartan type self.

The index set for all standard finite Cartan types is of the form $\{1, \dots, n\}$. (See [type_I](#) for a slight abuse of this).

EXAMPLES:

```
sage: CartanType(['A', NN]).index_set()
Non negative integer semiring
sage: CartanType(['A', ZZ]).index_set()
Integer Ring
```

is_affine()

Return False because self is not (untwisted) affine.

EXAMPLES:

```
sage: CartanType(['A', NN]).is_affine()
False
sage: CartanType(['A', ZZ]).is_affine()
False
```

is_crystallographic()

Return False because self is not crystallographic.

EXAMPLES:

```
sage: CartanType(['A', NN]).is_crystallographic()
True
sage: CartanType(['A', ZZ]).is_crystallographic()
True
```

is_finite()

Return True because self is not finite.

EXAMPLES:

```
sage: CartanType(['A', NN]).is_finite()
False
sage: CartanType(['A', ZZ]).is_finite()
False
```

is_simply_laced()

Return True because self is simply laced.

EXAMPLES:

```
sage: CartanType(['A', NN]).is_simply_laced()
True
sage: CartanType(['A', ZZ]).is_simply_laced()
True
```

is_untwisted_affine()

Return False because self is not (untwisted) affine.

EXAMPLES:

```
sage: CartanType(['A', NN]).is_untwisted_affine()
False
sage: CartanType(['A', ZZ]).is_untwisted_affine()
False
```

rank()

Return the rank of self which for type X_n is n .

EXAMPLES:

```
sage: CartanType(['A', NN]).rank()
+Infinity
sage: CartanType(['A', ZZ]).rank()
+Infinity
```

As this example shows, the rank is slightly ambiguous because the root systems of type $[A', NN]$ and type $[A', ZZ]$ have the same rank. Instead, it is better to use `index_set()` to differentiate between these two root systems.

type()

Return the type of self.

EXAMPLES:

```
sage: CartanType(['A', NN]).type()
'A'
sage: CartanType(['A', ZZ]).type()
'A'
```

5.1.242 Root system data for type B

class sage.combinat.root_system.type_B.AmbientSpace(*root_system*, *base_ring*, *index_set=None*)

Bases: `sage.combinat.root_system.ambient_space.AmbientSpace`

dimension()

EXAMPLES:

```
sage: e = RootSystem(['B', 3]).ambient_space()
sage: e.dimension()
3
```

fundamental_weight(*i*)

EXAMPLES:

```
sage: RootSystem(['B',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

negative_roots()

EXAMPLES:

```
sage: RootSystem(['B',3]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, -1, 0),
 (-1, 0, 1),
 (-1, 0, -1),
 (0, -1, 1),
 (0, -1, -1),
 (-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1)]
```

positive_roots()

EXAMPLES:

```
sage: RootSystem(['B',3]).ambient_space().positive_roots()
[(1, -1, 0),
 (1, 1, 0),
 (1, 0, -1),
 (1, 0, 1),
 (0, 1, -1),
 (0, 1, 1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1)]
```

root(*i, j*)

Note that indexing starts at 0.

EXAMPLES:

```
sage: e = RootSystem(['B',3]).ambient_space()
sage: e.root(0,1)
(1, -1, 0)
```

simple_root(*i*)

EXAMPLES:

```
sage: e = RootSystem(['B',4]).ambient_space()
sage: e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 1)}
sage: e.positive_roots()
[(1, -1, 0, 0),
 (1, 1, 0, 0),
 (1, 0, -1, 0),
 (1, 0, 1, 0),
```

(continues on next page)

(continued from previous page)

```

(1, 0, 0, -1),
(1, 0, 0, 1),
(0, 1, -1, 0),
(0, 1, 1, 0),
(0, 1, 0, -1),
(0, 1, 0, 1),
(0, 0, 1, -1),
(0, 0, 1, 1),
(1, 0, 0, 0),
(0, 1, 0, 0),
(0, 0, 1, 0),
(0, 0, 0, 1)]
sage: e.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0), 4: (1/2, 1/2, ↵
↵1/2, 1/2)}

```

class `sage.combinat.root_system.type_B.CartanType(n)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_finite`, `sage.combinat.root_system.cartan_type.CartanType_simple`, `sage.combinat.root_system.cartan_type.CartanType_crystallographic`

EXAMPLES:

```

sage: ct = CartanType(['B', 4])
sage: ct
['B', 4]
sage: ct._repr_(compact = True)
'B4'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.affine()
['B', 4, 1]
sage: ct.dual()
['C', 4]

sage: ct = CartanType(['B', 1])
sage: ct.is_simply_laced()
True
sage: ct.affine()
['B', 1, 1]

```

AmbientSpace

alias of `AmbientSpace`

PieriFactors

alias of `sage.combinat.root_system.pieri_factors.PieriFactors_type_B`

ascii_art(label=<function CartanType.<lambda> at 0x7f874982b4c0>, node=None)

Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['B',1]).ascii_art())
0
1
sage: print(CartanType(['B',2]).ascii_art())
0=>=0
1 2
sage: print(CartanType(['B',5]).ascii_art(label = lambda x: x+2))
0---0---0---0=>=0
3 4 5 6 7
```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['B',4]).coxeter_number()
8
```

dual()

Types B and C are in duality:

EXAMPLES:

```
sage: CartanType(['C', 3]).dual()
['B', 3]
```

dual_coxeter_number()

Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['B',4]).dual_coxeter_number()
7
```

dynkin_diagram()

Returns a Dynkin diagram for type B.

EXAMPLES:

```
sage: b = CartanType(['B',3]).dynkin_diagram()
sage: b
0---0=>=0
1 2 3
B3
sage: b.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]

sage: b = CartanType(['B',1]).dynkin_diagram()
sage: b
```

(continues on next page)

(continued from previous page)

```

0
1
B1
sage: b.edges(sort=True)
[]

```

5.1.243 Root system data for type BC affine

class sage.combinat.root_system.type_BC_affine.CartanType(*n*)

Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_affine*

EXAMPLES:

```

sage: ct = CartanType(['BC', 4, 2])
sage: ct
['BC', 4, 2]
sage: ct._repr_(compact = True)
'BC4~'
sage: ct.dynkin_diagram()
0=<=0---0---0=<=0
0 1 2 3 4
BC4~

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['C', 4]

sage: dual = ct.dual()
sage: dual.dynkin_diagram()
0=>=0---0---0=>=0
0 1 2 3 4
BC4~*

sage: dual.special_node()
0
sage: dual.classical().dynkin_diagram()
0---0---0=>=0
1 2 3 4
B4

sage: CartanType(['BC', 1, 2]).dynkin_diagram()
4

```

(continues on next page)

(continued from previous page)

```
0=<=0
0  1
BC1~
```

ascii_art(label=<function CartanType.<lambda> at 0x7f874983f670>, node=None)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['BC',2,2]).ascii_art())
0=<=0=<=0
0  1  2
sage: print(CartanType(['BC',3,2]).ascii_art())
0=<=0---0=<=0
0  1  2  3
sage: print(CartanType(['BC',5,2]).ascii_art(label = lambda x: x+2))
0=<=0---0---0---0=<=0
2  3  4  5  6  7

sage: print(CartanType(['BC',1,2]).ascii_art(label = lambda x: x+2))
  4
0=<=0
2  3
```

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n . In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

```
sage: CartanType(['A', 2, 2]).basic_untwisted()
['A', 2]
sage: CartanType(['A', 4, 2]).basic_untwisted()
['A', 4]
sage: CartanType(['BC', 4, 2]).basic_untwisted()
['A', 8]
```

classical()

Returns the classical Cartan type associated with self

```
sage: CartanType(["BC", 3, 2]).classical() ['C', 3]
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type BC.

EXAMPLES:

```
sage: c = CartanType(['BC',3,2]).dynkin_diagram()
sage: c
0=<=0---0=<=0
0  1  2  3
BC3~
sage: c.edges(sort=True)
```

(continues on next page)

(continued from previous page)

```

[(0, 1, 1), (1, 0, 2), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]

sage: c = CartanType(["A", 6, 2]).dynkin_diagram() # should be the same as_
↳above; did fail at some point!
sage: c
0=<=0---0=<=0
0  1  2  3
BC3~
sage: c.edges(sort=True)
[(0, 1, 1), (1, 0, 2), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]

sage: c = CartanType(['BC', 2, 2]).dynkin_diagram()
sage: c
0=<=0=<=0
0  1  2
BC2~
sage: c.edges(sort=True)
[(0, 1, 1), (1, 0, 2), (1, 2, 1), (2, 1, 2)]

sage: c = CartanType(['BC', 1, 2]).dynkin_diagram()
sage: c
4
0=<=0
0  1
BC1~
sage: c.edges(sort=True)
[(0, 1, 1), (1, 0, 4)]

```

5.1.244 Root system data for (untwisted) type B affine

class sage.combinat.root_system.type_B_affine.**CartanType**(*n*)

Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine*

EXAMPLES:

```

sage: ct = CartanType(['B', 4, 1])
sage: ct
['B', 4, 1]
sage: ct._repr_(compact = True)
'B4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True

```

(continues on next page)

(continued from previous page)

```

sage: ct.is_simply_laced()
False
sage: ct.classical()
['B', 4]
sage: ct.dual()
['B', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False

```

PieriFactors

alias of `sage.combinat.root_system.pieri_factors.PieriFactors_type_B_affine`

ascii_art(label=<function CartanType.<lambda> at 0x7f87498a53a0>, node=None)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```

sage: print(CartanType(['B',3,1]).ascii_art())
  0 0
  |
  |
0---0=>=0
1  2  3

sage: print(CartanType(['B',5,1]).ascii_art(label = lambda x: x+2))
  0 2
  |
  |
0---0---0---0=>=0
3  4  5  6  7

sage: print(CartanType(['B',2,1]).ascii_art(label = lambda x: x+2))
0=>=0<=0
2  4  3

sage: print(CartanType(['B',1,1]).ascii_art(label = lambda x: x+2))
0<=>0
2  3

```

dynkin_diagram()

Return the extended Dynkin diagram for affine type B .

EXAMPLES:

```

sage: b = CartanType(['B',3,1]).dynkin_diagram()
sage: b
  0 0
  |
  |
0---0=>=0
1  2  3
B3~
sage: b.edges(sort=True)
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]

```

(continues on next page)

(continued from previous page)

```

sage: b = CartanType(['B',2,1]).dynkin_diagram(); b
0=>=0<=0
0  2  1
B2~
sage: b.edges(sort=True)
[(0, 2, 2), (1, 2, 2), (2, 0, 1), (2, 1, 1)]

sage: b = CartanType(['B',1,1]).dynkin_diagram(); b
0<=>0
0  1
B1~
sage: b.edges(sort=True)
[(0, 1, 2), (1, 0, 2)]

```

5.1.245 Root system data for type C

class sage.combinat.root_system.type_C.AmbientSpace(*root_system, base_ring, index_set=None*)
 Bases: *sage.combinat.root_system.ambient_space.AmbientSpace*

EXAMPLES:

```

sage: e = RootSystem(['C',2]).ambient_space(); e
Ambient space of the Root system of type ['C', 2]

```

One cannot construct the ambient lattice because the fundamental coweights have rational coefficients:

```

sage: e.smallest_base_ring()
Rational Field

sage: RootSystem(['B',2]).ambient_space().fundamental_weights()
Finite family {1: (1, 0), 2: (1/2, 1/2)}

```

dimension()

EXAMPLES:

```

sage: e = RootSystem(['C',3]).ambient_space()
sage: e.dimension()
3

```

fundamental_weight(*i*)

EXAMPLES:

```

sage: RootSystem(['C',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1, 1, 1)}

```

negative_roots()

EXAMPLES:

```

sage: RootSystem(['C',3]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, 0, 1),
 (0, -1, 1),

```

(continues on next page)

(continued from previous page)

```
(-1, -1, 0),
(-1, 0, -1),
(0, -1, -1),
(-2, 0, 0),
(0, -2, 0),
(0, 0, -2)]
```

positive_roots()

EXAMPLES:

```
sage: RootSystem(['C',3]).ambient_space().positive_roots()
[(1, 1, 0),
 (1, 0, 1),
 (0, 1, 1),
 (1, -1, 0),
 (1, 0, -1),
 (0, 1, -1),
 (2, 0, 0),
 (0, 2, 0),
 (0, 0, 2)]
```

root(*i, j, p1, p2*)

Note that indexing starts at 0.

EXAMPLES:

```
sage: e = RootSystem(['C',3]).ambient_space()
sage: e.root(0, 1, 1, 1)
(-1, -1, 0)
```

simple_root(*i*)

EXAMPLES:

```
sage: RootSystem(['C',3]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0), 2: (0, 1, -1), 3: (0, 0, 2)}
```

class sage.combinat.root_system.type_C.CartanType(*n*)

Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_finite*, *sage.combinat.root_system.cartan_type.CartanType_simple*, *sage.combinat.root_system.cartan_type.CartanType_crystallographic*

EXAMPLES:

```
sage: ct = CartanType(['C',4])
sage: ct
['C', 4]
sage: ct._repr_(compact = True)
'C4'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
```

(continues on next page)

(continued from previous page)

```

True
sage: ct.is_simply_laced()
False
sage: ct.affine()
['C', 4, 1]
sage: ct.dual()
['B', 4]

sage: ct = CartanType(['C', 1])
sage: ct.is_simply_laced()
True
sage: ct.affine()
['C', 1, 1]

```

AmbientSpacealias of *AmbientSpace***ascii_art**(label=<function CartanType.<lambda> at 0x7f87498483a0>, node=None)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```

sage: print(CartanType(['C', 1]).ascii_art())
0
1
sage: print(CartanType(['C', 2]).ascii_art())
0=<=0
1 2
sage: print(CartanType(['C', 3]).ascii_art())
0---0=<=0
1 2 3
sage: print(CartanType(['C', 5]).ascii_art(label = lambda x: x+2))
0---0---0---0=<=0
3 4 5 6 7

```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```

sage: CartanType(['C', 4]).coxeter_number()
8

```

dual()

Types B and C are in duality:

EXAMPLES:

```

sage: CartanType(["C", 3]).dual()
['B', 3]

```

dual_coxeter_number()

Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['C',4]).dual_coxeter_number()
5
```

dynkin_diagram()

Returns a Dynkin diagram for type C.

EXAMPLES:

```
sage: c = CartanType(['C',3]).dynkin_diagram()
sage: c
0---0=<=0
1  2  3
C3
sage: c.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]

sage: b = CartanType(['C',1]).dynkin_diagram()
sage: b
0
1
C1
sage: b.edges(sort=True)
[]
```

5.1.246 Root system data for (untwisted) type C affine

class sage.combinat.root_system.type_C_affine.**CartanType**(*n*)

Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine*

EXAMPLES:

```
sage: ct = CartanType(['C',4,1])
sage: ct
['C', 4, 1]
sage: ct._repr_(compact = True)
'C4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['C', 4]
sage: ct.dual()
```

(continues on next page)

(continued from previous page)

```
['C', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

PieriFactors

alias of `sage.combinat.root_system.pieri_factors.PieriFactors_type_C_affine`

ascii_art(label=<function CartanType.<lambda> at 0x7f87498a58b0>, node=None)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['C',5,1]).ascii_art(label = lambda x: x+2))
0=>=0---0---0---0<=0
2 3 4 5 6 7

sage: print(CartanType(['C',3,1]).ascii_art())
0=>=0---0<=0
0 1 2 3

sage: print(CartanType(['C',2,1]).ascii_art())
0=>=0<=0
0 1 2

sage: print(CartanType(['C',1,1]).ascii_art())
0<=>0
0 1
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type C.

EXAMPLES:

```
sage: c = CartanType(['C',3,1]).dynkin_diagram()
sage: c
0=>=0---0<=0
0 1 2 3
C3~
sage: c.edges(sort=True)
[(0, 1, 2), (1, 0, 1), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
```

5.1.247 Root system data for type D

class `sage.combinat.root_system.type_D.AmbientSpace`(*root_system*, *base_ring*, *index_set=None*)

Bases: `sage.combinat.root_system.ambient_space.AmbientSpace`

dimension()

EXAMPLES:

```
sage: e = RootSystem(['D',3]).ambient_space()
sage: e.dimension()
3
```

fundamental_weight(*i*)

EXAMPLES:

```
sage: RootSystem(['D',4]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1/2, 1/2, 1/2, -1/2), 4:
↪(1/2, 1/2, 1/2, 1/2)}
```

negative_roots()

EXAMPLES:

```
sage: RootSystem(['D',4]).ambient_space().negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (0, -1, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 0, 1),
 (0, 0, -1, 1),
 (-1, -1, 0, 0),
 (-1, 0, -1, 0),
 (0, -1, -1, 0),
 (-1, 0, 0, -1),
 (0, -1, 0, -1),
 (0, 0, -1, -1)]
```

positive_roots()

EXAMPLES:

```
sage: RootSystem(['D',4]).ambient_space().positive_roots()
[(1, 1, 0, 0),
 (1, 0, 1, 0),
 (0, 1, 1, 0),
 (1, 0, 0, 1),
 (0, 1, 0, 1),
 (0, 0, 1, 1),
 (1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]
```

root(*i, j, p1, p2*)

Note that indexing starts at 0.

EXAMPLES:

```
sage: e = RootSystem(['D',3]).ambient_space()
sage: e.root(0, 1, 1, 1)
(-1, -1, 0)
sage: e.root(0, 0, 1, 1)
(-1, 0, 0)
```

simple_root(*i*)

EXAMPLES:

```
sage: RootSystem(['D',4]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 1,
↪1, 1)}
```

class sage.combinat.root_system.type_D.**CartanType**(*n*)

Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_finite*, *sage.combinat.root_system.cartan_type.CartanType_simply_laced*

EXAMPLES:

```
sage: ct = CartanType(['D',4])
sage: ct
['D', 4]
sage: ct._repr_(compact = True)
'D4'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.dual()
['D', 4]
sage: ct.affine()
['D', 4, 1]

sage: ct = CartanType(['D',2])
sage: ct.is_irreducible()
False
sage: ct.dual()
['D', 2]
sage: ct.affine()
Traceback (most recent call last):
...
ValueError: ['D', 2, 1] is not a valid Cartan type
```

AmbientSpace

alias of *AmbientSpace*

ascii_art(*label=<function CartanType.<lambda> at 0x7f8749848dc0>*, *node=None*)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['D',3]).ascii_art())
0 3
|
|
0---0
1 2
sage: print(CartanType(['D',4]).ascii_art())
```

(continues on next page)

(continued from previous page)

```

    0 4
    |
    |
0---0---0
1  2  3
sage: print(CartanType(['D',4]).ascii_art(label = lambda x: x+2))
    0 6
    |
    |
0---0---0
3  4  5
sage: print(CartanType(['D',6]).ascii_art(label = lambda x: x+2))
                0 8
                |
                |
0---0---0---0---0
3  4  5  6  7

```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['D',4]).coxeter_number()
6
```

dual_coxeter_number()

Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['D',4]).dual_coxeter_number()
6
```

dynkin_diagram()

Returns a Dynkin diagram for type D.

EXAMPLES:

```
sage: d = CartanType(['D',5]).dynkin_diagram(); d
    0 5
    |
    |
0---0---0---0
1  2  3  4
D5
sage: d.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 1), (3, 4, 1), (3, 5, 1), (4, 3, 1),
↪(5, 3, 1)]

sage: d = CartanType(['D',4]).dynkin_diagram(); d
    0 4
    |
    |

```

(continues on next page)

(continued from previous page)

```

0---0---0
1  2  3
D4
sage: d.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (2, 4, 1), (3, 2, 1), (4, 2, 1)]

sage: d = CartanType(['D',3]).dynkin_diagram(); d
0 3
|
|
0---0
1  2
D3
sage: d.edges(sort=True)
[(1, 2, 1), (1, 3, 1), (2, 1, 1), (3, 1, 1)]

sage: d = CartanType(['D',2]).dynkin_diagram(); d
0  0
1  2
D2
sage: d.edges(sort=True)
[]

```

is_atomic()

Implements `CartanType_abstract.is_atomic()`

D_2 is atomic, like all D_n , despite being non irreducible.

EXAMPLES:

```

sage: CartanType(["D",2]).is_atomic()
True
sage: CartanType(["D",2]).is_irreducible()
False

```

5.1.248 Root system data for (untwisted) type D affine

class `sage.combinat.root_system.type_D_affine.CartanType(n)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine`,
`sage.combinat.root_system.cartan_type.CartanType_simply_laced`

EXAMPLES:

```

sage: ct = CartanType(['D',4,1])
sage: ct
['D', 4, 1]
sage: ct._repr_(compact = True)
'D4~'

sage: ct.is_irreducible()
True

```

(continues on next page)

(continued from previous page)

```

sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['D', 4]
sage: ct.dual()
['D', 4, 1]

```

PieriFactors

alias of `sage.combinat.root_system.pieri_factors.PieriFactors_type_D_affine`

ascii_art(label=<function CartanType.<lambda> at 0x7f87498a5dc0>, node=None)

Return an ascii art representation of the extended Dynkin diagram.

dynkin_diagram()

Returns the extended Dynkin diagram for affine type D.

EXAMPLES:

```

sage: d = CartanType(['D', 6, 1]).dynkin_diagram()
sage: d
  0 0          0 6
  |           |
  |           |
0---0---0---0---0
1  2  3  4  5
D6~
sage: d.edges(sort=True)
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 1),
 (3, 2, 1), (3, 4, 1), (4, 3, 1), (4, 5, 1), (4, 6, 1), (5, 4, 1), (6, 4, 1)]

sage: d = CartanType(['D', 4, 1]).dynkin_diagram()
sage: d
  0 4
  |
  |
0---0---0
1  |2  3
  |
  0 0
D4~
sage: d.edges(sort=True)
[(0, 2, 1),
 (1, 2, 1),
 (2, 0, 1),
 (2, 1, 1),
 (2, 3, 1),

```

(continues on next page)

(continued from previous page)

```

(2, 4, 1),
(3, 2, 1),
(4, 2, 1)]

sage: d = CartanType(['D', 3, 1]).dynkin_diagram()
sage: d
0
0-----+
|         |
|         |
0---0---0
3   1   2
D3~
sage: d.edges(sort=True)
[(0, 2, 1), (0, 3, 1), (1, 2, 1), (1, 3, 1), (2, 0, 1), (2, 1, 1), (3, 0, 1), ↵
↵(3, 1, 1)]

```

5.1.249 Root system data for type E

class sage.combinat.root_system.type_E.AmbientSpace(*root_system, baseRing*)

Bases: *sage.combinat.root_system.ambient_space.AmbientSpace*

The lattice behind E6, E7, or E8. The computations are based on Bourbaki, Groupes et Algèbres de Lie, Ch. 4,5,6 (planche V-VII).

dimension()

EXAMPLES:

```

sage: e = RootSystem(['E', 6]).ambient_space()
sage: e.dimension()
8

```

fundamental_weights()

EXAMPLES:

```

sage: e = RootSystem(['E', 6]).ambient_space()
sage: e.fundamental_weights()
Finite family {1: (0, 0, 0, 0, 0, -2/3, -2/3, 2/3), 2: (1/2, 1/2, 1/2, 1/2, 1/2,
↵ -1/2, -1/2, 1/2), 3: (-1/2, 1/2, 1/2, 1/2, 1/2, -5/6, -5/6, 5/6), 4: (0, 0, ↵
↵1, 1, 1, -1, -1, 1), 5: (0, 0, 0, 1, 1, -2/3, -2/3, 2/3), 6: (0, 0, 0, 0, 1, -
↵1/3, -1/3, 1/3)}

```

negative_roots()

The negative roots.

EXAMPLES:

```

sage: e = RootSystem(['E', 6]).ambient_space()
sage: e.negative_roots()
[(-1, -1, 0, 0, 0, 0, 0, 0),
(-1, 0, -1, 0, 0, 0, 0, 0),
(-1, 0, 0, -1, 0, 0, 0, 0),

```

(continues on next page)

(continued from previous page)

```

(-1, 0, 0, 0, -1, 0, 0, 0),
(0, -1, -1, 0, 0, 0, 0, 0),
(0, -1, 0, -1, 0, 0, 0, 0),
(0, -1, 0, 0, -1, 0, 0, 0),
(0, 0, -1, -1, 0, 0, 0, 0),
(0, 0, -1, 0, -1, 0, 0, 0),

```

positive_roots()

These are the roots positive w.r. to lexicographic ordering of the basis elements ($e_1 < \dots < e_4$).

EXAMPLES:

```

sage: e = RootSystem(['E', 6]).ambient_space()
sage: e.positive_roots()
[(1, 1, 0, 0, 0, 0, 0, 0),
 (1, 0, 1, 0, 0, 0, 0, 0),
 (1, 0, 0, 1, 0, 0, 0, 0),
 (1, 0, 0, 0, 1, 0, 0, 0),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 0, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 1, 0, 0, 0),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 0, 1, 0, 1, 0, 0, 0),
 (0, 0, 0, 1, 1, 0, 0, 0),
 (-1, 1, 0, 0, 0, 0, 0, 0),
 (-1, 0, 1, 0, 0, 0, 0, 0),

```

```

sage: e.rho()

(0, 1, 2, 3, 4, 5, 6, 23)

root(i1, i2=None, i3=None, i4=None, i5=None, i6=None, i7=None, i8=None, p1=0, p2=0, p3=0, p4=0, p5=0, p6=0, p7=0, p8=0)

Compute an element of the underlying lattice, using the specified elements of the standard basis, with signs dictated by the corresponding ‘pi’ arguments. We rely on the caller to provide the correct arguments. This is typically used to generate roots, although the generated elements need not be roots themselves. We assume

that if one of the indices is not given, the rest are not as well. This should work for E6, E7, E8.

EXAMPLES:

```
sage: e = RootSystem(['E',6]).ambient_space()
sage: [ e.root(i, j, p3=1) for i in range(e.n) for j in range(i+1, e.n) ]
[(1, 1, 0, 0, 0, 0, 0, 0),
 (1, 0, 1, 0, 0, 0, 0, 0),
 (1, 0, 0, 1, 0, 0, 0, 0),
 (1, 0, 0, 0, 1, 0, 0, 0),
 (1, 0, 0, 0, 0, 1, 0, 0),
 (1, 0, 0, 0, 0, 0, 1, 0),
 (1, 0, 0, 0, 0, 0, 0, 1),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 0, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 1, 0, 0, 0),
 (0, 1, 0, 0, 0, 1, 0, 0),
 (0, 1, 0, 0, 0, 0, 1, 0),
 (0, 1, 0, 0, 0, 0, 0, 1),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 0, 1, 0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0, 1, 0, 0),
 (0, 0, 1, 0, 0, 0, 1, 0),
 (0, 0, 1, 0, 0, 0, 0, 1),
 (0, 0, 0, 1, 1, 0, 0, 0),
 (0, 0, 0, 1, 0, 1, 0, 0),
 (0, 0, 0, 1, 0, 0, 1, 0),
 (0, 0, 0, 1, 0, 0, 0, 1),
 (0, 0, 0, 0, 1, 1, 0, 0),
 (0, 0, 0, 0, 1, 0, 1, 0),
 (0, 0, 0, 0, 1, 0, 0, 1),
 (0, 0, 0, 0, 0, 1, 1, 0),
 (0, 0, 0, 0, 0, 1, 0, 1),
 (0, 0, 0, 0, 0, 0, 1, 1)]
```

`simple_root(i)`

There are computed as what Bourbaki calls the Base: $a_1 = e_2 - e_3$, $a_2 = e_3 - e_4$, $a_3 = e_4$, $a_4 = 1/2*(e_1 - e_2 - e_3 - e_4)$

EXAMPLES:

```
sage: LE6 = RootSystem(['E',6]).ambient_space()
sage: LE6.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2, -1/2, -1/2, -1/2, 1/2), 2: (1, 1, 0,
↪0, 0, 0, 0, 0), 3: (-1, 1, 0, 0, 0, 0, 0, 0), 4: (0, -1, 1, 0, 0, 0, 0, 0),
↪5: (0, 0, -1, 1, 0, 0, 0, 0), 6: (0, 0, 0, -1, 1, 0, 0, 0)}
```

`class sage.combinat.root_system.type_E.CartanType(n)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_finite`, `sage.combinat.root_system.cartan_type.CartanType_simple`, `sage.combinat.root_system.cartan_type.CartanType_simply_laced`

EXAMPLES:

```

sage: ct = CartanType(['E',6])
sage: ct
['E', 6]
sage: ct._repr_(compact = True)
'E6'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.affine()
['E', 6, 1]
sage: ct.dual()
['E', 6]

```

AmbientSpace

alias of [AmbientSpace](#)

ascii_art(label=<function CartanType.<lambda> at 0x7f8749853790>, node=None)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```

sage: print(CartanType(['E',6]).ascii_art(label = lambda x: x+2))
      0 4
      |
      |
0---0---0---0---0
3  5  6  7  8
sage: print(CartanType(['E',7]).ascii_art(label = lambda x: x+2))
      0 4
      |
      |
0---0---0---0---0---0
3  5  6  7  8  9
sage: print(CartanType(['E',8]).ascii_art(label = lambda x: x+1))
      0 3
      |
      |
0---0---0---0---0---0---0
2  4  5  6  7  8  9

```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```

sage: CartanType(['E',6]).coxeter_number()
12

```

(continues on next page)

(continued from previous page)

```
sage: CartanType(['E',7]).coxeter_number()
18
sage: CartanType(['E',8]).coxeter_number()
30
```

dual_coxeter_number()

Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['E',6]).dual_coxeter_number()
12
sage: CartanType(['E',7]).dual_coxeter_number()
18
sage: CartanType(['E',8]).dual_coxeter_number()
30
```

dynkin_diagram()

Returns a Dynkin diagram for type E.

EXAMPLES:

```
sage: e = CartanType(['E',6]).dynkin_diagram()
sage: e
      0 2
      |
      |
0---0---0---0---0
1  3  4  5  6
E6
sage: e.edges(sort=True)
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1), (4, 3, 1), (4, 5, 1),
 (5, 4, 1), (5, 6, 1), (6, 5, 1)]
sage: e = CartanType(['E',7]).dynkin_diagram()
sage: e
      0 2
      |
      |
0---0---0---0---0---0
1  3  4  5  6  7
E7
sage: e.edges(sort=True)
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1),
 (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1), (6, 5, 1),
 (6, 7, 1), (7, 6, 1)]
sage: e = CartanType(['E',8]).dynkin_diagram()
sage: e
      0 2
      |
      |
0---0---0---0---0---0---0
1  3  4  5  6  7  8
E8
```

(continues on next page)

(continued from previous page)

```

sage: e.edges(sort=True)
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1),
 (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1), (6, 5, 1),
 (6, 7, 1), (7, 6, 1), (7, 8, 1), (8, 7, 1)]

```

5.1.250 Root system data for (untwisted) type E affine

class `sage.combinat.root_system.type_E_affine.CartanType(n)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine`,
`sage.combinat.root_system.cartan_type.CartanType_simply_laced`

EXAMPLES:

```

sage: ct = CartanType(['E',6,1])
sage: ct
['E', 6, 1]
sage: ct._repr_(compact = True)
'E6~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['E', 6]
sage: ct.dual()
['E', 6, 1]

```

ascii_art(*label=<function CartanType.<lambda> at 0x7f8749853c10>*, *node=None*)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```

sage: print(CartanType(['E',6,1]).ascii_art(label = lambda x: x+2))
      0 2
      |
      |
      0 4
      |
      |
0---0---0---0---0
3  5  6  7  8
sage: print(CartanType(['E',7,1]).ascii_art(label = lambda x: x+2))
      0 4

```

(continues on next page)

(continued from previous page)

```

      |
      |
0---0---0---0---0---0---0
2  3  5  6  7  8  9
sage: print(CartanType(['E',8,1]).ascii_art(label = lambda x: x-3))
      0 -1
      |
      |
0---0---0---0---0---0---0
-2  0  1  2  3  4  5  -3

```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type E.

EXAMPLES:

```

sage: e = CartanType(['E', 6, 1]).dynkin_diagram()
sage: e
      0 0
      |
      |
      0 2
      |
      |
0---0---0---0---0
1  3  4  5  6
E6~
sage: e.edges(sort=True)
[(0, 2, 1),
 (1, 3, 1),
 (2, 0, 1),
 (2, 4, 1),
 (3, 1, 1),
 (3, 4, 1),
 (4, 2, 1),
 (4, 3, 1),
 (4, 5, 1),
 (5, 4, 1),
 (5, 6, 1),
 (6, 5, 1)]

sage: e = CartanType(['E', 7, 1]).dynkin_diagram()
sage: e
      0 2
      |
      |
0---0---0---0---0---0
0  1  3  4  5  6  7
E7~
sage: e.edges(sort=True)
[(0, 1, 1), (1, 0, 1), (1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1),
 (4, 2, 1), (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1),
 (6, 5, 1), (6, 7, 1), (7, 6, 1)]

```

(continues on next page)

(continued from previous page)

```

sage: e = CartanType(['E', 8, 1]).dynkin_diagram()
sage: e
      0 2
      |
      |
0---0---0---0---0---0---0---0
1  3  4  5  6  7  8  0
E8~
sage: e.edges(sort=True)
[(0, 8, 1), (1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1),
 (4, 2, 1), (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1),
 (6, 5, 1), (6, 7, 1), (7, 6, 1), (7, 8, 1), (8, 0, 1), (8, 7, 1)]

```

5.1.251 Root system data for type F

class sage.combinat.root_system.type_F.AmbientSpace(*root_system, base_ring*)

Bases: *sage.combinat.root_system.ambient_space.AmbientSpace*

The lattice behind F_4 . The computations are based on Bourbaki, Groupes et Algèbres de Lie, Ch. 4,5,6 (planche VIII).

dimension()

Return the dimension of self.

EXAMPLES:

```

sage: e = RootSystem(['F', 4]).ambient_space()
sage: e.dimension()
4

```

fundamental_weights()

Return the fundamental weights of self.

EXAMPLES:

```

sage: e = RootSystem(['F', 4]).ambient_space()
sage: e.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1,
↪ 0, 0, 0)}

```

negative_roots()

Return the negative roots.

EXAMPLES:

```

sage: e = RootSystem(['F', 4]).ambient_space()
sage: e.negative_roots()
[(-1, 0, 0, 0),
 (0, -1, 0, 0),
 (0, 0, -1, 0),
 (0, 0, 0, -1),
 (-1, -1, 0, 0),
 (-1, 0, -1, 0),

```

(continues on next page)

(continued from previous page)

```

(-1, 0, 0, -1),
(0, -1, -1, 0),
(0, -1, 0, -1),
(0, 0, -1, -1),
(-1, 1, 0, 0),
(-1, 0, 1, 0),
(-1, 0, 0, 1),
(0, -1, 1, 0),
(0, -1, 0, 1),
(0, 0, -1, 1),
(-1/2, -1/2, -1/2, -1/2),
(-1/2, -1/2, -1/2, 1/2),
(-1/2, -1/2, 1/2, -1/2),
(-1/2, -1/2, 1/2, 1/2),
(-1/2, 1/2, -1/2, -1/2),
(-1/2, 1/2, -1/2, 1/2),
(-1/2, 1/2, 1/2, -1/2),
(-1/2, 1/2, 1/2, 1/2)]

```

positive_roots()

Return the positive roots.

These are the roots which are positive with respect to the lexicographic ordering of the basis elements $(\epsilon_1 < \epsilon_2 < \epsilon_3 < \epsilon_4)$.

EXAMPLES:

```

sage: e = RootSystem(['F', 4]).ambient_space()
sage: e.positive_roots()
[(1, 0, 0, 0),
(0, 1, 0, 0),
(0, 0, 1, 0),
(0, 0, 0, 1),
(1, 1, 0, 0),
(1, 0, 1, 0),
(1, 0, 0, 1),
(0, 1, 1, 0),
(0, 1, 0, 1),
(0, 0, 1, 1),
(1, -1, 0, 0),
(1, 0, -1, 0),
(1, 0, 0, -1),
(0, 1, -1, 0),
(0, 1, 0, -1),
(0, 0, 1, -1),
(1/2, 1/2, 1/2, 1/2),
(1/2, 1/2, 1/2, -1/2),
(1/2, 1/2, -1/2, 1/2),
(1/2, 1/2, -1/2, -1/2),
(1/2, -1/2, 1/2, 1/2),
(1/2, -1/2, 1/2, -1/2),
(1/2, -1/2, -1/2, 1/2),
(1/2, -1/2, -1/2, -1/2)]

```

(continues on next page)

(continued from previous page)

```
sage: e.rho()
(11/2, 5/2, 3/2, 1/2)
```

root(*i*, *j=None*, *k=None*, *l=None*, *p1=0*, *p2=0*, *p3=0*, *p4=0*)

Compute a root from base elements of the underlying lattice. The arguments specify the basis elements and the signs. Sadly, the base elements are indexed zero-based. We assume that if one of the indices is not given, the rest are not as well.

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: [ e.root(i,j,p2=1) for i in range(e.n) for j in range(i+1,e.n) ]
[(1, -1, 0, 0), (1, 0, -1, 0), (1, 0, 0, -1), (0, 1, -1, 0), (0, 1, 0, -1), (0, 0, 1, -1)]
```

simple_root(*i*)

Return the *i*-th simple root.

It is computed according to what Bourbaki calls the Base:

$$\alpha_1 = \epsilon_2 - \epsilon_3, \alpha_2 = \epsilon_3 - \epsilon_4, \alpha_3 = \epsilon_4, \alpha_4 = \frac{1}{2}(\epsilon_1 - \epsilon_2 - \epsilon_3 - \epsilon_4).$$

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}
```

class sage.combinat.root_system.type_F.CartanType

Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_finite*, *sage.combinat.root_system.cartan_type.CartanType_simple*, *sage.combinat.root_system.cartan_type.CartanType_crystallographic*

EXAMPLES:

```
sage: ct = CartanType(['F',4])
sage: ct
['F', 4]
sage: ct._repr_(compact = True)
'F4'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.affine()
['F', 4, 1]
```

AmbientSpacealias of *AmbientSpace***ascii_art**(label=<function CartanType.<lambda> at 0x7f874985b8b0>, node=None)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['F',4]).ascii_art(label = lambda x: x+2))
0---0=>=0---0
3  4  5  6
sage: print(CartanType(['F',4]).ascii_art(label = lambda x: x-2))
0---0=>=0---0
-1  0  1  2
```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['F',4]).coxeter_number()
12
```

dual()

Return the dual Cartan type.

This uses that F_4 is self-dual up to relabelling.

EXAMPLES:

```
sage: F4 = CartanType(['F',4])
sage: F4.dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}

sage: F4.dynkin_diagram()
0---0=>=0---0
1  2  3  4
F4
sage: F4.dual().dynkin_diagram()
0---0=>=0---0
4  3  2  1
F4 relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

dual_coxeter_number()

Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['F',4]).dual_coxeter_number()
9
```

dynkin_diagram()

Returns a Dynkin diagram for type F.

EXAMPLES:

```
sage: f = CartanType(['F',4]).dynkin_diagram()
sage: f
```

(continues on next page)

(continued from previous page)

```

0---0=>=0---0
1  2  3  4
F4
sage: f.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1), (3, 4, 1), (4, 3, 1)]

```

5.1.252 Root system data for (untwisted) type F affine

class `sage.combinat.root_system.type_F_affine.CartanType`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine`

EXAMPLES:

```

sage: ct = CartanType(['F', 4, 1])
sage: ct
['F', 4, 1]
sage: ct._repr_(compact = True)
'F4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['F', 4]
sage: ct.dual()
['F', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False

```

ascii_art(*label*=<function CartanType.<lambda> at 0x7f874985bdc0>, *node*=None)

Returns a ascii art representation of the extended Dynkin diagram

EXAMPLES:

```

sage: print(CartanType(['F', 4, 1]).ascii_art(label = lambda x: x+2))
0---0---0=>=0---0
2  3  4  5  6

```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type F.

EXAMPLES:

```

sage: f = CartanType(['F', 4, 1]).dynkin_diagram()
sage: f
0---0---0=>=0---0
0  1  2  3  4
F4~
sage: f.edges(sort=True)
[(0, 1, 1), (1, 0, 1), (1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1), (3, 4, 1),
 ↪(4, 3, 1)]

```

5.1.253 Root system data for type G

```

class sage.combinat.root_system.type_G.AmbientSpace(root_system, base_ring, index_set=None)
Bases: sage.combinat.root_system.ambient_space.AmbientSpace

```

EXAMPLES:

```

sage: e = RootSystem(['G', 2]).ambient_space(); e
Ambient space of the Root system of type ['G', 2]

```

One can not construct the ambient lattice because the simple coroots have rational coefficients:

```

sage: e.simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
sage: e.smallest_base_ring()
Rational Field

```

By default, this ambient space uses the barycentric projection for plotting:

```

sage: L = RootSystem(["G", 2]).ambient_space()
sage: e = L.basis()
sage: L._plot_projection(e[0])
(1/2, 989/1142)
sage: L._plot_projection(e[1])
(-1, 0)
sage: L._plot_projection(e[2])
(1/2, -989/1142)
sage: L = RootSystem(["A", 3]).ambient_space()
sage: l = L.an_element(); l
(2, 2, 3, 0)
sage: L._plot_projection(l)
(0, -1121/1189, 7/3)

```

See also:

- `sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations.ParentMethods._plot_projection()`

dimension()

EXAMPLES:

```

sage: e = RootSystem(['G', 2]).ambient_space()
sage: e.dimension()
3

```

fundamental_weights()

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

negative_roots()

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().negative_roots()
[(0, -1, 1), (-1, 2, -1), (-1, 1, 0), (-1, 0, 1), (-1, -1, 2), (-2, 1, 1)]
```

positive_roots()

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

simple_root(i)

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

class sage.combinat.root_system.type_G.CartanType

Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_finite*, *sage.combinat.root_system.cartan_type.CartanType_simple*, *sage.combinat.root_system.cartan_type.CartanType_crystallographic*

EXAMPLES:

```
sage: ct = CartanType(['G',2])
sage: ct
['G', 2]
sage: ct._repr(compact = True)
'G2'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.dual()
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
['G', 2, 1]
```

AmbientSpacealias of *AmbientSpace***ascii_art(label=<function CartanType.<lambda> at 0x7f87497e1820>, node=None)**

Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['G',2]).ascii_art(label= $\lambda$  x: x+2))
3
0=<=0
3 4
```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['G',2]).coxeter_number()
6
```

dual()

Return the dual Cartan type.

This uses that G_2 is self-dual up to relabelling.

EXAMPLES:

```
sage: G2 = CartanType(['G',2])
sage: G2.dual()
['G', 2] relabelled by {1: 2, 2: 1}

sage: G2.dynkin_diagram()
3
0=<=0
1 2
G2
sage: G2.dual().dynkin_diagram()
3
0=<=0
2 1
G2 relabelled by {1: 2, 2: 1}
```

dual_coxeter_number()

Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['G',2]).dual_coxeter_number()
4
```

dynkin_diagram()

Returns a Dynkin diagram for type G.

EXAMPLES:

```
sage: g = CartanType(['G',2]).dynkin_diagram()
sage: g
3
0=<=0
1 2
G2
sage: g.edges(sort=True)
[(1, 2, 1), (2, 1, 3)]
```

5.1.254 Root system data for (untwisted) type G affine

class `sage.combinat.root_system.type_G_affine.CartanType`
 Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine`

EXAMPLES:

```
sage: ct = CartanType(['G',2,1])
sage: ct
['G', 2, 1]
sage: ct._repr_(compact = True)
'G2~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['G', 2]
sage: ct.dual()
['G', 2, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

ascii_art(*label=<function CartanType.<lambda> at 0x7f87497e1dc0>, node=None*)
 Returns an ascii art representation of the Dynkin diagram

EXAMPLES:

```
sage: print(CartanType(['G',2,1]).ascii_art(label = lambda x: x+2))
  3
0=<=0---0
3  4  2
```

dynkin_diagram()

Returns the extended Dynkin diagram for type G.

EXAMPLES:

```
sage: g = CartanType(['G',2,1]).dynkin_diagram()
sage: g
  3
0=<=0---0
1  2  0
G2~
sage: g.edges(sort=True)
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 3)]
```

5.1.255 Root system data for type H

class `sage.combinat.root_system.type_H.CartanType(n)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_finite`, `sage.combinat.root_system.cartan_type.CartanType_simple`

EXAMPLES:

```
sage: ct = CartanType(['H', 3])
sage: ct
['H', 3]
sage: ct._repr_(compact = True)
'H3'
sage: ct.rank()
3

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
False
sage: ct.is_simply_laced()
False
```

coxeter_diagram()

Returns a Coxeter diagram for type H.

EXAMPLES:

```
sage: ct = CartanType(['H', 3])
sage: ct.coxeter_diagram()
Graph on 3 vertices
sage: ct.coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 5)]
sage: ct.coxeter_matrix()
[1 3 2]
[3 1 5]
[2 5 1]

sage: ct = CartanType(['H', 4])
sage: ct.coxeter_diagram()
Graph on 4 vertices
sage: ct.coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 3), (3, 4, 5)]
sage: ct.coxeter_matrix()
[1 3 2 2]
[3 1 3 2]
[2 3 1 5]
[2 2 5 1]
```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['H', 3]).coxeter_number()
10
sage: CartanType(['H', 4]).coxeter_number()
30
```

5.1.256 Root system data for type I

class `sage.combinat.root_system.type_I.CartanType(n)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_standard_finite`, `sage.combinat.root_system.cartan_type.CartanType_simple`

EXAMPLES:

```
sage: ct = CartanType(['I', 5])
sage: ct
['I', 5]
sage: ct._repr_(compact = True)
'I5'
sage: ct.rank()
2
sage: ct.index_set()
(1, 2)

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
False
sage: ct.is_simply_laced()
False
```

coxeter_diagram()

Returns the Coxeter matrix for this type.

EXAMPLES:

```
sage: ct = CartanType(['I', 4])
sage: ct.coxeter_diagram()
Graph on 2 vertices
sage: ct.coxeter_diagram().edges(sort=True)
[(1, 2, 4)]
sage: ct.coxeter_matrix()
[1 4]
[4 1]
```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['I', 3]).coxeter_number()
3
sage: CartanType(['I', 12]).coxeter_number()
12
```

index_set()

Type $I_2(p)$ is indexed by $\{1, 2\}$.

EXAMPLES:

```
sage: CartanType(['I', 5]).index_set()
(1, 2)
```

rank()

Type $I_2(p)$ is of rank 2.

EXAMPLES:

```
sage: CartanType(['I', 5]).rank()
2
```

5.1.257 Root system data for type Q

class sage.combinat.root_system.type_Q.CartanType(*m*)

Bases: *sage.combinat.root_system.cartan_type.CartanType_standard_finite*

Cartan Type Q_n

See also:

CartanType()

dual()

Return dual of self.

EXAMPLES:

```
sage: Q = CartanType(['Q', 3])
sage: Q.dual()
['Q', 3]
```

index_set()

Return the index set for Cartan type Q.

The index set for type Q is of the form $\{-n, \dots, -1, 1, \dots, n\}$.

EXAMPLES:

```
sage: CartanType(['Q', 3]).index_set()
(1, 2, -2, -1)
```

is_irreducible()

Return whether this Cartan type is irreducible.

EXAMPLES:

```
sage: Q = CartanType(['Q', 3])
sage: Q.is_irreducible()
True
```

is_simply_laced()

Return whether this Cartan type is simply-laced.

EXAMPLES:

```
sage: Q = CartanType(['Q', 3])
sage: Q.is_simply_laced()
True
```

root_system()

Return the root system of `self`.

EXAMPLES:

```
sage: Q = CartanType(['Q', 3])
sage: Q.root_system()
Root system of type ['A', 2]
```

5.1.258 Root system data for affine Cartan types

class `sage.combinat.root_system.type_affine.AmbientSpace`(*root_system, base_ring*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

Ambient space for affine types.

This is constructed from the data in the corresponding classical ambient space. Namely, this space is obtained by adding two elements δ and δ^\vee to the basis of the classical ambient space, and by endowing it with the canonical scalar product.

The coefficient of an element in δ^\vee , thus its scalar product with δ^\vee gives its level, and dually for the covelevel. The canonical projection onto the classical ambient space (by killing δ and δ^\vee) maps the simple roots (except α_0) onto the corresponding classical simple roots, and similarly for the coroots, fundamental weights, ... Altogether, this uniquely determines the embedding of the root, coroot, weight, and coweight lattices. See `simple_root()` and `fundamental_weight()` for the details.

Warning: In type BC , the null root is in fact:

```
sage: R = RootSystem(["BC", 3, 2]).ambient_space()
sage: R.null_root()
2*e['delta']
```

Warning: In the literature one often considers a larger affine ambient space obtained from the classical ambient space by adding four dimensions, namely for the fundamental weight Λ_0 the fundamental coweight Λ_0^\vee , the null root δ , and the null coroot c (aka central element). In this larger ambient space, the scalar product is degenerate: $\langle \delta, \delta \rangle = 0$ and similarly for the null coroot.

In the current implementation, Λ_0 and the null coroot are identified:

```
sage: L = RootSystem(["A",3,1]).ambient_space() sage: Lambda = L.fundamental_weights()
sage: Lambda[0] e['deltacheck'] sage: L.null_coroot() e['deltacheck']
```

Therefore the scalar product of the null coroot with itself differs from the larger ambient space:

```
sage: L.null_coroot().scalar(L.null_coroot())
1
```

In general, scalar products between two elements that do not live on “opposite sides” won’t necessarily match.

EXAMPLES:

```
sage: R = RootSystem(["A",3,1])
sage: e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3, 1]
sage: TestSuite(e).run()
```

Systematic checks on all affine types:

```
sage: for ct in CartanType.samples(affine=True, crystallographic=True):
.....:     if ct.classical().root_system().ambient_space() is not None:
.....:         print(ct)
.....:         L = ct.root_system().ambient_space()
.....:         assert L
.....:         TestSuite(L).run()
['A', 1, 1]
['A', 5, 1]
['B', 1, 1]
['B', 5, 1]
['C', 1, 1]
['C', 5, 1]
['D', 3, 1]
['D', 5, 1]
['E', 6, 1]
['E', 7, 1]
['E', 8, 1]
['F', 4, 1]
['G', 2, 1]
['BC', 1, 2]
['BC', 5, 2]
['B', 5, 1]^*
['C', 4, 1]^*
['F', 4, 1]^*
['G', 2, 1]^*
['BC', 1, 2]^*
['BC', 5, 2]^*
```

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

associated_coroot()

Return the coroot associated to `self`.

INPUT:

- `self` – a root

EXAMPLES:

```

sage: alpha = RootSystem(['C',2,1]).ambient_space().simple_roots()
sage: alpha
Finite family {0: -2*e[0] + e['delta'], 1: e[0] - e[1], 2: 2*e[1]}
sage: alpha[0].associated_coroot()
-e[0] + e['deltacheck']
sage: alpha[1].associated_coroot()
e[0] - e[1]
sage: alpha[2].associated_coroot()
e[1]

```

inner_product(*other*)Implement the canonical inner product of *self* with *other*.

EXAMPLES:

```

sage: e = RootSystem(['B',3,1]).ambient_space()
sage: B = e.basis()
sage: matrix([[x.inner_product(y) for x in B] for y in B])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
sage: x.inner_product(x)
17

```

scalar() is an alias for this method:

```

sage: x.scalar(x)
17

```

Todo: Lift to CombinatorialFreeModule.Element as canonical_inner_product**scalar**(*other*)Implement the canonical inner product of *self* with *other*.

EXAMPLES:

```

sage: e = RootSystem(['B',3,1]).ambient_space()
sage: B = e.basis()
sage: matrix([[x.inner_product(y) for x in B] for y in B])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
sage: x.inner_product(x)
17

```

`scalar()` is an alias for this method:

```
sage: x.scalar(x)
17
```

Todo: Lift to CombinatorialFreeModule.Element as canonical_inner_product

`coroot_lattice()`

EXAMPLES:

```
sage: RootSystem(["A",3,1]).ambient_lattice().coroot_lattice()
Ambient lattice of the Root system of type ['A', 3, 1]
```

Todo: Factor out this code with the classical ambient space.

`fundamental_weight(i)`

Return the fundamental weight Λ_i in this ambient space.

It is constructed by taking the corresponding fundamental weight of the classical ambient space (or 0 for Λ_0) and raising it to the appropriate level by adding a suitable multiple of δ^\vee .

EXAMPLES:

```
sage: RootSystem(['A',3,1]).ambient_space().fundamental_weight(2)
e[0] + e[1] + e['deltacheck']
sage: RootSystem(['A',3,1]).ambient_space().fundamental_weights()
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'],
               2: e[0] + e[1] + e['deltacheck'], 3: e[0] + e[1] + e[2] +
↪e['deltacheck']}
sage: RootSystem(['A',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
sage: RootSystem(['A',3,1]).weight_lattice().fundamental_weights().
↪map(attrcall("level"))
Finite family {0: 1, 1: 1, 2: 1, 3: 1}

sage: RootSystem(['B',3,1]).ambient_space().fundamental_weights()
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'],
               2: e[0] + e[1] + 2*e['deltacheck'], 3: 1/2*e[0] + 1/
↪2*e[1] + 1/2*e[2] + e['deltacheck']}
sage: RootSystem(['B',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
sage: RootSystem(['B',3,1]).weight_lattice().fundamental_weights().
↪map(attrcall("level"))
Finite family {0: 1, 1: 1, 2: 2, 3: 1}
```

In type BC dual, the coefficient of 'delta^vee' is the level divided by 2 to take into account that the null coroot is $2\delta^\vee$:

```
sage: R = CartanType(['BC',3,2]).dual().root_system()
sage: R.ambient_space().fundamental_weights()
```

(continues on next page)

(continued from previous page)

```

Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'],
              2: e[0] + e[1] + e['deltacheck'],
              3: 1/2*e[0] + 1/2*e[1] + 1/2*e[2] + 1/2*e['deltacheck']}
sage: R.weight_lattice().fundamental_weights().map(attrcall("level"))
Finite family {0: 2, 1: 2, 2: 2, 3: 1}
sage: R.ambient_space().null_coroot()
2*e['deltacheck']

```

By a slight naming abuse this function also accepts "delta" as input so that it can be used to implement the embedding from the extended weight lattice::

```

sage: RootSystem(['A',3,1]).ambient_space().fundamental_weight("delta")
e['delta']

```

is_extended()

Return whether this is a realization of the extended weight lattice: yes!

See also:

- [sage.combinat.root_system.weight_space.WeightSpace](#)
- [sage.combinat.root_system.weight_lattice_realizations.WeightLatticeRealizations.ParentMethods.is_extended\(\)](#)

EXAMPLES:

```

sage: RootSystem(['A',3,1]).ambient_space().is_extended()
True

```

simple_coroot(i)

Return the i -th simple coroot α_i^\vee of this affine ambient space.

EXAMPLES:

```

sage: RootSystem(["A",3,1]).ambient_space().simple_coroot(1)
e[0] - e[1]

```

It is built as the coroot associated to the simple root α_i :

```

sage: RootSystem(["B",3,1]).ambient_space().simple_roots()
Finite family {0: -e[0] - e[1] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3:
↪ e[2]}
sage: RootSystem(["B",3,1]).ambient_space().simple_coroots()
Finite family {0: -e[0] - e[1] + e['deltacheck'], 1: e[0] - e[1], 2: e[1] -
↪ e[2], 3: 2*e[2]}

```

Todo: Factor out this code with the classical ambient space.

simple_root(i)

Return the i -th simple root of this affine ambient space.

EXAMPLES:

It is built straightforwardly from the corresponding simple root α_i in the classical ambient space:

```
sage: RootSystem(["A", 3, 1]).ambient_space().simple_root(1)
e[0] - e[1]
```

For the special node (typically $i = 0$), α_0 is built from the other simple roots using the column annihilator of the Cartan matrix and adding δ , where δ is the null root:

```
sage: RootSystem(["A", 3]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
sage: RootSystem(["A", 3, 1]).ambient_space().simple_roots()
Finite family {0: -e[0] + e[3] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3:
↪e[2] - e[3]}
```

Here is a twisted affine example:

```
sage: RootSystem(CartanType(["B", 3, 1]).dual()).ambient_space().simple_roots()
Finite family {0: -e[0] - e[1] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3:
↪2*e[2]}
```

In fact δ is really $1/a_0$ times the null root (see the discussion in [WeightSpace](#)) but this only makes a difference in type BC :

```
sage: L = RootSystem(CartanType(["BC", 3, 2])).ambient_space()
sage: L.simple_roots()
Finite family {0: -e[0] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3: 2*e[2]}
sage: L.null_root()
2*e['delta']
```

Note: An alternative would have been to use the default implementation of the simple roots as linear combinations of the fundamental weights. However, as in type A_n it is preferable to take a slight variant to avoid rational coefficient (the usual GL_n vs SL_n issue).

See also:

- [simple_root\(\)](#)
- [WeightSpace](#)
- [CartanType.col_annihilator\(\)](#)
- [null_root\(\)](#)

classmethod `smallest_base_ring(cartan_type)`

Return the smallest base ring the ambient space can be defined on.

This is the smallest base ring for the associated classical ambient space.

See also:

[smallest_base_ring\(\)](#)

EXAMPLES:

```
sage: cartan_type = CartanType(["A", 3, 1])
sage: cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
```

(continues on next page)

(continued from previous page)

```
Integer Ring
sage: cartan_type = CartanType(["B",3,1])
sage: cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
Rational Field
```

5.1.259 Root system data for dual Cartan types

class `sage.combinat.root_system.type_dual.AmbientSpace`(*root_system, base_ring, index_set=None*)
 Bases: `sage.combinat.root_system.ambient_space.AmbientSpace`

Ambient space for a dual finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type by switching the roles of simple roots, fundamental weights, etc.

Note: Recall that, for any finite Cartan type, and in particular the a simply laced one, the dual Cartan type is constructed as another preexisting Cartan type. Furthermore the ambient space for an affine type is constructed from the ambient space for its classical type. Thus this code is not actually currently used.

It is kept for cross-checking and for reference in case it could become useful, e.g., for dual of general Kac-Moody types.

For the doctests, we need to explicitly create a dual type. Subsequently, since reconstruction of the dual of type F_4 is the relabelled Cartan type, pickling fails on the TestSuite run.

EXAMPLES:

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: L = ct.root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4]^*
sage: TestSuite(L).run(skip=["_test_elements", "_test_pickling"])
```

dimension()

Return the dimension of this ambient space.

See also:

`sage.combinat.root_system.ambient_space.AmbientSpace.dimension()`

EXAMPLES:

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: L = ct.root_system().ambient_space()
sage: L.dimension()
4
```

fundamental_weights()

Return the fundamental weights.

They are computed from the simple roots by inverting the Cartan matrix. This is acceptable since this is only about ambient spaces for finite Cartan types. Also, we do not have to worry about the usual GL_n vs SL_n catch because type A is self dual.

An alternative would have been to start from the fundamental coweights in the dual ambient space, but those are not yet implemented.

EXAMPLES:

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: L = ct.root_system().ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3, 1, 1, 1), 4: (2, 0, 0, 1)
↪ 0}
```

Note that this ambient space is isomorphic, but not equal, to that obtained by constructing F_4 dual by relabelling:

```
sage: ct = CartanType(['F',4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (3/2, 1/2, 1/2, 1/2), 3: (2, 1, 1, 0), 4: (1,
↪ 1, 0, 0)}
```

`simple_root(i)`

Return the i -th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the dual Cartan type.

EXAMPLES:

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: ct.root_system().ambient_space().simple_root(1)
(0, 1, -1, 0)

sage: ct.root_system().ambient_space().simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -
↪ 1, -1)}

sage: ct.dual().root_system().ambient_space().simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -
↪ 1, -1)}
```

Note that this ambient space is isomorphic, but not equal, to that obtained by constructing F_4 dual by relabelling:

```
sage: ct = CartanType(['F',4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.root_system().ambient_space().simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 0, 0, 1), 3: (0, 0, 1, -1), 4:
↪ (0, 1, -1, 0)}
```

`class sage.combinat.root_system.type_dual.CartanType(type)`

Bases: `sage.combinat.root_system.cartan_type.CartanType_decorator`, `sage.combinat.root_system.cartan_type.CartanType_crystallographic`

A class for dual Cartan types.

The dual of a (crystallographic) Cartan type is a Cartan type with the same index set, but all arrows reversed in the Dynkin diagram (otherwise said, the Cartan matrix is transposed). It shares a lot of properties in common with its dual. In particular, the Weyl group is isomorphic to that of the dual as a Coxeter group.

EXAMPLES:

For all finite Cartan types, and in particular the simply laced ones, the dual Cartan type is given by another preexisting Cartan type:

```
sage: CartanType(['A',4]).dual()
['A', 4]
sage: CartanType(['B',4]).dual()
['C', 4]
sage: CartanType(['C',4]).dual()
['B', 4]
sage: CartanType(['F',4]).dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

So to exercise this class we consider some non simply laced affine Cartan types and also create explicitly F_4^* as a dual cartan type:

```
sage: from sage.combinat.root_system.type_dual import CartanType as CartanTypeDual
sage: F4d = CartanTypeDual(CartanType(['F',4])); F4d
['F', 4]^*
sage: G21d = CartanType(['G',2,1]).dual(); G21d
['G', 2, 1]^*
```

They share many properties with their original Cartan types:

```
sage: F4d.is_irreducible()
True
sage: F4d.is_crystallographic()
True
sage: F4d.is_simply_laced()
False
sage: F4d.is_finite()
True
sage: G21d.is_finite()
False
sage: F4d.is_affine()
False
sage: G21d.is_affine()
True
```

Note: F4d is pickled by construction as F4.dual() hence the above failure.

ascii_art(label=<function CartanType.<lambda> at 0x7f87497e8670>, node=None)

Return an ascii art representation of this Cartan type

(by hacking the ascii art representation of the dual Cartan type)

EXAMPLES:

```
sage: print(CartanType(["B", 3, 1]).dual().ascii_art())
  0 0
  |
  |
0---0=<=0
1  2  3
```

(continues on next page)

(continued from previous page)

```

sage: print(CartanType(["C", 4, 1]).dual().ascii_art())
0=<=0---0---0=>=0
0  1  2  3  4
sage: print(CartanType(["G", 2, 1]).dual().ascii_art())
  3
0=>=0---0
1  2  0
sage: print(CartanType(["F", 4, 1]).dual().ascii_art())
0---0---0=<=0---0
0  1  2  3  4
sage: print(CartanType(["BC", 4, 2]).dual().ascii_art())
0=>=0---0---0=>=0
0  1  2  3  4

```

dual()

EXAMPLES:

```

sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.dual()
['F', 4, 1]

```

dynkin_diagram()

EXAMPLES:

```

sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.dynkin_diagram()
0---0---0=<=0---0
0  1  2  3  4
F4~*

```

class sage.combinat.root_system.type_dual.**CartanType_affine**(*type*)Bases: `sage.combinat.root_system.type_dual.CartanType`, `sage.combinat.root_system.cartan_type.CartanType_affine`**basic_untwisted()**

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n . In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

```

sage: CartanType(['A', 7, 2]).basic_untwisted()
['A', 7]
sage: CartanType(['E', 6, 2]).basic_untwisted()
['E', 6]
sage: CartanType(['D', 4, 3]).basic_untwisted()
['D', 4]

```

classical()

Return the classical Cartan type associated with self (which should be affine).

EXAMPLES:

```

sage: CartanType(['A',3,1]).dual().classical()
['A', 3]
sage: CartanType(['B',3,1]).dual().classical()
['C', 3]
sage: CartanType(['F',4,1]).dual().classical()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: CartanType(['BC',4,2]).dual().classical()
['B', 4]

```

special_node()

Implement *CartanType_affine.special_node()*

The special node of the dual of an affine type T is the special node of T .

EXAMPLES:

```

sage: CartanType(['A',3,1]).dual().special_node()
0
sage: CartanType(['B',3,1]).dual().special_node()
0
sage: CartanType(['F',4,1]).dual().special_node()
0
sage: CartanType(['BC',4,2]).dual().special_node()
0

```

class sage.combinat.root_system.type_dual.**CartanType_finite**(*type*)

Bases: *sage.combinat.root_system.type_dual.CartanType*, *sage.combinat.root_system.cartan_type.CartanType_finite*

sage.combinat.root_system.extended_affine_weyl_group.**ExtendedAffineWeylGroup**(*cartan_type*,
general_linear=None,
***print_options*)

The extended affine Weyl group.

INPUT:

- *cartan_type* – An affine or finite Cartan type (a finite Cartan type is an abbreviation for its untwisted affinization)

- `general_linear` – (default: None) If True and `cartan_type` indicates untwisted type A, returns the universal central extension
- `print_options` – Special instructions for printing elements (see below)

Mnemonics

- “P” – subgroup of translations
- “Pv” – subgroup of translations in a dual form
- “W0” – classical Weyl group
- “W” – affine Weyl group
- “F” – fundamental group of length zero elements

There are currently six realizations: “PW0”, “W0P”, “WF”, “FW”, “PvW0”, and “W0Pv”.

“PW0” means the semidirect product of “P” with “W0” acting from the right. “W0P” is similar but with “W0” acting from the left. “WF” is the semidirect product of “W” with “F” acting from the right, etc.

Recognized arguments for `print_options` are:

- `print_tuple` – True or False (default: False) If True, elements are printed (a, b) , otherwise as $a * b$
- `affine` – Prefix for simple reflections in the affine Weyl group
- `classical` – Prefix for simple reflections in the classical Weyl group
- `translation` – Prefix for the translation elements
- `fundamental` – Prefix for the elements of the fundamental group

These options are not mutable.

The *extended affine Weyl group* was introduced in the following references.

REFERENCES:

- [Ka1990]

Notation

- R – An irreducible affine root system
- I – Set of nodes of the Dynkin diagram of R
- R_0 – The classical subsystem of R
- I_0 – Set of nodes of the Dynkin diagram of R_0
- E – Extended affine Weyl group of type R
- W – Affine Weyl group of type R
- W_0 – finite (classical) Weyl group (of type R_0)
- M – translation lattice for W
- L – translation lattice for E
- F – Fundamental subgroup of E (the length zero elements)
- P – Finite weight lattice

- Q – Finite root lattice
- P^\vee – Finite coweight lattice
- Q^\vee – Finite coroot lattice

Translation lattices

The styles “PW0” and “WOP” use the following lattices:

- Untwisted affine: $L = P^\vee, M = Q^\vee$
- Dual of untwisted affine: $L = P, M = Q$
- $BC_n (A_{2n}^{(2)})$: $L = M = P$
- Dual of $BC_n (A_{2n}^{(2)\dagger})$: $L = M = P^\vee$

The styles “PvW0” and “WOPv” use the following lattices:

- Untwisted affine: The weight lattice of the dual finite Cartan type.
- Dual untwisted affine: The same as for “PW0” and “WOP”.

For mixed affine type ($A_{2n}^{(2)}$, aka \tilde{BC}_n , and their affine duals) the styles “PvW0” and “WOPv” are not implemented.

Finite and affine Weyl groups W_0 and W

The finite Weyl group W_0 is generated by the simple reflections s_i for $i \in I_0$ where s_i is the reflection across a suitable hyperplane H_i through the origin in the real span V of the lattice M .

R specifies another (affine) hyperplane H_0 . The affine Weyl group W is generated by W_0 and the reflection S_0 across H_0 .

Extended affine Weyl group E

The complement in V of the set H of hyperplanes obtained from the H_i by the action of W , has connected components called alcoves. W acts freely and transitively on the set of alcoves. After the choice of a certain alcove (the fundamental alcove), there is an induced bijection from W to the set of alcoves under which the identity in W maps to the fundamental alcove.

Then L is the largest sublattice of V , whose translations stabilize the set of alcoves.

There are isomorphisms

$$\begin{aligned} W &\cong M \rtimes W_0 \cong W_0 \rtimes M \\ E &\cong L \rtimes W_0 \cong W_0 \rtimes L \end{aligned}$$

Fundamental group of affine Dynkin automorphisms

Since L acts on the set of alcoves, the group $F = L/M$ may be viewed as a subgroup of the symmetries of the fundamental alcove or equivalently the symmetries of the affine Dynkin diagram. F acts on the set of alcoves and hence on W . Conjugation by an element of F acts on W by permuting the indices of simple reflections.

There are isomorphisms

$$E \cong F \ltimes W \cong W \rtimes F$$

An affine Dynkin node is *special* if it is conjugate to the zero node under some affine Dynkin automorphism.

There is a bijection $i \mapsto \pi_i$ from the set of special nodes to the group F , where π_i is the unique element of F that sends 0 to i . When $L = P$ (resp. $L = P^\vee$) the element π_i is induced (under the isomorphism $F \cong L/M$) by addition of the coset of the i -th fundamental weight (resp. coweight).

The length function of the Coxeter group W may be extended to E by $\ell(w\pi) = \ell(w)$ where $w \in W$ and $\pi \in F$. This is the number of hyperplanes in H separating the fundamental alcove from its image by $w\pi$ (or equivalently w).

It is known that if G is the compact Lie group of adjoint type with root system R_0 then F is isomorphic to the fundamental group of G , or to the center of its simply-connected covering group. That is why we call F the *fundamental group*.

In the future we may want to build an element of the group from an appropriate linear map f on some of the root lattice realizations for this Cartan type: `W.from_endomorphism(f)`.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(["A", 2, 1]); E
Extended affine Weyl group of type ['A', 2, 1]
sage: type(E)
<class 'sage.combinat.root_system.extended_affine_weyl_group.
↳ExtendedAffineWeylGroup_Class_with_category'>

sage: PW0=E.PW0(); PW0
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
↳Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted
↳upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight
↳lattice)

sage: W0P = E.W0P(); W0P
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
↳Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
↳acting on Multiplicative form of Coweight lattice of the Root system of type ['A',
↳ 2]

sage: PvW0 = E.PvW0(); PvW0
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
↳Multiplicative form of Weight lattice of the Root system of type ['A', 2] acted
↳upon by Weyl Group of type ['A', 2] (as a matrix group acting on the weight
↳lattice)

sage: W0Pv = E.W0Pv(); W0Pv
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
↳Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
↳acting on Multiplicative form of Weight lattice of the Root system of type ['A',
↳2]

```

(continues on next page)

(continued from previous page)

```

sage: WF = E.WF(); WF
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
↳Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)↳
↳acted upon by Fundamental group of type ['A', 2, 1]

sage: FW = E.FW(); FW
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
↳Fundamental group of type ['A', 2, 1] acting on Weyl Group of type ['A', 2, 1]↳
↳(as a matrix group acting on the root lattice)

```

When the realizations are constructed from each other as above, there are built-in coercions between them.

```

sage: F = E.fundamental_group()
sage: x = WF.from_reduced_word([0,1,2]) * WF(F(2)); x
S0*S1*S2 * pi[2]
sage: FW(x)
pi[2] * S1*S2*S0
sage: WOP(x)
s1*s2*s1 * t[-2*Lambdacheck[1] - Lambdacheck[2]]
sage: PW0(x)
t[Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2*s1
sage: PvW0(x)
t[Lambda[1] + 2*Lambda[2]] * s1*s2*s1

```

The translation lattice and its distinguished basis are obtained from E:

```

sage: L = E.lattice(); L
Coweight lattice of the Root system of type ['A', 2]
sage: b = E.lattice_basis(); b
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}

```

Translation lattice elements can be coerced into any realization:

```

sage: PW0(b[1]-b[2])
t[Lambdacheck[1] - Lambdacheck[2]]
sage: FW(b[1]-b[2])
pi[2] * S0*S1

```

The dual form of the translation lattice and its basis are similarly obtained:

```

sage: Lv = E.dual_lattice(); Lv
Weight lattice of the Root system of type ['A', 2]
sage: bv = E.dual_lattice_basis(); bv
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: FW(bv[1]-bv[2])
pi[2] * S0*S1

```

The abstract fundamental group is accessed from E:

```

sage: F = E.fundamental_group(); F
Fundamental group of type ['A', 2, 1]

```

Its elements are indexed by the set of special nodes of the affine Dynkin diagram:

```

sage: E.cartan_type().special_nodes()
(0, 1, 2)
sage: F.special_nodes()
(0, 1, 2)
sage: [F(i) for i in F.special_nodes()]
[pi[0], pi[1], pi[2]]

```

There is a coercion from the fundamental group into each realization:

```

sage: F(2)
pi[2]
sage: WF(F(2))
pi[2]
sage: WOP(F(2))
s2*s1 * t[-Lambdacheck[1]]
sage: WOPv(F(2))
s2*s1 * t[-Lambda[1]]

```

Using E one may access the classical and affine Weyl groups and their morphisms into each realization:

```

sage: W0 = E.classical_weyl(); W0
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
sage: v = W0.from_reduced_word([1,2,1]); v
s1*s2*s1
sage: PW0(v)
s1*s2*s1
sage: WF(v)
S1*S2*S1
sage: W = E.affine_weyl(); W
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
sage: w = W.from_reduced_word([2,1,0]); w
S2*S1*S0
sage: WF(w)
S2*S1*S0
sage: PW0(w)
t[Lambdacheck[1] - 2*Lambdacheck[2]] * s1

```

Note that for untwisted affine type, the dual form of the classical Weyl group is isomorphic to the usual one, but acts on a different lattice and is therefore different to sage:

```

sage: W0v = E.dual_classical_weyl(); W0v
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
sage: v = W0v.from_reduced_word([1,2])
sage: x = PvW0(v); x
s1*s2
sage: y = PW0(v); y
s1*s2
sage: x.parent() == y.parent()
False

```

However, because there is a coercion from PvW0 to PW0, the elements x and y compare as equal:

```

sage: x == y
True

```

An element can be created directly from a reduced word:

```
sage: PW0.from_reduced_word([2,1,0])
t[Lambdacheck[1] - 2*Lambdacheck[2]] * s1
```

Here is a demonstration of the printing options:

```
sage: E = ExtendedAffineWeylGroup(["A",2,1], affine="sx", classical="Sx",
↳translation="x", fundamental="pix")
sage: PW0 = E.PW0()
sage: y = PW0(E.lattice_basis()[1])
sage: y
x[Lambdacheck[1]]
sage: FW = E.FW()
sage: FW(y)
pix[1] * sx2*sx1
sage: PW0.an_element()
x[2*Lambdacheck[1] + 2*Lambdacheck[2]] * Sx1*Sx2
```

Todo:

- Implement a “slow” action of E on any affine root or weight lattice realization.
- Implement the level m actions of E and W on the lattices of finite type.
- Implement the relevant methods from the usual affine Weyl group
- Implementation by matrices: style “M”.
- Use case: implement the Hecke algebra on top of this

The semidirect product construction in sage currently only admits multiplicative groups. Therefore for the styles involving “P” and “Pv”, one must convert the additive group of translations L into a multiplicative group by applying the `sage.groups.group_exp.GroupExp` functor.

The general linear case

The general linear group is not semisimple. Sage can build its extended affine Weyl group:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1], general_linear=True); E
Extended affine Weyl group of GL(3)
```

If the Cartan type is $['A', n-1, 1]$ and the parameter `general_linear` is not `True`, the extended affine Weyl group that is built will be for SL_n , not GL_n . But if `general_linear` is `True`, let W_a and W_e be the affine and extended affine Weyl groups. We make the following nonstandard definition: the extended affine Weyl group $W_e(GL_n)$ is defined by

$$W_e(GL_n) = P(GL_n) \rtimes W$$

where W is the finite Weyl group (the symmetric group S_n) and $P(GL_n)$ is the weight lattice of GL_n , which is usually identified with the lattice \mathbf{Z}^n of n -tuples of integers:

```
sage: PW0 = E.PW0(); PW0
Extended affine Weyl group of GL(3) realized by Semidirect product of
↳Multiplicative form of Ambient space of the Root system of type ['A', 2] acted
↳upon by Weyl Group of type ['A', 2] (as a matrix group acting on the ambient
↳space) (continues on next page)
```

(continued from previous page)

```
sage: PW0.an_element()
t[(2, 2, 3)] * s1*s2
```

There is an isomorphism

$$W_e(GL_n) = \mathbf{Z} \ltimes W_a$$

where the group of integers \mathbf{Z} (with generator π) acts on W_a by

$$\pi s_i \pi^{-1} = s_{i+1}$$

and the indices of the simple reflections are taken modulo n :

```
sage: FW = E.FW(); FW
Extended affine Weyl group of GL(3) realized by Semidirect product of Fundamental_
→group of GL(3) acting on Weyl Group of type ['A', 2, 1] (as a matrix group acting_
→on the root lattice)
sage: FW.an_element()
pi[5] * S0*S1*S2
```

We regard \mathbf{Z} as the fundamental group of affine type GL_n :

```
sage: F = E.fundamental_group(); F
Fundamental group of GL(3)
sage: F.special_nodes()
Integer Ring

sage: x = FW.from_fundamental(F(10)); x
pi[10]
sage: x*x
pi[20]
sage: E.PvW0()(x*x)
t[(7, 7, 6)] * s2*s1
```

```
class sage.combinat.root_system.extended_affine_weyl_group.ExtendedAffineWeylGroup_Class(cartan_type,
                                                                                               gen-
                                                                                               eral_linear,
                                                                                               **print_options)
```

```
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.
parent.Parent
```

The parent-with-realization class of an extended affine Weyl group.

```
class ExtendedAffineWeylGroupFW(E)
```

```
Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.
bindable_class.BindableClass
```

Extended affine Weyl group, realized as the semidirect product of the affine Weyl group by the fundamental group.

INPUT:

- E – A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Fundamental group of type ['A', 2, 1] acting on Weyl Group of type ['A', 2,
↳ 1] (as a matrix group acting on the root lattice)
```

Element

alias of `ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupFWElement`

from_affine_weyl(w)

Return the image of w under the map of the affine Weyl group into the right (affine Weyl group) factor in the “FW” style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.FW().from_affine_weyl(E.affine_weyl().from_reduced_word([0,2,1]))
(pi[0], S0*S2*S1)
```

from_fundamental(f)

Return the image of the fundamental group element f into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.FW().from_fundamental(E.fundamental_group()(2))
(pi[2], 1)
```

simple_reflections()

Return the family of simple reflections of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1],print_tuple=True).FW().simple_
↳ reflections()
Finite family {0: (pi[0], S0), 1: (pi[0], S1), 2: (pi[0], S2)}
```

class ExtendedAffineWeylGroupFWElement

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProductElement`

The element class for the “FW” realization.

action_on_affine_roots(β)

Act by self on the affine root lattice element β .

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: v = RootSystem(['A',2,1]).root_lattice().an_element(); v
2*alpha[0] + 2*alpha[1] + 3*alpha[2]
sage: x.action_on_affine_roots(v)
alpha[0] + alpha[1]
```

has_descent(i , $side='right'$, $positive=False$)

Return whether self has descent at i .

INPUT:

- i – an affine Dynkin index.
- OPTIONAL:
- `side` – ‘left’ or ‘right’ (default: ‘right’)
 - `positive` – True or False (default: False)

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: x = E.FW().an_element(); x
pi[2] * S0*S1*S2
sage: [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, False), (1, False), (2, True)]
```

to_affine_weyl_right()

Project `self` to the right (affine Weyl group) factor in the “FW” style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: x = E.FW().from_translation(E.lattice_basis()[1]); x
pi[1] * S2*S1
sage: x.to_affine_weyl_right()
S2*S1
```

to_fundamental_group()

Return the projection of `self` to the fundamental group in the “FW” style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: x = E.FW().from_translation(E.lattice_basis()[2]); x
pi[2] * S1*S2
sage: x.to_fundamental_group()
pi[2]
```

class ExtendedAffineWeylGroupPW0(E)

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProduct`, `sage.misc.bindable_class.BindableClass`

Extended affine Weyl group, realized as the semidirect product of the translation lattice by the finite Weyl group.

INPUT:

- E – A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A', 2, 1]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Multiplicative form of Coweight lattice of the Root system of type ['A',
↳ 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the
↳ coweight lattice)
```

Element

alias of `ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupPW0Element`

S0()

Return the affine simple reflection.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['B', 2]).PW0().S0()
t[Lambdacheck[2]] * s2*s1*s2
```

from_classical_weyl(*w*)

Return the image of *w* under the homomorphism of the classical Weyl group into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup("A3", print_tuple=True)
sage: E.PW0().from_classical_weyl(E.classical_weyl().from_reduced_word([1,
↪ 2]))
(t[0], s1*s2)
```

from_translation(*la*)

Map the translation lattice element *la* into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1], translation="tau", print_tuple_
↪ = True)
sage: la = E.lattice().an_element(); la
2*Lambdacheck[1] + 2*Lambdacheck[2]
sage: E.PW0().from_translation(la)
(tau[2*Lambdacheck[1] + 2*Lambdacheck[2]], 1)
```

simple_reflection(*i*)

Return the *i*-th simple reflection in self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup("G2")
sage: [(i, E.PW0().simple_reflection(i)) for i in E.cartan_type().index_
↪ set()]
[(0, t[Lambdacheck[2]] * s2*s1*s2*s1*s2), (1, s1), (2, s2)]
```

simple_reflections()

Return a family for the simple reflections of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup("A3").PW0().simple_reflections()
Finite family {0: t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1, 1:
↪ s1, 2: s2, 3: s3}
```

class ExtendedAffineWeylGroupPW0Element

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProductElement`

The element class for the “PW0” realization.

action(*la*)

Return the action of self on an element *la* of the translation lattice.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1]); PW0=E.PW0()
sage: x = PW0.an_element(); x
```

(continues on next page)

(continued from previous page)

```
t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2
sage: la = E.lattice().an_element(); la
2*Lambdacheck[1] + 2*Lambdacheck[2]
sage: x.action(la)
-2*Lambdacheck[1] + 4*Lambdacheck[2]
```

has_descent(*i*, *side*='right', *positive*=False)

Return whether *self* has *i* as a descent.

INPUT:

- *i* – an affine Dynkin node

OPTIONAL:

- *side* – 'left' or 'right' (default: 'right')
- *positive* – True or False (default: False)

EXAMPLES:

```
sage: w = ExtendedAffineWeylGroup(['A',4,2]).PW0().from_reduced_word([0,1]);
↪ w
t[Lambda[1]] * s1*s2
sage: w.has_descent(0, side='left')
True
```

to_classical_weyl()

Return the image of *self* under the homomorphism that projects to the classical Weyl group factor after rewriting it in either style “PW0” or “W0P”.

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PW0().S0(); s
t[Lambdacheck[1] + Lambdacheck[2]] * s1*s2*s1
sage: s.to_classical_weyl()
s1*s2*s1
```

to_translation_left()

The image of *self* under the map that projects to the translation lattice factor after factoring it to the left as in style “PW0”.

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PW0().S0(); s
t[Lambdacheck[1] + Lambdacheck[2]] * s1*s2*s1
sage: s.to_translation_left()
Lambdacheck[1] + Lambdacheck[2]
```

class ExtendedAffineWeylGroupPvW0(*E*)

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProduct`, `sage.misc.bindable_class.BindableClass`

Extended affine Weyl group, realized as the semidirect product of the dual form of the translation lattice by the finite Weyl group.

INPUT:

- *E* – A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).PvW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Multiplicative form of Weight lattice of the Root system of type ['A', 2]
↳ acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the
↳ weight lattice)
```

Element

alias of `ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupPvW0Element`

from_dual_classical_weyl(*w*)

Return the image of *w* under the homomorphism of the dual form of the classical Weyl group into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1],print_tuple=True)
sage: E.PvW0().from_dual_classical_weyl(E.dual_classical_weyl().from_
↳ reduced_word([1,2]))
(t[0], s1*s2)
```

from_dual_translation(*la*)

Map the dual translation lattice element *la* into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1], translation="tau", print_tuple_
↳ = True)
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: E.PvW0().from_dual_translation(la)
(tau[2*Lambda[1] + 2*Lambda[2]], 1)
```

simple_reflections()

Return a family for the simple reflections of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflections()
Finite family {0: t[Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1, 1: s1, 2: s2,
↳ 3: s3}
```

class ExtendedAffineWeylGroupPvW0Element

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProductElement`

The element class for the “PvW0” realization.

dual_action(*la*)

Return the action of self on an element *la* of the dual version of the translation lattice.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.PvW0().an_element(); x
t[2*Lambda[1] + 2*Lambda[2]] * s1*s2
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
```

(continues on next page)

(continued from previous page)

```
sage: x.dual_action(1a)
-2*Lambda[1] + 4*Lambda[2]
```

has_descent(*i*, *side*='right', *positive*=False)

Return whether *self* has *i* as a descent.

INPUT:

- *i* - an affine Dynkin index

OPTIONAL:

- *side* - 'left' or 'right' (default: 'right')
- *positive* - True or False (default: False)

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',4,2])
sage: w = E.PvW0().from_reduced_word([0,1]); w
t[Lambda[1]] * s1*s2
sage: [(i, w.has_descent(i, side='left')) for i in E.cartan_type().index_
->set()]
[(0, True), (1, False), (2, False)]
```

to_dual_classical_weyl()

Return the image of *self* under the homomorphism that projects to the dual classical Weyl group factor after rewriting it in either style "PvW0" or "W0Pv".

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PvW0().simple_reflection(0); s
t[Lambda[1] + Lambda[2]] * s1*s2*s1
sage: s.to_dual_classical_weyl()
s1*s2*s1
```

to_dual_translation_left()

The image of *self* under the map that projects to the dual translation lattice factor after factoring it to the left as in style "PvW0".

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PvW0().simple_reflection(0); s
t[Lambda[1] + Lambda[2]] * s1*s2*s1
sage: s.to_dual_translation_left()
Lambda[1] + Lambda[2]
```

class ExtendedAffineWeylGroupWOP(*E*)

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProduct`, `sage.misc.bindable_class.BindableClass`

Extended affine Weyl group, realized as the semidirect product of the finite Weyl group by the translation lattice.

INPUT:

- *E* - A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).WOP()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Weyl Group of type ['A', 2] (as a matrix group acting on the coweight
↳ lattice) acting on Multiplicative form of Coweight lattice of the Root system
↳ of type ['A', 2]
```

Element

alias of `ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupWOPElement`

S0()

Return the zero-th simple reflection in style “WOP”.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(["A",3,1]).WOP().S0()
s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]]
```

from_classical_weyl(w)

Return the image of the classical Weyl group element w in self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.WOP().from_classical_weyl(E.classical_weyl().from_reduced_word([2,
↳ 1]))
(s2*s1, t[0])
```

from_translation(la)

Return the image of the lattice element la in self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.WOP().from_translation(E.lattice().an_element())
(1, t[2*Lambdacheck[1] + 2*Lambdacheck[2]])
```

simple_reflection(i)

Return the i -th simple reflection in self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); WOP = E.WOP()
sage: [(i, WOP.simple_reflection(i)) for i in E.cartan_type().index_set()]
[(0, s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]]), (1, s1), (2,
↳ s2), (3, s3)]
```

simple_reflections()

Return the family of simple reflections.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(["A",3,1]).WOP().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]], 1:
↳ s1, 2: s2, 3: s3}
```

class ExtendedAffineWeylGroupWOPElement

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProductElement`

The element class for the WOP realization.

has_descent(*i*, *side*='right', *positive*=False)

Return whether `self` has *i* as a descent.

INPUT:

- *i* - an index.

OPTIONAL:

- *side* - 'left' or 'right' (default: 'right')
- *positive* - True or False (default: False)

EXAMPLES:

```
sage: WOP = ExtendedAffineWeylGroup(['A', 4, 2]).WOP()
sage: w = WOP.from_reduced_word([0, 1]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
sage: w.has_descent(0, side='left')
True
```

to_classical_weyl()

Project `self` into the classical Weyl group.

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A', 2, 1]).WOP().simple_reflection(0); x
s1*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[2]]
sage: x.to_classical_weyl()
s1*s2*s1
```

to_translation_right()

Project onto the right (translation) factor in the “WOP” style.

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A', 2, 1]).WOP().simple_reflection(0); x
s1*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[2]]
sage: x.to_translation_right()
-Lambdacheck[1] - Lambdacheck[2]
```

class ExtendedAffineWeylGroupWOPv(*E*)

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProduct`, `sage.misc.bindable_class.BindableClass`

Extended affine Weyl group, realized as the semidirect product of the finite Weyl group, acting on the dual form of the translation lattice.

INPUT:

- *E* – A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A', 2, 1]).WOPv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Weyl Group of type ['A', 2] (as a matrix group acting on the weight
↳ lattice) acting on Multiplicative form of Weight lattice of the Root system
↳ of type ['A', 2]
```

Element

alias of `ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupWOPvElement`

from_dual_classical_weyl(*w*)

Return the image of *w* under the homomorphism of the dual form of the classical Weyl group into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 3, 1], print_tuple=True)
sage: E.WOPv().from_dual_classical_weyl(E.dual_classical_weyl().from_
↪reduced_word([1, 2]))
(s1*s2, t[0])
```

from_dual_translation(*la*)

Map the dual translation lattice element *la* into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1], translation="tau", print_tuple_
↪= True)
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: E.WOPv().from_dual_translation(la)
(1, tau[2*Lambda[1] + 2*Lambda[2]])
```

simple_reflections()

Return a family for the simple reflections of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A', 3, 1]).WOPv().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambda[1] - Lambda[3]], 1: s1, 2: s2,
↪3: s3}
```

class ExtendedAffineWeylGroupWOPvElement

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProductElement`

The element class for the “WOPv” realization.

dual_action(*la*)

Return the action of self on an element *la* of the dual version of the translation lattice.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: x = E.WOPv().an_element(); x
s1*s2 * t[2*Lambda[1] + 2*Lambda[2]]
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: x.dual_action(la)
-8*Lambda[1] + 4*Lambda[2]
```

has_descent(*i*, *side*='right', *positive*=False)

Return whether self has *i* as a descent.

INPUT:

- *i* - an affine Dynkin index

OPTIONAL:

- *side* - ‘left’ or ‘right’ (default: ‘right’)
- *positive* - True or False (default: False)

EXAMPLES:

```
sage: w = ExtendedAffineWeylGroup(['A', 4, 2]).WOPv().from_reduced_word([0,
↪ 1]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
sage: w.has_descent(0, side='left')
True
```

`to_dual_classical_weyl()`

Return the image of `self` under the homomorphism that projects to the dual classical Weyl group factor after rewriting it in either style “PvW0” or “WOPv”.

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A', 2, 1]).WOPv().simple_reflection(0); s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
sage: s.to_dual_classical_weyl()
s1*s2*s1
```

`to_dual_translation_right()`

The image of `self` under the map that projects to the dual translation lattice factor after factoring it to the right as in style “WOPv”.

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A', 2, 1]).WOPv().simple_reflection(0); s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
sage: s.to_dual_translation_right()
-Lambda[1] - Lambda[2]
```

`class ExtendedAffineWeylGroupWF(E)`

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProduct`, `sage.misc.bindable_class.BindableClass`

Extended affine Weyl group, realized as the semidirect product of the affine Weyl group by the fundamental group.

INPUT:

- E – A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A', 2, 1]).WF()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↪ of Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root
↪ lattice) acted upon by Fundamental group of type ['A', 2, 1]
```

Element

alias of `ExtendedAffineWeylGroup_Class.ExtendedAffineWeylGroupWFElement`

`from_affine_weyl(w)`

Return the image of the affine Weyl group element w in `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['C', 2, 1], print_tuple=True)
sage: E.WF().from_affine_weyl(E.affine_weyl().from_reduced_word([1, 2, 1, 0]))
(S1*S2*S1*S0, pi[0])
```

from_fundamental(*f*)

Return the image of *f* under the homomorphism from the fundamental group into the right (fundamental group) factor in “WF” style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['E',6,1],print_tuple=True); WF = E.WF();
↳F = E.fundamental_group()
sage: [(x,WF.from_fundamental(x)) for x in F]
[(pi[0], (1, pi[0])), (pi[1], (1, pi[1])), (pi[6], (1, pi[6]))]
```

simple_reflections()

Return the family of simple reflections.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(["A",3,1],affine="r").WF().simple_
↳reflections()
Finite family {0: r0, 1: r1, 2: r2, 3: r3}
```

class ExtendedAffineWeylGroupWFElement

Bases: `sage.groups.group_semidirect_product.GroupSemidirectProductElement`

Element class for the “WF” realization.

bruhat_le(*x*)

Return whether `self` is less than or equal to *x* in the Bruhat order.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s", print_tuple=True);
↳WF=E.WF()
sage: r = E.affine_weyl().from_reduced_word
sage: v = r([1,0])
sage: w = r([1,2,0])
sage: v.bruhat_le(w)
True
sage: vv = WF.from_affine_weyl(v); vv
(s1*s0, pi[0])
sage: ww = WF.from_affine_weyl(w); ww
(s1*s2*s0, pi[0])
sage: vv.bruhat_le(ww)
True
sage: f = E.fundamental_group()(2); f
pi[2]
sage: ff = WF.from_fundamental(f); ff
(1, pi[2])
sage: vv.bruhat_le(ww*ff)
False
sage: (vv*ff).bruhat_le(ww*ff)
True
```

has_descent(*i*, *side*='right', *positive*=False)

Return whether `self` has *i* as a descent.

INPUT:

- *i* – an affine Dynkin index

OPTIONAL:

- `side` – ‘left’ or ‘right’ (default: ‘right’)
- `positive` – True or False (default: False)

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
sage: [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, True), (1, False), (2, False)]
```

`to_affine_weyl_left()`

Project self to the left (affine Weyl group) factor in the “WF” style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().from_translation(E.lattice_basis()[1]); x
S0*S2 * pi[1]
sage: x.to_affine_weyl_left()
S0*S2
```

`to_fundamental_group()`

Project self to the right (fundamental group) factor in the “WF” style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().from_translation(E.lattice_basis()[1]); x
S0*S2 * pi[1]
sage: x.to_fundamental_group()
pi[1]
```

`FW()`

Realizes self in “FW”-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Fundamental group of type ['A', 2, 1] acting on Weyl Group of type ['A', 2,
↳ 1] (as a matrix group acting on the root lattice)
```

`PW0()`

Realizes self in “PW0”-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Multiplicative form of Coweight lattice of the Root system of type ['A',
↳ 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the
↳ coweight lattice)
```

`PW0_to_WF_func(x)`

Implements coercion from style “PW0” to “WF”.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(["A", 2, 1])
sage: x = E.PW0().an_element(); x
t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2
sage: E.PW0_to_WF_func(x)
S0*S1*S2*S0*S1*S0

```

Warning: This function cannot use coercion, because it is used to define the coercion maps.

PvW0()

Realizes self in “PvW0”-style.

EXAMPLES:

```

sage: ExtendedAffineWeylGroup(['A',2,1]).PvW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
of Multiplicative form of Weight lattice of the Root system of type ['A', 2]
acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the
weight lattice)

```

class Realizations(parent_with_realization)

Bases: `sage.categories.realizations.Category_realization_of_parent`

The category of the realizations of an extended affine Weyl group

class ElementMethods

Bases: object

action(la)

Action of self on a lattice element la.

INPUT:

- self – an element of the extended affine Weyl group
- la – an element of the translation lattice of the extended affine Weyl group, the lattice denoted by the mnemonic “P” in the documentation for `ExtendedAffineWeylGroup()`.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: la = E.lattice().an_element(); la
2*Lambdacheck[1] + 2*Lambdacheck[2]
sage: x.action(la)
5*Lambdacheck[1] - 3*Lambdacheck[2]
sage: E = ExtendedAffineWeylGroup(['C',2,1],affine="s")
sage: x = E.PW0().from_translation(E.lattice_basis()[1])
sage: x.action(E.lattice_basis()[2])
Lambdacheck[1] + Lambdacheck[2]

```

Warning: Must be implemented by style “PW0”.

action_on_affine_roots(beta)

Act by self on the affine root lattice element beta.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: beta = E.cartan_type().root_system().root_lattice().an_element();
beta
2*alpha[0] + 2*alpha[1] + 3*alpha[2]
sage: x = E.FW().an_element(); x
pi[2] * S0*S1*S2
sage: x.action_on_affine_roots(beta)
alpha[0] + alpha[1]
```

Warning: Must be implemented by style “FW”.

`alcove_walk_signs()`

Return a signed alcove walk for `self`.

INPUT:

- An element `self` of the extended affine Weyl group.

OUTPUT:

- A 3-tuple $(g, rw, signs)$.

ALGORITHM:

The element `self` can be uniquely written $self = g * w$ where g has length zero and w is an element of the nonextended affine Weyl group. Let w have reduced word `rw`. Starting with g and applying simple reflections from `rw`, one obtains a sequence of extended affine Weyl group elements (that is, alcoves) and simple roots. The signs give the sequence of sides on which the alcoves lie, relative to the face indicated by the simple roots.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 3, 1]); FW=E.FW()
sage: w = FW.from_reduced_word([0, 2, 1, 3, 0])*FW.from_fundamental(1); w
pi[1] * S3*S1*S2*S0*S3
sage: w.alcove_walk_signs()
(pi[1], [3, 1, 2, 0, 3], [-1, 1, -1, -1, 1])
```

`apply_simple_projection(i, side='right', length_increasing=True)`

Return the product of `self` by the simple reflection s_i if that product is of greater length than `self` and otherwise return `self`.

INPUT:

- `self` – an element of the extended affine Weyl group
- i – a Dynkin node (index of a simple reflection s_i)
- `side` – ‘right’ or ‘left’ (default: ‘right’) according to which side of `self` the reflection s_i should be multiplied
- `length_increasing` – True or False (default True). If False do the above with the word “greater” replaced by “less”.

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A', 3, 1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.apply_simple_projection(1)
S0*S1*S2*S3*S0 * pi[3]
```

(continues on next page)

(continued from previous page)

```
sage: x.apply_simple_projection(1, length_increasing=False)
S0*S1*S2*S3 * pi[3]
```

apply_simple_reflection(*i*, *side*='right')

Apply the *i*-th simple reflection to self.

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A', 3, 1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.apply_simple_reflection(1)
S0*S1*S2*S3*S0 * pi[3]
sage: x.apply_simple_reflection(0, side='left')
S1*S2*S3 * pi[3]
```

bruhat_le(*x*)

Return whether self $\leq x$ in Bruhat order.

INPUT:

- self – an element of the extended affine Weyl group
- *x* – another element with the same parent as self

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 2, 1], print_tuple=True); WF=E.WF()
sage: W = E.affine_weyl()
sage: v = W.from_reduced_word([2, 1, 0])
sage: w = W.from_reduced_word([2, 0, 1, 0])
sage: v.bruhat_le(w)
True
sage: vx = WF.from_affine_weyl(v); vx
(S2*S1*S0, pi[0])
sage: wx = WF.from_affine_weyl(w); wx
(S2*S0*S1*S0, pi[0])
sage: vx.bruhat_le(wx)
True
sage: F = E.fundamental_group()
sage: f = WF.from_fundamental(F(2))
sage: vx.bruhat_le(wx*f)
False
sage: (vx*f).bruhat_le(wx*f)
True
```

Warning: Must be implemented by “WF”.

coset_representative(*index_set*, *side*='right')

Return the minimum length representative in the coset of self with respect to the subgroup generated by the reflections given by *index_set*.

INPUT:

- self – an element of the extended affine Weyl group
- *index_set* – a subset of the set of Dynkin nodes
- *side* – ‘right’ or ‘left’ (default: ‘right’) the side on which the subgroup acts

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A', 3, 1]); WF = E.WF()
sage: b = E.lattice_basis()
sage: I0 = E.cartan_type().classical().index_set()
sage: [WF.from_translation(x).coset_representative(index_set=I0) for x
↳ in b]
[pi[1], pi[2], pi[3]]

```

dual_action(*la*)

Action of `self` on a dual lattice element `la`.

INPUT:

- `self` – an element of the extended affine Weyl group
- `la` – an element of the dual translation lattice of the extended affine Weyl group, the lattice denoted by the mnemonic “Pv” in the documentation for `ExtendedAffineWeylGroup()`.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A', 2, 1], affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: x.dual_action(la)
5*Lambda[1] - 3*Lambda[2]
sage: E = ExtendedAffineWeylGroup(['C', 2, 1], affine="s")
sage: x = E.PvW0().from_dual_translation(E.dual_lattice_basis()[1])
sage: x.dual_action(E.dual_lattice_basis()[2])
Lambda[1] + Lambda[2]

```

Warning: Must be implemented by style “PvW0”.

face_data(*i*)

Return a description of one of the bounding hyperplanes of the alcove of an extended affine Weyl group element.

INPUT:

- `self` – An element of the extended affine Weyl group
- `i` – an affine Dynkin node

OUTPUT:

- A 2-tuple (m, β) defined as follows.

ALGORITHM:

Each element of the extended affine Weyl group corresponds to an alcove, and each alcove has a face for each affine Dynkin node. Given the data of `self` and `i`, let the extended affine Weyl group element `self` act on the affine simple root α_i , yielding a real affine root, which can be expressed uniquely as

$$\text{“self”} \cdot \alpha_i = m\delta + \beta$$

where m is an integer (the height of the i -th bounding hyperplane of the alcove of `self`) and β is a classical root (the normal vector for the hyperplane which points towards the alcove).

EXAMPLES:

```

sage: x = ExtendedAffineWeylGroup(['A', 2, 1]).PW0().an_element(); x
t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2
sage: x.face_data(0)
(-1, alpha[1])

```

first_descent(*side='right', positive=False, index_set=None*)

Return the first descent of self.

INPUT:

- *side* – ‘left’ or ‘right’ (default: ‘right’)
- *positive* – True or False (default: False)
- *index_set* – an optional subset of Dynkin nodes

If *index_set* is not None, then the descent must be in the *index_set*.

EXAMPLES:

```

sage: x = ExtendedAffineWeylGroup(['A', 3, 1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.first_descent()
0
sage: x.first_descent(side='left')
0
sage: x.first_descent(positive=True)
1
sage: x.first_descent(side='left', positive=True)
1

```

has_descent(*i, side='right', positive=False*)

Return whether $\text{self} * s_i < \text{self}$ where s_i is the i -th simple reflection in the realized group.

INPUT:

- *i* – an affine Dynkin index

OPTIONAL:

- *side* – ‘right’ or ‘left’ (default: ‘right’)
- *positive* – True or False (default: False)

If *side* = ‘left’ then the reflection acts on the left. If *positive* = True then the inequality is reversed.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A', 3, 1]); WF=E.WF()
sage: F = E.fundamental_group()
sage: x = WF.an_element(); x
S0*S1*S2*S3 * pi[3]
sage: I = E.cartan_type().index_set()
sage: [(i, x.has_descent(i)) for i in I]
[(0, True), (1, False), (2, False), (3, False)]
sage: [(i, x.has_descent(i, side='left')) for i in I]
[(0, True), (1, False), (2, False), (3, False)]
sage: [(i, x.has_descent(i, positive=True)) for i in I]
[(0, False), (1, True), (2, True), (3, True)]

```

Warning: This method is abstract because it is used in the recursive coercions between “PW0” and “WF” and other methods use this coercion.

is_affine_grassmannian()

Return whether `self` is affine Grassmannian.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PW0=E.PW0()
sage: F = E.fundamental_group()
sage: [(x,PW0.from_fundamental(x).is_affine_grassmannian()) for x in F]
[(pi[0], True), (pi[1], True), (pi[2], True)]
sage: b = E.lattice_basis()
sage: [(-x,PW0.from_translation(-x).is_affine_grassmannian()) for x in b]
[(-Lambdacheck[1], True), (-Lambdacheck[2], True)]
```

is_grassmannian(index_set, side='right')

Return whether `self` is of minimum length in its coset with respect to the subgroup generated by the reflections of `index_set`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: x = PW0.from_translation(E.lattice_basis()[1]); x
t[Lambdacheck[1]]
sage: I = E.cartan_type().index_set()
sage: [(i, x.is_grassmannian(index_set=[i])) for i in I]
[(0, True), (1, False), (2, True), (3, True)]
sage: [(i, x.is_grassmannian(index_set=[i], side='left')) for i in I]
[(0, False), (1, True), (2, True), (3, True)]
```

is_translation()

Return whether `self` is a translation element or not.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); FW=E.FW()
sage: F = E.fundamental_group()
sage: FW.from_affine_weyl(E.affine_weyl().from_reduced_word([1,2,1,0])).
↪is_translation()
True
sage: FW.from_translation(E.lattice_basis()[1]).is_translation()
True
sage: FW.simple_reflection(0).is_translation()
False
```

length()

Return the length of `self` in the Coxeter group sense.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: I0 = E.cartan_type().classical().index_set()
sage: [PW0.from_translation(E.lattice_basis()[i]).length() for i in I0]
[3, 4, 3]
```

to_affine_grassmannian()

Return the unique affine Grassmannian element in the same coset of `self` with respect to the finite Weyl group acting on the right.

EXAMPLES:

```

sage: elts = ExtendedAffineWeylGroup(['A', 2, 1]).PW0().some_elements()
sage: [(x, x.to_affine_grassmannian()) for x in elts]
[(t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2, t[2*Lambdacheck[1] +
↪ 2*Lambdacheck[2]] * s1*s2*s1)]

```

to_affine_weyl_left()

Return the projection of `self` to the affine Weyl group on the left, after factorizing using the style “WF”.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A', 3, 1]); PW0 = E.PW0()
sage: b = E.lattice_basis()
sage: [(x, PW0.from_translation(x).to_affine_weyl_left()) for x in b]
[(Lambdacheck[1], S0*S3*S2), (Lambdacheck[2], S0*S3*S1*S0), ↪
↪ (Lambdacheck[3], S0*S1*S2)]

```

Warning: Must be implemented in style “WF”.

to_affine_weyl_right()

Return the projection of `self` to the affine Weyl group on the right, after factorizing using the style “FW”.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A', 3, 1]); PW0=E.PW0()
sage: b = E.lattice_basis()
sage: [(x, PW0.from_translation(x).to_affine_weyl_right()) for x in b]
[(Lambdacheck[1], S3*S2*S1), (Lambdacheck[2], S2*S3*S1*S2), ↪
↪ (Lambdacheck[3], S1*S2*S3)]

```

Warning: Must be implemented in style “FW”.

to_classical_weyl()

Return the image of `self` under the homomorphism to the classical Weyl group.

EXAMPLES:

```

sage: ExtendedAffineWeylGroup(['A', 3, 1]).WF().simple_reflection(0).to_
↪ classical_weyl()
s1*s2*s3*s2*s1

```

Warning: Must be implemented in style “PW0”.

to_dual_classical_weyl()

Return the image of `self` under the homomorphism to the dual form of the classical Weyl group.

EXAMPLES:

```

sage: x = ExtendedAffineWeylGroup(['A', 3, 1]).WF().simple_reflection(0).
↳to_dual_classical_weyl(); x
s1*s2*s3*s2*s1
sage: x.parent()
Weyl Group of type ['A', 3] (as a matrix group acting on the weight
↳lattice)

```

Warning: Must be implemented in style “PvW0”.

to_dual_translation_left()

Return the projection of `self` to the dual translation lattice after factorizing it to the left using the style “PvW0”.

EXAMPLES:

```

sage: ExtendedAffineWeylGroup(['A', 3, 1]).PvW0().simple_reflection(0).to_
↳dual_translation_left()
Lambda[1] + Lambda[3]

```

Warning: Must be implemented in style “PvW0”.

to_dual_translation_right()

Return the projection of `self` to the dual translation lattice after factorizing it to the right using the style “W0Pv”.

EXAMPLES:

```

sage: ExtendedAffineWeylGroup(['A', 3, 1]).PW0().simple_reflection(0).to_
↳dual_translation_right()
-Lambda[1] - Lambda[3]

```

Warning: Must be implemented in style “W0Pv”.

to_fundamental_group()

Return the image of `self` under the homomorphism to the fundamental group.

EXAMPLES:

```

sage: PW0 = ExtendedAffineWeylGroup(['A', 3, 1]).PW0()
sage: b = PW0.realization_of().lattice_basis()
sage: [(x, PW0.from_translation(x).to_fundamental_group()) for x in b]
[(Lambdacheck[1], pi[1]), (Lambdacheck[2], pi[2]), (Lambdacheck[3],
↳pi[3])]

```

Warning: Must be implemented in style “WF”.

to_translation_left()

Return the projection of `self` to the translation lattice after factorizing it to the left using the style

“PW0”.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A', 3, 1]).PW0().simple_reflection(0).to_
↳translation_left()
Lambdacheck[1] + Lambdacheck[3]
```

Warning: Must be implemented in style “PW0”.

to_translation_right()

Return the projection of `self` to the translation lattice after factorizing it to the right using the style “WOP”.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A', 3, 1]).PW0().simple_reflection(0).to_
↳translation_right()
-Lambdacheck[1] - Lambdacheck[3]
```

Warning: Must be implemented in style “WOP”.

class ParentMethods

Bases: object

from_affine_weyl(*w*)

Return the image of *w* under the homomorphism from the affine Weyl group into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 3, 1]); PW0=E.PW0()
sage: W = E.affine_weyl()
sage: w = W.from_reduced_word([2, 1, 3, 0])
sage: x = PW0.from_affine_weyl(w); x
t[Lambdacheck[1] - 2*Lambdacheck[2] + Lambdacheck[3]] * s3*s1
sage: FW = E.FW()
sage: y = FW.from_affine_weyl(w); y
S2*S3*S1*S0
sage: FW(x) == y
True
```

Warning: Must be implemented in style “WF” and “FW”.

from_classical_weyl(*w*)

Return the image of *w* from the finite Weyl group into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A', 3, 1]); PW0=E.PW0()
sage: W0 = E.classical_weyl()
sage: w = W0.from_reduced_word([2, 1, 3])
```

(continues on next page)

(continued from previous page)

```

sage: y = PW0.from_classical_weyl(w); y
s2*s3*s1
sage: y.parent() == PW0
True
sage: y.to_classical_weyl() == w
True
sage: W0P = E.W0P()
sage: z = W0P.from_classical_weyl(w); z
s2*s3*s1
sage: z.parent() == W0P
True
sage: W0P(y) == z
True
sage: FW = E.FW()
sage: x = FW.from_classical_weyl(w); x
S2*S3*S1
sage: x.parent() == FW
True
sage: FW(y) == x
True
sage: FW(z) == x
True

```

Warning: Must be implemented in style “PW0” and “W0P”.

`from_dual_classical_weyl(w)`

Return the image of w from the finite Weyl group of dual form into `self`.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A', 3, 1]); PvW0 = E.PvW0()
sage: W0v = E.dual_classical_weyl()
sage: w = W0v.from_reduced_word([2, 1, 3])
sage: y = PvW0.from_dual_classical_weyl(w); y
s2*s3*s1
sage: y.parent() == PvW0
True
sage: y.to_dual_classical_weyl() == w
True
sage: x = E.FW().from_dual_classical_weyl(w); x
S2*S3*S1
sage: PvW0(x) == y
True

```

Warning: Must be implemented in style “PvW0” and “W0Pv”.

`from_dual_translation(la)`

Return the image of la under the homomorphism of the dual version of the translation lattice into `self`.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A',2,1]); PvW0 = E.PvW0()
sage: bv = E.dual_lattice_basis(); bv
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: x = PvW0.from_dual_translation(2*bv[1]-bv[2]); x
t[2*Lambda[1] - Lambda[2]]
sage: FW = E.FW()
sage: y = FW.from_dual_translation(2*bv[1]-bv[2]); y
S0*S2*S0*S1
sage: FW(x) == y
True

```

from_fundamental(*x*)Return the image of *x* under the homomorphism from the fundamental group into self.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A',3,1])
sage: PW0=E.PW0()
sage: F = E.fundamental_group()
sage: Is = F.special_nodes()
sage: [(i, PW0.from_fundamental(F(i))) for i in Is]
[(0, 1), (1, t[Lambdacheck[1]] * s1*s2*s3), (2, t[Lambdacheck[2]] *
↪s2*s3*s1*s2), (3, t[Lambdacheck[3]] * s3*s2*s1)]
sage: [(i, E.WOP().from_fundamental((F(i)))) for i in Is]
[(0, 1), (1, s1*s2*s3 * t[-Lambdacheck[3]]), (2, s2*s3*s1*s2 * t[-
↪Lambdacheck[2]]), (3, s3*s2*s1 * t[-Lambdacheck[1]])]
sage: [(i, E.WF().from_fundamental(F(i))) for i in Is]
[(0, 1), (1, pi[1]), (2, pi[2]), (3, pi[3])]

```

Warning: This method must be implemented by the “WF” and “FW” realizations.

from_reduced_word(*word*)

Converts an affine or finite reduced word into a group element.

EXAMPLES:

```

sage: ExtendedAffineWeylGroup(['A',2,1]).PW0().from_reduced_word([1,0,1,
↪2])
t[-Lambdacheck[1] + 2*Lambdacheck[2]]

```

from_translation(*la*)Return the element of translation by *la* in self.

INPUT:

- self – a realization of the extended affine Weyl group
- la – an element of the translation lattice

In the notation of the documentation for *ExtendedAffineWeylGroup()*, *la* must be an element of “P”.

EXAMPLES:

```

sage: E = ExtendedAffineWeylGroup(['A', 2, 1]); PW0=E.PW0()
sage: b = E.lattice_basis(); b
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}
sage: x = PW0.from_translation(2*b[1]-b[2]); x
t[2*Lambdacheck[1] - Lambdacheck[2]]
sage: FW = E.FW()
sage: y = FW.from_translation(2*b[1]-b[2]); y
S0*S2*S0*S1
sage: FW(x) == y
True

```

Since the implementation as a semidirect product requires wrapping the lattice group to make it multiplicative, we cannot declare that this map is a morphism for sage Groups().

Warning: This method must be implemented by the “PW0” and “WOP” realizations.

simple_reflection(*i*)

Return the *i*-th simple reflection in self.

INPUT:

- self – a realization of the extended affine Weyl group
- *i* – An affine Dynkin node

EXAMPLES:

```

sage: ExtendedAffineWeylGroup(['A', 3, 1]).PW0().simple_reflection(0)
t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1
sage: ExtendedAffineWeylGroup(['C', 2, 1]).WF().simple_reflection(0)
S0
sage: ExtendedAffineWeylGroup(['D', 3, 2]).PvW0().simple_reflection(1)
s1

```

simple_reflections()

Return a family from the set of affine Dynkin nodes to the simple reflections in the realization of the extended affine Weyl group.

EXAMPLES:

```

sage: ExtendedAffineWeylGroup(['A', 3, 1]).WOP().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]], 1:
↪ s1, 2: s2, 3: s3}
sage: ExtendedAffineWeylGroup(['A', 3, 1]).WF().simple_reflections()
Finite family {0: S0, 1: S1, 2: S2, 3: S3}
sage: ExtendedAffineWeylGroup(['A', 3, 1], print_tuple=True).FW().simple_
↪ reflections()
Finite family {0: (pi[0], S0), 1: (pi[0], S1), 2: (pi[0], S2), 3: (pi[0],
↪ S3)}
sage: ExtendedAffineWeylGroup(['A', 3, 1], fundamental="f", print_
↪ tuple=True).FW().simple_reflections()
Finite family {0: (f[0], S0), 1: (f[0], S1), 2: (f[0], S2), 3: (f[0],
↪ S3)}
sage: ExtendedAffineWeylGroup(['A', 3, 1]).PvW0().simple_reflections()
Finite family {0: t[Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1, 1: s1, 2:
↪ s2, 3: s3}

```

super_categories()

EXAMPLES:

```
sage: R = ExtendedAffineWeylGroup(['A',2,1]).Realizations(); R
Category of realizations of Extended affine Weyl group of type ['A', 2, 1]
sage: R.super_categories()
[Category of associative inverse realizations of unital magmas]
```

WOP()

Realizes self in “WOP”-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).WOP()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Weyl Group of type ['A', 2] (as a matrix group acting on the coweight
↳ lattice) acting on Multiplicative form of Coweight lattice of the Root system
↳ of type ['A', 2]
```

WOPv()

Realizes self in “WOPv”-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).WOPv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Weyl Group of type ['A', 2] (as a matrix group acting on the weight
↳ lattice) acting on Multiplicative form of Weight lattice of the Root system
↳ of type ['A', 2]
```

WF()

Realizes self in “WF”-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).WF()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root
↳ lattice) acted upon by Fundamental group of type ['A', 2, 1]
```

WF_to_PW0_func(x)

Coercion from style “WF” to “PW0”.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(["A", 2, 1])
sage: x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
sage: E.WF_to_PW0_func(x)
t[Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2*s1
```

Warning: Since this is used to define some coercion maps it cannot itself use coercion.

a_realization()

Return the default realization of an extended affine Weyl group.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).a_realization()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
↳ of Multiplicative form of Coweight lattice of the Root system of type ['A',
↳ 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the
↳ coweight lattice)
```

affine_weyl()

Return the affine Weyl group of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).affine_weyl()
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).affine_weyl()
Weyl Group of type ['B', 3, 1]^* (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(['A',4,2]).affine_weyl()
Weyl Group of type ['BC', 2, 2] (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).affine_weyl()
Weyl Group of type ['BC', 2, 2]^* (as a matrix group acting on the root lattice)
```

cartan_type()

The Cartan type of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(["D",3,2]).cartan_type()
['C', 2, 1]^*
```

classical_weyl()

Return the classical Weyl group of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(['A',4,2]).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the coweight lattice)
```

classical_weyl_to_affine(w)

The image of w under the homomorphism from the classical Weyl group into the affine Weyl group.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: W0 = E.classical_weyl()
sage: w = W0.from_reduced_word([1,2]); w
s1*s2
sage: v = E.classical_weyl_to_affine(w); v
S1*S2
```

dual_classical_weyl()

Return the dual version of the classical Weyl group of `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
```

dual_classical_weyl_to_affine(w)

The image of w under the homomorphism from the dual version of the classical Weyl group into the affine Weyl group.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: W0v = E.dual_classical_weyl()
sage: w = W0v.from_reduced_word([1,2]); w
s1*s2
sage: v = E.dual_classical_weyl_to_affine(w); v
S1*S2
```

dual_lattice()

Return the dual version of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_lattice()
Weight lattice of the Root system of type ['A', 2]
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_lattice()
Weight lattice of the Root system of type ['C', 3]
```

dual_lattice_basis()

Return the distinguished basis of the dual version of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
```

exp_dual_lattice()

Return the multiplicative version of the dual version of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).exp_dual_lattice()
Multiplicative form of Weight lattice of the Root system of type ['A', 2]
```

exp_lattice()

Return the multiplicative version of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).exp_lattice()
Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
```

fundamental_group()

Return the abstract fundamental group.

EXAMPLES:

```
sage: F = ExtendedAffineWeylGroup(['D',5,1]).fundamental_group(); F
Fundamental group of type ['D', 5, 1]
sage: [a for a in F]
[pi[0], pi[1], pi[4], pi[5]]
```

group_generators()

Return a set of generators for the default realization of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).group_generators()
(t[Lambdaheck[1]], t[Lambdaheck[2]], s1, s2)
```

lattice()

Return the translation lattice for self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).lattice()
Coweight lattice of the Root system of type ['A', 2]
sage: ExtendedAffineWeylGroup(['A',5,2]).lattice()
Weight lattice of the Root system of type ['C', 3]
sage: ExtendedAffineWeylGroup(['A',4,2]).lattice()
Weight lattice of the Root system of type ['C', 2]
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).lattice()
Coweight lattice of the Root system of type ['B', 2]
sage: ExtendedAffineWeylGroup(CartanType(['A',2,1]), general_linear=True).
↪lattice()
Ambient space of the Root system of type ['A', 2]
```

lattice_basis()

Return the distinguished basis of the translation lattice for self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).lattice_basis()
Finite family {1: Lambdaheck[1], 2: Lambdaheck[2]}
sage: ExtendedAffineWeylGroup(['A',5,2]).lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
sage: ExtendedAffineWeylGroup(['A',4,2]).lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).lattice_basis()
Finite family {1: Lambdaheck[1], 2: Lambdaheck[2]}
```

5.1.261 Fundamental Group of an Extended Affine Weyl Group

AUTHORS:

- Mark Shimozono (2013) initial version

class `sage.combinat.root_system.fundamental_group.FundamentalGroupElement`(*parent, x*)
 Bases: `sage.structure.element.MultiplicativeGroupElement`

This should not be called directly

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import _
      ↪FundamentalGroupOfExtendedAffineWeylGroup
sage: x = FundamentalGroupOfExtendedAffineWeylGroup(['A', 4, 1], prefix="f").an_
      ↪element()
sage: TestSuite(x).run()
```

act_on_affine_lattice(*wt*)

Act by self on the element *wt* of an affine root/weight lattice realization.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import _
      ↪FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 3, 1])
sage: wt = RootSystem(F.cartan_type()).weight_lattice().an_element(); wt
2*Lambda[0] + 2*Lambda[1] + 3*Lambda[2]
sage: F(3).act_on_affine_lattice(wt)
2*Lambda[0] + 3*Lambda[1] + 2*Lambda[3]
```

Warning: Doesn't work on ambient spaces.

act_on_affine_weyl(*w*)

Act by self on the element *w* of the affine Weyl group.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import _
      ↪FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 3, 1])
sage: W = WeylGroup(F.cartan_type(), prefix="s")
sage: w = W.from_reduced_word([2, 3, 0])
sage: F(1).act_on_affine_weyl(w).reduced_word()
[3, 0, 1]
```

inverse()

Return the inverse element of self.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import _
      ↪FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 3, 1])
sage: F(1).inverse()
```

(continues on next page)

(continued from previous page)

```

pi[3]
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['E',6,1], prefix="f")
sage: F(1).inverse()
f[6]

```

value()

Return the special node which indexes the special automorphism self.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1], prefix="f")
sage: F.special_nodes()
(0, 1, 2, 3, 4)
sage: x = F(4); x
f[4]
sage: x.value()
4

```

class sage.combinat.root_system.fundamental_group.FundamentalGroupGL(*cartan_type*, *prefix='pi'*)

Bases: *sage.combinat.root_system.fundamental_group.FundamentalGroupOfExtendedAffineWeylGroup_Class*

Fundamental group of GL_n . It is just the integers with extra privileges.

Element

alias of *FundamentalGroupGLElement*

action(*i*)

The action of the *i*-th automorphism on the affine Dynkin node set.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_
↳ linear=True)
sage: F.action(4)(2)
0
sage: F.action(-4)(2)
1

```

an_element()

An element of self.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).
↳ an_element()
pi[5]

```

dual_node(*i*)

The node whose special automorphism is inverse to that of *i*.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_
↳ linear=True)
sage: F.dual_node(2)
-2

```

family()

The family associated with the set of special nodes.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: fam = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_
↳ linear=True).family() # indirect doctest
sage: fam
Lazy family (<lambda>(i))_{i in Integer Ring}
sage: fam[-3]
-3

```

group_generators()

Return group generators for self.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).
↳ group_generators()
(pi[1],)

```

one()

Return the identity element of the fundamental group.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).
↳ one()
pi[0]

```

product(x, y)

Return the product of x and y .

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_
↳ linear=True)
sage: F.special_nodes()
Integer Ring
sage: F(2)*F(3)

```

(continues on next page)

(continued from previous page)

```

pi[5]
sage: F(1)*F(3)^(-1)
pi[-2]

```

reduced_word(*i*)

A reduced word for the finite permutation part of the special automorphism indexed by *i*.

More precisely, return a reduced word for the finite Weyl group element *u* where *i*-th automorphism (expressed in the extended affine Weyl group) has the form *tu* where *t* is a translation element.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_
↳ linear=True)
sage: F.reduced_word(10)
(1, 2)

```

some_elements()

Return some elements of self.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).
↳ some_elements()
[pi[-2], pi[2], pi[5]]

```

class `sage.combinat.root_system.fundamental_group.FundamentalGroupGLElement`(*parent*, *x*)
 Bases: `sage.combinat.root_system.fundamental_group.FundamentalGroupElement`

act_on_classical_ambient(*wt*)

Act by self on the classical ambient weight vector *wt*.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_
↳ linear=True)
sage: f = F.an_element(); f
pi[5]
sage: la = F.cartan_type().classical().root_system().ambient_space().an_
↳ element(); la
(2, 2, 3)
sage: f.act_on_classical_ambient(la)
(2, 3, 2)

```

`sage.combinat.root_system.fundamental_group.FundamentalGroupOfExtendedAffineWeylGroup`(*cartan_type*,
pre_fix='pi',
general_linear=None)

Factory for the fundamental group of an extended affine Weyl group.

INPUT:

- `cartan_type` – a Cartan type that is either affine or finite, with the latter being a shorthand for the untwisted affinization
- `prefix` (default: ‘pi’) – string that labels the elements of the group
- `general_linear` – (default: None, meaning False) In untwisted type A, if True, use the universal central extension

Fundamental group

Associated to each affine Cartan type \tilde{X} is an extended affine Weyl group E . Its subgroup of length-zero elements is called the fundamental group F . The group F can be identified with a subgroup of the group of automorphisms of the affine Dynkin diagram. As such, every element of F can be viewed as a permutation of the set I of affine Dynkin nodes.

Let $0 \in I$ be the distinguished affine node; it is the one whose removal produces the associated finite Cartan type (call it X). A node $i \in I$ is called *special* if some automorphism of the affine Dynkin diagram, sends 0 to i . The node 0 is always special due to the identity automorphism. There is a bijection of the set of special nodes with the fundamental group. We denote the image of i by π_i . The structure of F is determined as follows.

- \tilde{X} is untwisted – F is isomorphic to P^\vee/Q^\vee where P^\vee and Q^\vee are the coweight and coroot lattices of type X . The group P^\vee/Q^\vee consists of the cosets $\omega_i^\vee + Q^\vee$ for special nodes i , where $\omega_0^\vee = 0$ by convention. In this case the special nodes i are the *cominuscule* nodes, the ones such that $\omega_i^\vee(\alpha_j)$ is 0 or 1 for all $j \in I_0 = I \setminus \{0\}$. For i special, addition by $\omega_i^\vee + Q^\vee$ permutes P^\vee/Q^\vee and therefore permutes the set of special nodes. This permutation extends uniquely to an automorphism of the affine Dynkin diagram.
- \tilde{X} is dual untwisted – (that is, the dual of \tilde{X} is untwisted) F is isomorphic to P/Q where P and Q are the weight and root lattices of type X . The group P/Q consists of the cosets $\omega_i + Q$ for special nodes i , where $\omega_0 = 0$ by convention. In this case the special nodes i are the *minuscule* nodes, the ones such that $\alpha_j^\vee(\omega_i)$ is 0 or 1 for all $j \in I_0$. For i special, addition by $\omega_i + Q$ permutes P/Q and therefore permutes the set of special nodes. This permutation extends uniquely to an automorphism of the affine Dynkin diagram.
- \tilde{X} is mixed – (that is, not of the above two types) F is the trivial group.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import _
      ↪ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 3, 1]); F

sage: x.act_on_affine_weyl(w)
s2*s0*s1

```

`class sage.combinat.root_system.fundamental_group.FundamentalGroupOfExtendedAffineWeylGroup_Class` (*cartan*, *pre-*, *fix*, *fi-*, *nite=T*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The group of length zero elements in the extended affine Weyl group.

Element

alias of `FundamentalGroupElement`

action(*i*)

Return a function which permutes the affine Dynkin node set by the *i*-th special automorphism.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1])
sage: [[(i, j, F.action(i)(j)) for j in F.index_set()] for i in F.special_
↳ nodes()]
[[ (0, 0, 0), (0, 1, 1), (0, 2, 2), [(1, 0, 1), (1, 1, 2), (1, 2, 0)], [(2, 0,
↳ 2), (2, 1, 0), (2, 2, 1)] ]
sage: G = FundamentalGroupOfExtendedAffineWeylGroup(['D',4,1])
sage: [[(i, j, G.action(i)(j)) for j in G.index_set()] for i in G.special_
↳ nodes()]
[[ (0, 0, 0), (0, 1, 1), (0, 2, 2), (0, 3, 3), (0, 4, 4), [(1, 0, 1), (1, 1, 0),
↳ (1, 2, 2), (1, 3, 4), (1, 4, 3)], [(3, 0, 3), (3, 1, 4), (3, 2, 2), (3, 3,
↳ 0), (3, 4, 1)], [(4, 0, 4), (4, 1, 3), (4, 2, 2), (4, 3, 1), (4, 4, 0)] ]
```

an_element()

Return an element of self.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1],prefix="f").an_
↳ element()
f[4]
```

cartan_type()

The Cartan type of self.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1]).cartan_type()
['A', 3, 1]
```

dual_node(*i*)

Return the node that indexes the inverse of the *i*-th element.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import
↳FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1])
sage: [(i, F.dual_node(i)) for i in F.special_nodes()]
[(0, 0), (1, 4), (2, 3), (3, 2), (4, 1)]
sage: G = FundamentalGroupOfExtendedAffineWeylGroup(['E',6,1])
sage: [(i, G.dual_node(i)) for i in G.special_nodes()]
[(0, 0), (1, 6), (6, 1)]
sage: H = FundamentalGroupOfExtendedAffineWeylGroup(['D',5,1])
sage: [(i, H.dual_node(i)) for i in H.special_nodes()]
[(0, 0), (1, 1), (4, 5), (5, 4)]

```

group_generators()

Return a tuple of generators of the fundamental group.

Warning: This returns the entire group, a necessary behavior because it is used in `__iter__()`.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import
↳FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['E',6,1],prefix="f").group_
↳generators()
Finite family {0: f[0], 1: f[1], 6: f[6]}

```

index_set()

The node set of the affine Cartan type of self.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import
↳FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1]).index_set()
(0, 1, 2)

```

one()

Return the identity element of the fundamental group.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import
↳FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: F.one()
pi[0]

```

product(x, y)

Return the product of x and y .

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import
↳FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])

```

(continues on next page)

(continued from previous page)

```

sage: F.special_nodes()
(0, 1, 2, 3)
sage: F(2)*F(3)
pi[1]
sage: F(1)*F(3)^(-1)
pi[2]

```

reduced_word(*i*)

Return a reduced word for the finite Weyl group element associated with the *i*-th special automorphism.

More precisely, for each special node *i*, `self.reduced_word(i)` is a reduced word for the element *v* in the finite Weyl group such that in the extended affine Weyl group, the *i*-th special automorphism is equal to *tv* where *t* is a translation element.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 3, 1])
sage: [(i, F.reduced_word(i)) for i in F.special_nodes()]
[(0, ()), (1, (1, 2, 3)), (2, (2, 1, 3, 2)), (3, (3, 2, 1))]

```

special_nodes()

Return the special nodes of `self`.

See `sage.combinat.root_system.cartan_type.special_nodes()`.

EXAMPLES:

```

sage: from sage.combinat.root_system.fundamental_group import _
↳ FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['D', 4, 1]).special_nodes()
(0, 1, 3, 4)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A', 2, 1]).special_nodes()
(0, 1, 2)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['C', 3, 1]).special_nodes()
(0, 3)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['D', 4, 2]).special_nodes()
(0, 3)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A', 2, 1], general_linear=True).
↳ special_nodes()
Integer Ring

```

5.1.262 Root system data for folded Cartan types

AUTHORS:

- Travis Scrimshaw (2013-01-12) - Initial version

class `sage.combinat.root_system.type_folded.CartanTypeFolded`(*cartan_type*, *folding_of_orbit*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.sage_object.SageObject`

A Cartan type realized from a (Dynkin) diagram folding.

Given a Cartan type X , we say \hat{X} is a folded Cartan type of X if there exists a diagram folding of the Dynkin diagram of \hat{X} onto X .

A folding of a simply-laced Dynkin diagram D with index set I is an automorphism σ of D where all nodes any orbit of σ are not connected. The resulting Dynkin diagram \hat{D} is induced by I/σ where we identify edges in \hat{D} which are not incident and add a k -edge if we identify k incident edges and the arrow is pointing towards the incident node. We denote the index set of \hat{D} by \hat{I} , and by abuse of notation, we denote the folding by σ .

We also have scaling factors γ_i for $i \in \hat{I}$ and defined as the unique numbers such that the map $\Lambda_j \mapsto \gamma_j \sum_{i \in \sigma^{-1}(j)} \Lambda_i$ is the smallest proper embedding of the weight lattice of X to \hat{X} .

If the Cartan type is simply laced, the default folding is the one induced from the identity map on D .

If X is affine type, the default embeddings we consider here are:

$$\begin{aligned} C_n^{(1)}, A_{2n}^{(2)}, A_{2n}^{(2)\dagger}, D_{n+1}^{(2)} &\hookrightarrow A_{2n-1}^{(1)}, \\ A_{2n-1}^{(2)}, B_n^{(1)} &\hookrightarrow D_{n+1}^{(1)}, \\ E_6^{(2)}, F_4^{(1)} &\hookrightarrow E_6^{(1)}, \\ D_4^{(3)}, G_2^{(1)} &\hookrightarrow D_4^{(1)}, \end{aligned}$$

and were chosen based on virtual crystals. In particular, the diagram foldings extend to crystal morphisms and gives a realization of Kirillov-Reshetikhin crystals for non-simply-laced types as simply-laced types. See [OSShimo03] and [FOS2009] for more details. Here we can compute $\gamma_i = \max(c)/c_i$ where $(c_i)_i$ are the translation factors of the root system. In a more type-dependent way, we can define γ_i as follows:

1. There exists a unique arrow (multiple bond) in X .
 - a. Suppose the arrow points towards 0. Then $\gamma_i = 1$ for all $i \in I$.
 - b. Otherwise γ_i is the order of σ for all i in the connected component of 0 after removing the arrow, else $\gamma_i = 1$.
2. There is not a unique arrow. Thus $\hat{X} = A_{2n-1}^{(1)}$ and $\gamma_i = 1$ for all $1 \leq i \leq n-1$. If $i \in \{0, n\}$, then $\gamma_i = 2$ if the arrow incident to i points away and is 1 otherwise.

We note that γ_i only depends upon X .

If the Cartan type is finite, then we consider the classical foldings/embeddings induced by the above affine foldings/embeddings:

$$\begin{aligned} C_n &\hookrightarrow A_{2n-1}, \\ B_n &\hookrightarrow D_{n+1}, \\ F_4 &\hookrightarrow E_6, \\ G_2 &\hookrightarrow D_4. \end{aligned}$$

For more information on Cartan types, see `sage.combinat.root_system.cartan_type`.

Other foldings may be constructed by passing in an optional `folding_of` second argument. See below.

INPUT:

- `cartan_type` – the Cartan type X to create the folded type
- `folding_of` – the Cartan type \hat{X} which X is a folding of
- `orbit` – the orbit of the Dynkin diagram automorphism σ given as a list of lists where the a -th list corresponds to the a -th entry in I or a dictionary with keys in I and values as lists

Note: If X is an affine type, we assume the special node is fixed under σ .

EXAMPLES:

```

sage: fct = CartanType(['C',4,1]).as_folding(); fct
['C', 4, 1] as a folding of ['A', 7, 1]
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}

```

A simply laced Cartan type can be considered as a virtual type of itself:

```

sage: fct = CartanType(['A',4,1]).as_folding(); fct
['A', 4, 1] as a folding of ['A', 4, 1]
sage: fct.scaling_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1,), 2: (2,), 3: (3,), 4: (4,)}

```

Finite types:

```

sage: fct = CartanType(['C',4]).as_folding(); fct
['C', 4] as a folding of ['A', 7]
sage: fct.scaling_factors()
Finite family {1: 1, 2: 1, 3: 1, 4: 2}
sage: fct.folding_orbit()
Finite family {1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}

sage: fct = CartanType(['F',4]).dual().as_folding(); fct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1} as a folding of ['E', 6]
sage: fct.scaling_factors()
Finite family {1: 1, 2: 1, 3: 2, 4: 2}
sage: fct.folding_orbit()
Finite family {1: (1, 6), 2: (3, 5), 3: (4,), 4: (2,)}

```

REFERENCES:

- [Wikipedia article Dynkin_diagram#Folding](#)

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```

sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.cartan_type()
['C', 4, 1]

```

folding_of()

Return the Cartan type of the virtual space.

EXAMPLES:

```

sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.folding_of()
['A', 7, 1]

```

folding_orbit()

Return the orbits under the automorphism σ as a dictionary (of tuples).

EXAMPLES:

```
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}
```

scaling_factors()

Return the scaling factors of self.

EXAMPLES:

```
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct = CartanType(['BC', 4, 2]).as_folding()
sage: fct.scaling_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct = CartanType(['BC', 4, 2]).dual().as_folding()
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}
sage: CartanType(['BC', 4, 2]).relabel({0:4, 1:3, 2:2, 3:1, 4:0}).as_folding().
↳ scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}
```

5.1.263 Root system data for Cartan types with marked nodes

class `sage.combinat.root_system.type_marked.AmbientSpace`(*root_system, base_ring, index_set=None*)
 Bases: `sage.combinat.root_system.ambient_space.AmbientSpace`

Ambient space for a marked finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type.

EXAMPLES:

```
sage: L = CartanType(['F', 4]).marked_nodes([1, 3]).root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4] with nodes (1, 3) marked
sage: TestSuite(L).run()
```

dimension()

Return the dimension of this ambient space.

See also:

`sage.combinat.root_system.ambient_space.AmbientSpace.dimension()`

EXAMPLES:

```
sage: L = CartanType(['F', 4]).marked_nodes([1, 3]).root_system().ambient_space()
sage: L.dimension()
4
```

fundamental_weight(*i*)

Return the *i*-th fundamental weight.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: L = CartanType(["F",4]).marked_nodes([1,3]).root_system().ambient_space()
sage: L.fundamental_weight(1)
(1, 1, 0, 0)
sage: L.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0),
               3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
```

simple_root(*i*)

Return the *i*-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: L = CartanType(["F",4]).marked_nodes([1,3]).root_system().ambient_space()
sage: L.simple_root(1)
(0, 1, -1, 0)
sage: L.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1),
               3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}
sage: L.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1),
               3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
```

class sage.combinat.root_system.type_marked.**CartanType**(*ct*, *marked_nodes*)

Bases: *sage.combinat.root_system.cartan_type.CartanType_decorator*

A class for Cartan types with marked nodes.

INPUT:

- *ct* – a Cartan type
- *marked_nodes* – a list of marked nodes

EXAMPLES:

We take the Cartan type B_4 :

```
sage: T = CartanType(['B',4])
sage: T.dynkin_diagram()
0---0---0=>=0
1  2  3  4
B4
```

And mark some of its nodes:

```
sage: T = T.marked_nodes([2,3])
sage: T.dynkin_diagram()
0---X---X=>=0
1  2  3  4
B4 with nodes (2, 3) marked
```

Markings are not additive:

```
sage: T.marked_nodes([1,4]).dynkin_diagram()
```

```
X---0---0=>=X
```

```
1 2 3 4
```

```
B4 with nodes (1, 4) marked
```

And trivial relabelling are honoured nicely:

```
sage: T = T.marked_nodes([])
```

```
sage: T.dynkin_diagram()
```

```
0---0---0=>=0
```

```
1 2 3 4
```

```
B4
```

ascii_art(label=<function CartanType.<lambda> at 0x7f87497bae50>, node=None)

Return an ascii art representation of this Cartan type.

EXAMPLES:

```
sage: print(CartanType(["G", 2]).marked_nodes([2]).ascii_art())
```

```
3
```

```
0=<=X
```

```
1 2
```

```
sage: print(CartanType(["B", 3, 1]).marked_nodes([0, 3]).ascii_art())
```

```
X 0
```

```
|
```

```
|
```

```
0---0=>=X
```

```
1 2 3
```

```
sage: print(CartanType(["F", 4, 1]).marked_nodes([0, 2]).ascii_art())
```

```
X---0---X=>=0---0
```

```
0 1 2 3 4
```

dual()

Implements `sage.combinat.root_system.cartan_type.CartanType_abstract.dual()`, using that taking the dual and marking nodes are commuting operations.

EXAMPLES:

```
sage: T = CartanType(["BC", 3, 2])
```

```
sage: T.marked_nodes([1,3]).dual().dynkin_diagram()
```

```
0=>=X---0=>=X
```

```
0 1 2 3
```

```
BC3~* with nodes (1, 3) marked
```

```
sage: T.dual().marked_nodes([1,3]).dynkin_diagram()
```

```
0=>=X---0=>=X
```

```
0 1 2 3
```

```
BC3~* with nodes (1, 3) marked
```

dynkin_diagram()

Return the Dynkin diagram for this Cartan type.

EXAMPLES:

```
sage: CartanType(["G", 2]).marked_nodes([2]).dynkin_diagram()
```

```
3
```

(continues on next page)

(continued from previous page)

```

0=<=X
1 2
G2 with node 2 marked

```

marked_nodes(*marked_nodes*)Return self with nodes `marked_nodes` marked.

EXAMPLES:

```

sage: ct = CartanType(['A', 12])
sage: m = ct.marked_nodes([1, 4, 6, 7, 8, 12]); m
['A', 12] with nodes (1, 4, 6, 7, 8, 12) marked
sage: m.marked_nodes([2])
['A', 12] with node 2 marked
sage: m.marked_nodes([]) is ct
True

```

relabel(*relabelling*)

Return the relabelling of self.

EXAMPLES:

```

sage: T = CartanType(["BC", 3, 2])
sage: T.marked_nodes([1, 3]).relabel(lambda x: x+2).dynkin_diagram()
0=<=X---0=<=X
2 3 4 5
BC3~ relabelled by {0: 2, 1: 3, 2: 4, 3: 5} with nodes (3, 5) marked
sage: T.relabel(lambda x: x+2).marked_nodes([3, 5]).dynkin_diagram()
0=<=X---0=<=X
2 3 4 5
BC3~ relabelled by {0: 2, 1: 3, 2: 4, 3: 5} with nodes (3, 5) marked

```

type()

Return the type of self or None if unknown.

EXAMPLES:

```

sage: ct = CartanType(['F', 4]).marked_nodes([1, 3])
sage: ct.type()
'F'

```

class `sage.combinat.root_system.type_marked.CartanType_affine`(*ct, marked_nodes*)Bases: `sage.combinat.root_system.type_marked.CartanType`, `sage.combinat.root_system.cartan_type.CartanType_affine`**basic_untwisted**()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n . In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

```

sage: CartanType(['A', 7, 2]).marked_nodes([1, 3]).basic_untwisted()
['A', 7] with nodes (1, 3) marked

```

(continues on next page)

(continued from previous page)

```
sage: CartanType(['D', 4, 3]).marked_nodes([0,2]).basic_untwisted()
['D', 4] with node 2 marked
```

classical()

Return the classical Cartan type associated with self.

EXAMPLES:

```
sage: T = CartanType(['A', 4, 1]).marked_nodes([0, 2, 4])
sage: T.dynkin_diagram()
0
X-----+
|         |
|         |
0---X---0---X
1  2  3  4
A4~ with nodes (0, 2, 4) marked

sage: T0 = T.classical()
sage: T0
['A', 4] with nodes (2, 4) marked
sage: T0.dynkin_diagram()
0---X---0---X
1  2  3  4
A4 with nodes (2, 4) marked
```

is_untwisted_affine()

Implement *CartanType_affine.is_untwisted_affine()*.

A marked Cartan type is untwisted affine if the original is.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).marked_nodes([1,3]).is_untwisted_affine()
True
```

special_node()

Return the special node of the Cartan type.

See also:

`special_node()`

It is the special node of the non-marked Cartan type..

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).marked_nodes([1,3]).special_node()
0
```

class sage.combinat.root_system.type_marked.**CartanType_finite**(*ct, marked_nodes*)

Bases: *sage.combinat.root_system.type_marked.CartanType*, *sage.combinat.root_system.cartan_type.CartanType_finite*

AmbientSpace

alias of *AmbientSpace*

affine()

Return the affine Cartan type associated with self.

EXAMPLES:

```
sage: B4 = CartanType(['B',4]).marked_nodes([1,3])
sage: B4.dynkin_diagram()
X---0---X=>=0
1  2  3  4
B4 with nodes (1, 3) marked
sage: B4.affine().dynkin_diagram()
  0 0
  |
  |
X---0---X=>=0
1  2  3  4
B4~ with nodes (1, 3) marked
```

5.1.264 Root system data for reducible Cartan types

class sage.combinat.root_system.type_reducible.**AmbientSpace**(*root_system, base_ring, index_set=None*)

Bases: *sage.combinat.root_system.ambient_space.AmbientSpace*

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space()
Ambient space of the Root system of type A2xB2
```

ambient_spaces()

Returns a list of the irreducible Cartan types of which the given reducible Cartan type is a product.

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().ambient_spaces()
[Ambient space of the Root system of type ['A', 2],
 Ambient space of the Root system of type ['B', 2]]
```

cartan_type()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().cartan_type()
A2xB2
```

component_types()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().component_types()
[['A', 2], ['B', 2]]
```

dimension()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().dimension()
5
```

fundamental_weights()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0, 0), 2: (1, 1, 0, 0, 0), 3: (0, 0, 0, 1, 0), 4: ↵
↵(0, 0, 0, 1/2, 1/2)}
```

inject_weights(i, v)

Produces the corresponding element of the lattice.

INPUT:

- *i* - an integer in range(self.components)
- *v* - a vector in the *i*-th component weight lattice

EXAMPLES:

```
sage: V = RootSystem("A2xB2").ambient_space()
sage: [V.inject_weights(i, V.ambient_spaces()[i].fundamental_weights()[1]) for i ↵
↵in range(2)]
[(1, 0, 0, 0, 0), (0, 0, 0, 1, 0)]
sage: [V.inject_weights(i, V.ambient_spaces()[i].fundamental_weights()[2]) for i ↵
↵in range(2)]
[(1, 1, 0, 0, 0), (0, 0, 0, 1/2, 1/2)]
```

negative_roots()

EXAMPLES:

```
sage: RootSystem("A1xA2").ambient_space().negative_roots()
[(-1, 1, 0, 0, 0), (0, 0, -1, 1, 0), (0, 0, -1, 0, 1), (0, 0, 0, -1, 1)]
```

positive_roots()

EXAMPLES:

```
sage: RootSystem("A1xA2").ambient_space().positive_roots()
[(1, -1, 0, 0, 0), (0, 0, 1, -1, 0), (0, 0, 1, 0, -1), (0, 0, 0, 1, -1)]
```

simple_coroot(i)

EXAMPLES:

```
sage: A = RootSystem("A1xB2").ambient_space()
sage: A.simple_coroot(2)
(0, 0, 1, -1)
sage: A.simple_coroots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2)}
```

simple_root(i)

EXAMPLES:

```
sage: A = RootSystem("A1xB2").ambient_space()
sage: A.simple_root(2)
(0, 0, 1, -1)
sage: A.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1)}
```

```
class sage.combinat.root_system.type_reducible.CartanType(types)
```

```
Bases: sage.structure.sage_object.SageObject, sage.combinat.root_system.cartan_type.
CartanType_abstract
```

A class for reducible Cartan types.

Reducible root systems are ones that can be factored as direct products. Strictly speaking type D_2 (corresponding to orthogonal groups of degree 4) is reducible since it is isomorphic to $A_1 \times A_1$. However type D_2 is not built using this class for our purposes.

INPUT:

- `types` – a list of simple Cartan types

EXAMPLES:

```
sage: t1, t2 = [CartanType(x) for x in (['A',1], ['B',2])]
sage: CartanType([t1, t2])
A1xB2
sage: t = CartanType("A2xB2")
```

A reducible Cartan type is finite (resp. crystallographic, simply laced) if all its components are:

```
sage: t.is_finite()
True
sage: t.is_crystallographic()
True
sage: t.is_simply_laced()
False
```

This is implemented by inserting the appropriate abstract super classes (see `_add_abstract_superclass()`):

```
sage: t.__class__.mro()
[<class 'sage.combinat.root_system.type_reducible.CartanType_with_superclass'>,
 ↪<class 'sage.combinat.root_system.type_reducible.CartanType'>, <class 'sage.
 ↪structure.sage_object.SageObject'>, <class 'sage.combinat.root_system.cartan_type.
 ↪CartanType_finite'>, <class 'sage.combinat.root_system.cartan_type.CartanType_
 ↪crystallographic'>, <class 'sage.combinat.root_system.cartan_type.CartanType_
 ↪abstract'>, <class 'object'>]
```

The index set of the reducible Cartan type is obtained by relabelling successively the nodes of the Dynkin diagrams of the components by 1,2,...:

```
sage: t = CartanType(["A",4], ["BC",5,2], ["C",3])
sage: t.index_set()
(1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13)

sage: t.dynkin_diagram()
0---0---0---0
1  2  3  4
0=<=0---0---0---0=<=0
5  6  7  8  9  10
0---0=<=0
11 12 13
A4xBC5~xC3
```

AmbientSpacealias of *AmbientSpace***ascii_art**(label=<function CartanType.<lambda> at 0x7f87497cd3a0>, node=None)

Return an ascii art representation of this reducible Cartan type.

EXAMPLES:

```

sage: print(CartanType("F4xA2").ascii_art(label = lambda x: x+2))
0---0=>=0---0
3  4  5  6
0---0
7  8

sage: print(CartanType(["BC",5,2], ["A",4]).ascii_art())
0=<=0---0---0---0=<=0
1  2  3  4  5  6
0---0---0---0
7  8  9  10

sage: print(CartanType(["A",4], ["BC",5,2], ["C",3]).ascii_art())
0---0---0---0
1  2  3  4
0=<=0---0---0---0=<=0
5  6  7  8  9  10
0---0=<=0
11  12  13

```

cartan_matrix(subdivide=True)

Return the Cartan matrix associated with self. By default the Cartan matrix is a subdivided block matrix showing the reducibility but the subdivision can be suppressed with the option subdivide = False.

EXAMPLES:

```

sage: ct = CartanType("A2", "B2")
sage: ct.cartan_matrix()
[ 2 -1| 0  0]
[-1  2| 0  0]
[-----+-----]
[ 0  0| 2 -1]
[ 0  0|-2  2]
sage: ct.cartan_matrix(subdivide=False)
[ 2 -1  0  0]
[-1  2  0  0]
[ 0  0  2 -1]
[ 0  0 -2  2]
sage: ct.index_set() == ct.cartan_matrix().index_set()
True

```

component_types()

A list of Cartan types making up the reducible type.

EXAMPLES:

```

sage: CartanType(['A',2], ['B',2]).component_types()
[['A', 2], ['B', 2]]

```

coxeter_diagram()

Return the Coxeter diagram for self.

EXAMPLES:

```
sage: cd = CartanType("A2xB2xF4").coxeter_diagram()
sage: cd
Graph on 8 vertices
sage: cd.edges(sort=True)
[(1, 2, 3), (3, 4, 4), (5, 6, 3), (6, 7, 4), (7, 8, 3)]

sage: CartanType("F4xA2").coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4), (3, 4, 3), (5, 6, 3)]

sage: cd = CartanType("A1xH3").coxeter_diagram(); cd
Graph on 4 vertices
sage: cd.edges(sort=True)
[(2, 3, 3), (3, 4, 5)]
```

dual()

EXAMPLES:

```
sage: CartanType("A2xB2").dual()
A2xC2
```

dynkin_diagram()

Returns a Dynkin diagram for type reducible.

EXAMPLES:

```
sage: dd = CartanType("A2xB2xF4").dynkin_diagram()
sage: dd
0---0
1  2
0=>=0
3  4
0---0=>=0---0
5  6  7  8
A2xB2xF4
sage: dd.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (3, 4, 2), (4, 3, 1), (5, 6, 1), (6, 5, 1), (6, 7, 2),
↪(7, 6, 1), (7, 8, 1), (8, 7, 1)]

sage: CartanType("F4xA2").dynkin_diagram()
0---0=>=0---0
1  2  3  4
0---0
5  6
F4xA2
```

index_set()

Implements *CartanType_abstract.index_set()*.

For the moment, the index set is always of the form $\{1, \dots, n\}$.

EXAMPLES:

```
sage: CartanType("A2", "A1").index_set()
(1, 2, 3)
```

is_affine()

Report that this reducible Cartan type is not affine

EXAMPLES:

```
sage: CartanType(['A', 2], ['B', 2]).is_affine()
False
```

is_finite()

EXAMPLES:

```
sage: ct1 = CartanType(['A', 2], ['B', 2])
sage: ct1.is_finite()
True
sage: ct2 = CartanType(['A', 2], ['B', 2, 1])
sage: ct2.is_finite()
False
```

is_irreducible()

Report that this Cartan type is not irreducible.

EXAMPLES:

```
sage: ct = CartanType(['A', 2], ['B', 2])
sage: ct.is_irreducible()
False
```

rank()

Returns the rank of self.

EXAMPLES:

```
sage: CartanType("A2", "A1").rank()
3
```

type()

Returns “reducible” since the type is reducible.

EXAMPLES:

```
sage: CartanType(['A', 2], ['B', 2]).type()
'reducible'
```

5.1.265 Root system data for relabelled Cartan types

class `sage.combinat.root_system.type_relabel.AmbientSpace`(*root_system*, *base_ring*,
index_set=None)

Bases: `sage.combinat.root_system.ambient_space.AmbientSpace`

Ambient space for a relabelled finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type, by relabelling the simple roots, fundamental weights, etc.

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4] relabelled by {1: 2, 2: 3, 3: 4,
↪4: 1}
sage: TestSuite(L).run()
```

dimension()

Return the dimension of this ambient space.

See also:

`sage.combinat.root_system.ambient_space.AmbientSpace.dimension()`

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space()
sage: L.dimension()
4
```

fundamental_weight(*i*)

Return the *i*-th fundamental weight.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space()
sage: K = CartanType(["F",4]).root_system().ambient_space()
sage: K.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1,
↪0, 0, 0)}
sage: L.fundamental_weight(1)
(1, 0, 0, 0)
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (2, 1, 1, 0), 4: (3/2, 1/2,
↪1/2, 1/2)}
```

simple_root(*i*)

Return the *i*-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```

sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F", 4]).relabel(cycle).root_system().ambient_space()
sage: K = CartanType(["F", 4]).root_system().ambient_space()
sage: K.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}
sage: K.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
sage: L.simple_root(1)
(1/2, -1/2, -1/2, -1/2)

sage: L.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 1)}
sage: L.simple_coroots()
Finite family {1: (1, -1, -1, -1), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 2)}

```

class `sage.combinat.root_system.type_relabel.CartanType`(*type*, *relabelling*)

Bases: `sage.combinat.root_system.cartan_type.CartanType_decorator`

A class for relabelled Cartan types.

ascii_art(*label*=<function CartanType.<lambda> at 0x7f87497d50d0>, *node*=None)

Return an ascii art representation of this Cartan type.

EXAMPLES:

```

sage: print(CartanType(["G", 2]).relabel({1:2,2:1}).ascii_art())
  3
0=<=0
2 1
sage: print(CartanType(["B", 3, 1]).relabel([1,3,2,0]).ascii_art())
  0 1
  |
  |
0---0=>=0
3 2 0
sage: print(CartanType(["F", 4, 1]).relabel(lambda n: 4-n).ascii_art())
0---0---0=>=0---0
4 3 2 1 0

```

coxeter_diagram()

Return the Coxeter diagram for self.

EXAMPLES:

```

sage: ct = CartanType(['H', 3]).relabel({1:3,2:2,3:1})
sage: G = ct.coxeter_diagram(); G
Graph on 3 vertices
sage: G.edges(sort=True)
[(1, 2, 5), (2, 3, 3)]

```

dual()

Implements `sage.combinat.root_system.cartan_type.CartanType_abstract.dual()`, using that taking the dual and relabelling are commuting operations.

EXAMPLES:

```
sage: T = CartanType(["BC", 3, 2])
sage: cycle = {1:2, 2:3, 3:0, 0:1}
sage: T.relabel(cycle).dual().dynkin_diagram()
0=>=0---0=>=0
1  2  3  0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
sage: T.dual().relabel(cycle).dynkin_diagram()
0=>=0---0=>=0
1  2  3  0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
```

dynkin_diagram()

Returns the Dynkin diagram for this Cartan type.

EXAMPLES:

```
sage: CartanType(["G", 2]).relabel({1:2,2:1}).dynkin_diagram()
3
0=<=0
2  1
G2 relabelled by {1: 2, 2: 1}
```

index_set()

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.index_set()
(1, 2)
```

type()

Return the type of `self` or `None` if unknown.

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.type()
'G'
```

class `sage.combinat.root_system.type_relabel.CartanType_affine`(*type*, *relabelling*)

Bases: `sage.combinat.root_system.type_relabel.CartanType`, `sage.combinat.root_system.cartan_type.CartanType_affine`

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n . In other words, it is the classical Cartan type that is twisted to obtain `self`.

EXAMPLES:

```
sage: ct = CartanType(['A', 5, 2]).relabel({0:1, 1:0, 2:2, 3:3})
sage: ct.basic_untwisted()
['A', 5]
```

classical()

Return the classical Cartan type associated with self.

EXAMPLES:

```
sage: A41 = CartanType(['A', 4, 1])
sage: A41.dynkin_diagram()
0
0-----+
|         |
|         |
0---0---0---0
1  2  3  4
A4~

sage: T = A41.relabel({0:1, 1:2, 2:3, 3:4, 4:0})
sage: T
['A', 4, 1] relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}
sage: T.dynkin_diagram()
1
0-----+
|         |
|         |
0---0---0---0
2  3  4  0
A4~ relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}

sage: T0 = T.classical()
sage: T0
['A', 4] relabelled by {1: 2, 2: 3, 3: 4, 4: 0}
sage: T0.dynkin_diagram()
0---0---0---0
2  3  4  0
A4 relabelled by {1: 2, 2: 3, 3: 4, 4: 0}
```

is_untwisted_affine()

Implement *CartanType_affine.is_untwisted_affine()*

A relabelled Cartan type is untwisted affine if the original is.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).relabel({1:2, 2:3, 3:0, 0:1}).is_untwisted_
↪affine()
True
```

special_node()

Returns a special node of the Dynkin diagram

See also:

`special_node()`

It is obtained by relabelling of the special node of the non relabelled Dynkin diagram.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).special_node()
0
sage: CartanType(['B', 3, 1]).relabel({1:2, 2:3, 3:0, 0:1}).special_node()
1
```

class `sage.combinat.root_system.type_relabel.CartanType_finite`(*type, relabelling*)

Bases: `sage.combinat.root_system.type_relabel.CartanType`, `sage.combinat.root_system.cartan_type.CartanType_finite`

AmbientSpace

alias of `AmbientSpace`

affine()

Return the affine Cartan type associated with self.

EXAMPLES:

```
sage: B4 = CartanType(['B', 4])
sage: B4.dynkin_diagram()
0---0---0=>=0
1  2  3  4
B4
sage: B4.affine().dynkin_diagram()
  0 0
  |
  |
0---0---0=>=0
1  2  3  4
B4~
```

If possible, this reuses the original label for the special node:

```
sage: T = B4.relabel({1:2, 2:3, 3:4, 4:1}); T.dynkin_diagram()
0---0---0=>=0
2  3  4  1
B4 relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
sage: T.affine().dynkin_diagram()
  0 0
  |
  |
0---0---0=>=0
2  3  4  1
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}
```

Otherwise, it chooses a label for the special_node in 0, 1, ...:

```
sage: T = B4.relabel({1:0, 2:1, 3:2, 4:3}); T.dynkin_diagram()
0---0---0=>=0
0  1  2  3
B4 relabelled by {1: 0, 2: 1, 3: 2, 4: 3}
sage: T.affine().dynkin_diagram()
  0 4
```

(continues on next page)

(continued from previous page)

```

|
|
0---0---0=>=0
0  1  2  3
B4~ relabelled by {0: 4, 1: 0, 2: 1, 3: 2, 4: 3}

```

This failed before [trac ticket #13724](#):

```

sage: ct = CartanType(["G",2]).dual(); ct
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
['G', 2, 1] relabelled by {0: 0, 1: 2, 2: 1}

sage: ct = CartanType(["F",4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.affine()
['F', 4, 1] relabelled by {0: 0, 1: 4, 2: 3, 3: 2, 4: 1}

```

Check that we don't inadvertently change the internal relabelling of `ct`:

```

sage: ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}

```

5.1.266 Weight lattice realizations

`class sage.combinat.root_system.weight_lattice_realizations.WeightLatticeRealizations`(*base*, *name=None*)

Bases: `sage.categories.category_types.Category_over_base_ring`

The category of weight lattice realizations over a given base ring

A *weight lattice realization* L over a base ring R is a free module (or vector space if R is a field) endowed with an embedding of the root lattice of some root system. By restriction, this embedding defines an embedding of the root lattice of this root system, which makes L a root lattice realization.

Typical weight lattice realizations over \mathbf{Z} include the weight lattice, and ambient lattice. Typical weight lattice realizations over \mathbf{Q} include the weight space, and ambient space.

To describe the embedding, a weight lattice realization must implement a method `fundamental_weight`i)` returning for each ``i()` in the index set the image of the fundamental weight Λ_i under the embedding.

In order to be a proper root lattice realization, a weight lattice realization should also implement the scalar product with the coroot lattice; on the other hand, the embedding of the simple roots is given for free.

See also:

- [RootSystem](#)
- [RootLatticeRealizations](#)
- [WeightSpace](#)
- [AmbientSpace](#)

EXAMPLES:

Here, we consider the root system of type A_7 , and embed the weight lattice element $x = \Lambda_1 + 2\Lambda_3$ in several root lattice realizations:

```
sage: R = RootSystem(["A", 7])
sage: Lambda = R.weight_lattice().fundamental_weights()
sage: x = Lambda[2] + 2 * Lambda[5]

sage: L = R.weight_space()
sage: L(x)
Lambda[2] + 2*Lambda[5]

sage: L = R.ambient_lattice()
sage: L(x)
(3, 3, 2, 2, 2, 0, 0, 0)
```

We embed the weight space element $x = \Lambda_1 + 1/2\Lambda_3$ in the ambient space:

```
sage: Lambda = R.weight_space().fundamental_weights()
sage: x = Lambda[2] + 1/2 * Lambda[5]

sage: L = R.ambient_space()
sage: L(x)
(3/2, 3/2, 1/2, 1/2, 1/2, 0, 0, 0)
```

Of course, one can't embed the weight space in the ambient lattice:

```
sage: L = R.ambient_lattice()
sage: L(x)
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[2] + 1/2*Lambda[5]) an element of L
↳self (=Ambient lattice of the Root system of type ['A', 7])
```

If K_1 is a subring of K_2 , then one could in theory have an embedding from the weight space over K_1 to any weight lattice realization over K_2 ; this is not implemented:

```
sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.ambient_space(K2)

sage: Lambda = R.weight_space(K2).fundamental_weights()
sage: L(Lambda[1])
(1, 0, 0, 0, 0, 0, 0, 0)

sage: Lambda = R.weight_space(K1).fundamental_weights()
sage: L(Lambda[1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[1]) an element of self (=Ambient_
↳space of the Root system of type ['A', 7])
```

```
class ElementMethods
    Bases: object
```

symmetric_form(*la*)

Return the symmetric form of *self* with *la*.

Return the pairing ($()$) on the weight lattice. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

Warning: For affine root systems, if you are not working in the extended weight lattice/space, this may return incorrect results.

EXAMPLES:

```

sage: P = RootSystem(['C',2]).weight_lattice()
sage: al = P.simple_roots()
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[2].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2]).root_lattice()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
.....:     for i in P.index_set() for j in P.index_set())
True

sage: P = RootSystem(['C',2,1]).weight_lattice(extended=True)
sage: al = P.simple_roots()
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[1].symmetric_form(al[0])
-2
sage: al[0].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2,1]).root_lattice()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
.....:     for i in P.index_set() for j in P.index_set())
True
sage: La = P.basis()
sage: [La['delta'].symmetric_form(al) for al in P.simple_roots()]
[0, 0, 0]
sage: [La[0].symmetric_form(al) for al in P.simple_roots()]
[1, 0, 0]

sage: P = RootSystem(['C',2,1]).weight_lattice()
sage: Q = RootSystem(['C',2,1]).root_lattice()
sage: al = P.simple_roots()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
.....:     for i in P.index_set() for j in P.index_set())
True

```

The result of $(\Lambda_0|\alpha_0)$ should be 1, however we get 0 because we are not working in the extended weight lattice:

```
sage: La = P.basis()
sage: [La[0].symmetric_form(al) for al in P.simple_roots()]
[0, 0, 0]
```

to_weight_space(*base_ring=None*)
Map self to the weight space.

Warning: Implemented for finite Cartan type.

EXAMPLES:

```
sage: b = CartanType(['B',2]).root_system().ambient_space().from_
->vector(vector([1,-2])); b
(1, -2)
sage: b.to_weight_space()
3*Lambda[1] - 4*Lambda[2]
sage: b = CartanType(['B',2]).root_system().ambient_space().from_
->vector(vector([1/2,0])); b
(1/2, 0)
sage: b.to_weight_space()
1/2*Lambda[1]
sage: b.to_weight_space(ZZ)
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
sage: b = CartanType(['G',2]).root_system().ambient_space().from_
->vector(vector([4,-5,1])); b
(4, -5, 1)
sage: b.to_weight_space()
-6*Lambda[1] + 5*Lambda[2]
```

class ParentMethods

Bases: object

dynkin_diagram_automorphism_of_alcove_morphism(*f*)

Return the Dynkin diagram automorphism induced by an alcove morphism

INPUT:

- *f* - a linear map from self to self which preserves alcoves

This method returns the Dynkin diagram automorphism for the decomposition $f = dw$ (see [reduced_word_of_alcove_morphism\(\)](#)), as a dictionary mapping elements of the index set to itself.

EXAMPLES:

```
sage: R = RootSystem(["A",2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: Lambda = R.fundamental_weights()
```

Translations by elements of the root lattice induce a trivial Dynkin diagram automorphism:

```

sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[0].translation)
{0: 0, 1: 1, 2: 2}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[1].translation)
{0: 0, 1: 1, 2: 2}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[2].translation)
{0: 0, 1: 1, 2: 2}

```

This is no more the case for translations by general elements of the (classical) weight lattice at level 0:

```

sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - Lambda[0]

sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 2, 2: 0}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 2, 1: 0, 2: 1}

sage: R = RootSystem(['C', 2, 1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[1].translation)
{0: 2, 1: 1, 2: 0}

sage: R = RootSystem(['D', 5, 1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - 2*Lambda[0]
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 0, 2: 2, 3: 3, 4: 5, 5: 4}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 0, 1: 1, 2: 2, 3: 3, 4: 4, 5: 5}

```

Algorithm: computes w of the decomposition, and see how $f \circ w^{-1}$ permutes the simple roots.

embed_at_level(x , $level=1$)

Embed the classical weight x in the level $level$ hyperplane

This is achieved by translating the straightforward embedding of x by $c\Lambda_0$ for c some appropriate scalar.

INPUT:

- x – an element of the corresponding classical weight/ambient lattice
- $level$ – an integer or element of the base ring (default: 1)

EXAMPLES:

```

sage: L = RootSystem(["B", 3, 1]).weight_space()
sage: L0 = L.classical()
sage: alpha = L0.simple_roots()
sage: omega = L0.fundamental_weights()
sage: L.embed_at_level(omega[1], 1)
Lambda[1]
sage: L.embed_at_level(omega[2], 1)
-Lambda[0] + Lambda[2]
sage: L.embed_at_level(omega[3], 1)
Lambda[3]

```

(continues on next page)

(continued from previous page)

```
sage: L.embed_at_level(alpha[1], 1)
Lambda[0] + 2*Lambda[1] - Lambda[2]
```

fundamental_weight(*i*)

Returns the i^{th} fundamental weight

INPUT:

- *i* – an element of the index set

By a slight notational abuse, for an affine type this method should also accept "delta" as input, and return the image of δ of the extended weight lattice in this realization.

This should be overridden by any subclass, and typically be implemented as a cached method for efficiency.

EXAMPLES:

```
sage: L = RootSystem(["A", 3]).ambient_lattice()
sage: L.fundamental_weight(1)
(1, 0, 0, 0)

sage: L = RootSystem(["A", 3, 1]).weight_lattice(extended=True)
sage: L.fundamental_weight(1)
Lambda[1]
sage: L.fundamental_weight("delta")
delta
```

fundamental_weights()

Returns the family $(\Lambda_i)_{i \in I}$ of the fundamental weights.

EXAMPLES:

```
sage: e = RootSystem(['A', 3]).ambient_lattice()
sage: f = e.fundamental_weights()
sage: [f[i] for i in [1, 2, 3]]
[(1, 0, 0, 0), (1, 1, 0, 0), (1, 1, 1, 0)]
```

is_extended()

Return whether this is a realization of the extended weight lattice

See also:

[*sage.combinat.root_system.weight_space.WeightSpace*](#)

EXAMPLES:

```
sage: RootSystem(["A", 3, 1]).weight_lattice().is_extended()
False
sage: RootSystem(["A", 3, 1]).weight_lattice(extended=True).is_extended()
True
```

This method is irrelevant for finite root systems, since the weight lattice need not be extended to ensure that the root lattice embeds faithfully:

```
sage: RootSystem(["A", 3]).weight_lattice().is_extended()
False
```

reduced_word_of_alcove_morphism(*f*)

Return the reduced word of an alcove morphism.

INPUT:

- *f* – a linear map from `self` to `self` which preserves alcoves

Let *A* be the fundamental alcove. This returns a reduced word i_1, \dots, i_k such that the affine Weyl group element $w = s_{i_1} \circ \dots \circ s_{i_k}$ maps the alcove $f(A)$ back to *A*. In other words, the alcove walk i_1, \dots, i_k brings the fundamental alcove to the corresponding translated alcove.

Let us throw in a bit of context to explain the main use case. It is customary to realize the alcove picture in the coroot or coweight lattice R^\vee . The extended affine Weyl group is then the group of linear maps on R^\vee which preserve the alcoves. By [Kac “Infinite-dimensional Lie algebra”, Proposition 6.5] the affine Weyl group is the semidirect product of the associated finite Weyl group and the group of translations in the coroot lattice (the extended affine Weyl group uses the coweight lattice instead). In other words, an element of the extended affine Weyl group admits a unique decomposition of the form:

$$f = dw,$$

where *w* is in the Weyl group, and *d* is a function which maps the fundamental alcove to itself. As *d* permutes the walls of the fundamental alcove, it permutes accordingly the corresponding simple roots, which induces an automorphism of the Dynkin diagram.

This method returns a reduced word for *w*, whereas the method `dynkin_diagram_automorphism_of_alcove_morphism()` returns *d* as a permutation of the nodes of the Dynkin diagram.

Nota bene: recall that the coroot (resp. coweight) lattice is implemented as the root (resp weight) lattice of the dual root system. Hence, this method is implemented for weight lattice realizations, but in practice is most of the time used on the dual side.

EXAMPLES:

We start with type *A* which is simply laced; hence we do not have to worry about the distinction between the weight and coweight lattice:

```
sage: R = RootSystem(["A", 2, 1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: Lambda = R.fundamental_weights()
```

We consider first translations by elements of the root lattice:

```
sage: R.reduced_word_of_alcove_morphism(alpha[0].translation)
[1, 2, 1, 0]
sage: R.reduced_word_of_alcove_morphism(alpha[1].translation)
[0, 2, 0, 1]
sage: R.reduced_word_of_alcove_morphism(alpha[2].translation)
[0, 1, 0, 2]
```

We continue with translations by elements of the classical weight lattice, embedded at level 0:

```
sage: omega1 = Lambda[1] - Lambda[0] sage: omega2 = Lambda[2] - Lambda[0]
```

```
sage: R.reduced_word_of_alcove_morphism(omega1.translation) [0, 2] sage:
R.reduced_word_of_alcove_morphism(omega2.translation) [0, 1]
```

The following tests ensure that the code agrees with the tables in Kashiwara’s private notes on affine quantum algebras (2008).

reduced_word_of_translation(*t*)

Given an element of the root lattice, this returns a reduced word i_1, \dots, i_k such that the Weyl group element $s_{i_1} \circ \dots \circ s_{i_k}$ implements the “translation” where *x* maps to $x + level(x) * t$. In other words,

the alcove walk i_1, \dots, i_k brings the fundamental alcove to the corresponding translated alcove.

Note: There are some technical conditions for t to actually be a translation; those are not tested (TODO: detail).

EXAMPLES:

```
sage: R = RootSystem(["A",2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: R.reduced_word_of_translation(alpha[1])
[0, 2, 0, 1]
sage: R.reduced_word_of_translation(alpha[2])
[0, 1, 0, 2]
sage: R.reduced_word_of_translation(alpha[0])
[1, 2, 1, 0]

sage: R = RootSystem(['D',5,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - 2*Lambda[0]
sage: R.reduced_word_of_translation(omega1)
[0, 2, 3, 4, 5, 3, 2, 0]
sage: R.reduced_word_of_translation(omega2)
[0, 2, 1, 3, 2, 4, 3, 5, 3, 2, 1, 4, 3, 2]
```

A non simply laced case:

```
sage: R = RootSystem(["C",2,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: c = R.cartan_type().translation_factors()
sage: c
Finite family {0: 1, 1: 2, 2: 1}
sage: R.reduced_word_of_translation((Lambda[1]-Lambda[0]) * c[1])
[0, 1, 2, 1]
sage: R.reduced_word_of_translation((Lambda[2]-Lambda[0]) * c[2])
[0, 1, 0]
```

See also `_test_reduced_word_of_translation()`.

Todo:

- Add a picture in the doc
 - Add a method which, given an element of the classical weight lattice, constructs the appropriate value for t
-

rho()

EXAMPLES:

```
sage: RootSystem(['A',3]).ambient_lattice().rho()
(3, 2, 1, 0)
```

rho_classical()

Return the embedding at level 0 of ρ of the classical lattice.

EXAMPLES:

```
sage: RootSystem(['C',4,1]).weight_lattice().rho_classical()
-4*Lambda[0] + Lambda[1] + Lambda[2] + Lambda[3] + Lambda[4]
sage: L = RootSystem(['D',4,1]).weight_lattice()
sage: L.rho_classical().scalar(L.null_coroot())
0
```

Warning: In affine type BC dual, this does not live in the weight lattice:

```
sage: L = CartanType(["BC",2,2]).dual().root_system().weight_space()
sage: L.rho_classical()
-3/2*Lambda[0] + Lambda[1] + Lambda[2]
sage: L = CartanType(["BC",2,2]).dual().root_system().weight_lattice()
sage: L.rho_classical()
Traceback (most recent call last):
...
ValueError: 5 is not divisible by 2
```

`signs_of_alcovewalk(walk)`

Let $walk = [i_1, \dots, i_n]$ denote an alcove walk starting from the fundamental alcove y_0 , crossing at step 1 the wall i_1 , and so on.

For each k , set $w_k = s_{i_1} \circ s_{i_2} \circ \dots \circ s_{i_k}$, and denote by $y_k = w_k(y_0)$ the alcove reached after k steps. Then, y_k is obtained recursively from y_{k-1} by applying the following reflection:

$$y_k = s_{w_{k-1}\alpha_{i_k}} y_{k-1}.$$

The step is said positive if $w_{k-1}\alpha_{i_k}$ is a negative root (considering w_{k-1} as element of the classical Weyl group and α_{i_k} as a classical root) and negative otherwise. The algorithm implemented here use the equivalent property:

```
.. MATH:: \langle w_{k-1}^{-1} \rho_0, \alpha_{i_k} \rangle > 0
```

Where ρ_0 is the sum of the classical fundamental weights embedded at level 0 in this space (see `rho_classical()`), and $\alpha_{i_k}^\vee$ is the simple coroot associated to α_{i_k} .

This function returns a list of the form $[+1, +1, -1, \dots]$, where the k^{th} entry denotes whether the k^{th} step was positive or negative.

See equation 3.4, of Ram: Alcove walks ..., [arXiv math/0601343v1](https://arxiv.org/abs/math/0601343v1)

EXAMPLES:

```
sage: L = RootSystem(['C',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([1,2,0,1,2,1,2,0,1,2])
[-1, -1, 1, -1, 1, 1, 1, 1, 1, 1]

sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,1,2,0,1,2,0,1,2,0])
[1, 1, 1, 1, -1, 1, -1, 1, -1, 1, -1, 1]

sage: L = RootSystem(['B',2,1]).coweight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,0,1,2])
[1, -1, 1, -1, 1, 1]
```

Warning: This method currently does not work in the weight lattice for type BC dual because ρ_0 does not live in this lattice (but an integral multiple of it would do the job as well).

simple_root(*i*)

Returns the *i*-th simple root

This default implementation takes the *i*-th simple root in the weight lattice and embeds it in self.

EXAMPLES:

Since all the weight lattice realizations in Sage currently implement a simple_root method, we have to call this one by hand:

```
sage: from sage.combinat.root_system.weight_lattice_realizations import_
      ↪WeightLatticeRealizations
sage: simple_root = WeightLatticeRealizations(QQ).parent_class.simple_root.f
sage: L = RootSystem("A3").ambient_space()
sage: simple_root(L, 1)
(1, -1, 0, 0)
sage: simple_root(L, 2)
(0, 1, -1, 0)
sage: simple_root(L, 3)
(1, 1, 2, 0)
```

Note that this last root differs from the one implemented in L by a multiple of the vector (1, 1, 1, 1):

```
sage: L.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

This is a harmless artefact of the *SL* versus *GL* interpretation of type *A*; see the thematic tutorial on Lie Methods and Related Combinatorics in Sage for details.

weyl_dimension(*highest_weight*)

Return the dimension of the highest weight representation of highest weight highest_weight.

EXAMPLES:

```
sage: RootSystem(['A', 3]).ambient_lattice().weyl_dimension([2, 1, 0, 0])
20
sage: P = RootSystem(['C', 2]).weight_lattice()
sage: La = P.basis()
sage: P.weyl_dimension(La[1]+La[2])
16
sage: type(RootSystem(['A', 3]).ambient_lattice().weyl_dimension([2, 1, 0, 0]))
<class 'sage.rings.integer.Integer'>
```

super_categories()

EXAMPLES:

```
sage: from sage.combinat.root_system.weight_lattice_realizations import_
      ↪WeightLatticeRealizations
sage: WeightLatticeRealizations(QQ).super_categories()
[Category of root lattice realizations over Rational Field]
```

5.1.267 Weight lattices and weight spaces

class `sage.combinat.root_system.weight_space.WeightSpace`(*root_system*, *base_ring*, *extended*)
 Bases: `sage.combinat.free_module.CombinatorialFreeModule`

INPUT:

- *root_system* – a root system
- *base_ring* – a ring R
- *extended* – a boolean (default: False)

The weight space (or lattice if *base_ring* is \mathbf{Z}) of a root system is the formal free module $\bigoplus_i R\Lambda_i$ generated by the fundamental weights $(\Lambda_i)_{i \in I}$ of the root system.

This class is also used for coweight spaces (or lattices).

See also:

- `RootSystem()`
- `RootSystem.weight_lattice()` and `RootSystem.weight_space()`
- `WeightLatticeRealizations()`

EXAMPLES:

```
sage: Q = RootSystem(['A', 3]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3]
sage: Q.simple_roots()
Finite family {1: 2*Lambda[1] - Lambda[2], 2: -Lambda[1] + 2*Lambda[2] - Lambda[3],
->3: -Lambda[2] + 2*Lambda[3]}

sage: Q = RootSystem(['A', 3, 1]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3, 1]
sage: Q.simple_roots()
Finite family {0: 2*Lambda[0] - Lambda[1] - Lambda[3],
1: -Lambda[0] + 2*Lambda[1] - Lambda[2],
2: -Lambda[1] + 2*Lambda[2] - Lambda[3],
3: -Lambda[0] - Lambda[2] + 2*Lambda[3]}
```

For infinite types, the Cartan matrix is singular, and therefore the embedding of the root lattice is not faithful:

```
sage: sum(Q.simple_roots())
0
```

In particular, the null root is zero:

```
sage: Q.null_root()
0
```

This can be compensated by extending the basis of the weight space and slightly deforming the simple roots to make them linearly independent, without affecting the scalar product with the coroots. This feature is currently only implemented for affine types. In that case, if *extended* is set, then the basis of the weight space is extended by an element δ :

```
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended = True); Q
Extended weight lattice of the Root system of type ['A', 3, 1]
sage: Q.basis().keys()
{0, 1, 2, 3, 'delta'}
```

And the simple root α_0 associated to the special node is deformed as follows:

```
sage: Q.simple_roots()
Finite family {0: 2*Lambda[0] - Lambda[1] - Lambda[3] + delta,
1: -Lambda[0] + 2*Lambda[1] - Lambda[2],
2: -Lambda[1] + 2*Lambda[2] - Lambda[3],
3: -Lambda[0] - Lambda[2] + 2*Lambda[3]}
```

Now, the null root is nonzero:

```
sage: Q.null_root()
delta
```

Warning: By a slight notational abuse, the extra basis element used to extend the fundamental weights is called `\delta` in the current implementation. However, in the literature, `\delta` usually denotes instead the null root. Most of the time, those two objects coincide, but not for type *BC* (aka. $A_{2n}^{(2)}$). Therefore we currently have:

```
sage: Q = RootSystem(["A", 4, 2]).weight_lattice(extended=True)
sage: Q.simple_root(0)
2*Lambda[0] - Lambda[1] + delta
sage: Q.null_root()
2*delta
```

whereas, with the standard notations from the literature, one would expect to get respectively $2\Lambda_0 - \Lambda_1 + 1/2\delta$ and δ .

Other than this notational glitch, the implementation remains correct for type *BC*.

The notations may get improved in a subsequent version, which might require changing the index of the extra basis element. To guarantee backward compatibility in code not included in Sage, it is recommended to use the following idiom to get that index:

```
sage: F = Q.basis_extension(); F
Finite family {'delta': delta}
sage: index = F.keys()[0]; index
'delta'
```

Then, for example, the coefficient of an element of the extended weight lattice on that basis element can be recovered with:

```
sage: Q.null_root()[index]
2
```

Element

alias of *WeightSpaceElement*

basis_extension()

Return the basis elements used to extend the fundamental weights

EXAMPLES:

```

sage: Q = RootSystem(["A", 3, 1]).weight_lattice()
sage: Q.basis_extension()
Family ()

sage: Q = RootSystem(["A", 3, 1]).weight_lattice(extended=True)
sage: Q.basis_extension()
Finite family {'delta': delta}

```

This method is irrelevant for finite types:

```

sage: Q = RootSystem(["A", 3]).weight_lattice()
sage: Q.basis_extension()
Family ()

```

fundamental_weight(*i*)

Returns the i -th fundamental weight

INPUT:

- i – an element of the index set or "delta"

By a slight notational abuse, for an affine type this method also accepts "delta" as input, and returns the image of δ of the extended weight lattice in this realization.

See also:

`fundamental_weight()`

EXAMPLES:

```

sage: Q = RootSystem(["A", 3]).weight_lattice()
sage: Q.fundamental_weight(1)
Lambda[1]

sage: Q = RootSystem(["A", 3, 1]).weight_lattice(extended=True)
sage: Q.fundamental_weight(1)
Lambda[1]
sage: Q.fundamental_weight("delta")
delta

```

is_extended()

Return whether this is an extended weight lattice.

See also:

`is_extended()`

EXAMPLES:

```

sage: RootSystem(["A", 3, 1]).weight_lattice().is_extended()
False
sage: RootSystem(["A", 3, 1]).weight_lattice(extended=True).is_extended()
True

```

simple_root(*j*)

Returns the j^{th} simple root

EXAMPLES:

```
sage: L = RootSystem(["C",4]).weight_lattice()
sage: L.simple_root(3)
-Lambda[2] + 2*Lambda[3] - Lambda[4]
```

Its coefficients are given by the corresponding column of the Cartan matrix:

```
sage: L.cartan_type().cartan_matrix()[:,2]
[ 0]
[-1]
[ 2]
[-1]
```

Here are all simple roots:

```
sage: L.simple_roots()
Finite family {1: 2*Lambda[1] - Lambda[2],
                2: -Lambda[1] + 2*Lambda[2] - Lambda[3],
                3: -Lambda[2] + 2*Lambda[3] - Lambda[4],
                4: -2*Lambda[3] + 2*Lambda[4]}
```

For the extended weight lattice of an affine type, the simple root associated to the special node is deformed by adding δ , where δ is the null root:

```
sage: L = RootSystem(["C",4,1]).weight_lattice(extended=True)
sage: L.simple_root(0)
2*Lambda[0] - 2*Lambda[1] + delta
```

In fact δ is really $1/a_0$ times the null root (see the discussion in [WeightSpace](#)) but this only makes a difference in type BC :

```
sage: L = RootSystem(CartanType(["BC",4,2])).weight_lattice(extended=True)
sage: L.simple_root(0)
2*Lambda[0] - Lambda[1] + delta
sage: L.null_root()
2*delta
```

See also:

- [simple_root\(\)](#)
- [CartanType.col_annihilator\(\)](#)

`to_ambient_space_morphism()`

The morphism from `self` to its associated ambient space.

EXAMPLES:

```
sage: CartanType(['A',2]).root_system().weight_lattice().to_ambient_space_
      ↪morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['A', 2]
To:   Ambient space of the Root system of type ['A', 2]
```

Warning: Implemented only for finite Cartan type.

class sage.combinat.root_system.weight_space.**WeightSpaceElement**

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

is_dominant()

Checks whether an element in the weight space lies in the positive cone spanned by the basis elements (fundamental weights).

EXAMPLES:

```
sage: W = RootSystem(['A',3]).weight_space()
sage: Lambda = W.basis()
sage: w = Lambda[1]+Lambda[3]
sage: w.is_dominant()
True
sage: w = Lambda[1]-Lambda[2]
sage: w.is_dominant()
False
```

In the extended affine weight lattice, ‘delta’ is orthogonal to the positive coroots, so adding or subtracting it should not effect dominance

```
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=true)
sage: Lambda = P.fundamental_weights()
sage: delta = P.null_root()
sage: w = Lambda[1]-delta
sage: w.is_dominant()
True
```

scalar(*lambdacheck*)

The canonical scalar product between the weight lattice and the coroot lattice.

Todo:

- merge with `with_apply_multi_module_morphism`
- allow for any root space / lattice
- define properly the return type (depends on the base rings of the two spaces)
- make this robust for extended weight lattices (*i* might be “delta”)

EXAMPLES:

```
sage: L = RootSystem(["C",4,1]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: alphacheck = L.simple_coroots()
sage: Lambda[1].scalar(alphacheck[1])
1
sage: Lambda[1].scalar(alphacheck[2])
0
```

The fundamental weights and the simple coroots are dual bases:

```

sage: matrix([ [ Lambda[i].scalar(alphacheck[j])
.....:         for i in L.index_set() ]
.....:         for j in L.index_set() ])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]

```

Note that the scalar product is not yet implemented between the weight space and the coweight space; in any cases, that won't be the job of this method:

```

sage: R = RootSystem(["A", 3])
sage: alpha = R.weight_space().roots()
sage: alphacheck = R.coweight_space().roots()
sage: alpha[1].scalar(alphacheck[1])
Traceback (most recent call last):
...
ValueError: -Lambdacheck[1] + 2*Lambdacheck[2] - Lambdacheck[3] is not in the
↳ coroot space

```

to_ambient()

Maps `self` to the ambient space.

EXAMPLES:

```

sage: mu = CartanType(['B', 2]).root_system().weight_lattice().an_element(); mu
2*Lambda[1] + 2*Lambda[2]
sage: mu.to_ambient()
(3, 1)

```

Warning: Only implemented in finite Cartan type. Does not work for coweight lattices because there is no implemented map from the coweight lattice to the ambient space.

to_weight_space()

Map `self` to the weight space.

Since `self.parent()` is the weight space, this map just returns `self`. This overrides the generic method in *WeightSpaceRealizations*.

EXAMPLES:

```

sage: mu = CartanType(['A', 2]).root_system().weight_lattice().an_element(); mu
2*Lambda[1] + 2*Lambda[2]
sage: mu.to_weight_space()
2*Lambda[1] + 2*Lambda[2]

```

5.1.268 Weyl Character Rings

class `sage.combinat.root_system.weyl_characters.WeightRing`(*parent, prefix*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

The weight ring, which is the group algebra over a weight lattice.

A Weyl character may be regarded as an element of the weight ring. In fact, an element of the weight ring is an element of the *Weyl character ring* if and only if it is invariant under the action of the Weyl group.

The advantage of the weight ring over the Weyl character ring is that one may conduct calculations in the weight ring that involve sums of weights that are not Weyl group invariant.

EXAMPLES:

```
sage: A2 = WeylCharacterRing(['A', 2])
sage: a2 = WeightRing(A2)
sage: wd = prod(a2(x/2)-a2(-x/2) for x in a2.space().positive_roots()); wd
a2(-1,1,0) - a2(-1,0,1) - a2(1,-1,0) + a2(1,0,-1) + a2(0,-1,1) - a2(0,1,-1)
sage: chi = A2([5,3,0]); chi
A2(5,3,0)
sage: a2(chi)
a2(1,2,5) + 2*a2(1,3,4) + 2*a2(1,4,3) + a2(1,5,2) + a2(2,1,5)
+ 2*a2(2,2,4) + 3*a2(2,3,3) + 2*a2(2,4,2) + a2(2,5,1) + 2*a2(3,1,4)
+ 3*a2(3,2,3) + 3*a2(3,3,2) + 2*a2(3,4,1) + a2(3,5,0) + a2(3,0,5)
+ 2*a2(4,1,3) + 2*a2(4,2,2) + 2*a2(4,3,1) + a2(4,4,0) + a2(4,0,4)
+ a2(5,1,2) + a2(5,2,1) + a2(5,3,0) + a2(5,0,3) + a2(0,3,5)
+ a2(0,4,4) + a2(0,5,3)
sage: a2(chi)*wd
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
sage: sum((-1)^w.length()*a2([6,3,-1]).weyl_group_action(w) for w in a2.space().
->weyl_group())
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
sage: a2(chi)*wd == sum((-1)^w.length()*a2([6,3,-1]).weyl_group_action(w) for w in
->a2.space().weyl_group())
True
```

class `Element`

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

A class for weight ring elements.

cartan_type()

Return the Cartan type.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2([0,1,0]).cartan_type()
['A', 2]
```

character()

Assuming that `self` is invariant under the Weyl group, this will express it as a linear combination of characters. If `self` is not Weyl group invariant, this method will not terminate.

EXAMPLES:

```

sage: A2 = WeylCharacterRing(['A', 2])
sage: a2 = WeightRing(A2)
sage: W = a2.space().weyl_group()
sage: mu = a2(2, 1, 0)
sage: nu = sum(mu.weyl_group_action(w) for w in W) ; nu
a2(1, 2, 0) + a2(1, 0, 2) + a2(2, 1, 0) + a2(2, 0, 1) + a2(0, 1, 2) + a2(0, 2, 1)
sage: nu.character()
-2*A2(1, 1, 1) + A2(2, 1, 0)

```

demazure(w , $debug=False$)

Return the result of applying the Demazure operator ∂_w to `self`.

INPUT:

- w – a Weyl group element, or its reduced word

If $w = s_i$ is a simple reflection, the operation ∂_w sends the weight λ to

$$\frac{\lambda - s_i \cdot \lambda + \alpha_i}{1 + \alpha_i},$$

where the numerator is divisible the denominator in the weight ring. This is extended by multiplicativity to all w in the Weyl group.

EXAMPLES:

```

sage: B2 = WeylCharacterRing("B2", style="coroots")
sage: b2 = WeightRing(B2)
sage: b2(1, 0).demazure([1])
b2(1, 0) + b2(-1, 2)
sage: b2(1, 0).demazure([2])
b2(1, 0)
sage: r = b2(1, 0).demazure([1, 2]); r
b2(1, 0) + b2(-1, 2)
sage: r.demazure([1])
b2(1, 0) + b2(-1, 2)
sage: r.demazure([2])
b2(0, 0) + b2(1, 0) + b2(1, -2) + b2(-1, 2)

```

demazure_lusztig(i , v)

Return the result of applying the Demazure-Lusztig operator T_i to `self`.

INPUT:

- i – an element of the index set (or a reduced word or Weyl group element)
- v – an element of the base ring

If R is the parent `WeightRing`, the Demazure-Lusztig operator T_i is the linear map $R \rightarrow R$ that sends (for a weight λ) $R(\lambda)$ to

$$(R(\alpha_i) - 1)^{-1} (R(\lambda) - R(s_i \lambda) - v(R(\lambda) - R(\alpha_i + s_i \lambda)))$$

where the numerator is divisible by the denominator in R . The Demazure-Lusztig operators give a representation of the Iwahori–Hecke algebra associated to the Weyl group. See

- Lusztig, Equivariant K -theory and representations of Hecke algebras, Proc. Amer. Math. Soc. 94 (1985), no. 2, 337-342.
- Cherednik, *Nonsymmetric Macdonald polynomials*. IMRN 10, 483-515 (1995).

In the examples, we confirm the braid and quadratic relations for type B_2 .

EXAMPLES:

```

sage: P.<v> = PolynomialRing(QQ)
sage: B2 = WeylCharacterRing("B2",style="coroots",base_ring=P); b2 = B2.
↳ambient()
sage: def T1(f): return f.demazure_lusztig(1,v)
sage: def T2(f): return f.demazure_lusztig(2,v)
sage: T1(T2(T1(T2(b2(1,-1)))))
(v^2-v)*b2(0,-1) + v^2*b2(-1,1)
sage: [T1(T1(f))==v*(v-1)*T1(f)+v*f for f in [b2(0,0), b2(1,0), b2(2,3)]]
[True, True, True]
sage: [T1(T2(T1(T2(b2(i,j))))) == T2(T1(T2(T1(b2(i,j))))) for i in [-2..2]
↳for j in [-1,1]]
[True, True, True, True, True, True, True, True, True]

```

Instead of an index i one may use a reduced word or Weyl group element:

```

sage: b2(1,0).demazure_lusztig([2,1],v)==T2(T1(b2(1,0)))
True
sage: W = B2.space().weyl_group(prefix="s")
sage: [s1,s2]=W.simple_reflections()
sage: b2(1,0).demazure_lusztig(s2*s1,v)==T2(T1(b2(1,0)))
True

```

scale(k)

Multiply a weight by k .

The operation is extended by linearity to the weight ring.

INPUT:

- k – a nonzero integer

EXAMPLES:

```

sage: g2 = WeylCharacterRing("G2",style="coroots").ambient()
sage: g2(2,3).scale(2)
g2(4,6)

```

shift(μ)

Add μ to any weight.

Extended by linearity to the weight ring.

INPUT:

- μ – a weight

EXAMPLES:

```

sage: g2 = WeylCharacterRing("G2",style="coroots").ambient()
sage: [g2(1,2).shift(fw) for fw in g2.fundamental_weights()]
[g2(2,2), g2(1,3)]

```

weyl_group_action(w)

Return the action of the Weyl group element w on self.

EXAMPLES:

```

sage: G2 = WeylCharacterRing(['G',2])
sage: g2 = WeightRing(G2)
sage: L = g2.space()

```

(continues on next page)

(continued from previous page)

```

sage: [fw1, fw2] = L.fundamental_weights()
sage: sum(g2(fw2).weyl_group_action(w) for w in L.weyl_group())
2*g2(-2,1,1) + 2*g2(-1,-1,2) + 2*g2(-1,2,-1) + 2*g2(1,-2,1) + 2*g2(1,1,-2)
↪+ 2*g2(2,-1,-1)

```

cartan_type()

Return the Cartan type.

EXAMPLES:

```

sage: A2 = WeylCharacterRing("A2")
sage: WeightRing(A2).cartan_type()
['A', 2]

```

fundamental_weights()

Return the fundamental weights.

EXAMPLES:

```

sage: WeightRing(WeylCharacterRing("G2")).fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}

```

one_basis()

Return the index of 1.

EXAMPLES:

```

sage: A3 = WeylCharacterRing("A3")
sage: WeightRing(A3).one_basis()
(0, 0, 0, 0)
sage: WeightRing(A3).one()
a3(0,0,0,0)

```

parent()

Return the parent Weyl character ring.

EXAMPLES:

```

sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2.parent()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
sage: a2.parent() == A2
True

```

positive_roots()

Return the positive roots.

EXAMPLES:

```

sage: WeightRing(WeylCharacterRing("G2")).positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]

```

product_on_basis(a, b)

Return the product of basis elements indexed by a and b.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2(1,0,0) * a2(0,1,0) # indirect doctest
a2(1,1,0)
```

simple_roots()

Return the simple roots.

EXAMPLES:

```
sage: WeightRing(WeylCharacterRing("G2")).simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

some_elements()

Return some elements of self.

EXAMPLES:

```
sage: A3 = WeylCharacterRing("A3")
sage: a3 = WeightRing(A3)
sage: a3.some_elements()
[a3(1,0,0,0), a3(1,1,0,0), a3(1,1,1,0)]
```

space()

Return the weight space realization associated to self.

EXAMPLES:

```
sage: E8 = WeylCharacterRing(['E',8])
sage: e8 = WeightRing(E8)
sage: e8.space()
Ambient space of the Root system of type ['E', 8]
```

weyl_character_ring()

Return the parent Weyl Character Ring.

A synonym for self.parent().

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2.weyl_character_ring()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

wt_repr(wt)

Return a string representing the irreducible character with highest weight vector wt.

Uses coroot notation if the associated Weyl character ring is defined with style="coroots".

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
['g2(1,0,-1)', 'g2(2,-1,-1)']
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
['g2(1,0)', 'g2(0,1)']
```

```
class sage.combinat.root_system.weyl_characters.WeylCharacterRing(ct, base_ring=Integer Ring,
                                                                prefix=None, style='lattice',
                                                                k=None, conjugate=False,
                                                                cyclotomic_order=None)
```

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

A class for rings of Weyl characters.

Let K be a compact Lie group, which we assume is semisimple and simply-connected. Its complexified Lie algebra L is the Lie algebra of a complex analytic Lie group G . The following three categories are equivalent: finite-dimensional representations of K ; finite-dimensional representations of L ; and finite-dimensional analytic representations of G . In every case, there is a parametrization of the irreducible representations by their highest weight vectors. For this theory of Weyl, see (for example):

- Adams, *Lectures on Lie groups*
- Broecker and Tom Dieck, *Representations of Compact Lie groups*
- Bump, *Lie Groups*
- Fulton and Harris, *Representation Theory*
- Goodman and Wallach, *Representations and Invariants of the Classical Groups*
- Hall, *Lie Groups, Lie Algebras and Representations*
- Humphreys, *Introduction to Lie Algebras and their representations*
- Procesi, *Lie Groups*
- Samelson, *Notes on Lie Algebras*
- Varadarajan, *Lie groups, Lie algebras, and their representations*
- Zhelobenko, *Compact Lie Groups and their Representations.*

Computations that you can do with these include computing their weight multiplicities, products (thus decomposing the tensor product of a representation into irreducibles) and branching rules (restriction to a smaller group).

There is associated with K , L or G as above a lattice, the weight lattice, whose elements (called weights) are characters of a Cartan subgroup or subalgebra. There is an action of the Weyl group W on the lattice, and elements of a fixed fundamental domain for W , the positive Weyl chamber, are called dominant. There is for each representation a unique highest dominant weight that occurs with nonzero multiplicity with respect to a certain partial order, and it is called the highest weight vector.

EXAMPLES:

```
sage: L = RootSystem("A2").ambient_space()
sage: [fw1, fw2] = L.fundamental_weights()
sage: R = WeylCharacterRing(['A', 2], prefix="R")
sage: [R(1), R(fw1), R(fw2)]
[R(0, 0, 0), R(1, 0, 0), R(1, 1, 0)]
```

Here $R(1)$, $R(\text{fw1})$, and $R(\text{fw2})$ are irreducible representations with highest weight vectors 0 , Λ_1 , and Λ_2 respectively (the first two fundamental weights).

For type A (also G_2 , F_4 , E_6 and E_7) we will take as the weight lattice not the weight lattice of the semisimple group, but for a larger one. For type A , this means we are concerned with the representation theory of $K = U(n)$ or $G = GL(n, \mathbb{C})$ rather than $SU(n)$ or $SU(n, \mathbb{C})$. This is useful since the representation theory of $GL(n)$ is ubiquitous, and also since we may then represent the fundamental weights (in `sage.combinat.root_system.root_system`) by vectors with integer entries. If you are only interested in $SL(3)$, say, use `WeylCharacterRing(['A', 2])` as above but be aware that $R([a, b, c])$ and $R([a+1, b+1, c+1])$ represent the same character of $SL(3)$ since $R([1, 1, 1])$ is the determinant.

For more information, see the thematic tutorial *Lie Methods and Related Combinatorics in Sage*, available at: https://doc.sagemath.org/html/en/thematic_tutorials/lie.html

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

A class for Weyl characters.

adams_operation(*r*)

Return the *r*-th Adams operation of `self`.

INPUT:

- *r* – a positive integer

This is a virtual character, whose weights are the weights of `self`, each multiplied by *r*.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2(1,1,0).adams_operation(3)
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```

branch(*S*, rule='default')

Return the restriction of the character to the subalgebra.

If no rule is specified, we will try to specify one.

INPUT:

- *S* – a Weyl character ring for a Lie subgroup or subalgebra
- *rule* – a branching rule

See `branch_weyl_character()` for more information about branching rules.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: A2 = WeylCharacterRing(['A',2])
sage: [B3(w).branch(A2,rule="levi") for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]
```

cartan_type()

Return the Cartan type of `self`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2([1,0,0]).cartan_type()
['A', 2]
```

degree()

Return the degree of `self`.

This is the dimension of the associated module.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).degree() for x in B3.fundamental_weights()]
[7, 21, 8]
```

dual()

The involution that replaces a representation with its contragredient. (For Fusion rings, this is the conjugation map.)

EXAMPLES:

```
sage: A3 = WeylCharacterRing("A3", style="coroots")
sage: A3(1,0,0)^2
A3(0,1,0) + A3(2,0,0)
sage: (A3(1,0,0)^2).dual()
A3(0,1,0) + A3(0,0,2)
```

exterior_power(k)

Return the k -th exterior power of `self`.

INPUT:

- k – a nonnegative integer

The algorithm is based on the identity $ke_k = \sum_{r=1}^k (-1)^{k-1} p_k e_{k-r}$ relating the power-sum and elementary symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation `self`, the e_k become exterior powers and the p_k become Adams operations, giving an efficient recursive implementation.

EXAMPLES:

```
sage: B3 = WeylCharacterRing("B3", style="coroots")
sage: spin = B3(0,0,1)
sage: spin.exterior_power(6)
B3(1,0,0) + B3(0,1,0)
```

exterior_square()

Return the exterior square of the character.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: A2(1,0).exterior_square()
A2(0,1)
```

frobenius_schur_indicator()

Return:

- 1 if the representation is real (orthogonal)
- -1 if the representation is quaternionic (symplectic)
- 0 if the representation is complex (not self dual)

The Frobenius-Schur indicator of a character χ of a compact group G is the Haar integral over the group of $\chi(g^2)$. Its value is 1, -1 or 0. This method computes it for irreducible characters of compact Lie groups by checking whether the symmetric and exterior square characters contain the trivial character.

Todo: Try to compute this directly without actually calculating the full symmetric and exterior squares.

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2", style="coroots")
sage: B2(1,0).frobenius_schur_indicator()
1
```

(continues on next page)

(continued from previous page)

```
sage: B2(0,1).frobenius_schur_indicator()
-1
```

highest_weight()

This method is only available for basis elements. Returns the parametrizing dominant weight of an irreducible character.

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2", style="coroots")
sage: [x.highest_weight() for x in [G2(1,0),G2(0,1)]]
[(1, 0, -1), (2, -1, -1)]
```

inner_product(*other*)

Compute the inner product with another character.

The irreducible characters are an orthonormal basis with respect to the usual inner product of characters, interpreted as functions on a compact Lie group, by Schur orthogonality.

INPUT:

- *other* – another character

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: [f1,f2] = A2.fundamental_weights()
sage: r1 = A2(f1)*A2(f2); r1
A2(1,1,1) + A2(2,1,0)
sage: r2 = A2(f1)^3; r2
A2(1,1,1) + 2*A2(2,1,0) + A2(3,0,0)
sage: r1.inner_product(r2)
3
```

invariant_degree()

Return the multiplicity of the trivial representation in *self*.

Multiplicities of other irreducibles may be obtained using *multiplicity()*.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: rep = A2(1,0)^2*A2(0,1)^2; rep
2*A2(0,0) + A2(0,3) + 4*A2(1,1) + A2(3,0) + A2(2,2)
sage: rep.invariant_degree()
2
```

is_irreducible()

Return whether *self* is an irreducible character.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).is_irreducible() for x in B3.fundamental_weights()]
[True, True, True]
sage: sum(B3(x) for x in B3.fundamental_weights()).is_irreducible()
False
```

multiplicity(*other*)

Return the multiplicity of the irreducible *other* in *self*.

INPUT:

- *other* – an irreducible character

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2", style="coroots")
sage: rep = B2(1,1)^2; rep
B2(0,0) + B2(1,0) + 2*B2(0,2) + B2(2,0) + 2*B2(1,2) + B2(0,4) + B2(3,0) +
↪B2(2,2)
sage: rep.multiplicity(B2(0,2))
2
```

symmetric_power(*k*)

Return the *k*-th symmetric power of *self*.

INPUT:

- *k* – a nonnegative integer

The algorithm is based on the identity $kh_k = \sum_{r=1}^k p_k h_{k-r}$ relating the power-sum and complete symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation *self*, the h_k become symmetric powers and the p_k become Adams operations, giving an efficient recursive implementation.

EXAMPLES:

```
sage: B3 = WeylCharacterRing("B3", style="coroots")
sage: spin = B3(0,0,1)
sage: spin.symmetric_power(6)
B3(0,0,0) + B3(0,0,2) + B3(0,0,4) + B3(0,0,6)
```

symmetric_square()

Return the symmetric square of the character.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: A2(1,0).symmetric_square()
A2(2,0)
```

weight_multiplicities()

Return the dictionary of weight multiplicities for the Weyl character *self*.

The character does not have to be irreducible.

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2", style="coroots")
sage: B2(0,1).weight_multiplicities()
{(-1/2, -1/2): 1, (-1/2, 1/2): 1, (1/2, -1/2): 1, (1/2, 1/2): 1}
```

adjoint_representation()

Return the adjoint representation as an element of the WeylCharacterRing.

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2", style="coroots")
sage: G2.adjoint_representation()
G2(0, 1)
```

affine_reflect(*wt*, *k=0*)

INPUT:

- *wt* – a weight
- *k* – (optional) a positive integer

Returns the reflection of *wt* in the hyperplane θ . Optionally shifts by a multiple *k*.

EXAMPLES:

```
sage: B22 = FusionRing("B2", 2)
sage: fw = B22.fundamental_weights(); fw
Finite family {1: (1, 0), 2: (1/2, 1/2)}
sage: [B22.affine_reflect(x, 2) for x in fw]
[(2, 1), (3/2, 3/2)]
```

ambient()

Return the weight ring of self.

EXAMPLES:

```
sage: WeylCharacterRing("A2").ambient()
The Weight ring attached to The Weyl Character Ring of Type A2 with Integer
↪Ring coefficients
```

base_ring()

Return the base ring of self.

EXAMPLES:

```
sage: R = WeylCharacterRing(['A', 3], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision
```

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```
sage: WeylCharacterRing("A2").cartan_type()
['A', 2]
```

char_from_weights(*mdict*)

Construct a Weyl character from an invariant linear combination of weights.

INPUT:

- *mdict* – a dictionary mapping weights to coefficients, and representing a linear combination of weights which shall be invariant under the action of the Weyl group

OUTPUT: the corresponding Weyl character

EXAMPLES:

```

sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: d = dict([(x,1) for x in v.orbit()]); d
{(1, 3, 0): 1,
 (1, 0, 3): 1,
 (3, 1, 0): 1,
 (3, 0, 1): 1,
 (0, 1, 3): 1,
 (0, 3, 1): 1}
sage: A2.char_from_weights(d)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)

```

demazure_character(*hwv*, *word*, *debug=False*)

Compute the Demazure character.

INPUT:

- *hwv* – a (usually dominant) weight
- *word* – a Weyl group word

Produces the Demazure character with highest weight *hwv* and *word* as an element of the weight ring. Only available if *style="coroots"*. The Demazure operators are also available as methods of *WeightRing* elements, and as methods of crystals. Given a *CrystalOfTableaux* with given highest weight vector, the Demazure method on the crystal will give the equivalent of this method, except that the Demazure character of the crystal is given as a sum of monomials instead of an element of the *WeightRing*.

See *WeightRing.Element.demazure()* and *sage.categories.classical_crystals.ClassicalCrystals.ParentMethods.demazure_character()*

EXAMPLES:

```

sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: h = sum(A2.fundamental_weights()); h
(2, 1, 0)
sage: A2.demazure_character(h, word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
sage: A2.demazure_character((1,1), word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)

```

dot_reduce(*a*)

Auxiliary function for *product_on_basis()*.

Return a pair $[\epsilon, b]$ where b is a dominant weight and ϵ is 0, 1 or -1. To describe b , let w be an element of the Weyl group such that $w(a + \rho)$ is dominant. If $w(a + \rho) - \rho$ is dominant, then ϵ is the sign of w and b is $w(a + \rho) - \rho$. Otherwise, ϵ is zero.

INPUT:

- *a* – a weight

EXAMPLES:

```

sage: A2 = WeylCharacterRing("A2")
sage: weights = sorted(A2(2,1,0).weight_multiplicities().keys(), key=str);
↵weights
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]

```

(continues on next page)

(continued from previous page)

```
sage: [A2.dot_reduce(x) for x in weights]
[[0, (0, 0, 0)], [-1, (1, 1, 1)], [-1, (1, 1, 1)], [1, (1, 1, 1)], [0, (0, 0, 0),
-0)], [0, (0, 0, 0)], [1, (2, 1, 0)]]
```

dynkin_diagram()

Return the Dynkin diagram of self.

EXAMPLES:

```
sage: WeylCharacterRing("E7").dynkin_diagram()
```

```
      0 2
      |
      |
0---0---0---0---0---0
1   3   4   5   6   7
E7
```

extended_dynkin_diagram()

Return the extended Dynkin diagram, which is the Dynkin diagram of the corresponding untwisted affine type.

EXAMPLES:

```
sage: WeylCharacterRing("E7").extended_dynkin_diagram()
```

```
      0 2
      |
      |
0---0---0---0---0---0
0   1   3   4   5   6   7
E7~
```

fundamental_weights()

Return the fundamental weights.

EXAMPLES:

```
sage: WeylCharacterRing("G2").fundamental_weights()
```

```
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

highest_root()

Return the highest root.

EXAMPLES:

```
sage: WeylCharacterRing("G2").highest_root()
```

```
(2, -1, -1)
```

irr_repr(hwv)

Return a string representing the irreducible character with highest weight vector hwv.

EXAMPLES:

```
sage: B3 = WeylCharacterRing("B3")
```

```
sage: [B3.irr_repr(v) for v in B3.fundamental_weights()]
```

```
['B3(1,0,0)', 'B3(1,1,0)', 'B3(1/2,1/2,1/2)']
```

(continues on next page)

(continued from previous page)

```
sage: B3 = WeylCharacterRing("B3", style="coroots")
sage: [B3.irr_repr(v) for v in B3.fundamental_weights()]
['B3(1,0,0)', 'B3(0,1,0)', 'B3(0,0,1)']
```

level(wt)

Return the level of the weight, defined to be the value of the weight on the coroot associated with the highest root.

EXAMPLES:

```
sage: R = FusionRing("F4", 2); [R.level(x) for x in R.fundamental_weights()]
[2, 3, 2, 1]
sage: [CartanType("F4~").dual().a()[x] for x in [1..4]]
[2, 3, 2, 1]
```

lift()

The embedding of `self` into its weight ring.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2.lift
Generic morphism:
  From: The Weyl Character Ring of Type A2 with Integer Ring coefficients
  To:   The Weight ring attached to The Weyl Character Ring of Type A2 with
  ↪ Integer Ring coefficients
```

```
sage: x = -A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2.lift(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

As a shortcut, you may also do:

```
sage: x.lift()
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

Or even:

```
sage: a2 = WeightRing(A2)
sage: a2(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

lift_on_basis(irr)

Expand the basis element indexed by the weight `irr` into the weight ring of `self`.

INPUT:

- `irr` – a dominant weight

This is used to implement `lift()`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([2,1,0]); v
(2, 1, 0)
```

(continues on next page)

(continued from previous page)

```
sage: A2.lift_on_basis(v)
2*a2(1,1,1) + a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) + a2(0,
↪2,1)
```

This is consistent with the analogous calculation with symmetric Schur functions:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
```

maximal_subgroup(*ct*)

Return a branching rule or a list of branching rules.

INPUT:

- *ct* – the Cartan type of a maximal subgroup of *self*.

In rare cases where there is more than one maximal subgroup (up to outer automorphisms) with the given Cartan type, the function returns a list of branching rules.

EXAMPLES:

```
sage: WeylCharacterRing("E7").maximal_subgroup("A2")
miscellaneous branching rule E7 => A2
sage: WeylCharacterRing("E7").maximal_subgroup("A1")
[iii branching rule E7 => A1, iv branching rule E7 => A1]
```

For more information, see the related method `maximal_subgroups()`.

maximal_subgroups()

This method is only available if the Cartan type of *self* is irreducible and of rank no greater than 8. This method produces a list of the maximal subgroups of *self*, up to (possibly outer) automorphisms. Each line in the output gives the Cartan type of a maximal subgroup followed by a command that creates the branching rule.

EXAMPLES:

```
sage: WeylCharacterRing("E6").maximal_subgroups()
D5:branching_rule("E6","D5","levi")
C4:branching_rule("E6","C4","symmetric")
F4:branching_rule("E6","F4","symmetric")
A2:branching_rule("E6","A2","miscellaneous")
G2:branching_rule("E6","G2","miscellaneous")
A2xG2:branching_rule("E6","A2xG2","miscellaneous")
A1xA5:branching_rule("E6","A1xA5","extended")
A2xA2xA2:branching_rule("E6","A2xA2xA2","extended")
```

Note that there are other embeddings of (for example A_2 into E_6 as nonmaximal subgroups. These embeddings may be constructed by composing branching rules through various subgroups.

Once you know which maximal subgroup you are interested in, to create the branching rule, you may either paste the command to the right of the colon from the above output onto the command line, or alternatively invoke the related method `maximal_subgroup()`:

```
sage: branching_rule("E6","G2","miscellaneous")
miscellaneous branching rule E6 => G2
```

(continues on next page)

(continued from previous page)

```
sage: WeylCharacterRing("E6").maximal_subgroup("G2")
miscellaneous branching rule E6 => G2
```

It is believed that the list of maximal subgroups is complete, except that some subgroups may be not be invariant under outer automorphisms. It is reasonable to want a list of maximal subgroups that is complete up to conjugation, but to obtain such a list you may have to apply outer automorphisms. The group of outer automorphisms modulo inner automorphisms is isomorphic to the group of symmetries of the Dynkin diagram, and these are available as branching rules. The following example shows that while a branching rule from D_4 to $A_1 \times C_2$ is supplied, another different one may be obtained by composing it with the triality automorphism of D_4 :

```
sage: [D4,A1xC2]=[WeylCharacterRing(x,style="coroots") for x in ["D4","A1xC2"]]
sage: fw = D4.fundamental_weights()
sage: b = D4.maximal_subgroup("A1xC2")
sage: [D4(fw).branch(A1xC2,rule=b) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(0,0,1)]
sage: b1 = branching_rule("D4","D4","trinality")*b
sage: [D4(fw).branch(A1xC2,rule=b1) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
A1xC2(2,0,0) + A1xC2(0,0,1),
A1xC2(1,1,0)]
```

one_basis()

Return the index of 1 in self.

EXAMPLES:

```
sage: WeylCharacterRing("A3").one_basis()
(0, 0, 0, 0)
sage: WeylCharacterRing("A3").one()
A3(0,0,0,0)
```

positive_roots()

Return the positive roots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

product_on_basis(a, b)

Compute the tensor product of two irreducible representations a and b.

EXAMPLES:

```
sage: D4 = WeylCharacterRing(['D',4])
sage: spin_plus = D4(1/2,1/2,1/2,1/2)
sage: spin_minus = D4(1/2,1/2,1/2,-1/2)
sage: spin_plus * spin_minus # indirect doctest
D4(1,0,0,0) + D4(1,1,1,0)
```

(continues on next page)

(continued from previous page)

```
sage: spin_minus * spin_plus
D4(1,0,0,0) + D4(1,1,1,0)
```

Uses the Brauer-Klimyk method.

rank()

Return the rank.

EXAMPLES:

```
sage: WeylCharacterRing("G2").rank()
2
```

retract()

The partial inverse map from the weight ring into self.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: A2.retract
Generic morphism:
  From: The Weight ring attached to The Weyl Character Ring of Type A2 with
  ↪ Integer Ring coefficients
  To:   The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

```
sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: chi = a2.sum_of_monomials(v.orbit()); chi
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
sage: A2.retract(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

The input should be invariant:

```
sage: A2.retract(a2.monomial(v))
Traceback (most recent call last):
...
ValueError: multiplicity dictionary may not be Weyl group invariant
```

As a shortcut, you may use conversion:

```
sage: A2(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2(a2.monomial(v))
Traceback (most recent call last):
...
ValueError: multiplicity dictionary may not be Weyl group invariant
```

simple_coroots()

Return the simple coroots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
```

simple_roots()

Return the simple roots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

some_elements()

Return some elements of self.

EXAMPLES:

```
sage: WeylCharacterRing("A3").some_elements()
[A3(1,0,0,0), A3(1,1,0,0), A3(1,1,1,0)]
```

space()

Return the weight space associated to self.

EXAMPLES:

```
sage: WeylCharacterRing(['E',8]).space()
Ambient space of the Root system of type ['E', 8]
```

```
sage.combinat.root_system.weyl_characters.irreducible_character_freudenthal(hwv,
                                                                           debug=False)
```

Return the dictionary of multiplicities for the irreducible character with highest weight λ .

The weight multiplicities are computed by the Freudenthal multiplicity formula. The algorithm is based on recursion relation that is stated, for example, in Humphrey's book on Lie Algebras. The multiplicities are invariant under the Weyl group, so to compute them it would be sufficient to compute them for the weights in the positive Weyl chamber. However after some testing it was found to be faster to compute every weight using the recursion, since the use of the Weyl group is expensive in its current implementation.

INPUT:

- hwv – a dominant weight in a weight lattice.
- L – the ambient space

EXAMPLES:

```
sage: WeylCharacterRing("A2")(2,1,0).weight_multiplicities() # indirect doctest
{(1, 1, 1): 2, (1, 2, 0): 1, (1, 0, 2): 1, (2, 1, 0): 1,
 (2, 0, 1): 1, (0, 1, 2): 1, (0, 2, 1): 1}
```

5.1.269 Fusion Rings

class `sage.combinat.root_system.fusion_ring.FusionRing`(*ct*, *base_ring=Integer Ring*, *prefix=None*,
style='lattice', *k=None*, *conjugate=False*,
cyclotomic_order=None)

Bases: `sage.combinat.root_system.weyl_characters.WeylCharacterRing`

Return the Fusion Ring (Verlinde Algebra) of level *k*.

INPUT:

- *ct* – the Cartan type of a simple (finite-dimensional) Lie algebra
- *k* – a nonnegative integer
- *conjugate* – (default `False`) set `True` to obtain the complex conjugate ring
- *cyclotomic_order* – (default computed depending on *ct* and *k*)

The cyclotomic order is an integer N such that all computations will return elements of the cyclotomic field of N -th roots of unity. Normally you will never need to change this but consider changing it if `root_of_unity()` ever returns `None`.

This algebra has a basis (sometimes called *primary fields* but here called *simple objects*) indexed by the weights of level $\leq k$. These arise as the fusion algebras of Wess-Zumino-Witten (WZW) conformal field theories, or as Grothendieck groups of tilting modules for quantum groups at roots of unity. The `FusionRing` class is implemented as a variant of the `WeylCharacterRing`.

REFERENCES:

- [BaKi2001] Chapter 3
- [DFMS1996] Chapter 16
- [EGNO2015] Chapter 8
- [Feingold2004]
- [Fuchs1994]
- [Row2006]
- [Walton1990]
- [Wan2010]

EXAMPLES:

```
sage: A22 = FusionRing("A2",2)
sage: [f1, f2] = A22.fundamental_weights()
sage: M = [A22(x) for x in [0*f1, 2*f1, 2*f2, f1+f2, f2, f1]]
sage: [M[3] * x for x in M]
[A22(1,1),
 A22(0,1),
 A22(1,0),
 A22(0,0) + A22(1,1),
 A22(0,1) + A22(2,0),
 A22(1,0) + A22(0,2)]
```

You may assign your own labels to the basis elements. In the next example, we create the $SO(5)$ fusion ring of level 2, check the weights of the basis elements, then assign new labels to them while injecting them into the global namespace:

```

sage: B22 = FusionRing("B2", 2)
sage: b = [B22(x) for x in B22.get_order()]; b
[B22(0,0), B22(1,0), B22(0,1), B22(2,0), B22(1,1), B22(0,2)]
sage: [x.weight() for x in b]
[(0, 0), (1, 0), (1/2, 1/2), (2, 0), (3/2, 1/2), (1, 1)]
sage: B22.fusion_labels(['I0', 'Y1', 'X', 'Z', 'Xp', 'Y2'], inject_variables=True)
sage: b = [B22(x) for x in B22.get_order()]; b
[I0, Y1, X, Z, Xp, Y2]
sage: [(x, x.weight()) for x in b]
[(I0, (0, 0)),
 (Y1, (1, 0)),
 (X, (1/2, 1/2)),
 (Z, (2, 0)),
 (Xp, (3/2, 1/2)),
 (Y2, (1, 1))]
sage: X * Y1
X + Xp
sage: Z * Z
I0

```

A fixed order of the basis keys is available with `get_order()`. This is the order used by methods such as `s_matrix()`. You may use `CombinatorialFreeModule.set_order()` to reorder the basis:

```

sage: B22.set_order([x.weight() for x in [I0,Y1,Y2,X,Xp,Z]])
sage: [B22(x) for x in B22.get_order()]
[I0, Y1, Y2, X, Xp, Z]

```

To reset the labels, you may run `fusion_labels()` with no parameter:

```

sage: B22.fusion_labels()
sage: [B22(x) for x in B22.get_order()]
[B22(0,0), B22(1,0), B22(0,2), B22(0,1), B22(1,1), B22(2,0)]

```

To reset the order to the default, simply set it to the list of basis element keys:

```

sage: B22.set_order(B22.basis().keys().list())
sage: [B22(x) for x in B22.get_order()]
[B22(0,0), B22(1,0), B22(0,1), B22(2,0), B22(1,1), B22(0,2)]

```

The fusion ring has a number of methods that reflect its role as the Grothendieck ring of a *modular tensor category* (MTC). These include twist methods `Element.twist()` and `Element.ribbon()` for its elements related to the ribbon structure, and the S-matrix `s_ij()`.

There are two natural normalizations of the S-matrix. Both are explained in Chapter 3 of [BaKi2001]. The one that is computed by the method `s_matrix()`, or whose individual entries are computed by `s_ij()` is denoted \tilde{s} in [BaKi2001]. It is not unitary.

The unitary S-matrix is $s = D^{-1/2}\tilde{s}$ where

$$D = \sum_V d_i(V)^2.$$

The sum is over all simple objects V with $d_i(V)$ the *quantum dimension*. We will call quantity D the *global quantum dimension* and \sqrt{D} the *total quantum order*. They are computed by `global_q_dimension()` and `total_q_order()`. The unitary S-matrix s may be obtained using `s_matrix()` with the option `unitary=True`.

Let us check the Verlinde formula, which is [DFMS1996] (16.3). This famous identity states that

$$N_{ij}^k = \sum_{\ell} \frac{s(i, \ell) s(j, \ell) \overline{s(k, \ell)}}{s(I, \ell)},$$

where N_{ij}^k are the fusion coefficients, i.e. the structure constants of the fusion ring, and I is the unit object. The S -matrix has the property that if i^* denotes the dual object of i , implemented in Sage as `i.dual()`, then

$$s(i^*, j) = s(i, j^*) = \overline{s(i, j)}.$$

This is equation (16.5) in [DFMS1996]. Thus with $N_{ijk} = N_{ij}^{k^*}$ the Verlinde formula is equivalent to

$$N_{ijk} = \sum_{\ell} \frac{s(i, \ell) s(j, \ell) s(k, \ell)}{s(I, \ell)},$$

In this formula s is the normalized unitary S -matrix denoted s in [BaKi2001]. We may define a function that corresponds to the right-hand side, except using \tilde{s} instead of s :

```
sage: def V(i, j, k):
.....:     R = i.parent()
.....:     return sum(R.s_ij(i, l) * R.s_ij(j, l) * R.s_ij(k, l) / R.s_ij(R.one(), l)
.....:               for l in R.basis())
```

This does not produce `self.N_ijk(i, j, k)` exactly, because of the missing normalization factor. The following code to check the Verlinde formula takes this into account:

```
sage: def test_verlinde(R):
.....:     b0 = R.one()
.....:     c = R.global_q_dimension()
.....:     return all(V(i, j, k) == c * R.N_ijk(i, j, k) for i in R.basis()
.....:               for j in R.basis() for k in R.basis())
```

Every fusion ring should pass this test:

```
sage: test_verlinde(FusionRing("A2", 1))
True
sage: test_verlinde(FusionRing("B4", 2)) # long time (.56s)
True
```

As an exercise, the reader may verify the examples in Section 5.3 of [RoStWa2009]. Here we check the example of the Ising modular tensor category, which is related to the BPZ minimal model $M(4, 3)$ or to an E_8 coset model. See [DFMS1996] Sections 7.4.2 and 18.4.1. [RoStWa2009] Example 5.3.4 tells us how to construct it as the conjugate of the E_8 level 2 *FusionRing*:

```
sage: I = FusionRing("E8", 2, conjugate=True)
sage: I.fusion_labels(["i0", "p", "s"], inject_variables=True)
sage: b = I.basis().list(); b
[i0, p, s]
sage: [[x*y for x in b] for y in b]
[[i0, p, s], [p, i0, s], [s, s, i0 + p]]
sage: [x.twist() for x in b]
[0, 1, 1/8]
sage: [x.ribbon() for x in b]
[1, -1, zeta128^8]
```

(continues on next page)

(continued from previous page)

```

sage: [I.r_matrix(i, j, k) for (i,j,k) in [(s,s,i0), (p,p,i0), (p,s,s), (s,p,s), (s,
↪s,p)]]
[-zeta128^56, -1, -zeta128^32, -zeta128^32, zeta128^24]
sage: I.r_matrix(s, s, i0) == I.root_of_unity(-1/8)
True
sage: I.global_q_dimension()
4
sage: I.total_q_order()
2
sage: [x.q_dimension()^2 for x in b]
[1, 1, 2]
sage: I.s_matrix()
[
      1
      1
-zeta128^48 + zeta128^16  zeta128^48 - zeta128^16
      0]
sage: I.s_matrix().apply_map(lambda x:x^2)
[1 1 2]
[1 1 2]
[2 2 0]

```

The term *modular tensor category* refers to the fact that associated with the category there is a projective representation of the modular group $SL(2, \mathbf{Z})$. We recall that this group is generated by

$$S = \begin{pmatrix} & -1 \\ 1 & \end{pmatrix}, \quad T = \begin{pmatrix} 1 & 1 \\ & 1 \end{pmatrix}$$

subject to the relations $(ST)^3 = S^2$, $S^2T = TS^2$, and $S^4 = I$. Let s be the normalized S-matrix, and t the diagonal matrix whose entries are the twists of the simple objects. Let s the unitary S-matrix and t the matrix of twists, and C the conjugation matrix `conj_matrix()`. Let

$$D_+ = \sum_i d_i^2 \theta_i, \quad D_- = d_i^2 \theta_i^{-1},$$

where d_i and θ_i are the quantum dimensions and twists of the simple objects. Let c be the Virasoro central charge, a rational number that is computed in `virasoro_central_charge()`. It is known that

$$\sqrt{\frac{D_+}{D_-}} = e^{i\pi c/4}.$$

It is proved in [BaKi2001] Equation (3.1.17) that

$$(st)^3 = e^{i\pi c/4} s^2, \quad s^2 = C, \quad C^2 = 1, \quad Ct = tC.$$

Therefore $S \mapsto s, T \mapsto t$ is a projective representation of $SL(2, \mathbf{Z})$. Let us confirm these identities for the Fibonacci MTC `FusionRing("G2", 1)`:

```

sage: R = FusionRing("G2", 1)
sage: S = R.s_matrix(unitary=True)
sage: T = R.twists_matrix()
sage: C = R.conj_matrix()
sage: c = R.virasoro_central_charge(); c
14/5
sage: (S*T)^3 == R.root_of_unity(c/4) * S^2

```

(continues on next page)

(continued from previous page)

```
True
sage: S^2 == C
True
sage: C*T == T*C
True
```

D_minus()

Return $\sum d_i^2 \theta_i^{-1}$ where i runs through the simple objects, d_i is the quantum dimension and θ_i is the twist. This is denoted p_- in [BaKi2001] Chapter 3.

EXAMPLES:

```
sage: E83 = FusionRing("E8", 3, conjugate=True)
sage: [Dp, Dm] = [E83.D_plus(), E83.D_minus()]
sage: Dp*Dm == E83.global_q_dimension()
True
sage: c = E83.virasoro_central_charge(); c
-248/11
sage: Dp*Dm == E83.global_q_dimension()
True
```

D_plus()

Return $\sum d_i^2 \theta_i$ where i runs through the simple objects, d_i is the quantum dimension and θ_i is the twist. This is denoted p_+ in [BaKi2001] Chapter 3.

EXAMPLES:

```
sage: B31 = FusionRing("B3", 1)
sage: Dp = B31.D_plus(); Dp
2*zeta48^13 - 2*zeta48^5
sage: Dm = B31.D_minus(); Dm
-2*zeta48^3
sage: Dp*Dm == B31.global_q_dimension()
True
sage: c = B31.virasoro_central_charge(); c
7/2
sage: Dp/Dm == B31.root_of_unity(c/2)
True
```

class Element

Bases: *sage.combinat.root_system.weyl_characters.WeylCharacterRing.Element*

A class for FusionRing elements.

is_simple_object()

Determine whether `self` is a simple object of the fusion ring.

EXAMPLES:

```
sage: A22 = FusionRing("A2", 2)
sage: x = A22(1, 0); x
A22(1, 0)
sage: x.is_simple_object()
True
```

(continues on next page)

(continued from previous page)

```
sage: x^2
A22(0,1) + A22(2,0)
sage: (x^2).is_simple_object()
False
```

q_dimension()

Return the quantum dimension as an element of the cyclotomic field of the 2ℓ -th roots of unity, where $l = m(k + h^\vee)$ with $m = 1, 2, 3$ depending on whether type is simply, doubly or triply laced, k is the level and h^\vee is the dual Coxeter number.

EXAMPLES:

```
sage: B22 = FusionRing("B2", 2)
sage: [(b.q_dimension())^2 for b in B22.basis()]
[1, 4, 5, 1, 5, 4]
```

ribbon()

Return the twist or ribbon element of `self`.

If h is the rational number modulo 2 produced by `self.twist()`, this method produces $e^{i\pi h}$.

See also:

An additive version of this is available as `twist()`.

EXAMPLES:

```
sage: F = FusionRing("A1", 3)
sage: [x.twist() for x in F.basis()]
[0, 3/10, 4/5, 3/2]
sage: [x.ribbon() for x in F.basis()]
[1, zeta40^6, zeta40^12 - zeta40^8 + zeta40^4 - 1, -zeta40^10]
sage: [F.root_of_unity(x) for x in [0, 3/10, 4/5, 3/2]]
[1, zeta40^6, zeta40^12 - zeta40^8 + zeta40^4 - 1, -zeta40^10]
```

twist(reduced=True)

Return a rational number h such that $\theta = e^{i\pi h}$ is the twist of `self`. The quantity $e^{i\pi h}$ is also available using `ribbon()`.

This method is only available for simple objects. If λ is the weight of the object, then $h = \langle \lambda, \lambda + 2\rho \rangle$, where ρ is half the sum of the positive roots. As in [Row2006], this requires normalizing the invariant bilinear form so that $\langle \alpha, \alpha \rangle = 2$ for short roots.

INPUT:

- `reduced` – (default: `True`) boolean; if `True` then return the twist reduced modulo 2

EXAMPLES:

```
sage: G21 = FusionRing("G2", 1)
sage: [x.twist() for x in G21.basis()]
[0, 4/5]
sage: [G21.root_of_unity(x.twist()) for x in G21.basis()]
[1, zeta60^14 - zeta60^4]
sage: zeta60 = G21.field().gen()
sage: zeta60^((4/5)*(60/2))
zeta60^14 - zeta60^4
```

(continues on next page)

(continued from previous page)

```
sage: F42 = FusionRing("F4", 2)
sage: [x.twist() for x in F42.basis()]
[0, 18/11, 2/11, 12/11, 4/11]

sage: E62 = FusionRing("E6", 2)
sage: [x.twist() for x in E62.basis()]
[0, 26/21, 12/7, 8/21, 8/21, 26/21, 2/3, 4/7, 2/3]
```

weight()

Return the parametrizing dominant weight in the level k alcove.

This method is only available for basis elements.

EXAMPLES:

```
sage: A21 = FusionRing("A2", 1)
sage: [x.weight() for x in A21.basis().list()]
[(0, 0, 0), (2/3, -1/3, -1/3), (1/3, 1/3, -2/3)]
```

N_ijk(elt_i, elt_j, elt_k)

Return the symmetric fusion coefficient N_{ijk} .

INPUT:

- `elt_i, elt_j, elt_k` – elements of the fusion basis

This is the same as N_{ij}^{k*} , where N_{ij}^k are the structure coefficients of the ring (see `Nk_ij()`), and k^* denotes the dual element. The coefficient N_{ijk} is unchanged under permutations of the three basis vectors.

EXAMPLES:

```
sage: G23 = FusionRing("G2", 3)
sage: G23.fusion_labels("g")
sage: b = G23.basis().list(); b
[g0, g1, g2, g3, g4, g5]
sage: [(x,y,z) for x in b for y in b for z in b if G23.N_ijk(x,y,z) > 1]
[(g3, g3, g3), (g3, g3, g4), (g3, g4, g3), (g4, g3, g3)]
sage: all(G23.N_ijk(x,y,z)==G23.N_ijk(y,z,x) for x in b for y in b for z in b)
True
sage: all(G23.N_ijk(x,y,z)==G23.N_ijk(y,x,z) for x in b for y in b for z in b)
True
```

Nk_ij(elt_i, elt_j, elt_k)

Return the fusion coefficient N_{ij}^k .

These are the structure coefficients of the fusion ring, so

$$i * j = \sum_k N_{ij}^k k.$$

EXAMPLES:

```
sage: A22 = FusionRing("A2", 2)
sage: b = A22.basis().list()
sage: all(x*y == sum(A22.Nk_ij(x,y,k)*k for k in b) for x in b for y in b)
True
```

conj_matrix()

Return the conjugation matrix, which is the permutation matrix for the conjugation (dual) operation on basis elements.

EXAMPLES:

```
sage: FusionRing("A2",1).conj_matrix()
[1 0 0]
[0 0 1]
[0 1 0]
```

field()

Return a cyclotomic field large enough to contain the 2ℓ -th roots of unity, as well as all the S-matrix entries.

EXAMPLES:

```
sage: FusionRing("A2",2).field()
Cyclotomic Field of order 60 and degree 16
sage: FusionRing("B2",2).field()
Cyclotomic Field of order 40 and degree 16
```

fusion_l()

Return the product $\ell = m_g(k + h^\vee)$, where m_g denotes the square of the ratio of the lengths of long to short roots of the underlying Lie algebra, k denotes the level of the FusionRing, and h^\vee denotes the dual Coxeter number of the underlying Lie algebra.

This value is used to define the associated root 2ℓ -th of unity $q = e^{i\pi/\ell}$.

EXAMPLES:

```
sage: B22 = FusionRing('B2',2)
sage: B22.fusion_l()
10
sage: D52 = FusionRing('D5',2)
sage: D52.fusion_l()
10
```

fusion_labels(labels=None, inject_variables=False)

Set the labels of the basis.

INPUT:

- `labels` – (default: `None`) a list of strings or string
- `inject_variables` – (default: `False`) if `True`, then inject the variable names into the global namespace; note that this could override objects already defined

If `labels` is a list, the length of the list must equal the number of basis elements. These become the names of the basis elements.

If `labels` is a string, this is treated as a prefix and a list of names is generated.

If `labels` is `None`, then this resets the labels to the default.

EXAMPLES:

```
sage: A13 = FusionRing("A1", 3)
sage: A13.fusion_labels("x")
sage: fb = list(A13.basis()); fb
```

(continues on next page)

(continued from previous page)

```
[x0, x1, x2, x3]
sage: Matrix([[x*y for y in A13.basis()] for x in A13.basis()])
[  x0      x1      x2      x3]
[  x1 x0 + x2 x1 + x3      x2]
[  x2 x1 + x3 x0 + x2      x1]
[  x3      x2      x1      x0]
```

We give an example where the variables are injected into the global namespace:

```
sage: A13.fusion_labels("y", inject_variables=True)
sage: y0
y0
sage: y0.parent() is A13
True
```

We reset the labels to the default:

```
sage: A13.fusion_labels()
sage: fb
[A13(0), A13(1), A13(2), A13(3)]
sage: y0
A13(0)
```

fusion_level()

Return the level k of self.

EXAMPLES:

```
sage: B22 = FusionRing('B2', 2)
sage: B22.fusion_level()
2
```

get_order()

Return the weights of the basis vectors in a fixed order.

You may change the order of the basis using `CombinatorialFreeModule.set_order()`

EXAMPLES:

```
sage: A14 = FusionRing("A1", 4)
sage: w = A14.get_order(); w
[(0, 0), (1/2, -1/2), (1, -1), (3/2, -3/2), (2, -2)]
sage: A14.set_order([w[k] for k in [0, 4, 1, 3, 2]])
sage: [A14(x) for x in A14.get_order()]
[A14(0), A14(4), A14(1), A14(3), A14(2)]
```

Warning: This duplicates `get_order()` from `CombinatorialFreeModule` except the result is *not* cached. Caching of `CombinatorialFreeModule.get_order()` causes inconsistent results after calling `CombinatorialFreeModule.set_order()`.

global_q_dimension()

Return $\sum d_i^2$, where the sum is over all simple objects and d_i is the quantum dimension. It is a positive real number.

EXAMPLES:

```
sage: FusionRing("E6",1).global_q_dimension()
3
```

r_matrix(*i*, *j*, *k*)

Return the R-matrix entry corresponding to the subobject *k* in the tensor product of *i* with *j*.

Warning: This method only gives complete information when $N_{ij}^k = 1$ (an important special case). Tables of MTC including R-matrices may be found in Section 5.3 of [RoStWa2009] and in [Bond2007].

The R-matrix is a homomorphism $i \otimes j \rightarrow j \otimes i$. This may be hard to describe since the object $i \otimes j$ may be reducible. However if *k* is a simple subobject of $i \otimes j$ it is also a subobject of $j \otimes i$. If we fix embeddings $k \rightarrow i \otimes j$, $k \rightarrow j \otimes i$ we may ask for the scalar automorphism of *k* induced by the R-matrix. This method computes that scalar. It is possible to adjust the set of embeddings $k \rightarrow i \otimes j$ (called a *gauge*) so that this scalar equals

$$\pm \sqrt{\frac{\theta_k}{\theta_i \theta_j}}.$$

If $i \neq j$, the gauge may be used to control the sign of the square root. But if $i = j$ then we must be careful about the sign. These cases are computed by a formula of [BDGRTW2019], Proposition 2.3.

EXAMPLES:

```
sage: I = FusionRing("E8", 2, conjugate=True) # Ising MTC
sage: I.fusion_labels(["i0", "p", "s"], inject_variables=True)
sage: I.r_matrix(s,s,i0) == I.root_of_unity(-1/8)
True
sage: I.r_matrix(p,p,i0)
-1
sage: I.r_matrix(p,s,s) == I.root_of_unity(-1/2)
True
sage: I.r_matrix(s,p,s) == I.root_of_unity(-1/2)
True
sage: I.r_matrix(s,s,p) == I.root_of_unity(3/8)
True
```

root_of_unity(*r*)

Return $e^{i\pi r}$ as an element of `self.field()` if possible.

INPUT:

- *r* – a rational number

EXAMPLES:

```
sage: A11 = FusionRing("A1",1)
sage: A11.field()
Cyclotomic Field of order 24 and degree 8
sage: [A11.root_of_unity(2/x) for x in [1..7]]
[1, -1, zeta24^4 - 1, zeta24^6, None, zeta24^4, None]
```

s_ij(*elt_i*, *elt_j*)

Return the element of the S-matrix of this fusion ring corresponding to the given elements.

This is computed using the formula

$$s_{i,j} = \frac{1}{\theta_i \theta_j} \sum_k N_{ik}^j d_k \theta_k,$$

where θ_k is the twist and d_k is the quantum dimension. See [Row2006] Equation (2.2) or [EGNO2015] Proposition 8.13.8.

INPUT:

- `elt_i, elt_j` – elements of the fusion basis

EXAMPLES:

```
sage: G21 = FusionRing("G2", 1)
sage: b = G21.basis()
sage: [G21.s_ij(x, y) for x in b for y in b]
[1, -zeta60^14 + zeta60^6 + zeta60^4, -zeta60^14 + zeta60^6 + zeta60^4, -1]
```

s_matrix(unitary=False)

Return the S-matrix of this fusion ring.

OPTIONAL:

- `unitary` – (default: False) set to True to obtain the unitary S-matrix

Without the `unitary` parameter, this is the matrix denoted \tilde{s} in [BaKi2001].

EXAMPLES:

```
sage: D91 = FusionRing("D9", 1)
sage: D91.s_matrix()
[
  [ 1 1 1 1]
  [ 1 1 -1 -1]
  [ 1 -1 -zeta136^34 zeta136^34]
  [ 1 -1 zeta136^34 -zeta136^34]
]
sage: S = D91.s_matrix(unitary=True); S
[
  [ 1/2 1/2 1/2 1/2]
  [ 1/2 1/2 1/2 -1/2]
  [ 1/2 -1/2 -1/2*zeta136^34 1/2*zeta136^34]
  [ 1/2 -1/2 1/2*zeta136^34 -1/2*zeta136^34]
]
sage: S*S.conjugate()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

some_elements()

Return some elements of `self`.

EXAMPLES:

```
sage: D41 = FusionRing('D4', 1)
sage: D41.some_elements()
[D41(1,0,0,0), D41(0,0,1,0), D41(0,0,0,1)]
```

total_q_order()

Return the positive square root of `self.global_q_dimension()` as an element of `self.field()`.

EXAMPLES:

```

sage: F = FusionRing("G2", 1)
sage: tqo=F.total_q_order(); tqo
zeta60^15 - zeta60^11 - zeta60^9 + 2*zeta60^3 + zeta60
sage: tqo.is_real_positive()
True
sage: tqo^2 == F.global_q_dimension()
True

```

twists_matrix()

Return a diagonal matrix describing the twist corresponding to each simple object in the FusionRing.

EXAMPLES:

```

sage: B21=FusionRing("B2", 1)
sage: [x.twist() for x in B21.basis().list()]
[0, 1, 5/8]
sage: [B21.root_of_unity(x.twist()) for x in B21.basis().list()]
[1, -1, zeta32^10]
sage: B21.twists_matrix()
[ 1      0      0]
[ 0     -1      0]
[ 0      0 zeta32^10]

```

virasoro_central_charge()

Return the Virasoro central charge of the WZW conformal field theory associated with the Fusion Ring.

If \mathfrak{g} is the corresponding semisimple Lie algebra, this is

$$\frac{k \dim \mathfrak{g}}{k + h^\vee},$$

where k is the level and h^\vee is the dual Coxeter number. See [DFMS1996] Equation (15.61).

Let d_i and θ_i be the quantum dimensions and twists of the simple objects. By Proposition 2.3 in [RoStWa2009], there exists a rational number c such that $D_+/\sqrt{D} = e^{i\pi c/4}$, where $D_+ = \sum d_i^2 \theta_i$ is computed in `D_plus()` and $D = \sum d_i^2 > 0$ is computed by `global_q_dimension()`. Squaring this identity and remembering that $D_+ D_- = D$ gives

$$D_+/D_- = e^{i\pi c/2}.$$

EXAMPLES:

```

sage: R = FusionRing("A1", 2)
sage: c = R.virasoro_central_charge(); c
3/2
sage: Dp = R.D_plus(); Dp
2*zeta32^6
sage: Dm = R.D_minus(); Dm
-2*zeta32^10
sage: Dp / Dm == R.root_of_unity(c/2)
True

```

5.1.270 Weyl Groups

AUTHORS:

- Daniel Bump (2008): initial version
- Mike Hansen (2008): initial version
- Anne Schilling (2008): initial version
- Nicolas Thiery (2008): initial version
- Volker Braun (2013): LibGAP-based matrix groups

EXAMPLES:

More examples on Weyl Groups should be added here...

The Cayley graph of the Weyl Group of type ['A', 3]:

```
sage: w = WeylGroup(['A', 3])
sage: d = w.cayley_graph(); d
Digraph on 24 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03)
```

The Cayley graph of the Weyl Group of type ['D', 4]:

```
sage: w = WeylGroup(['D', 4])
sage: d = w.cayley_graph(); d
Digraph on 192 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03) #long time (less_
↳than one minute)
```

class sage.combinat.root_system.weyl_group.ClassicalWeylSubgroup(*domain, prefix*)

Bases: *sage.combinat.root_system.weyl_group.WeylGroup_gens*

A class for Classical Weyl Subgroup of an affine Weyl Group

EXAMPLES:

```
sage: G = WeylGroup(["A", 3, 1]).classical()
sage: G
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1] (as a matrix group acting_
↳on the root space)
sage: G.category()
Category of finite irreducible weyl groups
sage: G.cardinality()
24
sage: G.index_set()
(1, 2, 3)
sage: TestSuite(G).run()
```

Todo: implement:

- Parabolic subroot systems
- Parabolic subgroups with a set of nodes as argument

cartan_type()

EXAMPLES:

```
sage: WeylGroup(['A',3,1]).classical().cartan_type()
['A', 3]
sage: WeylGroup(['A',3,1]).classical().index_set()
(1, 2, 3)
```

Note: won't be needed, once the lattice will be a parabolic sub root system

simple_reflections()

EXAMPLES:

```
sage: WeylGroup(['A',2,1]).classical().simple_reflections()
Finite family {1: [ 1  0  0]
                  [ 1 -1  1]
                  [ 0  0  1],
                2: [ 1  0  0]
                  [ 0  1  0]
                  [ 1  1 -1]}
```

Note: won't be needed, once the lattice will be a parabolic sub root system

weyl_group(prefix='hereditary')

Return the Weyl group associated to the parabolic subgroup.

EXAMPLES:

```
sage: WeylGroup(['A',4,1]).classical().weyl_group()
Weyl Group of type ['A', 4, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['C',4,1]).classical().weyl_group()
Weyl Group of type ['C', 4, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['E',8,1]).classical().weyl_group()
Weyl Group of type ['E', 8, 1] (as a matrix group acting on the root space)
```

`sage.combinat.root_system.weyl_group.WeylGroup(x, prefix=None, implementation='matrix')`

Returns the Weyl group of the root system defined by the Cartan type (or matrix) `ct`.

INPUT:

- `x` - a root system or a Cartan type (or matrix)

OPTIONAL:

- `prefix` – changes the representation of elements from matrices to products of simple reflections
- `implementation` – one of the following: * `'matrix'` - as matrices acting on a root system * `"permutation"` - as a permutation group acting on the roots

EXAMPLES:

The following constructions yield the same result, namely a weight lattice and its corresponding Weyl group:

```
sage: G = WeylGroup(['F',4])
sage: L = G.domain()
```

or alternatively and equivalently:

```
sage: L = RootSystem(['F',4]).ambient_space()
sage: G = L.weyl_group()
sage: W = WeylGroup(L)
```

Either produces a weight lattice, with access to its roots and weights.

```
sage: G = WeylGroup(['F',4])
sage: G.order()
1152
sage: [s1,s2,s3,s4] = G.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: type(w) == G.element_class
True
sage: w.order()
12
sage: w.length() # length function on Weyl group
4
```

The default representation of Weyl group elements is as matrices. If you prefer, you may specify a prefix, in which case the elements are represented as products of simple reflections.

```
sage: W=WeylGroup("C3",prefix="s")
sage: [s1,s2,s3]=W.simple_reflections() # lets Sage parse its own output
sage: s2*s1*s2*s3
s1*s2*s3*s1
sage: s2*s1*s2*s3 == s1*s2*s3*s1
True
sage: (s2*s3)^2==(s3*s2)^2
True
sage: (s1*s2*s3*s1).matrix()
[ 0  0 -1]
[ 0  1  0]
[ 1  0  0]
```

```
sage: L = G.domain()
sage: fw = L.fundamental_weights(); fw
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 1,
→0, 0)}
sage: rho = sum(fw); rho
(11/2, 5/2, 3/2, 1/2)
sage: w.action(rho) # action of G on weight lattice
(5, -1, 3, 2)
```

We can also do the same for arbitrary Cartan matrices:

```
sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
sage: W = WeylGroup(cm)
sage: W.gens()
(
```

(continues on next page)

(continued from previous page)

```

[-1 5 0] [ 1 0 0] [ 1 0 0]
[ 0 1 0] [ 2 -1 1] [ 0 1 0]
[ 0 0 1], [ 0 0 1], [ 0 1 -1]
)
sage: s0,s1,s2 = W.gens()
sage: s1*s2*s1
[ 1 0 0]
[ 2 0 -1]
[ 2 -1 0]
sage: s2*s1*s2
[ 1 0 0]
[ 2 0 -1]
[ 2 -1 0]
sage: s0*s1*s0*s2*s0
[ 9 0 -5]
[ 2 0 -1]
[ 0 1 -1]

```

Same Cartan matrix, but with a prefix to display using simple reflections:

```

sage: W = WeylGroup(cm, prefix='s')
sage: s0,s1,s2 = W.gens()
sage: s0*s2*s1
s2*s0*s1
sage: (s1*s2)^3
1
sage: (s0*s1)^5
s0*s1*s0*s1*s0*s1*s0*s1*s0*s1*s0*s1
sage: s0*s1*s2*s1*s2
s2*s0*s1
sage: s0*s1*s2*s0*s2
s0*s1*s0

```

```

class sage.combinat.root_system.weyl_group.WeylGroupElement(parent, g, check=False)
Bases: sage.groups.matrix_gps.group_element.MatrixGroupElement_gap

```

Class for a Weyl Group elements

action(*v*)

Return the action of self on the vector *v*.

EXAMPLES:

```

sage: W = WeylGroup(['A', 2])
sage: s = W.simple_reflections()
sage: v = W.domain()([1, 0, 0])
sage: s[1].action(v)
(0, 1, 0)

sage: W = WeylGroup(RootSystem(['A', 2]).root_lattice())
sage: s = W.simple_reflections()
sage: alpha = W.domain().simple_roots()
sage: s[1].action(alpha[1])
-alpha[1]

```

(continues on next page)

(continued from previous page)

```

sage: W=WeylGroup(['A',2,1])
sage: alpha = W.domain().simple_roots()
sage: s = W.simple_reflections()
sage: s[1].action(alpha[1])
-alpha[1]
sage: s[1].action(alpha[0])
alpha[0] + alpha[1]

```

apply_simple_reflection(*i*, *side='right'*)

domain()

Returns the ambient lattice associated with self.

EXAMPLES:

```

sage: W = WeylGroup(['A',2])
sage: s1 = W.simple_reflection(1)
sage: s1.domain()
Ambient space of the Root system of type ['A', 2]

```

has_descent(*i*, *positive=False*, *side='right'*)

Test if **self** has a descent at position *i*.

An element w has a descent in position i if w is on the strict negative side of the i^{th} simple reflection hyperplane.

If **positive** is **True**, tests if it is on the strict positive side instead.

EXAMPLES:

```

sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [s[3].has_descent(i, True) for i in W.domain().index_set()]
[True, True, False]
sage: W = WeylGroup(['A',3,1])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False, False]
sage: [s[0].has_descent(i) for i in W.domain().index_set()]
[True, False, False, False]
sage: w = s[0] * s[1]
sage: [w.has_descent(i) for i in W.domain().index_set()]
[False, True, False, False]
sage: [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, False, False]
sage: w = s[0] * s[2]

```

(continues on next page)

(continued from previous page)

```

sage: [w.has_descent(i) for i in W.domain().index_set()]
[True, False, True, False]
sage: [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, True, False]

sage: W = WeylGroup(['A', 3])
sage: W.one().has_descent(0)
True
sage: W.w0.has_descent(0)
False

```

has_left_descent(*i*)

Test if self has a left descent at position *i*.

EXAMPLES:

```

sage: W = WeylGroup(['A', 3])
sage: s = W.simple_reflections()
sage: [W.one().has_left_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_left_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_left_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_left_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [(s[3]*s[2]).has_left_descent(i) for i in W.domain().index_set()]
[False, False, True]

```

has_right_descent(*i*)

Test if self has a right descent at position *i*.

EXAMPLES:

```

sage: W = WeylGroup(['A', 3])
sage: s = W.simple_reflections()
sage: [W.one().has_right_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_right_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_right_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [(s[3]*s[2]).has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]

```

to_matrix()

Return self as a matrix.

EXAMPLES:

```

sage: G = WeylGroup(['A', 2])
sage: s1 = G.simple_reflection(1)

```

(continues on next page)

(continued from previous page)

```
sage: s1.to_matrix() == s1.matrix()
True
```

to_permutation()

A first approximation of to_permutation ...

This assumes types A,B,C,D on the ambient lattice

This further assume that the basis is indexed by 0,1,... and returns a permutation of (5,4,2,3,1) (beuargl), as a tuple

to_permutation_string()

EXAMPLES:

```
sage: W = WeylGroup(["A", 3])
sage: s = W.simple_reflections()
sage: (s[1]*s[2]*s[3]).to_permutation_string()
'2341'
```

class sage.combinat.root_system.weyl_group.WeylGroup_gens(*domain, prefix*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.groups.matrix_gps.finitely_generated.FinitelyGeneratedMatrixGroup_gap

EXAMPLES:

```
sage: G = WeylGroup(['B', 3])
sage: TestSuite(G).run()
sage: cm = CartanMatrix([[2, -5, 0], [-2, 2, -1], [0, -1, 2]])
sage: W = WeylGroup(cm)
sage: TestSuite(W).run() # long time
```

Element

alias of *WeylGroupElement*

cartan_type()

Returns the CartanType associated to self.

EXAMPLES:

```
sage: G = WeylGroup(['F', 4])
sage: G.cartan_type()
['F', 4]
```

character_table()

Returns the character table as a matrix

Each row is an irreducible character. For larger tables you may preface this with a command such as `gap.eval("SizeScreen([120,40])")` in order to widen the screen.

EXAMPLES:

```
sage: WeylGroup(['A', 3]).character_table()
CT1

  2  3  2  2  .  3
  3  1  .  .  1  .
```

(continues on next page)

(continued from previous page)

	1a	4a	2a	3a	2b
X.1	1	-1	-1	1	1
X.2	3	1	-1	.	-1
X.3	2	.	.	-1	2
X.4	3	-1	1	.	-1
X.5	1	1	1	1	1

classical()

If `self` is a Weyl group from an affine Cartan Type, this give the classical parabolic subgroup of `self`.

Caveat: we assume that 0 is a special node of the Dynkin diagram

TODO: extract parabolic subgroup method

EXAMPLES:

```
sage: G = WeylGroup(['A',3,1])
sage: G.classical()
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1]
(as a matrix group acting on the root space)
sage: WeylGroup(['A',3]).classical()
Traceback (most recent call last):
...
ValueError: classical subgroup only defined for affine types
```

domain()

Returns the domain of the element of `self`, that is the root lattice realization on which they act.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.domain()
Ambient space of the Root system of type ['F', 4]
sage: G = WeylGroup(['A',3,1])
sage: G.domain()
Root space over the Rational Field of the Root system of type ['A', 3, 1]
```

from_morphism(*f*)**index_set()**

Returns the index set of `self`.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.index_set()
(1, 2, 3, 4)
sage: G = WeylGroup(['A',3,1])
sage: G.index_set()
(0, 1, 2, 3)
```

long_element_hardcoded()

Returns the long Weyl group element (hardcoded data)

Do we really want to keep it? There is a generic implementation which works in all cases. The hardcoded should have a better complexity (for large classical types), but there is a cache, so does this really matter?

EXAMPLES:

```
sage: types = [ ['A',5], ['B',3], ['C',3], ['D',4], ['G',2], ['F',4], ['E',6] ]
sage: [WeylGroup(t).long_element().length() for t in types]
[15, 9, 9, 12, 6, 24, 36]
sage: all( WeylGroup(t).long_element() == WeylGroup(t).long_element_hardcoded()
↳for t in types ) # long time (17s on sage.math, 2011)
True
```

morphism_matrix(*f*)

one()

Returns the unit element of the Weyl group

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```

reflections()

Return the reflections of self.

The reflections of a Coxeter group W are the conjugates of the simple reflections. They are in bijection with the positive roots, for given a positive root, we may have the reflection in the hyperplane orthogonal to it. This method returns a family indexed by the positive roots taking values in the reflections. This requires self to be a finite Weyl group.

Note: Prior to [trac ticket #20027](#), the reflections were the keys of the family and the values were the positive roots.

EXAMPLES:

```
sage: W = WeylGroup("B2", prefix="s")
sage: refdict = W.reflections(); refdict
Finite family {(1, -1): s1, (0, 1): s2, (1, 1): s2*s1*s2, (1, 0): s1*s2*s1}
sage: [r+refdict[r].action(r) for r in refdict.keys()]
[(0, 0), (0, 0), (0, 0), (0, 0)]

sage: W = WeylGroup(['A',2,1], prefix="s")
sage: W.reflections()
Lazy family (real root to reflection(i))_{i in
Positive real roots of type ['A', 2, 1]}
```

simple_reflection(*i*)

Returns the i^{th} simple reflection.

EXAMPLES:

```

sage: G = WeylGroup(['F',4])
sage: G.simple_reflection(1)
[1 0 0 0]
[0 0 1 0]
[0 1 0 0]
[0 0 0 1]
sage: W=WeylGroup(['A',2,1])
sage: W.simple_reflection(1)
[ 1  0  0]
[ 1 -1  1]
[ 0  0  1]

```

simple_reflections()

Returns the simple reflections of self, as a family.

EXAMPLES:

There are the simple reflections for the symmetric group:

```

sage: W=WeylGroup(['A',2])
sage: s = W.simple_reflections(); s
Finite family {1: [0 1 0]
[1 0 0]
[0 0 1], 2: [1 0 0]
[0 0 1]
[0 1 0]}

```

As a special feature, for finite irreducible root systems, `s[0]` gives the reflection along the highest root:

```

sage: s[0]
[0 0 1]
[0 1 0]
[1 0 0]

```

We now look at some further examples:

```

sage: W=WeylGroup(['A',2,1])
sage: W.simple_reflections()
Finite family {0: [-1  1  1]
[ 0  1  0]
[ 0  0  1], 1: [ 1  0  0]
[ 1 -1  1]
[ 0  0  1], 2: [ 1  0  0]
[ 0  1  0]
[ 1  1 -1]}
sage: W = WeylGroup(['F',4])
sage: [s1,s2,s3,s4] = W.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: s4^2 == W.one()
True

```

(continues on next page)

(continued from previous page)

```
sage: type(w) == W.element_class
True
```

unit()

Returns the unit element of the Weyl group

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```

class sage.combinat.root_system.weyl_group.WeylGroup_permutation(*cartan_type*, *prefix*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.groups.perm_gps.permgroup.PermutationGroup_generic

A Weyl group given as a permutation group.

class Element

Bases: sage.combinat.root_system.reflection_group_element.RealReflectionGroupElement

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.cartan_type()
['A', 4]
```

distinguished_reflections()

Return the reflections of self.

EXAMPLES:

```
sage: W = WeylGroup(['B',2], implementation="permutation")
sage: W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
               3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}
```

independent_roots()

Return the simple roots of self.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
               3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
```

index_set()

Return the index set of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.index_set()
(1, 2, 3, 4)
```

iteration(*algorithm='breadth', tracking_words=True*)

Return an iterator going through all elements in `self`.

INPUT:

- `algorithm` (default: 'breadth') – must be one of the following:
 - 'breadth' - iterate over in a linear extension of the weak order
 - 'depth' - iterate by a depth-first-search
- `tracking_words` (default: True) – whether or not to keep track of the reduced words and store them in `_reduced_word`

Note: The fastest iteration is the depth first algorithm without tracking words. In particular, 'depth' is ~1.5x faster.

EXAMPLES:

```
sage: W = WeylGroup(["B",2], implementation="permutation")

sage: for w in W.iteration("breadth", True):
.....:     print("%s %s"%(w, w._reduced_word))
() []
(1,3)(2,6)(5,7) [1]
(1,5)(2,4)(6,8) [0]
(1,7,5,3)(2,4,6,8) [0, 1]
(1,3,5,7)(2,8,6,4) [1, 0]
(2,8)(3,7)(4,6) [1, 0, 1]
(1,7)(3,5)(4,8) [0, 1, 0]
(1,5)(2,6)(3,7)(4,8) [0, 1, 0, 1]

sage: for w in W.iteration("depth", False): w
()
(1,3)(2,6)(5,7)
(1,5)(2,4)(6,8)
(1,3,5,7)(2,8,6,4)
(1,7)(3,5)(4,8)
(1,7,5,3)(2,4,6,8)
(2,8)(3,7)(4,6)
(1,5)(2,6)(3,7)(4,8)
```

number_of_reflections()

Return the number of reflections in `self`.

EXAMPLES:

```
sage: W = WeylGroup(['D',4], implementation="permutation")
sage: W.number_of_reflections()
12
```

positive_roots()

Return the positive roots of self.

EXAMPLES:

```
sage: W = WeylGroup(['C',3], implementation="permutation")
sage: W.positive_roots()
((1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (0, 2, 1),
 (1, 1, 1),
 (2, 2, 1),
 (1, 2, 1))
```

rank()

Return the rank of self.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.rank()
4
```

reflection_index_set()

Return the index set of reflections of self.

EXAMPLES:

```
sage: W = WeylGroup(['A',3], implementation="permutation")
sage: W.reflection_index_set()
(1, 2, 3, 4, 5, 6)
```

reflections()

Return the reflections of self.

EXAMPLES:

```
sage: W = WeylGroup(['B',2], implementation="permutation")
sage: W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
               3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}
```

roots()

Return the roots of self.

EXAMPLES:

```
sage: W = WeylGroup(['G',2], implementation="permutation")
sage: W.roots()
```

(continues on next page)

(continued from previous page)

```

((1, 0),
 (0, 1),
 (1, 1),
 (3, 1),
 (2, 1),
 (3, 2),
 (-1, 0),
 (0, -1),
 (-1, -1),
 (-3, -1),
 (-2, -1),
 (-3, -2))

```

simple_reflection(*i*)Return the *i*-th simple reflection of *self*.

EXAMPLES:

```

sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_reflection(1)
(1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20)
sage: W.simple_reflections()
Finite family {1: (1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20),
                2: (1,5)(2,12)(3,6)(7,9)(11,15)(13,16)(17,19),
                3: (2,6)(3,13)(4,7)(5,8)(12,16)(14,17)(15,18),
                4: (3,7)(4,14)(6,9)(8,10)(13,17)(16,19)(18,20)}

```

simple_root_index(*i*)Return the index of the simple root α_i .This is the position of α_i in the list of simple roots.

EXAMPLES:

```

sage: W = WeylGroup(['A',3], implementation="permutation")
sage: [W.simple_root_index(i) for i in W.index_set()]
[0, 1, 2]

```

simple_roots()Return the simple roots of *self*.

EXAMPLES:

```

sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
                3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}

```

5.1.271 Rooted (Unordered) Trees

AUTHORS:

- Florent Hivert (2011): initial version

```
class sage.combinat.rooted_tree.LabelledRootedTree(parent, children, label=None, check=True)
  Bases:      sage.combinat.abstract_tree.AbstractLabelledClonableTree,      sage.combinat.
             rooted_tree.RootedTree
```

Labelled rooted trees.

A labelled rooted tree is a rooted tree with a label attached at each node.

More formally: The *labelled rooted trees* are an inductive datatype defined as follows: A labelled rooted tree is a multiset of labelled rooted trees, endowed with a label (which can be any object, including None). The trees that belong to this multiset are said to be the *children* of the tree. (Notice that the labels of these children may and may not be of the same type as the label of the tree). A labelled rooted tree which has no children (so the only information it carries is its label) is said to be a *leaf*.

Every labelled rooted tree gives rise to an unlabelled rooted tree (*RootedTree*) by forgetting the labels. (This is implemented as a conversion.)

INPUT:

- `children` – a list or tuple or more generally any iterable of trees or objects convertible to trees
- `label` – any hashable Sage object (default is None)

EXAMPLES:

```
sage: x = LabelledRootedTree([], label = 3); x
3[]
sage: LabelledRootedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree([[[]],[[]], [[]]], label = 3)
3[None[], None[None[], None[]]]
```

Children are reordered using the value of the `sort_key()` method:

```
sage: y = LabelledRootedTree([], label = 5); y
5[]
sage: xyy2 = LabelledRootedTree((x, y, y), label = 2); xyy2
2[3[], 5[], 5[]]
sage: yxy2 = LabelledRootedTree((y, x, y), label = 2); yxy2
2[3[], 5[], 5[]]
sage: xyy2 == yxy2
True
```

Converting labelled into unlabelled rooted trees by forgetting the labels, and back (the labels are initialized as None):

```
sage: yxy2crude = RootedTree(yxy2); yxy2crude
[[], [], []]
sage: LabelledRootedTree(yxy2crude)
None[None[], None[], None[]]
```

sort_key()

Return a tuple of nonnegative integers encoding the labelled rooted tree `self`.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the labelled rooted tree uniquely, and can be used to sort the labelled rooted trees provided that the labels belong to a type which is totally ordered.

Note: The tree `self` must be normalized before calling this method (see `normalize()`). This doesn't matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note: This method overrides `RootedTree.sort_key()` and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of `RootedOrderedTree`; under some circumstances they could inherit it from another superclass instead of from `RootedTree`, which would cause the method to forget the labelling. See the docstrings of `RootedTree.sort_key()` and `sage.combinat.ordered_tree.OrderedTree.sort_key()`.

EXAMPLES:

```
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.sort_key()
((0, 3),)
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
sage: LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
sage: lb = RootedTrees((), [], []).canonical_labelling()
sage: lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```

class sage.combinat.rooted_tree.LabelledRootedTrees

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

This is a parent stub to serve as a factory class for labelled rooted trees.

EXAMPLES:

```
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.parent() is LRT
```

(continues on next page)

(continued from previous page)

```
True
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.parent() is LRT
True
```

Todo: Add the possibility to restrict the labels to a fixed set.

class `sage.combinat.rooted_tree.LabelledRootedTrees_all`(*category=None*)

Bases: `sage.combinat.rooted_tree.LabelledRootedTrees`

Class of all (unordered) labelled rooted trees.

See `LabelledRootedTree` for a definition.

Element

alias of `LabelledRootedTree`

labelled_trees()

Return the set of labelled trees associated to `self`.

EXAMPLES:

```
sage: LabelledRootedTrees().labelled_trees()
Labelled rooted trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

EXAMPLES:

```
sage: LabelledRootedTrees().unlabelled_trees()
Rooted trees
```

class `sage.combinat.rooted_tree.RootedTree`(*parent=None, children=[], check=True*)

Bases: `sage.combinat.abstract_tree.AbstractClonableTree`, `sage.structure.list_clone.NormalizedClonableList`

The class for unordered rooted trees.

The *unordered rooted trees* are an inductive datatype defined as follows: An unordered rooted tree is a multiset of unordered rooted trees. The trees that belong to this multiset are said to be the *children* of the tree. The tree that has no children is called a *leaf*.

The *labelled rooted trees* (`LabelledRootedTree`) form a subclass of this class; they carry additional data.

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree.

EXAMPLES:

```
sage: RootedTree([])
[]
sage: RootedTree([], [[]])
[[], [[]]]
sage: RootedTree([[], []])
[[], [[]]]
```

(continues on next page)

(continued from previous page)

```
sage: 0 = OrderedTree([[]], []); 0
[[], []]
sage: RootedTree(0) # this is 0 with the ordering forgotten
[[], [[]]]
```

One can also enter any small rooted tree (“small” meaning that no vertex has more than 15 children) by using a simple numerical encoding of rooted trees, namely, the `from_hexacode()` function. (This function actually parametrizes ordered trees, and here we make it parametrize unordered trees by forgetting the ordering.)

```
sage: from sage.combinat.abstract_tree import from_hexacode
sage: RT = RootedTrees()
sage: from_hexacode('32001010', RT)
[[], [], [], []]
```

Note: Unlike an ordered tree, an (unordered) rooted tree is a multiset (rather than a list) of children. That is, two ordered trees which differ from each other by switching the order of children are equal to each other as (unordered) rooted trees. Internally, rooted trees are encoded as `sage.structure.list_clone.NormalizedClonableList` instances, and instead of storing their children as an actual multiset, they store their children as a list which is sorted according to their `sort_key()` value. This is as good as storing them as multisets, since the `sort_key()` values are sortable and distinguish different (unordered) trees. However, if you wish to define a subclass of `RootedTree` which implements rooted trees with extra structure (say, a class of edge-colored rooted trees, or a class of rooted trees with a cyclic order on the list of children), then the inherited `sort_key()` method will no longer distinguish different trees (and, as a consequence, equal trees will be regarded as distinct). Thus, you will have to override the method by one that does distinguish different trees.

`graft_list(other)`

Return the list of trees obtained by grafting `other` on `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, chooses a node of `self`, and adds the root of `other` to the list of children of this node. The root of the resulting tree is the root of `self`. (This can be done for each node of `self`; this method returns the list of all results.)

This is useful for free pre-Lie algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_list(x)
[[], []]
sage: l = y.graft_list(x); l
[[], [], [], [], [], [], [], []]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

`graft_on_root(other)`

Return the tree obtained by grafting `other` on the root of `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, and adds the root of `other` to the list of children of `self`. The root of the resulting tree is the root of `self`.

This is useful for free Nap algebras.

EXAMPLES:

```

sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_on_root(x)
[[]]
sage: y.graft_on_root(x)
[[], [], []]
sage: x.graft_on_root(y)
[[[]], [[]]]

```

is_empty()

Return if `self` is the empty tree.

For rooted trees, this always returns `False`.

Note: This is not the same as `bool(t)`, which returns whether `t` has some child or not.

EXAMPLES:

```

sage: t = RootedTrees(4)([], [[]])
sage: t.is_empty()
False
sage: bool(t)
True
sage: t = RootedTrees(1)([])
sage: t.is_empty()
False
sage: bool(t)
False

```

normalize()

Normalize `self`.

This function is at the core of the implementation of rooted (unordered) trees. The underlying structure is provided by ordered rooted trees. Every rooted tree is represented by a normalized element in the set of its planar embeddings.

There should be no need to call `normalize` directly as it is called automatically upon creation and cloning or modification (by `NormalizedClonableList`).

The normalization has a recursive definition. It means first that every sub-tree is itself normalized, and also that sub-trees are sorted. Here the sort is performed according to the values of the `sort_key()` method.

EXAMPLES:

```

sage: RT = RootedTree
sage: RT([], [[]]) == RT([[[]], []]) # indirect doctest
True
sage: rt1 = RT([], [[]])
sage: rt2 = RT([[[]], []])
sage: rt1 is rt2
False
sage: rt1 == rt2
True

```

(continues on next page)

(continued from previous page)

```
sage: rt1._get_list() == rt2._get_list()
True
```

single_graft(*x*, *grafting_function*, *path_prefix*=())

Graft subtrees of *x* on *self* using the given function.

Let x_1, x_2, \dots, x_p be the children of the root of *x*. For each *i*, the subtree of *x* comprising all descendants of x_i is joined by a new edge to the vertex of *self* specified by the *i*-th path in the grafting function (i.e., by the path `grafting_function[i]`).

The number of vertices of the result is the sum of the numbers of vertices of *self* and *x* minus one, because the root of *x* is not used.

This is used to define the product of the Grossman-Larson algebras.

INPUT:

- *x* – a rooted tree
- *grafting_function* – a list of paths in *self*
- *path_prefix* – optional tuple (default ())

The *path_prefix* argument is only used for internal recursion.

EXAMPLES:

```
sage: LT = LabelledRootedTrees()
sage: y = LT([LT([],label='b')], label='a')
sage: x = LT([LT([],label='d')], label='c')
sage: y.single_graft(x,[(0,)])
a[b[d[]]]
sage: t = LT([LT([],label='b'),LT([],label='c')], label='a')
sage: s = LT([LT([],label='d'),LT([],label='e')], label='f')
sage: t.single_graft(s,[(0,),(1,)])
a[b[d[]], c[e[]]]
```

sort_key()

Return a tuple of nonnegative integers encoding the rooted tree *self*.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the rooted tree uniquely, and can be used to sort the rooted trees.

Note: The tree *self* must be normalized before calling this method (see [normalize\(\)](#)). This doesn't matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note: By default, this method does not encode any extra structure that *self* might have. If you have a subclass inheriting from [RootedTree](#) which allows for some extra structure, you need to override [sort_key\(\)](#) in order to preserve this structure (for example, the [LabelledRootedTree](#) class does this in [LabelledRootedTree.sort_key\(\)](#)). See the note in the docstring of [sage.combinat.ordered_tree.OrderedTree.sort_key\(\)](#) for a pitfall.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[[]],[[]]]) .sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[[]]]) .sort_key()
(2, 0, 1, 0)
```

class `sage.combinat.rooted_tree.RootedTrees`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Factory class for rooted trees.

INPUT:

- `size` – (optional) an integer

OUTPUT:

the set of all rooted trees (of the given size `size` if specified)

EXAMPLES:

```
sage: RootedTrees()
Rooted trees

sage: RootedTrees(2)
Rooted trees with 2 nodes
```

class `sage.combinat.rooted_tree.RootedTrees_all`

Bases: `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`, `sage.combinat.rooted_tree.RootedTrees`

Class of all (unordered, unlabelled) rooted trees.

See *RootedTree* for a definition.

Element

alias of *RootedTree*

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```
sage: RootedTrees().labelled_trees()
Labelled rooted trees
```

As a consequence:

```
sage: lb = RootedTrees()([[[]],[[]],[[]]]) .canonical_labelling()
sage: lb
1[2[], 3[4[], 5[]]]
sage: lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.element_
↳class'>
sage: lb.parent()
Labelled rooted trees
```

leaf()

Return a leaf tree with `self` as parent.

EXAMPLES:

```
sage: RootedTrees().leaf()
[]
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

EXAMPLES:

```
sage: RootedTrees().unlabelled_trees()
Rooted trees
```

class sage.combinat.rooted_tree.RootedTrees_size(*n*)

Bases: `sage.combinat.rooted_tree.RootedTrees`

The enumerated set of rooted trees with a given number of nodes.

The number of nodes of a rooted tree is defined recursively: The number of nodes of a rooted tree with a children is a plus the sum of the number of nodes of each of these children.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: RootedTrees(1).cardinality()
1
sage: RootedTrees(3).cardinality()
2
```

check_element(*el*, *check=True*)

Check that a given tree actually belongs to `self`.

This just checks the number of vertices.

EXAMPLES:

```
sage: RT3 = RootedTrees(3)
sage: RT3([[[]], [[]]]) # indirect doctest
[[[]], [[]]]
sage: RT3([[[]], [[]], [[]]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: wrong number of nodes
```

element_class()**sage.combinat.rooted_tree.number_of_rooted_trees(*n*)**

Return the number of rooted trees with n nodes.

Compute the number $a(n)$ of rooted trees with n nodes using the recursive formula ([SL000081]):

$$a(n+1) = \frac{1}{n} \sum_{k=1}^n \left(\sum_{d|k} da(d) \right) a(n-k+1)$$

EXAMPLES:

```
sage: from sage.combinat.rooted_tree import number_of_rooted_trees
sage: [number_of_rooted_trees(i) for i in range(10)]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

Introduction

The Robinson-Schensted-Knuth (RSK) correspondence is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape.

The basic operation in the RSK correspondence is a row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Different insertion algorithms have been implemented for the RSK correspondence and can be specified as an argument in the function call.

EXAMPLES:

We can perform RSK and its inverse map on a variety of objects:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: gp = RSK_inverse(p, q); gp
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK(*gp) # RSK of a biword
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
sage: RSK([2,3,2,1,2,3]) # Robinson-Schensted of a word
[[[1, 2, 2, 3], [2], [3]], [[1, 2, 5, 6], [3], [4]]]
sage: RSK([2,3,2,1,2,3], insertion=RSK.rules.EG) # Edelman-Greene
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
sage: m = RSK_inverse(p, q, 'matrix'); m # output as matrix
[0 1]
[1 0]
[0 2]
sage: RSK(m) # RSK of a matrix
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
```

Insertions currently available

The following insertion algorithms for RSK correspondence are currently available:

- RSK insertion (*RuleRSK*).
- Edelman-Greene insertion (*RuleEG*), an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion).
- Hecke RSK algorithm (*RuleHecke*), defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns).
- Dual RSK insertion (*RuleDualRSK*).
- CoRSK insertion (*RuleCoRSK*), defined in [GR2018v5sol].
- Super RSK insertion (*RuleSuperRSK*), a combination of row and column insertions defined in [Muth2019].
- Star insertion (*RuleStar*), defined in [MPPS2020].

Implementing your own insertion rule

The functions *RSK()* and *RSK_inverse()* are written so that it is easy to implement insertion algorithms you come across in your research.

To implement your own insertion algorithm, you first need to import the base class for a rule:

```
sage: from sage.combinat.rsk import Rule
```

Using the *Rule* class as parent class for your insertion rule, first implement the insertion and the reverse insertion algorithm for *RSK()* and *RSK_inverse()* respectively (as methods *forward_rule* and *backward_rule*). If your insertion algorithm uses the same forward and backward rules as *RuleRSK*, differing only in how an entry is inserted into a row, then this is not necessary, and it suffices to merely implement the *insertion* and *reverse_insertion* methods.

For more information, see *Rule*.

```

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i -th step inserts the number k_i into the i -th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i -th row, then k_i is simply appended to the row and the algorithm terminates at this point.

A *generalized permutation* (or *biword*) is a list $((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$ of pairs such that the letters $j_0, j_1, \dots, j_{\ell-1}$ are weakly increasing (that is, $j_0 \leq j_1 \leq \dots \leq j_{\ell-1}$), whereas the letters k_i satisfy $k_i \leq k_{i+1}$ whenever $j_i = j_{i+1}$. The ℓ -tuple $(j_0, j_1, \dots, j_{\ell-1})$ is called the *top line* of this generalized permutation, whereas the ℓ -tuple $(k_0, k_1, \dots, k_{\ell-1})$ is called its *bottom line*.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p , and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as “Construction A”.

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top row to be $(1, 2, \dots, n)$ where n is the length of w .

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

INPUT:

- `obj1, obj2` – can be one of the following:
 - a word in an ordered alphabet (in this case, `obj1` is said word, and `obj2` is `None`)
 - an integer matrix
 - two lists of equal length representing a generalized permutation (namely, the lists $(j_0, j_1, \dots, j_{\ell-1})$ and $(k_0, k_1, \dots, k_{\ell-1})$ represent the generalized permutation $((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$)
 - any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, `obj1` is said object, and `obj2` is `None`).
- `insertion` – (default: `RSK.rules.RSK`) the following types of insertion are currently supported:
 - `RSK.rules.RSK` (or `'RSK'`) – Robinson-Schensted-Knuth insertion (*RuleRSK*)
 - `RSK.rules.EG` (or `'EG'`) – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)

- `RSK.rules.Hecke` (or `'hecke'`) – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
 - `RSK.rules.dualRSK` (or `'dualRSK'`) – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
 - `RSK.rules.coRSK` (or `'coRSK'`) – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
 - `RSK.rules.superRSK` (or `'super'`) – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
 - `RSK.rules.Star` (or `'Star'`) – \star -insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)
- `check_standard` – (default: `False`) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular *Rule* class.

EXAMPLES:

If we only input one row, it is understood that the top row should be $(1, 2, \dots, n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

We can provide a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

We can provide a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also provide something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python `*` on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

`sage.combinat.rsk.RSK_inverse(p, q, output='array', insertion=<class 'sage.combinat.rsk.RuleRSK'>)`
 Return the generalized permutation corresponding to the pair of tableaux (p, q) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see [RSK\(\)](#).

INPUT:

- p, q – two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- `output` – (default: 'array') if q is semi-standard:
 - 'array' – as a two-line array (i.e. generalized permutation or biword)
 - 'matrix' – as an integer matrix

and if q is standard, we can also have the output:

- 'word' – as a word

and additionally if p is standard, we can also have the output:

- 'permutation' – as a permutation

- `insertion` – (default: `RSK.rules.RSK`) the insertion algorithm used in the bijection. Currently the following are supported:
 - `RSK.rules.RSK` (or 'RSK') – Robinson-Schensted-Knuth insertion ([RuleRSK](#))
 - `RSK.rules.EG` (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) ([RuleEG](#))
 - `RSK.rules.Hecke` (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) ([RuleHecke](#))
 - `RSK.rules.dualRSK` (or 'dualRSK') – Dual RSK insertion (only for strict biwords) ([RuleDualRSK](#))
 - `RSK.rules.coRSK` (or 'coRSK') – CoRSK insertion (only for strict cobiwords) ([RuleCoRSK](#))
 - `RSK.rules.superRSK` (or 'super') – Super RSK insertion (only for restricted super biwords) ([RuleSuperRSK](#))
 - `RSK.rules.Star` (or 'Star') – \star -insertion (only for fully commutative words in the 0-Hecke monoid) ([RuleStar](#))

For precise information about constraints on the input and output, see the particular [Rule](#) class.

Note: In the case of Hecke insertion, the input variable q should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both p and q are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
```

(continues on next page)

(continued from previous page)

```

sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]

```

If the first tableau is semistandard:

```

sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322

```

In general:

```

sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]

```

Using Hecke insertion:

```

sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]

```

Note: The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

class `sage.combinat.rsk.Rule`

Bases: `sage.structure.unique_representation.UniqueRepresentation`

Generic base class for an insertion rule for an RSK-type correspondence.

An instance of this class should implement a method `insertion()` (which can be applied to a letter `j` and a list `r`, and modifies `r` in place by “bumping” `j` into it appropriately; it then returns the bumped-out entry or `None` if no such entry exists) and a method `reverse_insertion()` (which does the same but for reverse

bumping). It may also implement `_backward_format_output()` and `_forward_format_output()` if the RSK correspondence should return something other than (semi)standard tableaux (in the forward direction) and matrices or biwords (in the backward direction). The `to_pairs()` method should also be overridden if the input for the (forward) RSK correspondence is not the usual kind of biwords (i.e., pairs of two n -tuples $[a_1, a_2, \dots, a_n]$ and $[b_1, b_2, \dots, b_n]$ satisfying $(a_1, b_1) \leq (a_2, b_2) \leq \dots \leq (a_n, b_n)$ in lexicographic order). Finally, it `forward_rule()` and `backward_rule()` have to be overridden if the overall structure of the RSK correspondence differs from that of classical RSK (see, e.g., the case of Hecke insertion, in which a letter bumped into a row may change a different row).

`backward_rule(p, q, output)`

Return the generalized permutation obtained by applying reverse insertion to a pair of tableaux (p, q).

INPUT:

- p, q – two tableaux of the same shape.
- output – (default: 'array') if q is semi-standard:
 - 'array' – as a two-line array (i.e. generalized permutation or biword)
 - 'matrix' – as an integer matrix

and if q is standard, we can also have the output:

- 'word' – as a word

and additionally if p is standard, we can also have the output:

- 'permutation' – as a permutation

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: t1 = Tableau([[1, 3, 4], [2], [3]])
sage: t2 = Tableau([[1, 2, 4], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 1, 1, 3, 7]])
sage: t2 = Tableau([[1, 2, 3, 4, 5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [1, 1, 1, 3, 7]]
sage: t1 = Tableau([[1, 3], [3], [6], [7]])
sage: t2 = Tableau([[1, 4], [2], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [7, 6, 3, 3, 1]]
```

`forward_rule(obj1, obj2, check_standard=False, check=True)`

Return a pair of tableaux obtained by applying forward insertion to the generalized permutation [obj1, obj2].

INPUT:

- obj1, obj2 – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
 - two lists obj1 and obj2 of equal length, to be interpreted as the top row and the bottom row of the biword
 - a matrix obj1 of nonnegative integers, to be interpreted as the generalized permutation in matrix form (in this case, obj2 is None)

- a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \dots, n)$ by default)
- any object `obj1` which has a method `_rsk_iter()`, as long as this method returns an iterator yielding pairs of numbers, which then are interpreted as top entries and bottom entries in the biword (in this case, `obj2` is `None`)
- `check_standard` – (default: `False`) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such
- `check` – (default: `True`) whether to check that `obj1` and `obj2` actually define a valid biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: RuleRSK().forward_rule([3, 3, 2, 4, 1], None)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RuleRSK().forward_rule([1, 1, 1, 3, 7], None)
[[[1, 1, 1, 3, 7]], [[1, 2, 3, 4, 5]]]
sage: RuleRSK().forward_rule([7, 6, 3, 3, 1], None)
[[[1, 3], [3], [6], [7]], [[1, 4], [2], [3], [5]]]
```

`to_pairs(obj1=None, obj2=None, check=True)`

Given a valid input for the RSK algorithm, such as two n -tuples `obj1` = $[a_1, a_2, \dots, a_n]$ and `obj2` = $[b_1, b_2, \dots, b_n]$ forming a biword (i.e., satisfying $a_1 \leq a_2 \leq \dots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i \leq b_{i+1}$), or a matrix (“generalized permutation”), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \dots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a biword (see the doc of `forward_rule()` for the encodings accepted).
- `check` – (default: `True`) whether to check that `obj1` and `obj2` actually define a valid biword.

EXAMPLES:

```
sage: from sage.combinat.rsk import Rule
sage: list(Rule().to_pairs([1, 2, 2, 2], [2, 1, 1, 2]))
[(1, 2), (2, 1), (2, 1), (2, 2)]
sage: m = Matrix(ZZ, 3, 2, [0, 1, 1, 0, 0, 2]) ; m
[0 1]
[1 0]
[0 2]
sage: list(Rule().to_pairs(m))
[(1, 2), (2, 1), (3, 2), (3, 2)]
```

class `sage.combinat.rsk.RuleCoRSK`

Bases: `sage.combinat.rsk.RuleRSK`

Rule for coRSK insertion.

CoRSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer a biword, but rather a strict cobiword – i.e., a pair of two lists $[a_1, a_2, \dots, a_n]$ and $[b_1, b_2, \dots, b_n]$ that satisfy the strict inequalities $(a_1, b_1) \tilde{<} (a_2, b_2) \tilde{<} \dots \tilde{<} (a_n, b_n)$, where the binary relation $\tilde{<}$ on pairs of integers is defined by having $(u_1, v_1) \tilde{<} (u_2, v_2)$ if and only if either $u_1 < u_2$ or $(u_1 = u_2$ and $v_1 > v_2)$. In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a $\{0, 1\}$ -matrix (i.e., a matrix whose entries are 0’s and 1’s).

- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now Q is row-strict (i.e., its transpose is semistandard) while P is semistandard.

Bumping proceeds in the same way as for RSK insertion.

The RSK and coRSK algorithms agree for permutation matrices.

For more information, see Section A.4 in [Ful1997] (specifically, construction (1d)) or the second solution to Exercise 2.7.12(a) in [GR2018v5sol].

EXAMPLES:

```
sage: RSK([1,2,5,3,1], insertion = RSK.rules.coRSK)
[[[1, 1, 3], [2], [5]], [[1, 2, 3], [4], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion = RSK.rules.coRSK)
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
sage: RSK(Word([3,3,2,4,1]), insertion = RSK.rules.coRSK)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: from sage.combinat.rsk import to_matrix
sage: RSK(to_matrix([1, 1, 3, 3, 4], [3, 2, 2, 1, 3]), insertion = RSK.rules.coRSK)
[[[1, 2, 3], [2], [3]], [[1, 3, 4], [1], [3]]]
```

Using coRSK insertion with a $\{0,1\}$ -matrix:

```
sage: RSK(matrix([[0,1],[1,0]]), insertion = RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0,1],[1,0]], insertion = RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

We can also use the inverse correspondence:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 3, 2, 1],
.....: insertion=RSK.rules.coRSK),insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 3, 2, 1],insertion=RSK.rules.coRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
```

When applied to two standard tableaux, backwards coRSK insertion behaves identically to the usual backwards RSK insertion:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.coRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word', insertion=RSK.rules.coRSK)
word: 14532
sage: RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.coRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
```

(continues on next page)

(continued from previous page)

```

sage: RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 5, 4, 2, 3]

```

For coRSK, the first tableau is semistandard while the second tableau is transpose semistandard:

```

sage: p = Tableau([[1,2,2],[5]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q, insertion=RSK.rules.coRSK); ret
[[1, 2, 3, 4], [1, 5, 2, 2]]
sage: RSK_inverse(p, q, 'word', insertion=RSK.rules.coRSK)
word: 1522

```

backward_rule(*p*, *q*, *output*)

Return the strict cobword obtained by applying reverse coRSK insertion to a pair of tableaux (*p*, *q*).

INPUT:

- *p*, *q* – two tableaux of the same shape
- *output* – (default: 'array') if *q* is row-strict:
 - 'array' – as a two-line array (i.e. strict cobword)
 - 'matrix' – as a $\{0, 1\}$ -matrix

and if *q* is standard, we can have the output:

- 'word' – as a word

and additionally if *p* is standard, we can also have the output:

- 'permutation' – as a permutation

EXAMPLES:

```

sage: from sage.combinat.rsk import RuleCoRSK
sage: t1 = Tableau([[1, 1, 2], [2, 3], [4]])
sage: t2 = Tableau([[1, 4, 5], [1, 4], [2]])
sage: RuleCoRSK().backward_rule(t1, t2, 'array')
[[1, 1, 2, 4, 4, 5], [4, 2, 1, 3, 1, 2]]

```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the coRSK algorithm, such as two n -tuples $\text{obj1} = [a_1, a_2, \dots, a_n]$ and $\text{obj2} = [b_1, b_2, \dots, b_n]$ forming a strict cobword (i.e., satisfying $a_1 \leq a_2 \leq \dots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i > b_{i+1}$), or a $\{0, 1\}$ -matrix (“rook placement”), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \dots, (a_n, b_n)]$.

INPUT:

- *obj1*, *obj2* – anything representing a strict cobword (see the doc of `forward_rule()` for the encodings accepted)
- *check* – (default: True) whether to check that *obj1* and *obj2* actually define a valid strict cobword

EXAMPLES:

```

sage: from sage.combinat.rsk import RuleCoRSK
sage: list(RuleCoRSK().to_pairs([1, 2, 2, 2], [2, 3, 2, 1]))
[(1, 2), (2, 3), (2, 2), (2, 1)]
sage: RuleCoRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])
Traceback (most recent call last):
...
ValueError: invalid strict cobiword
sage: m = Matrix(ZZ, 3, 2, [0,1,1,1,0,1]) ; m
[0 1]
[1 1]
[0 1]
sage: list(RuleCoRSK().to_pairs(m))
[(1, 2), (2, 2), (2, 1), (3, 2)]
sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: RuleCoRSK().to_pairs(m)
Traceback (most recent call last):
...
ValueError: coRSK requires a {0, 1}-matrix

```

class sage.combinat.rsk.RuleDualRSK

Bases: [sage.combinat.rsk.Rule](#)

Rule for dual RSK insertion.

Dual RSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a strict biword (i.e., a pair of two lists $[a_1, a_2, \dots, a_n]$ and $[b_1, b_2, \dots, b_n]$ that satisfy the strict inequalities $(a_1, b_1) < (a_2, b_2) < \dots < (a_n, b_n)$ in lexicographic order). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a $\{0, 1\}$ -matrix (i.e., a matrix whose entries are 0's and 1's).
- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now P is row-strict (i.e., its transpose is semistandard) while Q is semistandard.
- The main difference is in the way bumping works. Namely, when a number k_i is inserted into the i -th row of P , it bumps out the first integer greater **or equal to** k_i in this row (rather than greater than k_i).

The RSK and dual RSK algorithms agree for permutation matrices.

For more information, see Chapter 7, Section 14 in [Sta-EC2] (where dual RSK is called RSK^{*}) or the third solution to Exercise 2.7.12(a) in [GR2018v5sol].

EXAMPLES:

```

sage: RSK([3,3,2,4,1], insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]), insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [2, 3], [2, 3], [3]], [[1, 2, 8], [3, 6], [4, 7], [5]]]

```

Using dual RSK insertion with a strict biword:

```

sage: RSK([1,1,2,4,4,5],[2,4,1,1,3,2], insertion=RSK.rules.dualRSK)
[[[1, 2], [1, 3], [2, 4]], [[1, 1], [2, 4], [4, 5]]]
sage: RSK([1,1,2,3,3,4,5],[1,3,2,1,3,3,2], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1, 2], [3], [3]], [[1, 1, 3], [2, 4], [3], [5]]]
sage: RSK([1, 2, 2, 2], [2, 1, 2, 4], insertion=RSK.rules.dualRSK)
[[[1, 2, 4], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,1,2,1,7]), insertion=RSK.rules.dualRSK)
[[[1, 2, 7], [1], [6]], [[1, 3, 4], [3], [4]]]

```

Using dual RSK insertion with a $\{0, 1\}$ -matrix:

```

sage: RSK(matrix([[0,1],[1,1]]), insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]

```

We can also give it something looking like a matrix:

```

sage: RSK([[0,1],[1,1]], insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]

```

Let us now call the inverse correspondence:

```

sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 2, 3],
.....:               insertion=RSK.rules.dualRSK),insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 2, 3],insertion=RSK.rules.dualRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]

```

When applied to two standard tableaux, reverse dual RSK insertion behaves identically to the usual reverse RSK insertion:

```

sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word', insertion=RSK.rules.dualRSK)
word: 14532
sage: RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.dualRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 5, 4, 2, 3]

```

Let us check that forward and backward dual RSK are mutually inverse when the first tableau is merely transpose semistandard:

```
sage: p = Tableau([[1,2,2],[1]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q, insertion=RSK.rules.dualRSK); ret
[[1, 2, 3, 4], [1, 2, 1, 2]]
sage: RSK_inverse(p, q, 'word', insertion=RSK.rules.dualRSK)
word: 1212
```

In general for dual RSK:

```
sage: p = Tableau([[1,1,2],[1]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 3], [1, 1, 1, 2]]
sage: RSK_inverse(p, q, 'matrix', insertion=RSK.rules.dualRSK)
[1 0]
[1 0]
[1 1]
```

insertion(*j*, *r*)

Insert the letter *j* from the second row of the biword into the row *r* using dual RSK insertion, if there is bumping to be done.

The row *r* is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleDualRSK
sage: r = [1, 3, 4, 5]
sage: j = RuleDualRSK().insertion(4, r); j
4
sage: r
[1, 3, 4, 5]
sage: r = [1, 2, 3, 6, 7]
sage: j = RuleDualRSK().insertion(4, r); j
6
sage: r
[1, 2, 3, 4, 7]
sage: r = [1, 3]
sage: j = RuleDualRSK().insertion(4, r); j is None
True
sage: r
[1, 3]
```

reverse_insertion(*x*, *row*)

Reverse bump the row *row* of the current insertion tableau with the number *x* using dual RSK insertion.

The row *row* is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleDualRSK
sage: r = [1, 2, 4, 6, 7]
sage: x = RuleDualRSK().reverse_insertion(6, r); r
[1, 2, 4, 6, 7]
sage: x
```

(continues on next page)

(continued from previous page)

```

6
sage: r = [1, 2, 4, 5, 7]
sage: x = RuleDualRSK().reverse_insertion(6, r); r
[1, 2, 4, 6, 7]
sage: x
5

```

to_pairs(*obj1=None, obj2=None, check=True*)

Given a valid input for the dual RSK algorithm, such as two n -tuples $\text{obj1} = [a_1, a_2, \dots, a_n]$ and $\text{obj2} = [b_1, b_2, \dots, b_n]$ forming a strict biword (i.e., satisfying $a_1 \leq a_2 \leq \dots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i < b_{i+1}$) or a $\{0, 1\}$ -matrix (“rook placement”), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \dots, (a_n, b_n)]$.

INPUT:

- *obj1*, *obj2* – anything representing a strict biword (see the doc of `forward_rule()` for the encodings accepted)
- *check* – (default: `True`) whether to check that *obj1* and *obj2* actually define a valid strict biword

EXAMPLES:

```

sage: from sage.combinat.rsk import RuleDualRSK
sage: list(RuleDualRSK().to_pairs([1, 2, 2, 2], [2, 1, 2, 3]))
[(1, 2), (2, 1), (2, 2), (2, 3)]
sage: RuleDualRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])
Traceback (most recent call last):
...
ValueError: invalid strict biword
sage: m = Matrix(ZZ, 3, 2, [0,1,1,1,0,1]) ; m
[0 1]
[1 1]
[0 1]
sage: list(RuleDualRSK().to_pairs(m))
[(1, 2), (2, 1), (2, 2), (3, 2)]
sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: RuleDualRSK().to_pairs(m)
Traceback (most recent call last):
...
ValueError: dual RSK requires a {0, 1}-matrix

```

class `sage.combinat.rsk.RuleEG`

Bases: `sage.combinat.rsk.Rule`

Rule for Edelman-Greene insertion.

For a reduced word of a permutation (i.e., an element of a type A Coxeter group), one can use Edelman-Greene insertion, an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that (using the notations in the documentation of `RSK()`) if k_i and $k_i + 1$ both exist in row i , we *only* set $k_{i+1} = k_i + 1$ and continue.

EXAMPLES:

Let us reproduce figure 6.4 in [EG1987]:

```
sage: RSK([2,3,2,1,2,3], insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

Some more examples:

```
sage: a = [2, 1, 2, 3, 2]
sage: pq = RSK(a, insertion=RSK.rules.EG); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK(RSK_inverse(*pq, insertion=RSK.rules.EG, output='matrix'),
.....:      insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK_inverse(*pq, insertion=RSK.rules.EG)
[[1, 2, 3, 4, 5], [2, 1, 2, 3, 2]]
```

The RSK algorithm (*RSK()*) built using the Edelman-Greene insertion rule *RuleEG* is a bijection from reduced words of permutations/elements of a type A Coxeter group to pairs consisting of an increasing tableau and a standard tableau of the same shape (see [EG1987] Theorem 6.25). The inverse of this bijection is obtained using *RSK_inverse()*. If the optional parameter `output = 'permutation'` is set in *RSK_inverse()*, then the function returns not the reduced word itself but the permutation (of smallest possible size) whose reduced word it is (although the order of the letters is reverse to the usual Sage convention):

```
sage: w = RSK_inverse(*pq, insertion=RSK.rules.EG, output='permutation'); w
[4, 3, 1, 2]
sage: list(reversed(a)) in w.reduced_words()
True
```

insertion(j, r)

Insert the letter j from the second row of the biword into the row r using Edelman-Greene insertion, if there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleEG
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleEG().insertion(9, r)
sage: j is None
True
sage: qr, r = [1,2,3,4,5], [2,3,4,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 4, 5, 8]
sage: j
4
sage: qr, r = [1,2,3,4,5], [2,3,5,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 3, 5, 8]
sage: j
5
```

reverse_insertion(x, row)

Reverse bump the row `row` of the current insertion tableau with the number `x`.

The row `row` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```

sage: from sage.combinat.rsk import RuleEG
sage: r = [1,1,1,2,3,3]
sage: x = RuleEG().reverse_insertion(3, r); r
[1, 1, 1, 2, 3, 3]
sage: x
2

```

class sage.combinat.rsk.RuleHecke

Bases: *sage.combinat.rsk.Rule*

Rule for Hecke insertion.

The Hecke RSK algorithm is similar to the classical RSK algorithm, but is defined using the Hecke insertion introduced in in [BKSTY06] (but using rows instead of columns). It is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword p has top row $(1, 2, \dots, n)$ (or, at least, has its top row strictly increasing).

The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If $p = ((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$, then the algorithm recursively constructs pairs $(P_0, Q_0), (P_1, Q_1), \dots, (P_\ell, Q_\ell)$ of tableaux. The construction of P_{t+1} and Q_{t+1} from P_t, Q_t, j_t and k_t proceeds as follows: Set $i = j_t, x = k_t, P = P_t$ and $Q = Q_t$. We are going to insert x into the increasing tableau P and update the set-valued “recording tableau” Q accordingly. As in the classical RSK algorithm, we first insert x into row 1 of P , then into row 2 of the resulting tableau, and so on, until the construction terminates. The details are different: Suppose we are inserting x into row R of P . If (Case 1) there exists an entry y in row R such that $x < y$, then let y be the minimal such entry. We replace this entry y with x if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting y into the next row of P . If, on the other hand, (Case 2) no such y exists, then we append x to the end of R if the result is an increasing tableau (Subcase 2.1), and otherwise (Subcase 2.2) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with x in P to the shape of Q , and fill it with the one-element set $\{i\}$. In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row R , and add i to the entry of Q in this box (this entry is a set, since Q is set-valued). In either subcase, we terminate the recursion, and set $P_{t+1} = P$ and $Q_{t+1} = Q$.

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set (namely, the set of its entries).

EXAMPLES:

As an example of Hecke insertion, we reproduce Example 2.1 in arXiv 0801.1319v2:

```

sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: P,Q = RSK(w, insertion=RSK.rules.Hecke); [P,Q]
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],
  [(8, 10)]]]
sage: wp = RSK_inverse(P, Q, insertion=RSK.rules.Hecke,
.....:                  output='list'); wp
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: wp == w
True

```

backward_rule($p, q, output$)

Return the generalized permutation obtained by applying reverse Hecke insertion to a pair of tableaux (p, q) .

INPUT:

- p, q – two tableaux of the same shape
- output – (default: 'array') if q is semi-standard:
 - 'array' – as a two-line array (i.e. generalized permutation or biword)

and if q is standard set-valued, we can have the output:

- 'word' – as a word
- 'list' – as a list

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: t1 = Tableau([[1, 4], [2], [3]])
sage: t2 = Tableau([[1, 2), (4,)], [(3,)], [(5,)]])
sage: RuleHecke().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 4], [2, 3]])
sage: t2 = Tableau([[1, 2), (4,)], [(3,)], [(5,)]])
sage: RuleHecke().backward_rule(t1, t2, 'array')
Traceback (most recent call last):
...
ValueError: p(=[1, 4], [2, 3]) and
q(=[1, 2), (4,)], [(3,)], [(5,)]]) must have the same shape
```

forward_rule(*obj1*, *obj2*, *check_standard=False*)

Return a pair of tableaux obtained by applying Hecke insertion to the generalized permutation [*obj1*, *obj2*].

INPUT:

- *obj1*, *obj2* – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
 - two lists *obj1* and *obj2* of equal length, to be interpreted as the top row and the bottom row of the biword
 - a word *obj1* in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, *obj2* is None; the top row of the biword is understood to be $(1, 2, \dots, n)$ by default)
- *check_standard* – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: p, q = RuleHecke().forward_rule([3, 3, 2, 4, 1], None); p
[[1, 4], [2], [3]]
sage: q
[[1, 2), (4,)], [(3,)], [(5,)]])
sage: isinstance(p, SemistandardTableau)
True
sage: isinstance(q, Tableau)
True
```

insertion(*j, ir, r, p*)

Insert the letter *j* from the second row of the biword into the row *r* of the increasing tableau *p* using Hecke insertion, provided that *r* is the *ir*-th row of *p*, and provided that there is bumping to be done.

The row *r* is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_right
sage: p, q, r = [], [], [3,3,8,8,8,9]
sage: j, ir = 8, 1
sage: j1 = RuleHecke().insertion(j, ir, r, p)
sage: j1 == r[bisect_right(r, j)]
True
```

reverse_insertion(*i, x, row, p*)

Reverse bump the row *row* of the current insertion tableau *p* with the number *x*, provided that *row* is the *i*-th row of *p*.

The row *row* is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_left
sage: r = [2,3,3,4,8,9]
sage: x, i, p = 9, 1, [1, 2]
sage: x1 = RuleHecke().reverse_insertion(i, x, r, p)
sage: x1 == r[bisect_left(r,x) - 1]
True
```

class sage.combinat.rsk.RuleRSK

Bases: *sage.combinat.rsk.Rule*

Rule for the classical Robinson-Schensted-Knuth insertion.

See *RSK()* for the definition of this operation.

EXAMPLES:

```
sage: RSK([[1, 2, 2, 2], [2, 1, 1, 2], insertion=RSK.rules.RSK)
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q, insertion=RSK.rules.RSK)
[[1, 2, 3, 3], [2, 1, 2, 2]]
```

insertion(*j, r*)

Insert the letter *j* from the second row of the biword into the row *r* using classical Schensted insertion, if there is bumping to be done.

The row *r* is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleRSK().insertion(9, r)
```

(continues on next page)

(continued from previous page)

```

sage: j is None
True
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleRSK().insertion(3, r)
sage: j
4

```

reverse_insertion(*x*, *row*)

Reverse bump the row *row* of the current insertion tableau with the number *x*.

The row *row* is modified in place. The bumped-out entry is returned.

EXAMPLES:

```

sage: from sage.combinat.rsk import RuleRSK
sage: r = [2,3,3,4,8]
sage: x = RuleRSK().reverse_insertion(4, r); r
[2, 3, 4, 4, 8]
sage: x
3

```

class `sage.combinat.rsk.RuleStar`

Bases: `sage.combinat.rsk.Rule`

Rule for \star -insertion.

The \star -insertion is similar to the classical RSK algorithm and is defined in [MPPS2020]. The bottom row of the increasing Hecke biword is a word in the 0-Hecke monoid that is fully commutative. When inserting a letter x into a row R , there are three cases:

- Case 1: If R is empty or $x > \max(R)$, append x to row R and terminate.
- Case 2: Otherwise if x is not in R , locate the smallest y in R with $y > x$. Bump y with x and insert y into the next row.
- Case 3: Otherwise, if x is in R , locate the smallest y in R with $y \leq x$ and interval $[y, x]$ contained in R . Row R remains unchanged and y is to be inserted into the next row.

The \star -insertion returns a pair consisting a conjugate of a semistandard tableau and a semistandard tableau. It is a bijection from the collection of all increasing Hecke biwords whose bottom row is a fully commutative word to pairs (P, Q) of tableaux of the same shape such that P is conjugate semistandard, Q is semistandard and the row reading word of P is fully commutative [MPPS2020].

EXAMPLES:

As an example of \star -insertion, we reproduce Example 28 in [MPPS2020]:

```

sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
sage: ascii_art(p, q)
 1 2 4 1 1 2
 1 4   2 4
 3   4
sage: line1,line2 = RuleStar().backward_rule(p, q)
sage: line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')

```

(continues on next page)

(continued from previous page)

```

(4, 2)()(4, 2)(3, 1)
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import_
↳DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[4, 2], [], [4, 2], [3, 1]])
sage: RSK_inverse(*RSK(h,insertion='Star'),insertion='Star',
.....:             output='DecreasingHeckeFactorization')
(4, 2)()(4, 2)(3, 1)
sage: p,q = RSK(h, insertion='Star')
sage: ascii_art(p, q)
1 2 4 1 1 2
1 4   2 4
3     4
sage: RSK_inverse(p, q, insertion='Star')
[[1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4]]
sage: f = RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
sage: f == h
True

```

Warning: When output is set to 'DecreasingHeckeFactorization', the inverse of \star -insertion of (P, Q) returns a decreasing factorization whose number of factors is the maximum entry of Q :

```

sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import_
↳DecreasingHeckeFactorization
sage: h1 = DecreasingHeckeFactorization([[[]],[3,1],[1]]); h1
() (3, 1)(1)
sage: P,Q = RSK(h1, insertion='Star')
sage: ascii_art(P, Q)
1 3 1 2
1   2
sage: h2 = RSK_inverse(P, Q, insertion='Star',
.....: output='DecreasingHeckeFactorization'); h2
(3, 1)(1)

```

backward_rule($p, q, output='array'$)

Return the increasing Hecke biword obtained by applying reverse \star -insertion to a pair of tableaux (p, q) .

INPUT:

- p, q – two tableaux of the same shape, where p is the conjugate of a semistandard tableau, whose reading word is fully commutative and q is a semistandard tableau.
- output – (default: 'array') if q is semi-standard:
 - 'array' – as a two-line array (i.e. generalized permutation or biword) that is an increasing Hecke biword
 - 'DecreasingHeckeFactorization' – as a decreasing factorization in the 0-Hecke monoid
- and if q is standard:
 - 'word' – as a (possibly non-reduced) word in the 0-Hecke monoid

Warning: When output is 'DecreasingHeckeFactorization', the number of factors in the output is the largest number in obj1.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
sage: ascii_art(p, q)
  1 2 4 1 1 2
  1 4   2 4
  3     4
sage: line1,line2 = RuleStar().backward_rule(p, q); line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RuleStar().backward_rule(p, q, output = 'DecreasingHeckeFactorization')
(4, 2)(4, 2)(3, 1)
```

forward_rule(obj1, obj2=None, check_braid=True)

Return a pair of tableaux obtained by applying forward insertion to the increasing Hecke biword [obj1, obj2].

INPUT:

- obj1, obj2 – can be one of the following ways to represent a biword (or, equivalently, an increasing 0-Hecke factorization) that is fully commutative:
 - two lists obj1 and obj2 of equal length, to be interpreted as the top row and the bottom row of the biword.
 - a word obj1 in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, obj2 is None; the top row of the biword is understood to be $(1, 2, \dots, n)$ by default).
 - a DecreasingHeckeFactorization obj1, the whose increasing Hecke biword will be interpreted as the bottom row; the top row is understood to be the indices of the factors for each letter in this biword.
- check_braid – (default: True) indicator to validate that input is associated to a fully commutative word in the 0-Hecke monoid, validation is performed if set to True; otherwise, this validation is ignored.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,3,3], [2,3,3,1,3]); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
sage: p,q = RuleStar().forward_rule([2,3,3,1,3]); p,q
([[1, 3], [2, 3], [2]], [[1, 2], [3, 5], [4]])
sage: p,q = RSK([1,1,2,3,3], [2,3,3,1,3], insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])

sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import _
↪DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[3, 1], [3], [3, 2]])
sage: p,q = RSK(h, insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
```

insertion(b, r)

Insert the letter b from the second row of the biword into the row r using \star -insertion defined in [MPPS2020].

The row r is modified in place if bumping occurs and b is not in row r . The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().insertion(3, [1,2,4,5])
4
sage: RuleStar().insertion(3, [1,2,3,5])
1
sage: RuleStar().insertion(6, [1,2,3,5]) is None
True
```

reverse_insertion(x, r)

Reverse bump the row r of the current insertion tableau p with number x , provided that r is the i -th row of p .

The row r is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().reverse_insertion(4, [1,2,3,5])
3
sage: RuleStar().reverse_insertion(1, [1,2,3,5])
3
sage: RuleStar().reverse_insertion(5, [1,2,3,5])
5
```

class `sage.combinat.rsk.RuleSuperRSK`

Bases: `sage.combinat.rsk.RuleRSK`

Rule for super RSK insertion.

Super RSK is based on ϵ -insertion, a combination of row and column classical RSK insertion.

Super RSK insertion differs from the classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a restricted super biword (i.e., a pair of two lists $[a_1, a_2, \dots, a_n]$ and $[b_1, b_2, \dots, b_n]$ that contains entries with even and odd parity and pairs with mixed parity entries do not repeat).
- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now they are semistandard super tableaux.
- The main difference is in the way bumping works. Instead of having only row bumping super RSK uses ϵ -insertion, a combination of classical RSK bumping along the rows and a dual RSK like bumping (i.e. when a number k_i is inserted into the i -th row of P , it bumps out the first integer greater **or equal to** k_i in the column) along the column.

EXAMPLES:

```
sage: RSK([1], [1], insertion='superRSK')
[[[1]], [[1]]]
sage: RSK([1, 2], [1, 3], insertion='superRSK')
[[[1, 3]], [[1, 2]]]
sage: RSK([1, 2, 3], [1, 3, "3p"], insertion='superRSK')
[[[1, 3], [3']], [[1, 2], [3]]]
sage: RSK([1, 3, "3p", "2p"], insertion='superRSK')
```

(continues on next page)

(continued from previous page)

```

[[[1, 3', 3], [2']], [[1', 1, 2'], [2]]]
sage: RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
.....:    ["1p", 1, "2p", 2, "3p", "3p", "3p", 3], insertion='superRSK')
[[[1', 2, 3', 3], [1, 3'], [2'], [3']], [[1', 2, 3', 3], [2', 3'], [2], [3]]]
sage: P = SemistandardSuperTableau([[1, '3p', 3], ['2p']])
sage: Q = SemistandardSuperTableau([[1'p', 1, '2p'], [2]])
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2], [1, 3, 3', 2']]

```

We apply super RSK on Example 5.1 in [Muth2019]:

```

sage: P,Q = RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
.....:    ["3p", 1, 2, 3, "3p", "3p", "2p", "1p"], insertion='superRSK')
sage: (P, Q)
([[1', 2', 3', 3], [1, 2, 3'], [3']], [[1', 2, 2, 3'], [2', 3, 3], [3']])
sage: ascii_art((P, Q))
( 1' 2' 3' 3 1' 2 2 3' )
( 1 2 3' 2' 3 3 )
( 3' , 3' )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]

```

Example 6.1 in [Muth2019]:

```

sage: P,Q = RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
.....:    ["3p", 1, 2, 3, "3p", "3p", "2p", "1p"], insertion='superRSK')
sage: ascii_art((P, Q))
( 1' 2' 3' 3 1' 2 2 3' )
( 1 2 3' 2' 3 3 )
( 3' , 3' )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]

sage: P,Q = RSK(["1p", 1, "2p", 2, "3p", "3p", "3p", 3],
.....:    [3, "2p", 3, 2, "3p", "3p", "1p", 2], insertion='superRSK')
sage: ascii_art((P, Q))
( 1' 2 2 3' 1' 2' 3' 3 )
( 2' 3 3 1 2 3' )
( 3' , 3' )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2, 3', 3', 3', 3], [3, 2', 3, 2, 3', 3', 1', 2]]

```

Let us now call the inverse correspondence:

```

sage: P, Q = RSK([1, 2, 2, 2], [2, 1, 2, 3],
.....:    insertion=RSK.rules.superRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]

```

When applied to two tableaux with only even parity elements, reverse super RSK insertion behaves identically to the usual reversel RSK insertion:

```

sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.RSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: t1 = SemistandardSuperTableau([[1, 2, 5], [3], [4]])
sage: t2 = SemistandardSuperTableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.superRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]

```

backward_rule(*p*, *q*, *output*='array')

Return the restricted super biword obtained by applying reverse super RSK insertion to a pair of tableaux (*p*, *q*).

INPUT:

- *p*, *q* – two tableaux of the same shape
- *output* – (default: 'array') if *q* is row-strict:
 - 'array' – as a two-line array (i.e. restricted super biword)

and if *q* is standard, we can have the output:

- 'word' – as a word

EXAMPLES:

```

sage: from sage.combinat.rsk import RuleSuperRSK
sage: t1 = SemistandardSuperTableau(['1p', '3p', '4p'], [2], [3])
sage: t2 = SemistandardSuperTableau([[1, 2, 4], [3], [5]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [4', 3, 3', 2, 1']]
sage: t1 = SemistandardSuperTableau([[1, 3], ['3p']])
sage: t2 = SemistandardSuperTableau([[1, 2], [3]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3], [1, 3, 3']]

```

forward_rule(*obj1*, *obj2*, *check_standard*=False, *check*=True)

Return a pair of tableaux obtained by applying forward insertion to the restricted super biword [*obj1*, *obj2*].

INPUT:

- *obj1*, *obj2* – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
 - two lists *obj1* and *obj2* of equal length, to be interpreted as the top row and the bottom row of the biword
 - a word *obj1* in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, *obj2* is None; the top row of the biword is understood to be $(1, 2, \dots, n)$ by default)
 - any object *obj1* which has a method `_rsk_iter()`, as long as this method returns an iterator yielding pairs of numbers, which then are interpreted as top entries and bottom entries in the biword (in this case, *obj2* is None)
- *check_standard* – (default: False) check if either of the resulting tableaux is a standard super tableau, and if so, typecast it as such
- *check* – (default: True) whether to check that *obj1* and *obj2* actually define a valid restricted super biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: p, q = RuleSuperRSK().forward_rule([1, 2], [1, 3]); p
[[1, 3]]
sage: q
[[1, 2]]
sage: isinstance(p, SemistandardSuperTableau)
True
sage: isinstance(q, SemistandardSuperTableau)
True
```

insertion(*j*, *r*, *epsilon*=0)

Insert the letter *j* from the second row of the biword into the row *r* using dual RSK insertion or classical Schensted insertion depending on the value of *epsilon*, if there is bumping to be done.

The row *r* is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: from bisect import bisect_left, bisect_right
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=0); r
[1, 3, 3, 3, 3]
sage: j
4
sage: y_pos
4
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y_pos
1
```

reverse_insertion(*x*, *row*, *epsilon*=0)

Reverse bump the row *row* of the current insertion tableau with the number *x* using dual RSK insertion or classical Schensted insertion depending on the value of *epsilon*.

The row *row* is modified in place. The bumped-out entry is returned along with the bumped position.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: from bisect import bisect_left, bisect_right
sage: r = [1, 3, 3, 3, 4]
sage: j = 2
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
[2, 3, 3, 3, 4]
sage: j
1
sage: y
```

(continues on next page)

(continued from previous page)

```

0
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
[3, 3, 3, 3, 4]
sage: j
1
sage: y
0
sage: r = [1, 3, 3, 3, 4]
sage: j = (3)
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y
3

```

to_pairs(*obj1=None, obj2=None, check=True*)

Given a valid input for the super RSK algorithm, such as two n -tuples $\text{obj1} = [a_1, a_2, \dots, a_n]$ and $\text{obj2} = [b_1, b_2, \dots, b_n]$ forming a restricted super biword (i.e., entries with even and odd parity and no repetition of corresponding pairs with mixed parity entries) return the array $[(a_1, b_1), (a_2, b_2), \dots, (a_n, b_n)]$.

INPUT:

- *obj1, obj2* – anything representing a restricted super biword (see the doc of [forward_rule\(\)](#) for the encodings accepted)
- *check* – (default: True) whether to check that *obj1* and *obj2* actually define a valid restricted super biword

EXAMPLES:

```

sage: from sage.combinat.rsk import RuleSuperRSK
sage: list(RuleSuperRSK().to_pairs([2, '1p', 1],[1, 1, '1p']))
[(2, 1), (1', 1), (1, 1')]
sage: list(RuleSuperRSK().to_pairs([1, '1p', '2p']))
[(1', 1), (1, 1'), (2', 2')]
sage: list(RuleSuperRSK().to_pairs([1, 1], ['1p', '1p']))
Traceback (most recent call last):
...
ValueError: invalid restricted superbiword

```

`sage.combinat.rsk.robinson_schensted_knuth`(*obj1=None, obj2=None, insertion=<class 'sage.combinat.rsk.RuleRSK'>, check_standard=False, **options*)

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i -th step inserts the number k_i into the i -th row of P (we start counting the rows at 0) by replacing the first integer greater than

k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i -th row, then k_i is simply appended to the row and the algorithm terminates at this point.

A *generalized permutation* (or *biword*) is a list $((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$ of pairs such that the letters $j_0, j_1, \dots, j_{\ell-1}$ are weakly increasing (that is, $j_0 \leq j_1 \leq \dots \leq j_{\ell-1}$), whereas the letters k_i satisfy $k_i \leq k_{i+1}$ whenever $j_i = j_{i+1}$. The ℓ -tuple $(j_0, j_1, \dots, j_{\ell-1})$ is called the *top line* of this generalized permutation, whereas the ℓ -tuple $(k_0, k_1, \dots, k_{\ell-1})$ is called its *bottom line*.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p , and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as ‘‘Construction A’’.

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top row to be $(1, 2, \dots, n)$ where n is the length of w .

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

INPUT:

- `obj1, obj2` – can be one of the following:
 - a word in an ordered alphabet (in this case, `obj1` is said word, and `obj2` is `None`)
 - an integer matrix
 - two lists of equal length representing a generalized permutation (namely, the lists $(j_0, j_1, \dots, j_{\ell-1})$ and $(k_0, k_1, \dots, k_{\ell-1})$ represent the generalized permutation $((j_0, k_0), (j_1, k_1), \dots, (j_{\ell-1}, k_{\ell-1}))$)
 - any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, `obj1` is said object, and `obj2` is `None`).
- `insertion` – (default: `RSK.rules.RSK`) the following types of insertion are currently supported:
 - `RSK.rules.RSK` (or `'RSK'`) – Robinson-Schensted-Knuth insertion (*RuleRSK*)
 - `RSK.rules.EG` (or `'EG'`) – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)
 - `RSK.rules.Hecke` (or `'hecke'`) – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
 - `RSK.rules.dualRSK` (or `'dualRSK'`) – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
 - `RSK.rules.coRSK` (or `'coRSK'`) – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
 - `RSK.rules.superRSK` (or `'super'`) – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
 - `RSK.rules.Star` (or `'Star'`) – \star -insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)
- `check_standard` – (default: `False`) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular [Rule](#) class.

EXAMPLES:

If we only input one row, it is understood that the top row should be $(1, 2, \dots, n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

We can provide a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

We can provide a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also provide something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python `*` on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

```
sage.combinat.rsk.robinson_schensted_knuth_inverse(p, q, output='array', insertion=<class
'sage.combinat.rsk.RuleRSK'>)
```

Return the generalized permutation corresponding to the pair of tableaux (p, q) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see `RSK()`.

INPUT:

- p, q – two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- `output` – (default: 'array') if q is semi-standard:
 - 'array' – as a two-line array (i.e. generalized permutation or biword)

- 'matrix' – as an integer matrix

and if q is standard, we can also have the output:

- 'word' – as a word

and additionally if p is standard, we can also have the output:

- 'permutation' – as a permutation

- `insertion` – (default: `RSK.rules.RSK`) the insertion algorithm used in the bijection. Currently the following are supported:
 - `RSK.rules.RSK` (or 'RSK') – Robinson-Schensted-Knuth insertion (*RuleRSK*)
 - `RSK.rules.EG` (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)
 - `RSK.rules.Hecke` (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
 - `RSK.rules.dualRSK` (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
 - `RSK.rules.coRSK` (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
 - `RSK.rules.superRSK` (or 'super') – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
 - `RSK.rules.Star` (or 'Star') – \star -insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)

For precise information about constraints on the input and output, see the particular *Rule* class.

Note: In the case of Hecke insertion, the input variable q should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both p and q are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322
```

In general:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

Using Hecke insertion:

```
sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

Note: The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

`sage.combinat.rsk.to_matrix(t, b)`

Return the integer matrix corresponding to a two-line array.

INPUT:

- `t` – the top row of the array
- `b` – the bottom row of the array

OUTPUT:

An $m \times n$ -matrix (where m and n are the maximum entries in t and b respectively) whose (i, j) -th entry, for any i and j , is the number of all positions k satisfying $t_k = i$ and $b_k = j$.

EXAMPLES:

```
sage: from sage.combinat.rsk import to_matrix
sage: to_matrix([1, 1, 3, 3, 4], [2, 3, 1, 1, 3])
[0 1 1]
[0 0 0]
[2 0 0]
[0 0 1]
```

5.1.273 Schubert Polynomials

See [Wikipedia article Schubert_polynomial](#) and [SymmetricFunctions.com](#). Schubert polynomials are representatives of cohomology classes in flag varieties. In n variables, they are indexed by permutations $w \in S_n$. They also form a basis for the coinvariant ring of the S_n action on $\mathbf{Z}[x_1, x_2, \dots, x_n]$.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: w = [1,2,5,4,3]; # a list representing an element of `S_5`
sage: X(w)
X[1, 2, 5, 4, 3]
```

This can be expanded in terms of polynomial variables:

```
sage: X(w).expand()
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2
+ x0*x2^2 + x1*x2^2 + x0^2*x3 + x0*x1*x3 + x1^2*x3
+ x0*x2*x3 + x1*x2*x3 + x2^2*x3
```

We can also convert back from polynomial variables. For example, the longest permutation is a single term. In S_5 , this is the element (in one line notation) $w_0 = 54321$:

```
sage: w0 = [5,4,3,2,1]
sage: R.<x0, x1, x2, x3, x4> = PolynomialRing(ZZ)
sage: Sw0 = X(x0^4*x1^3*x2^2*x3); Sw0
X[5, 4, 3, 2, 1]
```

The polynomials also have the property that if the indexing permutation w is multiplied by a simple transposition $s_i = (i, i+1)$ such that the length of w is more than the length of ws_i , then the Schubert polynomial of the permutation ws_i is computed by applying the divided difference operator `divided_difference()` to the polynomial indexed by w . For example, applying the divided difference operator ∂_2 to the Schubert polynomial \mathfrak{S}_{w_0} :

```
sage: Sw0.divided_difference(2)
X[5, 3, 4, 2, 1]
```

We can also check the properties listed in [Wikipedia article Schubert_polynomial](#):

```
sage: X([1,2,3,4,5]) # the identity in one-line notation
X[1]
sage: X([1,3,2,4,5]).expand() # the transposition swapping 2 and 3
x0 + x1
sage: X([2,4,5,3,1]).expand()
x0^2*x1^2*x2*x3 + x0^2*x1*x2^2*x3 + x0*x1^2*x2^2*x3

sage: w = [4,5,1,2,3]
sage: s = SymmetricFunctions(QQ).schur()
sage: s[3,3].expand(2)
x0^3*x1^3
sage: X(w).expand()
x0^3*x1^3
```

```
sage.combinat.schubert_polynomial.SchubertPolynomialRing(R)
Return the Schubert polynomial ring over R on the X basis.
```

This is the basis made of the Schubert polynomials.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
sage: TestSuite(X).run()
sage: X(1)
X[1]
sage: X([1,2,3])*X([2,1,3])
X[2, 1]
sage: X([2,1,3])*X([2,1,3])
X[3, 1, 2]
sage: X([2,1,3])+X([3,1,2,4])
X[2, 1] + X[3, 1, 2]
sage: a = X([2,1,3])+X([3,1,2,4])
sage: a^2
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

```
class sage.combinat.schubert_polynomial.SchubertPolynomialRing_xbasis(R)
Bases: sage.combinat.free_module.CombinatorialFreeModule
```

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X == loads(dumps(X))
True
```

Element

alias of *SchubertPolynomial_class*

one_basis()

Return the index of the unit of this algebra.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X.one() # indirect doctest
X[1]
```

product_on_basis(left, right)

EXAMPLES:

```
sage: p1 = Permutation([3,2,1])
sage: p2 = Permutation([2,1,3])
sage: X = SchubertPolynomialRing(QQ)
sage: X.product_on_basis(p1,p2)
X[4, 2, 1, 3]
```

some_elements()

Return some elements.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X.some_elements()
[X[1], X[1] + 2*X[2, 1], -X[3, 2, 1] + X[4, 2, 1, 3]]
```

class sage.combinat.schubert_polynomial.SchubertPolynomial_class

Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

divided_difference(*i*, *algorithm*='sage')

Return the *i*-th divided difference operator, applied to `self`.

Here, *i* can be either a permutation or a positive integer.

INPUT:

- *i* – permutation or positive integer
- *algorithm* – (default: 'sage') either 'sage' or 'symmetrica'; this determines which software is called for the computation

OUTPUT:

The result of applying the *i*-th divided difference operator to `self`.

If *i* is a positive integer, then the *i*-th divided difference operator δ_i is the linear operator sending each polynomial $f = f(x_1, x_2, \dots, x_n)$ (in $n \geq i + 1$ variables) to the polynomial

$$\frac{f - f_i}{x_i - x_{i+1}}, \quad \text{where } f_i = f(x_1, x_2, \dots, x_{i-1}, x_{i+1}, x_i, x_{i+1}, \dots, x_n).$$

If σ is a permutation in the n -th symmetric group, then the σ -th divided difference operator δ_σ is the composition $\delta_{i_1} \delta_{i_2} \cdots \delta_{i_k}$, where $\sigma = s_{i_1} \circ s_{i_2} \circ \cdots \circ s_{i_k}$ is any reduced expression for σ (the precise choice of reduced expression is immaterial).

Note: The `expand()` method results in a polynomial in n variables named `x0`, `x1`, ..., `x(n-1)` rather than x_1, x_2, \dots, x_n . The variable named `xi` corresponds to x_{i+1} . Thus, `self.divided_difference(i)` involves the variables `x(i-1)` and `xi` getting switched (in the numerator).

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,1])
sage: a.divided_difference(1)
X[2, 3, 1]
sage: a.divided_difference([3,2,1])
X[1]
sage: a.divided_difference(5)
0
```

Any divided difference of 0 is 0:

```
sage: X.zero().divided_difference(2)
0
```

This is compatible when a permutation is given as input:

```
sage: a = X([3,2,4,1])
sage: a.divided_difference([2,3,1])
0
sage: a.divided_difference(1).divided_difference(2)
0
```

```

sage: a = X([4,3,2,1])
sage: a.divided_difference([2,3,1])
X[3, 2, 4, 1]
sage: a.divided_difference(1).divided_difference(2)
X[3, 2, 4, 1]
sage: a.divided_difference([4,1,3,2])
X[1, 4, 2, 3]
sage: b = X([4, 1, 3, 2])
sage: b.divided_difference(1).divided_difference(2)
X[1, 3, 4, 2]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3)
X[1, 3, 2]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3).
↳divided_difference(2)
X[1]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3).
↳divided_difference(3)
0
sage: b.divided_difference(1).divided_difference(2).divided_difference(1)
0

```

expand()

EXAMPLES:

```

sage: X = SchubertPolynomialRing(ZZ)
sage: X([2,1,3]).expand()
x0
sage: [X(p).expand() for p in Permutations(3)]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]

```

multiply_variable(i)Return the Schubert polynomial obtained by multiplying self by the variable x_i .

EXAMPLES:

```

sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.multiply_variable(0)
X[4, 2, 3, 1]
sage: a.multiply_variable(1)
X[3, 4, 2, 1]
sage: a.multiply_variable(2)
X[3, 2, 5, 1, 4] - X[3, 4, 2, 1] - X[4, 2, 3, 1]
sage: a.multiply_variable(3)
X[3, 2, 4, 5, 1]

```

scalar_product(x)

Return the standard scalar product of self and x.

EXAMPLES:

```

sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.scalar_product(a)

```

(continues on next page)

(continued from previous page)

```

0
sage: b = X([4,3,2,1])
sage: b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
sage: Permutation([1, 3, 4, 6, 2, 5, 7]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
sage: s = SymmetricFunctions(ZZ).schur()
sage: c = s([2,1,1])
sage: b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 +
↪ 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3 + x0*x1*x3^2 + x0*x2*x3^
↪ 2 + x1*x2*x3^2
sage: c.expand(4)
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 +
↪ 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3 + x0*x1*x3^2 + x0*x2*x3^
↪ 2 + x1*x2*x3^2

```

5.1.274 Set Partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration).
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through `SetPartition`.
- Martin Rubey (2017-10-10): Cleanup, add crossings and nestings, add random generation.

This module defines a class for immutable partitioning of a set. For mutable version see `DisjointSet()`.

class `sage.combinat.set_partition.AbstractSetPartition`

Bases: `sage.structure.list_clone.ClonableArray`

Methods of set partitions which are independent of the base set

base_set()

Return the base set of `self`, which is the union of all parts of `self`.

EXAMPLES:

```

sage: SetPartition([[1], [2,3], [4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([[1,2,3,4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([]).base_set()
{}

```

base_set_cardinality()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

coarsenings()

Return a list of coarsenings of `self`.

See also:

`refinements()`

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).coarsenings()
[{{1, 2, 3, 4}}, {{1, 3}, {2, 4}}]
sage: SetPartition([[1],[2,4],[3]]).coarsenings()
[{{1, 2, 3, 4}},
 {{1, 2, 4}, {3}},
 {{1, 3}, {2, 4}},
 {{1}, {2, 3, 4}},
 {{1}, {2, 4}, {3}}]
sage: SetPartition([]).coarsenings()
[{}]
```

conjugate()

An involution exchanging singletons and circular adjacencies.

This method implements the definition of the conjugate of a set partition defined in [Cal2005].

INPUT:

- `self` – a set partition of an ordered set

OUTPUT:

- a set partition

EXAMPLES:

```
sage: SetPartition([[1,6,7],[2,8],[3,4,5]]).conjugate()
{{1, 4, 7}, {2, 8}, {3}, {5}, {6}}
sage: all(sp.conjugate().conjugate()==sp for sp in SetPartitions([1,3,5,7]))
True
sage: SetPartition([]).conjugate()
{}
```

inf(*other*)

The product of the set partitions `self` and `other`.

The product of two set partitions B and C is defined as the set partition whose parts are the nonempty intersections between each part of B and each part of C . This product is also the infimum of B and C in the classical set partition lattice (that is, the coarsest set partition which is finer than each of B and C). Consequently, `inf` acts as an alias for this method.

See also:

`sup()`

EXAMPLES:

```

sage: x = SetPartition([ [1,2], [3,5,4] ])
sage: y = SetPartition(( (3,1,2), (5,4) ))
sage: x * y
{{1, 2}, {3}, {4, 5}}

sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[2,4], [3], [1]])
sage: sp1.inf(sp2) == s
True

```

max_block_size()

The maximum block size of the diagram.

EXAMPLES:

```

sage: from sage.combinat.diagram_algebras import PartitionDiagram, PartitionDiagrams
sage: pd = PartitionDiagram([[1, -3, -5], [2, 4], [3, -1, -2], [5], [-4]])
sage: pd.max_block_size()
3
sage: sorted(d.max_block_size() for d in PartitionDiagrams(2))
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 4]
sage: sorted(sp.max_block_size() for sp in SetPartitions(3))
[1, 2, 2, 2, 3]

```

standard_form()

Return `self` as a list of lists.

When the ground set is totally ordered, the elements of each block are listed in increasing order.

This is not related to standard set partitions (which simply means set partitions of $[n] = \{1, 2, \dots, n\}$ for some integer n) or standardization (`standardization()`).

EXAMPLES:

```

sage: [x.standard_form() for x in SetPartitions(4, [2,2])]
[[[1, 2], [3, 4]], [[1, 4], [2, 3]], [[1, 3], [2, 4]]]

```

sup(t)

Return the supremum of `self` and `t` in the classical set partition lattice.

The supremum of two set partitions B and C is obtained as the transitive closure of the relation which relates i to j if and only if i and j are in the same part in at least one of the set partitions B and C .

See also:

`__mul__()`

EXAMPLES:

```

sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[1,2,3,4]])
sage: sp1.sup(sp2) == s
True

```

class sage.combinat.set_partition.**SetPartition**(parent, s, check=True)

Bases: `sage.combinat.set_partition.AbstractSetPartition`

A partition of a set.

A set partition p of a set S is a partition of S into subsets called parts and represented as a set of sets. By extension, a set partition of a nonnegative integer n is the set partition of the integers from 1 to n . The number of set partitions of n is called the n -th Bell number.

There is a natural integer partition associated with a set partition, namely the nonincreasing sequence of sizes of all its parts.

There is a classical lattice associated with all set partitions of n . The infimum of two set partitions is the set partition obtained by intersecting all the parts of both set partitions. The supremum is obtained by transitive closure of the relation i related to j if and only if they are in the same part in at least one of the set partitions.

We will use terminology from partitions, in particular the *length* of a set partition $A = \{A_1, \dots, A_k\}$ is the number of parts of A and is denoted by $|A| := k$. The *size* of A is the cardinality of S . We will also sometimes use the notation $[n] := \{1, 2, \dots, n\}$.

EXAMPLES:

There are 5 set partitions of the set $\{1, 2, 3\}$:

```
sage: SetPartitions(3).cardinality()
5
```

Here is the list of them:

```
sage: SetPartitions(3).list()
[{{1, 2, 3}}, {{1, 2}, {3}}, {{1, 3}, {2}}, {{1}, {2, 3}}, {{1}, {2}, {3}}]
```

There are 6 set partitions of $\{1, 2, 3, 4\}$ whose underlying partition is $[2, 1, 1]$:

```
sage: SetPartitions(4, [2,1,1]).list()
[{{1}, {2, 4}, {3}},
 {{1}, {2}, {3, 4}},
 {{1, 4}, {2}, {3}},
 {{1, 3}, {2}, {4}},
 {{1, 2}, {3}, {4}},
 {{1}, {2, 3}, {4}}]
```

Since [trac ticket #14140](#), we can create a set partition directly by `SetPartition`, which creates the base set by taking the union of the parts passed in:

```
sage: s = SetPartition([[1,3],[2,4]]); s
{{1, 3}, {2, 4}}
sage: s.parent()
Set partitions
```

apply_permutation(p)

Apply p to the underlying set of self.

INPUT:

- p – a permutation

EXAMPLES:

```

sage: x = SetPartition([[1,2], [3,5,4]])
sage: p = Permutation([2,1,4,5,3])
sage: x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
sage: q = Permutation([3,2,1,5,4])
sage: x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}

sage: m = PerfectMatching([(1,4),(2,6),(3,5)])
sage: m.apply_permutation(Permutation([4,1,5,6,3,2]))
[(1, 2), (3, 5), (4, 6)]

```

arcs()

Return `self` as a list of arcs.

Assuming that the blocks are sorted, the arcs are the pairs of consecutive elements in the blocks.

EXAMPLES:

```

sage: A = SetPartition([[1],[2,3],[4]])
sage: A.arcs()
[(2, 3)]
sage: B = SetPartition([[1,3,6,7],[2,5],[4]])
sage: B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]

```

cardinality()

Return the len of `self`

EXAMPLES:

```

sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: len(IncreasingArrays()([1,2,3]))
3

```

check()

Check that we are a valid set partition.

EXAMPLES:

```

sage: S = SetPartitions(4)
sage: s = S([[1, 3], [2, 4]])
sage: s.check()

```

closers()

Return the maximal elements of the blocks.

EXAMPLES:

```

sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.closers()
[7, 8, 9, 12, 13]

```

crossings()

Return the crossing arcs of a set partition on a totally ordered set.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns a list of the pairs of crossing lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.crossings()
[((1, 4), (2, 5)), ((1, 4), (3, 6)), ((2, 5), (3, 6)), ((3, 6), (5, 7))]
```

`crossings_iterator()`

Return the crossing arcs of a set partition on a totally ordered set.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of crossing lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: next(p.crossings_iterator())
((1, 4), (2, 5))
```

`is_atomic()`

Return if `self` is an atomic set partition.

A (standard) set partition A can be split if there exist $j < i$ such that $\max(A_j) < \min(A_i)$ where A is ordered by minimal elements. This means we can write $A = B|C$ for some nonempty set partitions B and C . We call a set partition *atomic* if it cannot be split and is nonempty. Here, the pipe symbol $|$ is as defined in method `pipe()`.

EXAMPLES:

```
sage: SetPartition([[1,3], [2]]).is_atomic()
True
sage: SetPartition([[1,3], [2], [4]]).is_atomic()
False
sage: SetPartition([[1], [2,4], [3]]).is_atomic()
False
sage: SetPartition([[1,2,3,4]]).is_atomic()
True
sage: SetPartition([[1, 4], [2], [3]]).is_atomic()
True
sage: SetPartition([]).is_atomic()
False
```

`is_noncrossing()`

Check if `self` is noncrossing.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns `True` if the picture obtained this way has no crossings.

EXAMPLES:

```

sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.is_noncrossing()
False

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_noncrossing()
False
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_noncrossing()
True

```

is_nonnesting()

Return if `self` is nonnesting or not.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns `True` if the picture obtained this way has no nestings.

EXAMPLES:

```

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_nonnesting()
False
sage: PerfectMatching([(1, 3), (2, 5), (4, 6)]).is_nonnesting()
True

```

latex_options()

Return the latex options for use in the `_latex_` function as a dictionary. The default values are set using the global options.

Options can be found in [set_latex_options\(\)](#)

EXAMPLES:

```

sage: SP = SetPartition([[1,6], [3,5,4]]); SP.latex_options()
{'angle': 0,
 'color': 'black',
 'fill': False,
 'plot': None,
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 1}

```

nestings()

Return the nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the list of the pairs of nesting lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```

sage: m = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: m.nestings()
[[((1, 6), (3, 5)), ((2, 7), (3, 5))]

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.nestings()
[[((2, 8), (4, 7)), ((2, 8), (5, 6)), ((4, 7), (5, 6))]

```

nestings_iterator()

Iterate over the nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of nesting lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```

sage: n = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: it = n.nestings_iterator()
sage: next(it)
((1, 6), (3, 5))
sage: next(it)
((2, 7), (3, 5))
sage: next(it)
Traceback (most recent call last):
...
StopIteration

```

number_of_crossings()

Return the number of crossings.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the number the pairs of crossing lines.

EXAMPLES:

```

sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.number_of_crossings()
4

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1

```

number_of_nestings()

Return the number of nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the number the pairs of nesting lines.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_nestings()
3
```

openers()

Return the minimal elements of the blocks.

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.openers()
[1, 3, 5, 8, 12]
```

ordered_set_partition_action(s)Return the action of an ordered set partition s on `self`.

Let $A = \{A_1, A_2, \dots, A_k\}$ be a set partition of some set S and s be an ordered set partition (i.e., set composition) of a subset of $[k]$. Let A^\downarrow denote the standardization of A , and $A_{\{i_1, i_2, \dots, i_m\}}$ denote the subpartition $\{A_{i_1}, A_{i_2}, \dots, A_{i_m}\}$ for any subset $\{i_1, \dots, i_m\}$ of $\{1, \dots, k\}$. We define the set partition $s(A)$ by

$$s(A) = A_{s_1}^\downarrow | A_{s_2}^\downarrow | \cdots | A_{s_q}^\downarrow.$$

where $s = (s_1, s_2, \dots, s_q)$. Here, the pipe symbol $|$ is as defined in method `pipe()`.

This is $s[A]$ in section 2.3 in [LM2011].

INPUT:

- s – an ordered set partition with base set a subset of $\{1, \dots, k\}$

EXAMPLES:

```
sage: A = SetPartition([[1], [2,4], [3]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: A.ordered_set_partition_action(s)
{{1}, {2}, {3, 4}}
sage: s = OrderedSetPartition([[2,3], [1]])
sage: A.ordered_set_partition_action(s)
{{1, 3}, {2}, {4}}
```

We create Figure 1 in [LM2011] (we note that there is a typo in the lower-left corner of the table in the published version of the paper, whereas the arXiv version gives the correct partition):

```
sage: A = SetPartition([[1,3], [2,9], [4,5,8], [7]])
sage: B = SetPartition([[1,3], [2,8], [4,5,6], [7]])
sage: C = SetPartition([[1,5], [2,8], [3,4,6], [7]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: t = OrderedSetPartition([[2], [3,4]])
sage: u = OrderedSetPartition([[1], [2,3,4]])
sage: A.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: A.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 6}, {5}}
```

(continues on next page)

(continued from previous page)

```

sage: A.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 7}, {6}}
sage: B.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: B.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: B.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
sage: C.ordered_set_partition_action(s)
{{1, 4}, {2, 3, 5}, {6, 7}}
sage: C.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: C.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}

```

REFERENCES:

- [LM2011]

pipe(*other*)

Return the pipe of the set partitions `self` and `other`.

The pipe of two set partitions is defined as follows:

For any integer k and any subset I of \mathbf{Z} , let $I + k$ denote the subset of \mathbf{Z} obtained by adding k to every element of I .

If B and C are set partitions of $[n]$ and $[m]$, respectively, then the pipe of B and C is defined as the set partition

$$\{B_1, B_2, \dots, B_b, C_1 + n, C_2 + n, \dots, C_c + n\}$$

of $[n + m]$, where $B = \{B_1, B_2, \dots, B_b\}$ and $C = \{C_1, C_2, \dots, C_c\}$. This pipe is denoted by $B|C$.

EXAMPLES:

```

sage: SetPartition([[1,3],[2,4]]).pipe(SetPartition([[1,3],[2]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
sage: SetPartition([]).pipe(SetPartition([[1,2],[3,5],[4]]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3,5],[4]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3]]).pipe(SetPartition([[1]]))
{{1, 2}, {3}, {4}}

```

plot(*angle=None, color='black', base_set_dict=None*)

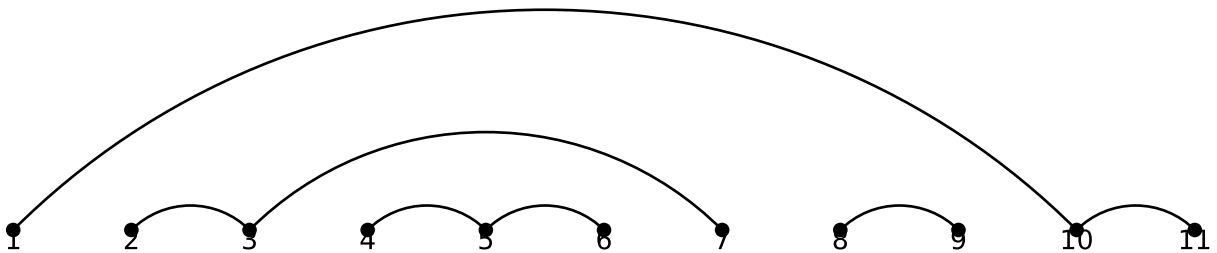

Return a plot of `self`.

INPUT:

- `angle` – (default: $\pi/4$) the angle at which the arcs take off (if angle is negative, the arcs are drawn below the horizontal line)
- `color` – (default: 'black') color of the arcs
- `base_set_dict` – (optional) dictionary with keys elements of `base_set()` and values as integer or float

EXAMPLES:

```
sage: p = SetPartition([[1,10,11],[2,3,7],[4,5,6],[8,9]])
sage: p.plot()
Graphics object consisting of 29 graphics primitives
```

```
sage: p = SetPartition([[1,3,4],[2,5]])
sage: print(p.plot().description())

  angle 0.0 inside the sector (0.785398163397..., 2.35619449019...)

```

refinements()

Return a list of refinements of self.

See also:

coarsenings()

EXAMPLES:

```

sage: SetPartition([[1,3],[2,4]]).refinements()
[{{1, 3}, {2, 4}},
 {{1, 3}, {2}, {4}},
 {{1}, {2, 4}, {3}},
 {{1}, {2}, {3}, {4}}]
sage: SetPartition([[1],[2,4],[3]]).refinements()
[{{1}, {2, 4}, {3}}, {{1}, {2}, {3}, {4}}]
sage: SetPartition([]).refinements()
[{}]

```

restriction(I)

Return the restriction of `self` to a subset `I` (which is given as a set or list or any other iterable).

EXAMPLES:

```
sage: A = SetPartition([[1], [2,3]])
sage: A.restriction([1,2])
{{1}, {2}}
sage: A.restriction([2,3])
{{2, 3}}
sage: A.restriction([])
{}
sage: A.restriction([4])
{}
```

set_latex_options(kwargs)**

Set the latex options for use in the `_latex_` function

- `tikz_scale` – (default: 1) scale for use with tikz package
- `plot` – (default: None) None returns the set notation, `linear` returns a linear plot, `cyclic` returns a cyclic plot
- `color` – (default: 'black') the arc colors
- `fill` – (default: False) if True then fills `color`, else you can pass in a color to alter the fill color - *only works with cyclic plot*
- `show_labels` – (default: True) if True shows labels - *only works with plots*
- `radius` – (default: "1cm") radius of circle for cyclic plot - *only works with cyclic plot*
- `angle` – (default: 0) angle for linear plot

EXAMPLES:

```
sage: SP = SetPartition([[1,6], [3,5,4]])
sage: SP.set_latex_options(tikz_scale=2,plot='linear',fill=True,color='blue',
↵angle=45)
sage: SP.set_latex_options(plot='cyclic')
sage: SP.latex_options()
{'angle': 45,
 'color': 'blue',
 'fill': True,
 'plot': 'cyclic',
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 2}
```

shape()

Return the integer partition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
```

(continues on next page)

(continued from previous page)

```
sage: y.shape()
[2, 2, 1]
```

shape_partition()

Return the integer partition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

size()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

standardization()

Return the standardization of `self`.

Given a set partition $A = \{A_1, \dots, A_n\}$ of an ordered set S , the standardization of A is the set partition of $\{1, 2, \dots, |S|\}$ obtained by replacing the elements of the parts of A by the integers $1, 2, \dots, |S|$ in such a way that their relative order is preserved (i. e., the smallest element in the whole set partition is replaced by 1, the next-smallest by 2, and so on).

EXAMPLES:

```
sage: SetPartition([[4], [1, 3]]).standardization()
{{1, 2}, {3}}
sage: SetPartition([[4], [6, 3]]).standardization()
{{1, 3}, {2}}
sage: SetPartition([]).standardization()
{}
sage: SetPartition([('c', 'b'), ('d', 'f'), ('e', 'a')]).standardization()
{{1, 5}, {2, 3}, {4, 6}}
```

strict_coarsenings()

Return all strict coarsenings of `self`.

Strict coarsening is the binary relation on set partitions defined as the transitive-and-reflexive closure of the relation \prec defined as follows: For two set partitions A and B , we have $A \prec B$ if there exist parts A_i, A_j of A such that $\max(A_i) < \min(A_j)$ and $B = A \setminus \{A_i, A_j\} \cup \{A_i \cup A_j\}$.

EXAMPLES:

```

sage: A = SetPartition([[1],[2,3],[4]])
sage: A.strict_coarsenings()
[{{1}, {2, 3}, {4}}, {{1, 2, 3}, {4}}, {{1, 4}, {2, 3}},
 {{1}, {2, 3, 4}}, {{1, 2, 3, 4}}]
sage: SetPartition([[1],[2,4],[3]]).strict_coarsenings()
[{{1}, {2, 4}, {3}}, {{1, 2, 4}, {3}}, {{1, 3}, {2, 4}}]
sage: SetPartition([]).strict_coarsenings()
[{}]

```

to_partition()

Return the integer partition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```

sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]

```

to_permutation()

Convert a set partition of $\{1, \dots, n\}$ to a permutation by considering the blocks of the partition as cycles.

The cycles are such that the number of excedences is maximised, that is, each cycle is of the form (a_1, a_2, \dots, a_k) with $a_1 < a_2 < \dots < a_k$.

EXAMPLES:

```

sage: s = SetPartition([[1,3],[2,4]])
sage: s.to_permutation()
[3, 4, 1, 2]

```

to_restricted_growth_word(bijection='blocks')

Convert a set partition of $\{1, \dots, n\}$ to a word of length n with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

INPUT:

- `bijection` (default: `blocks`) – defines the map from set partitions to restricted growth functions. These are currently:
 - `blocks`: `to_restricted_growth_word_blocks()`.
 - `intertwining`: `to_restricted_growth_word_intertwining()`.

OUTPUT:

A restricted growth word.

See also:

`SetPartitions.from_restricted_growth_word()`

EXAMPLES:

```

sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word()

```

(continues on next page)

(continued from previous page)

```
[0, 1, 2, 0, 2, 2, 3, 1, 2]
sage: P.to_restricted_growth_word("intertwining")
[0, 1, 2, 2, 1, 0, 3, 3, 2]
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.to_restricted_growth_word()
[0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 2, 4, 2]
sage: P.to_restricted_growth_word("intertwining")
[0, 0, 1, 1, 2, 0, 1, 3, 3, 3, 0, 4, 1]
```

to_restricted_growth_word_blocks()

Convert a set partition of $\{1, \dots, n\}$ to a word of length n with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

The word is obtained by sorting the blocks by their minimal element and setting the letters at the positions of the elements in the i -th block to i .

OUTPUT:

- a restricted growth word.

See also:

`to_restricted_growth_word()` *SetPartitions.from_restricted_growth_word()*

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word_blocks()
[0, 1, 2, 0, 2, 2, 3, 1, 2]
```

to_restricted_growth_word_intertwining()

Convert a set partition of $\{1, \dots, n\}$ to a word of length n with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

The i -th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at i , with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

OUTPUT:

- a restricted growth word.

See also:

`to_restricted_growth_word()` *SetPartitions.from_restricted_growth_word()*

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word_intertwining()
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

to_rook_placement(bijection='arcs')

Return a set of pairs defining a placement of non-attacking rooks on a triangular board.

The cells of the board corresponding to a set partition of $\{1, \dots, n\}$ are the pairs (i, j) with $0 < i < j < n + 1$.

INPUT:

- **bijection** (default: `arcs`) – defines the bijection from set partitions to rook placements. These are currently:
 - `arcs`: `arcs()`
 - `gamma`: `to_rook_placement_gamma()`
 - `rho`: `to_rook_placement_rho()`
 - `psi`: `to_rook_placement_psi()`

See also:

`SetPartitions.from_rook_placement()`

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.to_rook_placement()
[(1, 2), (2, 4), (4, 7), (3, 9), (5, 6), (6, 10), (10, 11), (11, 13)]
sage: P.to_rook_placement("gamma")
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
sage: P.to_rook_placement("rho")
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
sage: P.to_rook_placement("psi")
[(1, 2), (2, 6), (3, 4), (5, 9), (6, 7), (7, 10), (9, 11), (11, 13)]
```

`to_rook_placement_gamma()`

Return the rook diagram obtained by placing rooks according to Wachs and White's bijection `gamma`.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i -th column from the right and the j -th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the left column. If $n + 1 - i$ is an opener, column i remains empty. Otherwise, we place a rook into column i , such that the number of cells below the rook, which are not yet attacked by another rook, equals the index of the block to which $n + 1 - i$ belongs.

OUTPUT:

A list of coordinates.

See also:

- `to_rook_placement()`
- `SetPartitions.from_rook_placement()`
- `SetPartitions.from_rook_placement_gamma()`

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_gamma()
[(1, 3), (2, 7), (4, 5), (5, 6), (6, 9)]
```

Figure 5 in [WW1991]:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: r = P.to_rook_placement_gamma(); r
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

to_rook_placement_psi()

Return the rook diagram obtained by placing rooks according to Yip's bijection ψ .

OUTPUT:

A list of coordinates.

See also:

- `to_rook_placement()`
- `SetPartitions.from_rook_placement()`
- `SetPartitions.from_rook_placement_psi()`

EXAMPLES:

Example 36 (arXiv version: Example 4.5) in [Yip2018]:

```
sage: P = SetPartition([[1, 5], [2], [3, 8, 9], [4], [6, 7]])
sage: P.to_rook_placement_psi()
[(1, 7), (3, 8), (4, 5), (7, 9)]
```

Note that the columns corresponding to the minimal elements of the blocks remain empty.

to_rook_placement_rho()

Return the rook diagram obtained by placing rooks according to Wachs and White's bijection ρ .

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i -th column from the right and the j -th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the top row. The columns corresponding to the closers of the set partition remain empty. Let rs_j be the number of closers which are larger than j and whose block is before the block of j .

We then place a rook into row j , such that the number of cells to the left of the rook, which are not yet attacked by another rook and are not in a column corresponding to a closer, equals rs_j , unless there are not enough cells in this row available, in which case the row remains empty.

One can show that the precisely those rows which correspond to openers of the set partition remain empty.

OUTPUT:

A list of coordinates.

See also:

- `to_rook_placement()`
- `SetPartitions.from_rook_placement()`
- `SetPartitions.from_rook_placement_rho()`

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_rho()
[(1, 5), (2, 6), (3, 4), (5, 9), (6, 8)]
```

Figure 6 in [WW1991]:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: r = P.to_rook_placement_rho(); r
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]

sage: sorted(P.closers() + [i for i, _ in r]) == list(range(1,14))
True
sage: sorted(P.openers() + [j for _, j in r]) == list(range(1,14))
True
```

class sage.combinat.set_partition.SetPartitions

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

An (unordered) partition of a set S is a set of pairwise disjoint nonempty subsets with union S , and is represented by a sorted list of such subsets.

`SetPartitions(s)` returns the class of all set partitions of the set s , which can be given as a set or a string; if a string, each character is considered an element.

`SetPartitions(n)`, where n is an integer, returns the class of all set partitions of the set $\{1, 2, \dots, n\}$.

You may specify a second argument k . If k is an integer, `SetPartitions` returns the class of set partitions into k parts; if it is an integer partition, `SetPartitions` returns the class of set partitions whose block sizes correspond to that integer partition.

The Bell number B_n , named in honor of Eric Temple Bell, is the number of different partitions of a set with n elements.

EXAMPLES:

```
sage: S = [1,2,3,4]
sage: SetPartitions(S, 2)
Set partitions of {1, 2, 3, 4} with 2 parts
sage: SetPartitions([1,2,3,4], [3,1]).list()
[{{1}}, {2, 3, 4}], {{1, 2, 3}, {4}}, {{1, 2, 4}, {3}}, {{1, 3, 4}, {2}}]
sage: SetPartitions(7, [3,3,1]).cardinality()
70
```

In strings, repeated letters are not considered distinct as of [trac ticket #14140](#):

```
sage: SetPartitions('abcde').cardinality()
52
sage: SetPartitions('aabcd').cardinality()
15
```

REFERENCES:

- [Wikipedia article Partition_of_a_set](#)

Element

alias of `SetPartition`

from_arcs(arcs, n)

Return the coarsest set partition of $\{1, \dots, n\}$ such that any two elements connected by an arc are in the same block.

INPUT:

- n – an integer specifying the size of the set partition to be produced.
- arcs – a list of pairs specifying which elements are in the same block.

See also:

- [from_rook_placement\(\)](#)
- [SetPartition.to_rook_placement\(\)](#)
- [SetPartition.arcs\(\)](#)

EXAMPLES:

```
sage: SetPartitions().from_arcs([(2,3)], 5)
{{1}, {2, 3}, {4}, {5}}
```

from_restricted_growth_word(w, bijection='blocks')

Convert a word of length n with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, \dots, n\}$.

INPUT:

- w – a restricted growth word.
- bijection (default: blocks) – defines the map from restricted growth functions to set partitions. These are currently:
 - blocks: .
 - intertwining: [from_restricted_growth_word_intertwining\(\)](#).

OUTPUT:

A set partition.

See also:

[SetPartition.to_restricted_growth_word\(\)](#)

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word([0, 1, 2, 0, 2, 2, 3, 1, 2])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}
```

```
sage: SetPartitions().from_restricted_growth_word([0, 0, 1, 0, 2, 2, 0, 3, 1, 2,
↪ 2, 4, 2])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
sage: SetPartitions().from_restricted_growth_word([0, 0, 1, 0, 2, 2, 0, 3, 1, 2,
↪ 2, 4, 2], "intertwining")
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

from_restricted_growth_word_blocks(w)

Convert a word of length n with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, \dots, n\}$.

$w[i]$ is the index of the block containing $i+1$ when sorting the blocks by their minimal element.

INPUT:

- w – a restricted growth word.

OUTPUT:

A set partition.

See also:

[`from_restricted_growth_word\(\)`](#) [`SetPartition.to_restricted_growth_word\(\)`](#)

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word_blocks([0, 0, 1, 0, 2, 2, 0, 1,
↪3, 1, 2, 2, 4, 2])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_restricted_growth_word_intertwining(w)

Convert a word of length n with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, \dots, n\}$.

The i -th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at i , with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

INPUT:

- w – a restricted growth word.

OUTPUT:

A set partition.

See also:

[`from_restricted_growth_word\(\)`](#) [`SetPartition.to_restricted_growth_word\(\)`](#)

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word_intertwining([0, 0, 1, 0, 2, 1,
↪2, 0, 3, 1, 2, 2, 4, 2])
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

from_rook_placement($rooks$, $bijection='arcs'$, $n=None$)

Convert a rook placement of the triangular grid to a set partition of $\{1, \dots, n\}$.

If n is not given, it is first checked whether it can be determined from the parent, otherwise it is the maximal occurring integer in the set of rooks.

INPUT:

- $rooks$ – a list of pairs (i, j) satisfying $0 < i < j < n + 1$.
- $bijection$ (default: `arcs`) – defines the map from rook placements to set partitions. These are currently:
 - `arcs`: [`from_arcs\(\)`](#).
 - `gamma`: [`from_rook_placement_gamma\(\)`](#).
 - `rho`: [`from_rook_placement_rho\(\)`](#).
 - `psi`: [`from_rook_placement_psi\(\)`](#).

- n – (optional) the size of the ground set.

See also:

`SetPartition.to_rook_placement()`

EXAMPLES:

```
sage: SetPartitions(9).from_rook_placement([[1,4],[2,8],[3,5],[5,6],[6,9]])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}
```

```
sage: SetPartitions(13).from_rook_placement([[12,13],[10,12],[8,9],[7,11],[5,8],
↪[4,6],[3,5],[1,4]], "gamma")
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_rook_placement_gamma(*rooks*, *n*)

Return the set partition of $\{1, \dots, n\}$ corresponding to the given rook placement by applying Wachs and White's bijection γ .

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i -th column from the right and the j -th row from the top.

INPUT:

- n – an integer specifying the size of the set partition to be produced.
- *rooks* – a list of pairs (i, j) such that $0 < i < j < n + 1$.

OUTPUT:

A set partition.

See also:

- `from_rook_placement()`
- `SetPartition.to_rook_placement()`
- `SetPartition.to_rook_placement_gamma()`

EXAMPLES:

Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

Note that the rook $(1, 4)$, translated into Wachs and White's convention, is a rook in row 4 from the top and column 13 from the left. The corresponding set partition is:

```
sage: SetPartitions().from_rook_placement_gamma(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_rook_placement_psi(*rooks*, *n*)

Return the set partition of $\{1, \dots, n\}$ corresponding to the given rook placement by applying Yip's bijection ψ .

INPUT:

- n – an integer specifying the size of the set partition to be produced.
- *rooks* – a list of pairs (i, j) such that $0 < i < j < n + 1$.

OUTPUT:

A set partition.

See also:

- `from_rook_placement()`
- `SetPartition.to_rook_placement()`
- `SetPartition.to_rook_placement_psi()`

EXAMPLES:

Example 36 (arXiv version: Example 4.5) in [Yip2018] concerns the following rook placement:

```
sage: r = [(4,5), (1,7), (3, 8), (7,9)]
sage: SetPartitions().from_rook_placement_psi(r, 9)
{{1, 5}, {2}, {3, 8, 9}, {4}, {6, 7}}
```

from_rook_placement_rho(*rooks*, *n*)

Return the set partition of $\{1, \dots, n\}$ corresponding to the given rook placement by applying Wachs and White's bijection ρ .

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i -th column from the right and the j -th row from the top.

INPUT:

- *n* – an integer specifying the size of the set partition to be produced.
- *rooks* – a list of pairs (i, j) such that $0 < i < j < n + 1$.

OUTPUT:

A set partition.

See also:

- `from_rook_placement()`
- `SetPartition.to_rook_placement()`
- `SetPartition.to_rook_placement_rho()`

EXAMPLES:

Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
```

Note that the rook $(1, 2)$, translated into Wachs and White's convention, is a rook in row 2 from the top and column 13 from the left. The corresponding set partition is:

```
sage: SetPartitions().from_rook_placement_rho(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

is_less_than(*s*, *t*)

Check if $s < t$ in the refinement ordering on set partitions.

This means that s is a refinement of t and satisfies $s \neq t$.

A set partition s is said to be a refinement of a set partition t of the same set if and only if each part of s is a subset of a part of t .

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1, 3], [2, 4]])
sage: t = S([[1], [2], [3], [4]])
sage: S.is_less_than(t, s)
True
sage: S.is_less_than(s, t)
False
sage: S.is_less_than(s, s)
False
```

is_strict_refinement(s, t)

Return True if s is a strict refinement of t and satisfies $s \neq t$.

A set partition s is said to be a strict refinement of a set partition t of the same set if and only if one can obtain t from s by repeatedly combining pairs of parts whose convex hulls don't intersect (i. e., whenever we are combining two parts, the maximum of each of them should be smaller than the minimum of the other).

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1], [2], [3], [4]])
sage: t = S([[1, 3], [2, 4]])
sage: u = S([[1, 2, 3, 4]])
sage: S.is_strict_refinement(s, t)
True
sage: S.is_strict_refinement(t, u)
False
sage: A = SetPartition([[1, 3], [2, 4]])
sage: B = SetPartition([[1, 2, 3, 4]])
sage: S.is_strict_refinement(s, A)
True
sage: S.is_strict_refinement(t, B)
False
```

lt(s, t)

Check if $s < t$ in the refinement ordering on set partitions.

This means that s is a refinement of t and satisfies $s \neq t$.

A set partition s is said to be a refinement of a set partition t of the same set if and only if each part of s is a subset of a part of t .

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1, 3], [2, 4]])
sage: t = S([[1], [2], [3], [4]])
sage: S.is_less_than(t, s)
True
sage: S.is_less_than(s, t)
False
```

(continues on next page)

(continued from previous page)

```
sage: S.is_less_than(s, s)
False
```

class `sage.combinat.set_partition.SetPartitions_all`
 Bases: `sage.combinat.set_partition.SetPartitions`

All set partitions.

subset(*size=None, **kwargs*)

Return the subset of set partitions of a given size and additional keyword arguments.

EXAMPLES:

```
sage: P = SetPartitions()
sage: P.subset(4)
Set partitions of {1, 2, 3, 4}
```

class `sage.combinat.set_partition.SetPartitions_set(s)`
 Bases: `sage.combinat.set_partition.SetPartitions`

Set partitions of a fixed set S .

base_set()

Return the base set of self.

EXAMPLES:

```
sage: SetPartitions(3).base_set()
{1, 2, 3}

sage: sorted(SetPartitions(["a", "b", "c"]).base_set())
['a', 'b', 'c']
```

base_set_cardinality()

Return the cardinality of the base set of self.

EXAMPLES:

```
sage: SetPartitions(3).base_set_cardinality()
3
```

cardinality()

Return the number of set partitions of the set S .

The cardinality is given by the n -th Bell number where n is the number of elements in the set S .

EXAMPLES:

```
sage: SetPartitions([1,2,3,4]).cardinality()
15
sage: SetPartitions(3).cardinality()
5
sage: SetPartitions(3,2).cardinality()
3
sage: SetPartitions([]).cardinality()
1
```

random_element()

Return a random set partition.

This is a very naive implementation of Knuths outline in F3B, 7.2.1.5.

EXAMPLES:

```
sage: S = SetPartitions(10)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s

sage: S = SetPartitions(["a", "b", "c"])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

class sage.combinat.set_partition.**SetPartitions_setn**(*s*, *k*)

Bases: *sage.combinat.set_partition.SetPartitions_set*

Set partitions with a given number of blocks.

cardinality()

The Stirling number of the second kind is the number of partitions of a set of size n into k blocks.

EXAMPLES:

```
sage: SetPartitions(5, 3).cardinality()
25
sage: stirling_number2(5,3)
25
```

n

`self.n` is deprecated; use *number_of_blocks()* instead.

number_of_blocks()

Return the number of blocks of the set partitions in `self`.

EXAMPLES:

```
sage: SetPartitions(5, 3).number_of_blocks()
3
```

random_element()

Return a random set partition of `self`.

See <https://mathoverflow.net/questions/141999>.

EXAMPLES:

```
sage: S = SetPartitions(10, 4)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

(continues on next page)

(continued from previous page)

```

sage: S = SetPartitions(["a", "b", "c"], 2)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s

```

class `sage.combinat.set_partition.SetPartitions_setparts`(*s*, *parts*)

Bases: `sage.combinat.set_partition.SetPartitions_set`

Set partitions with fixed partition sizes corresponding to an integer partition λ .

cardinality()

Return the cardinality of `self`.

This algorithm counts for each block of the partition the number of ways to fill it using values from the set. Then, for each distinct value v of block size, we divide the result by the number of ways to arrange the blocks of size v in the set partition.

For example, if we want to count the number of set partitions of size 13 having $[3,3,3,2,2]$ as underlying partition we compute the number of ways to fill each block of the partition, which is $\binom{13}{3}\binom{10}{3}\binom{7}{3}\binom{4}{2}\binom{2}{2}$ and as we have three blocks of size 3 and two blocks of size 2, we divide the result by $3!2!$ which gives us 600600.

EXAMPLES:

```

sage: SetPartitions(3, [2,1]).cardinality()
3
sage: SetPartitions(13, Partition([3,3,3,2,2])).cardinality()
600600

```

parts

`self.parts` is deprecated; use `shape()` instead.

random_element()

Return a random set partition of `self`.

ALGORITHM:

Based on the cardinality method. For each block size k_i , we choose a uniformly random subset $X_i \subseteq S_i$ of size k_i of the elements S_i that have not yet been selected. Thus, we define $S_{i+1} = S_i \setminus X_i$ with $S_i = S$ being the defining set. This is not yet proven to be uniformly distributed, but numerical tests show this is likely uniform.

EXAMPLES:

```

sage: S = SetPartitions(10, [4,3,2,1])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s

sage: S = SetPartitions(["a", "b", "c", "d"], [2,2])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s

```

shape()

Return the partition of block sizes of the set partitions in `self`.

EXAMPLES:

```
sage: SetPartitions(5, [2,2,1]).shape()
[2, 2, 1]
```

`sage.combinat.set_partition.cyclic_permutations_of_set_partition(set_part)`

Return all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition
sage: cyclic_permutations_of_set_partition([[1,2,3,4],[5,6,7]])
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

`sage.combinat.set_partition.cyclic_permutations_of_set_partition_iterator(set_part)`

Iterates over all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition_
->iterator
sage: list(cyclic_permutations_of_set_partition_iterator([[1,2,3,4],[5,6,7]]))
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

5.1.275 Ordered Set Partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration)
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through `OrderedSetPartition`.

class `sage.combinat.set_partition_ordered.OrderedSetPartition`(*parent, s*)

Bases: `sage.structure.list_clone.ClonableArray`

An ordered partition of a set.

An ordered set partition p of a set s is a list of pairwise disjoint nonempty subsets of s such that the union of these subsets is s . These subsets are called the parts of the partition. We represent an ordered set partition as a list of sets. By extension, an ordered set partition of a nonnegative integer n is the set partition of the integers from 1 to n . The number of ordered set partitions of n is called the n -th ordered Bell number.

There is a natural integer composition associated with an ordered set partition, that is the sequence of sizes of all its parts in order.

The number T_n of ordered set partitions of $\{1, 2, \dots, n\}$ is the so-called n -th *Fubini number* (also known as the n -th ordered Bell number; see [Wikipedia article Ordered Bell number](#)). Its exponential generating function is

$$\sum_n \frac{T_n}{n!} x^n = \frac{1}{2 - e^x}.$$

(See sequence [OEIS sequence A000670](#) in OEIS.)

INPUT:

- `parts` – an object or iterable that defines an ordered set partition (e.g., a list of pairwise disjoint sets) or a packed word (e.g., a list of letters on some alphabet). If there is ambiguity and if the input should be treated as a packed word, the keyword `from_word` should be used.

EXAMPLES:

There are 13 ordered set partitions of $\{1, 2, 3\}$:

```
sage: OrderedSetPartitions(3).cardinality()
13
```

Here is the list of them:

```
sage: OrderedSetPartitions(3).list()
[[{1}, {2}, {3}],
 [{1}, {3}, {2}],
 [{2}, {1}, {3}],
 [{3}, {1}, {2}],
 [{2}, {3}, {1}],
 [{3}, {2}, {1}],
 [{1}, {2, 3}],
 [{2}, {1, 3}],
 [{3}, {1, 2}],
 [{1, 2}, {3}],
 [{1, 3}, {2}],
 [{2, 3}, {1}],
 [{1, 2, 3}]]
```

There are 12 ordered set partitions of $\{1, 2, 3, 4\}$ whose underlying composition is $[1, 2, 1]$:

```
sage: OrderedSetPartitions(4, [1, 2, 1]).list()
[[{1}, {2, 3}, {4}],
 [{1}, {2, 4}, {3}],
 [{1}, {3, 4}, {2}],
 [{2}, {1, 3}, {4}],
 [{2}, {1, 4}, {3}],
 [{3}, {1, 2}, {4}],
 [{4}, {1, 2}, {3}],
 [{3}, {1, 4}, {2}],
 [{4}, {1, 3}, {2}],
 [{2}, {3, 4}, {1}],
 [{3}, {2, 4}, {1}],
 [{4}, {2, 3}, {1}]]
```

Since [trac ticket #14140](#), we can create an ordered set partition directly by `OrderedSetPartition` which creates the parent object by taking the union of the partitions passed in. However it is recommended and (marginally) faster to create the parent first and then create the ordered set partition from that.

```
sage: s = OrderedSetPartition([[1, 3], [2, 4]]); s
[{1, 3}, {2, 4}]
sage: s.parent()
Ordered set partitions of {1, 2, 3, 4}
```

We can construct the ordered set partition from a word, which we consider as packed:

```
sage: OrderedSetPartition([2, 4, 1, 2])
[{3}, {1, 4}, {2}]
sage: OrderedSetPartition(from_word=[2, 4, 1, 2])
[{3}, {1, 4}, {2}]
sage: OrderedSetPartition(from_word='bdab')
[{3}, {1, 4}, {2}]
```

REFERENCES:

[Wikipedia article Ordered_partition_of_a_set](#)

`base_set()`

Return the base set of `self`, which is the union of all parts of `self`.

EXAMPLES:

```
sage: OrderedSetPartition([[1], [2, 3], [4]]).base_set()
{1, 2, 3, 4}
sage: OrderedSetPartition([[1, 2, 3, 4]]).base_set()
{1, 2, 3, 4}
sage: OrderedSetPartition([]).base_set()
{}
```

`base_set_cardinality()`

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of an ordered set partition.

EXAMPLES:

```
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: OrderedSetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

static bottom_up_osp(*X*, *comp*)

Return the ordered set partition obtained by listing the elements of the set *X* in increasing order, and placing bars between some of them according to the integer composition *comp* (namely, the bars are placed in such a way that the lengths of the resulting blocks are exactly the entries of *comp*).

INPUT:

- *X* – a finite set (or list or tuple)
- *comp* – a composition whose sum is the size of *X* (can be given as a list or tuple or composition)

EXAMPLES:

```
sage: buo = OrderedSetPartition.bottom_up_osp
sage: buo(Set([1, 4, 7, 9]), [2, 1, 1])
[{1, 4}, {7}, {9}]
sage: buo(Set([1, 4, 7, 9]), [1, 3])
[{1}, {4, 7, 9}]
sage: buo(Set([1, 4, 7, 9]), [1, 1, 1, 1])
[{1}, {4}, {7}, {9}]
sage: buo(range(8), [1, 4, 2, 1])
[{0}, {1, 2, 3, 4}, {5, 6}, {7}]
sage: buo([], [])
[]
```

check()

Check that we are a valid ordered set partition.

EXAMPLES:

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.check()
```

complement()

Return the complement of the ordered set partition *self*.

This assumes that *self* is an ordered set partition of an interval of \mathbf{Z} .

Let (P_1, P_2, \dots, P_k) be an ordered set partition of some interval *I* of \mathbf{Z} . Let ω be the unique strictly decreasing bijection $I \rightarrow I$. Then, the *complement* of (P_1, P_2, \dots, P_k) is defined to be the ordered set partition $(\omega(P_1), \omega(P_2), \dots, \omega(P_k))$.

EXAMPLES:

```
sage: OrderedSetPartition([[1, 2], [3]]).complement()
[{2, 3}, {1}]
sage: OrderedSetPartition([[1, 3], [2]]).complement()
[{1, 3}, {2}]
sage: OrderedSetPartition([[2, 3]]).complement()
[{2, 3}]
sage: OrderedSetPartition([[1, 5], [2, 3], [4]]).complement()
```

(continues on next page)

(continued from previous page)

```
[{1, 5}, {3, 4}, {2}]
sage: OrderedSetPartition([[ -1], [ -2], [1, 2], [0]]).complement()
[{1}, {2}, {-2, -1}, {0}]
sage: OrderedSetPartition([]).complement()
[]
```

fatten(grouping)

Return the ordered set partition fatter than `self`, obtained by grouping together consecutive parts according to the integer composition `grouping`.

See `finer()` for the definition of “fatter”.

INPUT:

- `grouping` – a composition whose sum is the length of `self`

EXAMPLES:

Let us start with the ordered set partition:

```
sage: c = OrderedSetPartition([[2, 5], [1], [3, 4]])
```

With `grouping` equal to $(1, \dots, 1)$, `c` is left unchanged:

```
sage: c.fatten(Composition([1,1,1]))
[{2, 5}, {1}, {3, 4}]
```

With `grouping` equal to (ℓ) where ℓ is the length of `c`, this yields the coarsest ordered set partition above `c`:

```
sage: c.fatten(Composition([3]))
[{1, 2, 3, 4, 5}]
```

Other values for `grouping` yield (all the) other ordered set partitions coarser than `c`:

```
sage: c.fatten(Composition([2,1]))
[{1, 2, 5}, {3, 4}]
sage: c.fatten(Composition([1,2]))
[{2, 5}, {1, 3, 4}]
```

fatter()

Return the set of ordered set partitions which are fatter than `self`.

See `finer()` for the definition of “fatter”.

EXAMPLES:

```
sage: C = OrderedSetPartition([[2, 5], [1], [3, 4]]).fatter()
sage: C.cardinality()
4
sage: sorted(C)
[[{1, 2, 3, 4, 5}],
 [{1, 2, 5}, {3, 4}],
 [{2, 5}, {1, 3, 4}],
 [{2, 5}, {1}, {3, 4}]]
```

(continues on next page)

(continued from previous page)

```
sage: OrderedSetPartition([[4, 9], [-1, 2]].fatter().list()
[[{4, 9}, {-1, 2}], [{-1, 2, 4, 9}]]
```

Some extreme cases:

```
sage: list(OrderedSetPartition([[5]]).fatter())
[[{5}]]
sage: list(Composition([]).fatter())
[[]]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).fatter())
[[{1, 2, 3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2}, {3}, {4}],
 [{1}, {2, 3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2}, {3}, {4}]]
```

finer()

Return the set of ordered set partitions which are finer than *self*.

See *is_finer()* for the definition of “finer”.

EXAMPLES:

```
sage: C = OrderedSetPartition([[1, 3], [2]]).finer()
sage: C.cardinality()
3
sage: C.list()
[[{1}, {3}, {2}], [{3}, {1}, {2}], [{1, 3}, {2}]]

sage: OrderedSetPartition([]).finer()
{[]}

sage: W = OrderedSetPartition([[4, 9], [-1, 2]])
sage: W.finer().list()
[[{9}, {4}, {2}, {-1}],
 [{9}, {4}, {-1}, {2}],
 [{9}, {4}, {-1, 2}],
 [{4}, {9}, {2}, {-1}],
 [{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {2}, {-1}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]
```

is_finer(co2)

Return True if the ordered set partition *self* is finer than the ordered set partition *co2*; otherwise, return False.

If *A* and *B* are two ordered set partitions of the same set, then *A* is said to be *finer* than *B* if *B* can be obtained from *A* by (repeatedly) merging consecutive parts. In this case, we say that *B* is *fatter* than *A*.

EXAMPLES:

```

sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_finer(B)
False
sage: B.is_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_finer(C)
False
sage: C.is_finer(A)
True
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_
↳ finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_
↳ finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_
↳ finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_finer(OrderedSetPartition([[2,
↳ 5], [1, 4]]))
False

```

is_strongly_finer(co2)

Return True if the ordered set partition `self` is strongly finer than the ordered set partition `co2`; otherwise, return False.

If A and B are two ordered set partitions of the same set, then A is said to be *strongly finer* than B if B can be obtained from A by (repeatedly) merging consecutive parts, provided that every time we merge two consecutive parts C_i and C_{i+1} , we have $\max C_i < \min C_{i+1}$. In this case, we say that B is *strongly fatter* than A .

EXAMPLES:

```

sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_strongly_finer(B)
False
sage: B.is_strongly_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_strongly_finer(C)
False
sage: C.is_strongly_finer(A)
False
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_strongly_
↳ finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_strongly_
↳ finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_strongly_
↳ finer(OrderedSetPartition([[2, 5], [1, 4]]))
False

```

(continues on next page)

(continued from previous page)

```
False
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_strongly_
↳ finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
```

length()

Return the number of parts of `self`.

EXAMPLES:

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.length()
2
```

number_of_inversions()

Return the number of inversions in `self`.

An inversion of an ordered set partition with blocks $[B_1, B_2, \dots, B_k]$ is a pair of letters i and j with $i < j$ such that i is minimal in B_m , $j \in B_l$, and $l < m$.

REFERENCES:

- [Wilson2016]

EXAMPLES:

```
sage: OrderedSetPartition([[2,5],[4,6],[1,3]]).number_of_inversions()
5
sage: OrderedSetPartition([[1,3,8],[2,4],[5,6,7]]).number_of_inversions()
3
```

reversed()

Return the reversal of the ordered set partition `self`.

The *reversal* of an ordered set partition (P_1, P_2, \dots, P_k) is defined to be the ordered set partition $(P_k, P_{k-1}, \dots, P_1)$.

EXAMPLES:

```
sage: OrderedSetPartition([[1, 3], [2]]).reversed()
[2], [1, 3]
sage: OrderedSetPartition([[1, 5], [2, 4]]).reversed()
[2, 4], [1, 5]
sage: OrderedSetPartition([-1], [-2], [3, 4], [0]).reversed()
[0], [3, 4], [-2], [-1]
sage: OrderedSetPartition([]).reversed()
[]
```

size()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of an ordered set partition.

EXAMPLES:

```
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: OrderedSetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

strongly_fatter()

Return the set of ordered set partitions which are strongly fatter than self.

See *strongly_finer()* for the definition of “strongly fatter”.

EXAMPLES:

```
sage: C = OrderedSetPartition([[2, 5], [1], [3, 4]]).strongly_fatter()
sage: C.cardinality()
2
sage: sorted(C)
[[{2, 5}, {1, 3, 4}],
 [{2, 5}, {1}, {3, 4}]]

sage: OrderedSetPartition([[4, 9], [-1, 2]]).strongly_fatter().list()
[[{4, 9}, {-1, 2}]]
```

Some extreme cases:

```
sage: list(OrderedSetPartition([[5]]).strongly_fatter())
[[{5}]]
sage: list(OrderedSetPartition([]).strongly_fatter())
[[]]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).strongly_fatter())
[[{1, 2, 3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2}, {3}, {4}],
 [{1}, {2, 3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2}, {3}, {4}]]
sage: sorted(OrderedSetPartition([[1], [3], [2], [4]]).strongly_fatter())
[[{1, 3}, {2, 4}],
 [{1, 3}, {2}, {4}],
 [{1}, {3}, {2, 4}],
 [{1}, {3}, {2}, {4}]]
sage: sorted(OrderedSetPartition([[4], [1], [5], [3]]).strongly_fatter())
[[{4}, {1, 5}, {3}], [{4}, {1}, {5}, {3}]]
```

strongly_finer()

Return the set of ordered set partitions which are strongly finer than self.

See *is_strongly_finer()* for the definition of “strongly finer”.

EXAMPLES:

```
sage: C = OrderedSetPartition([[1, 3], [2]]).strongly_finer()
sage: C.cardinality()
2
```

(continues on next page)

(continued from previous page)

```

sage: C.list()
[[{1}, {3}, {2}], [{1, 3}, {2}]]

sage: OrderedSetPartition([]).strongly_finer()
{[]}

sage: W = OrderedSetPartition([[4, 9], [-1, 2]])
sage: W.strongly_finer().list()
[[{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]

```

static sum(osps)

Return the concatenation of the given ordered set partitions osps (provided they have no elements in common).

INPUT:

- osps – a list (or iterable) of ordered set partitions

EXAMPLES:

```

sage: OrderedSetPartition.sum([OrderedSetPartition([[4, 1], [3]]),
OrderedSetPartition([[7], [2]]), OrderedSetPartition([[5, 6]])])
[{1, 4}, {3}, {7}, {2}, {5, 6}]

```

Any iterable can be provided as input:

```

sage: Composition.sum([OrderedSetPartition([[2*i, 2*i+1]]) for i in [4,1,3]])
[{8, 9}, {2, 3}, {6, 7}]

```

Empty inputs are handled gracefully:

```

sage: OrderedSetPartition.sum([]) == OrderedSetPartition([])
True

```

to_composition()

Return the integer composition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```

sage: S = OrderedSetPartitions(5)
sage: x = S([[3,5,4], [1, 2]])
sage: x.to_composition()
[3, 2]
sage: y = S([[3,1], [2], [5,4]])
sage: y.to_composition()
[2, 1, 2]

```

to_packed_word()

Return the packed word on alphabet $\{1, 2, 3, \dots\}$ corresponding to `self`.

A *packed word* on alphabet $\{1, 2, 3, \dots\}$ is any word whose maximum letter is the same as its total number of distinct letters. Let P be an ordered set partition of a set X . The corresponding packed word $w_1 w_2 \cdots w_n$ is constructed by having letter $w_i = j$ if the i -th smallest entry in X occurs in the j -th block of P .

See also:

Word.to_ordered_set_partition()

Warning: This assumes there is a total order on the underlying set (self._base_set).

EXAMPLES:

```

sage: S = OrderedSetPartitions()
sage: x = S([[3,5], [2], [1,4,6]])
sage: x.to_packed_word()
word: 321313
sage: x = S([[ 'a', 'c', 'e' ], [ 'b', 'd' ]])
sage: x.to_packed_word()
word: 12121

```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions**(*s*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Return the combinatorial class of ordered set partitions of *s*.

The optional argument *c*, if specified, restricts the parts of the partition to have certain sizes (the entries of *c*).

EXAMPLES:

```

sage: OS = OrderedSetPartitions([1,2,3,4]); OS
Ordered set partitions of {1, 2, 3, 4}
sage: OS.cardinality()
75
sage: OS.first()
[ {1}, {2}, {3}, {4} ]
sage: OS.last()
[ {1, 2, 3, 4} ]
sage: OS.random_element().parent() is OS
True

```

```

sage: OS = OrderedSetPartitions([1,2,3,4], [2,2]); OS
Ordered set partitions of {1, 2, 3, 4} into parts of size [2, 2]
sage: OS.cardinality()
6
sage: OS.first()
[ {1, 2}, {3, 4} ]
sage: OS.last()
[ {3, 4}, {1, 2} ]
sage: OS.list()
[[ {1, 2}, {3, 4} ],
 [ {1, 3}, {2, 4} ],
 [ {1, 4}, {2, 3} ],
 [ {2, 3}, {1, 4} ],
 [ {2, 4}, {1, 3} ],
 [ {3, 4}, {1, 2} ] ]

```

```

sage: OS = OrderedSetPartitions("cat")
sage: OS # random
Ordered set partitions of {'a', 't', 'c'}
sage: sorted(OS.list(), key=str)
[[{'a', 'c', 't'}],
 [ {'a', 'c'}, {'t'}],
 [ {'a', 't'}, {'c'}],
 [ {'a'}, {'c', 't'}],
 [ {'a'}, {'c'}, {'t'}],
 [ {'a'}, {'t'}, {'c'}],
 [ {'c', 't'}, {'a'}],
 [ {'c'}, {'a', 't'}],
 [ {'c'}, {'a'}, {'t'}],
 [ {'c'}, {'t'}, {'a'}],
 [ {'t'}, {'a', 'c'}],
 [ {'t'}, {'a'}, {'c'}],
 [ {'t'}, {'c'}, {'a'}]]

```

Elementalias of *OrderedSetPartition***from_finite_word(*w*)**Return the unique ordered set partition of $\{1, 2, \dots, n\}$ corresponding to a word w of length n .**See also:**`Word.to_ordered_set_partition()`**EXAMPLES:**

```

sage: A = OrderedSetPartitions().from_finite_word('abcabcabd'); A
[ {1, 4, 7}, {2, 5, 8}, {3, 6}, {9} ]
sage: B = OrderedSetPartitions().from_finite_word([1,2,3,1,2,3,1,2,4])
sage: A == B
True

```

class `sage.combinat.set_partition_ordered.OrderedSetPartitions_all`Bases: *sage.combinat.set_partition_ordered.OrderedSetPartitions*Ordered set partitions of $\{1, \dots, n\}$ for all $n \in \mathbf{Z}_{\geq 0}$.**class** `Element`(*parent*, *s*)Bases: *sage.combinat.set_partition_ordered.OrderedSetPartition***subset**(*size=None*, ***kwargs*)

Return the subset of ordered set partitions of a given size and additional keyword arguments.

EXAMPLES:

```

sage: P = OrderedSetPartitions()
sage: P.subset(4)
Ordered set partitions of {1, 2, 3, 4}

```

class `sage.combinat.set_partition_ordered.OrderedSetPartitions_s(s)`Bases: *sage.combinat.set_partition_ordered.OrderedSetPartitions*Class of ordered partitions of a set S .

cardinality()

EXAMPLES:

```

sage: OrderedSetPartitions(0).cardinality()
1
sage: OrderedSetPartitions(1).cardinality()
1
sage: OrderedSetPartitions(2).cardinality()
3
sage: OrderedSetPartitions(3).cardinality()
13
sage: OrderedSetPartitions([1,2,3]).cardinality()
13
sage: OrderedSetPartitions(4).cardinality()
75
sage: OrderedSetPartitions(5).cardinality()
541

```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_scomp**(*s, comp*)

Bases: *sage.combinat.set_partition_ordered.OrderedSetPartitions*

cardinality()

Return the cardinality of self.

The number of ordered set partitions of a set of length k with composition shape μ is equal to

$$\frac{k!}{\prod_{\mu_i \neq 0} \mu_i!}$$

EXAMPLES:

```

sage: OrderedSetPartitions(5, [2,3]).cardinality()
10
sage: OrderedSetPartitions(0, []).cardinality()
1
sage: OrderedSetPartitions(0, [0]).cardinality()
1
sage: OrderedSetPartitions(0, [0,0]).cardinality()
1
sage: OrderedSetPartitions(5, [2,0,3]).cardinality()
10

```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_sn**(*s, n*)

Bases: *sage.combinat.set_partition_ordered.OrderedSetPartitions*

cardinality()

Return the cardinality of self.

The number of ordered partitions of a set of size n into k parts is equal to $k!S(n, k)$ where $S(n, k)$ denotes the Stirling number of the second kind.

EXAMPLES:

```

sage: OrderedSetPartitions(4,2).cardinality()
14
sage: OrderedSetPartitions(4,1).cardinality()
1

```

```
class sage.combinat.set_partition_ordered.SplitNK(s, comp)
    Bases: sage.combinat.set_partition_ordered.OrderedSetPartitions_scomp
```

5.1.277 Characters of the symmetric group as bases of the symmetric functions

Just as the Schur functions are the irreducible characters of Gl_n and form a basis of the symmetric functions, the irreducible symmetric group character basis are the irreducible characters of S_n when the group is realized as the permutation matrices.

REFERENCES:

class sage.combinat.sf.character.**generic_character**(Sym, basis_name=None, prefix=None, graded=True)

Bases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic*

class sage.combinat.sf.character.**induced_trivial_character_basis**(Sym, pfix)

Bases: *sage.combinat.sf.character.generic_character*

The induced trivial symmetric group character basis of the symmetric functions.

This is a basis of the symmetric functions that has the property that `self(la).character_to_frobenius_image(n)` is equal to `h([n-sum(la)]+la)`.

It has the property that the (outer) structure constants are the analogue of the stable Kronecker coefficients on the complete basis.

This basis is introduced in [OZ2015].

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: ht = SymmetricFunctions(QQ).ht()
sage: st = SymmetricFunctions(QQ).st()
sage: ht(s[2,1])
ht[1, 1] + ht[2, 1] - ht[3]
sage: s(ht[2,1])
s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1] + s[3]
sage: ht(h[2,1])
ht[1] + 2*ht[1, 1] + ht[2, 1]
sage: h(ht[2,1])
h[1] - 2*h[1, 1] + h[2, 1]
sage: st(ht[2,1])
st[] + 2*st[1] + st[1, 1] + 2*st[2] + st[2, 1] + st[3]
sage: ht(st[2,1])
ht[1] - ht[1, 1] + ht[2, 1] - ht[3]
sage: ht[2]*ht[1,1]
ht[1, 1] + 2*ht[1, 1, 1] + ht[2, 1, 1]
sage: h[4,2].kronecker_product(h[4,1,1])
h[2, 2, 1, 1] + 2*h[3, 1, 1, 1] + h[4, 1, 1]
sage: s(st[2,1])
3*s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1]
sage: st(s[2,1])
st[] + 3*st[1] + 2*st[1, 1] + 2*st[2] + st[2, 1]
sage: st[2]*st[1]
st[1] + st[1, 1] + st[2] + st[2, 1] + st[3]
sage: s[4,2].kronecker_product(s[5,1])
s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2] + s[5, 1]
```

class `sage.combinat.sf.character.irreducible_character_basis`(*Sym, prefix*)

Bases: `sage.combinat.sf.character.generic_character`

The irreducible symmetric group character basis of the symmetric functions.

This is a basis of the symmetric functions that has the property that `self(la).character_to_frobenius_image(n)` is equal to `s([n-sum(la)]+la)`.

It should also have the property that the (outer) structure constants are the analogue of the stable Kronecker coefficients on the Schur basis.

This basis is introduced in [OZ2015].

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: ht = SymmetricFunctions(QQ).ht()
sage: st = SymmetricFunctions(QQ).st()
sage: st(ht[2,1])
st[] + 2*st[1] + st[1, 1] + 2*st[2] + st[2, 1] + st[3]
sage: ht(st[2,1])
ht[1] - ht[1, 1] + ht[2, 1] - ht[3]
sage: s(st[2,1])
3*s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1]
sage: st(s[2,1])
st[] + 3*st[1] + 2*st[1, 1] + 2*st[2] + st[2, 1]
sage: st[2]*st[1]
st[1] + st[1, 1] + st[2] + st[2, 1] + st[3]
sage: s[4,2].kronecker_product(s[5,1])
s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2] + s[5, 1]
sage: st[1,1,1].counit()
-1
sage: all(sum(c*st(la)*st(mu).antipode() for
.....:      ((la,mu),c) in st(ga).coproduct())==st(st(ga).counit())
.....:      for ga in Partitions(3))
True
```

5.1.278 Classical symmetric functions

class `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`(*Sym, basis_name=None, prefix=None, graded=True*)

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

The class of classical symmetric functions.

Todo: delete this class once all coercions will be handled by Sage's coercion model

class `Element`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

A symmetric function.

```
sage.combinat.sf.classical.init()
Set up the conversion functions between the classical bases.
```

EXAMPLES:

```
sage: from sage.combinat.sf.classical import init
sage: sage.combinat.sf.classical.conversion_functions = {}
sage: init()
sage: sage.combinat.sf.classical.conversion_functions[('Schur', 'powersum')]
<built-in function t_SCHUR_POWSYM_symmetrica>
```

The following checks if the bug described in [trac ticket #15312](#) is fixed.

```
sage: change = sage.combinat.sf.classical.conversion_functions[('powersum', 'Schur
↔')]
sage: hideme = change({Partition([1]*47):ZZ(1)}) # long time
sage: change({Partition([2,2]):QQ(1)})
s[1, 1, 1, 1] - s[2, 1, 1] + 2*s[2, 2] - s[3, 1] + s[4]
```

5.1.279 Generic dual bases symmetric functions

```
class sage.combinat.sf.dual.SymmetricFunctionAlgebra_dual(dual_basis, scalar, scalar_name="",
                                                         basis_name=None, prefix=None)
```

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`

Generic dual basis of a basis of symmetric functions.

INPUT:

- `dual_basis` – a basis of the ring of symmetric functions
- `scalar` – A function z on partitions which determines the scalar product on the power sum basis by $\langle p_\mu, p_\mu \rangle = z(\mu)$. (Independently on the function chosen, the power sum basis will always be orthogonal; the function `scalar` only determines the norms of the basis elements.) This defaults to the function `zee` defined in `sage.combinat.sf.sfa`, that is, the function is defined by:

$$\lambda \mapsto \prod_{i=1}^{\infty} m_i(\lambda)! i^{m_i(\lambda)^i},$$

where $m_i(\lambda)$ means the number of times i appears in λ . This default function gives the standard Hall scalar product on the ring of symmetric functions.

- `scalar_name` – (default: the empty string) a string giving a description of the scalar product specified by the parameter `scalar`
- `basis_name` – (optional) a string to serve as name for the basis to be generated (such as “forgotten” in “the forgotten basis”); don’t set it to any of the already existing basis names (such as `homogeneous`, `monomial`, `forgotten`, etc.).
- `prefix` – (default: ‘d’ and the prefix for `dual_basis`) a string to use as the symbol for the basis

OUTPUT:

The basis of the ring of symmetric functions dual to the basis `dual_basis` with respect to the scalar product determined by `scalar`.

EXAMPLES:

```

sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(prefix = "m", basis_name="Forgotten symmetric functions"); f
Symmetric Functions over Rational Field in the Forgotten symmetric functions basis
sage: TestSuite(f).run(elements = [f[1,1]+2*f[2], f[1]+3*f[1,1]])
sage: TestSuite(f).run() # long time (11s on sage.math, 2011)

```

This class defines canonical coercions between `self` and `self^*`, as follow:

Lookup for the canonical isomorphism from `self` to P (=powersum), and build the adjoint isomorphism from P^* to `self^*`. Since P is self-adjoint for this scalar product, derive an isomorphism from P to `self^*`, and by composition with the above get an isomorphism from `self` to `self^*` (and similarly for the isomorphism `self^*` to `self`).

This should be striped down to just (auto?) defining canonical isomorphism by adjunction (as in MuPAD-Combinat), and let the coercion handle the rest.

Inversions may not be possible if the base ring is not a field:

```

sage: m = SymmetricFunctions(ZZ).m()
sage: h = m.dual_basis(lambda x: 1)
sage: h[2,1]
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer

```

By transitivity, this defines indirect coercions to and from all other bases:

```

sage: s = SymmetricFunctions(QQ['t'].fraction_field()).s()
sage: t = QQ['t'].fraction_field().gen()
sage: zee_hl = lambda x: x.centralizer_size(t=t)
sage: S = s.dual_basis(zee_hl)
sage: S(s([2,1]))
(-t/(t^5-2*t^4+t^3-t^2+2*t-1))*d_s[1, 1, 1] + ((-t^2-1)/(t^5-2*t^4+t^3-t^2+2*t-
↪ 1))*d_s[2, 1] + (-t/(t^5-2*t^4+t^3-t^2+2*t-1))*d_s[3]

```

class Element(*A*, *dictionary=None*, *dual=None*)

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

An element in the dual basis.

INPUT:

At least one of the following must be specified. The one (if any) which is not provided will be computed.

- `dictionary` – an internal dictionary for the monomials and coefficients of `self`
- `dual` – `self` as an element of the dual basis.

dual()

Return `self` in the dual basis.

OUTPUT:

- the element `self` expanded in the dual basis to `self.parent()`

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)

```

(continues on next page)

(continued from previous page)

```

sage: a = h([2,1])
sage: a.parent()
Dual basis to Symmetric Functions over Rational Field in the monomial basis
sage: a.dual()
3*m[1, 1, 1] + 2*m[2, 1] + m[3]

```

expand(*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the *n* variables labelled by *alphabet*.

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: a = h([2,1])+h([3])
sage: a.expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
sage: a.dual().expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
sage: a.expand(2,alphabet='y')
2*y0^3 + 3*y0^2*y1 + 3*y0*y1^2 + 2*y1^3
sage: a.expand(2,alphabet='x,y')
2*x^3 + 3*x^2*y + 3*x*y^2 + 2*y^3
sage: h([1]).expand(0)
0
sage: (3*h([])).expand(0)
3

```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers *k* (where e_k stands for the *k*-th elementary symmetric function, and h_k stands for the *k*-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer *k*.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'}$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the result of applying omega to `self`

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: hh = SymmetricFunctions(QQ).homogeneous()
sage: hh([2,1]).omega()
h[1, 1, 1] - h[2, 1]
sage: h([2,1]).omega()
d_m[1, 1, 1] - d_m[2, 1]

```

omega_involution()Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the result of applying omega to `self`

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: hh = SymmetricFunctions(QQ).homogeneous()
sage: hh([2,1]).omega()
h[1, 1, 1] - h[2, 1]
sage: h([2,1]).omega()
d_m[1, 1, 1] - d_m[2, 1]

```

scalar(x)Return the standard scalar product of `self` and `x`.

INPUT:

- `x` – element of the symmetric functions

OUTPUT:

- the scalar product between `x` and `self`

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])

```

(continues on next page)

(continued from previous page)

```
sage: a.scalar(a)
2
```

scalar_hl(*x*)

Return the Hall-Littlewood scalar product of `self` and `x`.

INPUT:

- `x` – element of the same dual basis as `self`

OUTPUT:

- the Hall-Littlewood scalar product between `x` and `self`

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2, 1])
sage: a.scalar_hl(a)
(-t - 2)/(t^4 - 2*t^3 + 2*t - 1)
```

product(*left*, *right*)

Return product of `left` and `right`.

Multiplication is done by performing the multiplication in the dual basis of `self` and then converting back to `self`.

INPUT:

- `left`, `right` – elements of `self`

OUTPUT:

- the product of `left` and `right` in the basis `self`

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2])
sage: b = a*a; b # indirect doctest
d_m[2, 2]
sage: b.dual()
6*m[1, 1, 1, 1] + 4*m[2, 1, 1] + 3*m[2, 2] + 2*m[3, 1] + m[4]
```

transition_matrix(*basis*, *n*)

Returns the transition matrix between the n^{th} homogeneous components of `self` and `basis`.

INPUT:

- `basis` – a target basis of the ring of symmetric functions
- `n` – nonnegative integer

OUTPUT:

- A transition matrix from `self` to `basis` for the elements of degree `n`. The indexing order of the rows and columns is the order of `Partitions(n)`.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: e = Sym.elementary()
sage: f = e.dual_basis()
sage: f.transition_matrix(s, 5)
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
sage: Partitions(5).list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: s(f[2,2,1])
s[3, 2] - 2*s[4, 1] + 3*s[5]
sage: e.transition_matrix(s, 5).inverse().transpose()
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]

```

5.1.280 Elementary symmetric functions

```

class sage.combinat.sf.elementary.SymmetricFunctionAlgebra_elementary(Sym)
    Bases: sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative

```

A class for methods for the elementary basis of the symmetric functions.

INPUT:

- `self` – an elementary basis of the symmetric functions
- `Sym` – an instance of the ring of symmetric functions

```
class Element
```

```
    Bases: sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element
```

```
    expand(n, alphabet='x')
```

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` – a nonnegative integer
- `alphabet` – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the `n` variables labelled by `alphabet`.

EXAMPLES:

```

sage: e = SymmetricFunctions(QQ).e()
sage: e([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 3*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2

```

(continues on next page)

(continued from previous page)

```

sage: e([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: e([3]).expand(2)
0
sage: e([2]).expand(3)
x0*x1 + x0*x2 + x1*x2
sage: e([3]).expand(4,alphabet='x,y,z,t')
x*y*z + x*y*t + x*z*t + y*z*t
sage: e([3]).expand(4,alphabet='y')
y0*y1*y2 + y0*y1*y3 + y0*y2*y3 + y1*y2*y3
sage: e([]).expand(2)
1
sage: e([]).expand(0)
1
sage: (3*e([])).expand(0)
3

```

exponential_specialization(*t=None, q=1*)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q -exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R . It is defined whenever the base ring K is a \mathbf{Q} -algebra and t is an element of R . The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q -exponential specialization is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q -factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n , we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see [principal_specialization\(\)](#)). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \rightarrow 1$ is ex .

INPUT:

- t (default: None) – the value to use for t ; the default is to create a ring of polynomials in t .
- q (default: 1) – the value to use for q . If q is None, then a ring (or fraction field) of polynomials in q is created.

EXAMPLES:

```

sage: e = SymmetricFunctions(QQ).e()
sage: x = e[3,2]
sage: x.exponential_specialization()
1/12*t^5
sage: x = 5*e[2] + 3*e[1] + 1

```

(continues on next page)

(continued from previous page)

```
sage: x.exponential_specialization(t=var("t"), q=var("q"))
5*q*t^2/(q + 1) + 3*t + 1
```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2,1]).omega())
h[2, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2,1]).omega())
h[2, 1]
```

principal_specialization($n=+\infty$, $q=None$)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \dots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R , and we assume that the variables of our symmetric functions are x_1, x_2, x_3, \dots . (To be more precise, $ps_{n,q}$ is a K -algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i . This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- n (default: `infinity`) – a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order n or the stable principal specialization.
- q (default: `None`) – the value to use for q ; the default is to create a ring of polynomials in q (or a field of rational functions in q) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2] (using Gaussian binomial coefficients $\binom{u}{v}_q$):

$$ps_{n,q}(e_\lambda) = \prod_i q^{\binom{\lambda_i}{2}} \binom{n}{\lambda_i}_q,$$

$$ps_{n,1}(e_\lambda) = \prod_i \binom{n}{\lambda_i},$$

$$ps_q(e_\lambda) = \prod_i q^{\binom{\lambda_i}{2}} / \prod_{j=1}^{\lambda_i} (1 - q^j).$$

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: x = e[3,1]
sage: x.principal_specialization(3)
q^5 + q^4 + q^3
sage: x = 5*e[1,1,1] + 3*e[2,1] + 1
sage: x.principal_specialization(3)
5*q^6 + 18*q^5 + 36*q^4 + 44*q^3 + 36*q^2 + 18*q + 6
```

By default, we return a rational functions in q . Sometimes it is better to obtain an element of the symbolic ring:

```
sage: x.principal_specialization(q=var("q"))
-3*q/((q^2 - 1)*(q - 1)^2) - 5/(q - 1)^3 + 1
```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator \mathbf{V}_n is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator \mathbf{V}_n is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: e[3].verschiebung(2)
0
sage: e[4].verschiebung(4)
-e[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( e(lam).verschiebung(2) * e(mu).verschiebung(2)
.....:          == (e(lam) * e(mu)).verschiebung(2)
```

(continues on next page)

(continued from previous page)

```

.....:         for mu in Partitions(4) )
.....:         for lam in Partitions(4) )
True

```

coproduct_on_generators(*i*)Returns the coproduct on `self[i]`.

INPUT:

- `self` – an elementary basis of the symmetric functions
- `i` – a nonnegative integer

OUTPUT:

- returns the coproduct on the elementary generator $e(i)$

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: e = Sym.elementary()
sage: e.coproduct_on_generators(2)
e[] # e[2] + e[1] # e[1] + e[2] # e[]
sage: e.coproduct_on_generators(0)
e[] # e[]

```

5.1.281 Hall-Littlewood Polynomials

Notation used in the definitions follows mainly [Mac1995].

class `sage.combinat.sf.hall_littlewood.HallLittlewood(Sym, t='t')`Bases: `sage.structure.unique_representation.UniqueRepresentation`

The family of Hall-Littlewood symmetric function bases.

The Hall-Littlewood symmetric functions are a family of symmetric functions that depend on a parameter t .

INPUT:

By default the parameter for these functions is t , and whatever the parameter is, it must be in the base ring.

EXAMPLES:

```

sage: SymmetricFunctions(QQ).hall_littlewood(1)
Hall-Littlewood polynomials with t=1 over Rational Field
sage: SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood()
Hall-Littlewood polynomials over Fraction Field of Univariate Polynomial Ring in t_
↪ over Rational Field

```

P()Return the algebra of symmetric functions in the Hall-Littlewood P basis. This is the same as the HLL basis in John Stembridge's SF examples file.

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

The class of the Hall-Littlewood P basis.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P(); HLP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Hall-Littlewood P basis
sage: SP = Sym.hall_littlewood(t=-1).P(); SP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Hall-Littlewood P with t=-1 basis
sage: s = Sym.schur()
sage: s(HLP([2,1]))
(-t^2-t)*s[1, 1, 1] + s[2, 1]

```

The Hall-Littlewood polynomials in the P basis at $t = 0$ are the Schur functions:

```

sage: Sym = SymmetricFunctions(QQ)
sage: HLP = Sym.hall_littlewood(t=0).P()
sage: s = Sym.schur()
sage: s(HLP([2,1])) == s([2,1])
True

```

The Hall-Littlewood polynomials in the P basis at $t = 1$ are the monomial symmetric functions:

```

sage: Sym = SymmetricFunctions(QQ)
sage: HLP = Sym.hall_littlewood(t=1).P()
sage: m = Sym.monomial()
sage: m(HLP([2,2,1])) == m([2,2,1])
True

```

We end with some examples of coercions between:

1. Hall-Littlewood P basis.
2. Hall-Littlewood polynomials in the Q basis
3. Hall-Littlewood polynomials in the Q' basis (via the Schurs)
4. Classical symmetric functions

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.schur()
sage: p = Sym.power()
sage: HLP(HLQ([2])) # indirect doctest
(-t+1)*HLP[2]
sage: HLP(HLQp([2]))
t*HLP[1, 1] + HLP[2]
sage: HLP(s([2]))
t*HLP[1, 1] + HLP[2]
sage: HLP(p([2]))
(t-1)*HLP[1, 1] + HLP[2]
sage: s = HLQp.symmetric_function_ring().s()
sage: HLQp.transition_matrix(s,3)
[ 1 0 0]

```

(continues on next page)

(continued from previous page)

```

[      t      1      0]
[    t^3 t^2 + t      1]
sage: s.transition_matrix(HLP,3)
[      1      t      t^3]
[      0      1 t^2 + t]
[      0      0      1]

```

The method `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element.h1_creation_operator()` is a creation operator for the Q basis:

```

sage: HLQp[1].h1_creation_operator([3]).h1_creation_operator([3])
HLQp[3, 3, 1]

```

Transitions between bases with the parameter t specialized:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['y','z']))
sage: (y,z) = Sym.base_ring().gens()
sage: HLy = Sym.hall_littlewood(t=y)
sage: HLz = Sym.hall_littlewood(t=z)
sage: Qpy = HLy.Qp()
sage: Qpz = HLz.Qp()
sage: s = Sym.schur()
sage: s( Qpy[3,1] + z*Qpy[2,2] )
z*s[2, 2] + (y*z+1)*s[3, 1] + (y^2*z+y)*s[4]
sage: s( Qpy[3,1] + y*Qpz[2,2] )
y*s[2, 2] + (y*z+1)*s[3, 1] + (y*z^2+y)*s[4]
sage: s( Qpy[3,1] + y*Qpy[2,2] )
y*s[2, 2] + (y^2+1)*s[3, 1] + (y^3+y)*s[4]

sage: Qy = HLy.Q()
sage: Qz = HLz.Q()
sage: Py = HLy.P()
sage: Pz = HLz.P()
sage: Pz(Qpy[2,1])
(y*z^3+z^2+z)*HLP[1, 1, 1] + (y*z+1)*HLP[2, 1] + y*HLP[3]
sage: Pz(Qz[2,1])
(z^2-2*z+1)*HLP[2, 1]
sage: Qz(Py[2])
((-y+z)/(z^3-z^2-z+1))*HLQ[1, 1] + (1/(-z+1))*HLQ[2]
sage: Qy(Pz[2])
((-y-z)/(y^3-y^2-y+1))*HLQ[1, 1] + (1/(-y+1))*HLQ[2]
sage: Qy.hall_littlewood_family() == HLy
True
sage: Qy.hall_littlewood_family() == HLz
False
sage: Qz.symmetric_function_ring() == Qy.symmetric_function_ring()
True

sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
sage: q = Sym.base_ring().gen()
sage: HL = Sym.hall_littlewood(t=q)
sage: HLQp = HL.Qp()

```

(continues on next page)

(continued from previous page)

```

sage: HLQ = HL.Q()
sage: HLP = HL.P()
sage: s = Sym.schur()
sage: s(HLQp[3,2].plethysm((1-q)*s[1]))/(1-q)^2
(-q^5-q^4)*s[1, 1, 1, 1, 1] + (q^3+q^2)*s[2, 1, 1, 1] - q*s[2, 2, 1] - q*s[3, 1,
↪ 1] + s[3, 2]
sage: s(HLP[3,2])
(-q^5-q^4)*s[1, 1, 1, 1, 1] + (q^3+q^2)*s[2, 1, 1, 1] - q*s[2, 2, 1] - q*s[3, 1,
↪ 1] + s[3, 2]

```

The P and Q -Schur at $t = -1$ indexed by strict partitions are a basis for the space algebraically generated by the odd power sum symmetric functions:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
sage: SP = Sym.hall_littlewood(t=-1).P()
sage: SQ = Sym.hall_littlewood(t=-1).Q()
sage: p = Sym.power()
sage: SP(SQ[3,2,1])
8*HLP[3, 2, 1]
sage: SP(SQ[2,2,1])
0
sage: p(SP[3,2,1])
1/45*p[1, 1, 1, 1, 1, 1] - 1/9*p[3, 1, 1, 1] - 1/9*p[3, 3] + 1/5*p[5, 1]
sage: SP(p[3,3])
-4*HLP[3, 2, 1] + 2*HLP[4, 2] - 2*HLP[5, 1] + HLP[6]
sage: SQ( SQ[1]*SQ[3] -2*(1-q)*SQ[4] )
HLQ[3, 1] + 2*q*HLQ[4]

```

QC

Returns the algebra of symmetric functions in Hall-Littlewood Q basis. This is the same as the Q basis in John Stembridge's SF examples file.

More extensive examples can be found in the documentation for the Hall-Littlewood P basis.

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the class of the Hall-Littlewood Q basis

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQ = Sym.hall_littlewood().Q(); HLQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪ Rational Field in the Hall-Littlewood Q basis
sage: SQ = SymmetricFunctions(QQ).hall_littlewood(t=-1).Q(); SQ
Symmetric Functions over Rational Field in the Hall-Littlewood Q with t=-1 basis

```

Qp

Returns the algebra of symmetric functions in Hall-Littlewood Q' (Qp) basis. This is dual to the Hall-Littlewood P basis with respect to the standard scalar product.

More extensive examples can be found in the documentation for the Hall-Littlewood P basis.

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the class of the Hall-Littlewood Qp -basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQp = Sym.hall_littlewood().Qp(); HLQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪Rational Field in the Hall-Littlewood Qp basis
```

base_ring()

Returns the base ring of the symmetric functions where the Hall-Littlewood symmetric functions live

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

The base ring of the symmetric functions.

EXAMPLES:

```
sage: HL = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood(t=1)
sage: HL.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

symmetric_function_ring()

The ring of symmetric functions associated to the class of Hall-Littlewood symmetric functions

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT:

- returns the ring of symmetric functions

EXAMPLES:

```
sage: HL = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood()
sage: HL.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪Rational Field
```

class `sage.combinat.sf.hall_littlewood.HallLittlewood_generic`(*hall_littlewood*)

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

A class with methods for working with Hall-Littlewood symmetric functions which are common to all bases.

INPUT:

- `self` – a Hall-Littlewood symmetric function basis
- `hall_littlewood` – a class of Hall-Littlewood bases

class `Element`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

Methods for elements of a Hall-Littlewood basis that are common to all bases.

expand(*n*, *alphabet*='x')

Expands the symmetric function as a symmetric polynomial in *n* variables.

INPUT:

- *self* – an element of a Hall-Littlewood basis
- *n* – a positive integer
- *alphabet* – a string representing a variable name (default: 'x')

OUTPUT:

- returns a symmetric polynomial of *self* in *n* variables

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().PC()
sage: HLQ = Sym.hall_littlewood().QC()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).expand(2)
x0^2 + (-t + 1)*x0*x1 + x1^2
sage: HLQ([2]).expand(2)
(-t + 1)*x0^2 + (t^2 - 2*t + 1)*x0*x1 + (-t + 1)*x1^2
sage: HLQp([2]).expand(2)
x0^2 + x0*x1 + x1^2
sage: HLQp([2]).expand(2, 'y')
y0^2 + y0*y1 + y1^2
sage: HLQp([2]).expand(1)
x^2
```

scalar(*x*, *zee*=None)

Returns standard scalar product between *self* and *x*.

This is the default implementation that converts both *self* and *x* into Schur functions and performs the scalar product that basis.

The Hall-Littlewood *P* basis is dual to the *Qp* basis with respect to this scalar product.

INPUT:

- *self* – an element of a Hall-Littlewood basis
- *x* – another symmetric element of the symmetric functions

OUTPUT:

- returns the scalar product between *self* and *x*

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().PC()
sage: HLQ = Sym.hall_littlewood().QC()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).scalar(HLQp([2]))
1
sage: HLP([2]).scalar(HLQp([1,1]))
0
sage: HLP([2]).scalar(HLQ([2]), lambda mu: mu.centralizer_size(t = HLP.t))
1
sage: HLP([2]).scalar(HLQ([1,1]), lambda mu: mu.centralizer_size(t = HLP.t))
0
```

scalar_hl(*x*, *t*=None)

Returns the Hall-Littlewood (with parameter *t*) scalar product of *self* and *x*.

The Hall-Littlewood scalar product is defined in Macdonald's book [Mac1995]. The power sum basis is orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu \prod_i 1/(1 - t^{\mu_i})$

The Hall-Littlewood P basis is dual to the Q basis with respect to this scalar product.

INPUT:

- `self` – an element of a Hall-Littlewood basis
- `x` – another symmetric element of the symmetric functions
- `t` – an optional parameter, if this parameter is not specified then the value of the `t` from the basis is used in the calculation

OUTPUT:

- returns the Hall-Littlewood scalar product between `self` and `x`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLP([2]).scalar_hl(HLQ([2]))
1
sage: HLP([2]).scalar_hl(HLQ([1, 1]))
0
sage: HLQ([2]).scalar_hl(HLQ([2]))
-t + 1
sage: HLQ([2]).scalar_hl(HLQ([1, 1]))
0
sage: HLP([2]).scalar_hl(HLP([2]))
-1/(t - 1)
```

`hall_littlewood_family()`

The family of Hall-Littlewood bases associated to `self`

INPUT:

- `self` – a Hall-Littlewood symmetric function basis

OUTPUT:

- returns the class of Hall-Littlewood bases

EXAMPLES:

```
sage: HLP = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood(1).P()
sage: HLP.hall_littlewood_family()
Hall-Littlewood polynomials with t=1 over Fraction Field of Univariate_
↪Polynomial Ring in t over Rational Field
```

`product(left, right)`

Multiply an element of the Hall-Littlewood symmetric function basis `self` and another symmetric function

Convert to the Schur basis, do the multiplication there, and convert back to `self` basis.

INPUT:

- `self` – a Hall-Littlewood symmetric function basis
- `left` – an element of the basis `self`
- `right` – another symmetric function

OUTPUT:

the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])^2 # indirect doctest
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]

sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQ([2])^2 # indirect doctest
HLQ[2, 2] + (-t+1)*HLQ[3, 1] + (-t+1)*HLQ[4]

sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLQp([2])^2 # indirect doctest
HLQp[2, 2] + (-t+1)*HLQp[3, 1] + (-t+1)*HLQp[4]
```

transition_matrix(*basis*, *n*)

Returns the transitions matrix between `self` and `basis` for the homogeneous component of degree `n`.

INPUT:

- `self` – a Hall-Littlewood symmetric function basis
- `basis` – another symmetric function basis
- `n` – a non-negative integer representing the degree

OUTPUT:

- Returns a $r \times r$ matrix of elements of the base ring of `self` where r is the number of partitions of `n`. The entry corresponding to row μ , column ν is the coefficient of `basis` (ν) in `self` (μ)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: s = Sym.schur()
sage: HLP.transition_matrix(s, 4)
[
  [ 1      -t      0      t^2      -t^3]
  [ 0      1      -t      -t      t^3 + t^2]
  [ 0      0      1      -t      t^3]
  [ 0      0      0      0      1 -t^3 - t^2 - t]
  [ 0      0      0      0      0      0      1]
]

sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQ.transition_matrix(s, 3)
[
  [ -t + 1      t^2 - t]
  [-t^3 + t^2]
  [
  [ 0      t^2 - 2*t + 1      -t^4 + t]
  [-t^3 + t^2 - t]
  [
  [-t^2 - t + 1]
  [
  [ 0      0 -t^6 + t^5 + t^4]
]
]

sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLQp.transition_matrix(s, 3)
[
  [ 1      0      0]
  [ t      1      0]
  [ t^3 t^2 + t      1]
]
```

```
class sage.combinat.sf.hall_littlewood.HallLittlewood_p(hall_littlewood)
    Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic
```

A class representing the Hall-Littlewood P basis of symmetric functions

```
class Element
```

```
    Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element
```

```
class sage.combinat.sf.hall_littlewood.HallLittlewood_q(hall_littlewood)
    Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic
```

The Q basis is defined as a normalization of the P basis.

INPUT:

- `self` – an instance of the Hall-Littlewood P basis
- `hall_littlewood` – a class for the family of Hall-Littlewood bases

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Q = Sym.hall_littlewood().Q()
sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive, long time (3s on sage.math, 2012)
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]]) # long_
↪time (depends on previous)

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.schur(); p = Sym.power()
sage: HLQ( HLP([2,1]) + HLP([3]) )
(1/(t^2-2*t+1))*HLQ[2, 1] - (1/(t-1))*HLQ[3]
sage: HLQ(HLQp([2])) # indirect doctest
(t/(t^3-t^2-t+1))*HLQ[1, 1] - (1/(t-1))*HLQ[2]
sage: HLQ(s([2]))
(t/(t^3-t^2-t+1))*HLQ[1, 1] - (1/(t-1))*HLQ[2]
sage: HLQ(p([2]))
(1/(t^2-1))*HLQ[1, 1] - (1/(t-1))*HLQ[2]
```

```
class Element
```

```
    Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element
```

```
class sage.combinat.sf.hall_littlewood.HallLittlewood_qp(hall_littlewood)
    Bases: sage.combinat.sf.hall_littlewood.HallLittlewood_generic
```

The Hall-Littlewood Qp basis is calculated through the `symmetrica` library (see the function `HallLittlewood_qp._to_s()`).

INPUT:

- `self` – an instance of the Hall-Littlewood P basis
- `hall_littlewood` – a class for the family of Hall-Littlewood bases

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Qp = Sym.hall_littlewood().Q()
sage: TestSuite(Qp).run(skip=['_test_passassociativity', '_test_distributivity', '_
↳test_prod']) # products are too expensive, long time (3s on sage.math, 2012)
sage: TestSuite(Qp).run(elements = [Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]]) #_

```

class ElementBases: `sage.combinat.sf.hall_littlewood.HallLittlewood_generic.Element`**5.1.282 Hecke Character Basis**

The basis of symmetric functions given by characters of the Hecke algebra (of type A).

AUTHORS:

- Travis Scrimshaw (2017-08): Initial version

class `sage.combinat.sf.hecke.HeckeCharacter`(*sym, q='q'*)

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

Basis of the symmetric functions that gives the characters of the Hecke algebra in analogy to the Frobenius formula for the symmetric group.

Consider the Hecke algebra $H_n(q)$ with quadratic relations

$$T_i^2 = (q - 1)T_i + q.$$

Let μ be a partition of n with length ℓ . The character χ of a $H_n(q)$ -representation is completely determined by the elements T_{γ_μ} , where

$$\gamma_\mu = (\mu_1, \dots, 1)(\mu_2 + \mu_1, \dots, 1 + \mu_1) \cdots (n, \dots, 1 + \sum_{i < \ell} \mu_i),$$

(written in cycle notation). We define a basis of the symmetric functions by

$$\bar{q}_\mu = \sum_{\lambda \vdash n} \chi^\lambda(T_{\gamma_\mu}) s_\lambda.$$

INPUT:

- `sym` – the ring of symmetric functions
- `q` – (default: 'q') the parameter q

EXAMPLES:

```
sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character(q)
sage: qbar[2] * qbar[3] * qbar[3,1]
qbar[3, 3, 2, 1]

sage: s = Sym.s()
sage: s(qbar([2]))
-s[1, 1] + q*s[2]
sage: s(qbar([4]))
-s[1, 1, 1, 1] + q*s[2, 1, 1] - q^2*s[3, 1] + q^3*s[4]
sage: qbar(s[2])
(1/(q+1))*qbar[1, 1] + (1/(q+1))*qbar[2]
sage: qbar(s[1,1])
(q/(q+1))*qbar[1, 1] - (1/(q+1))*qbar[2]

sage: s(qbar[2,1])
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
sage: qbar(s[2,1])
(q/(q^2+q+1))*qbar[1, 1, 1] + ((q-1)/(q^2+q+1))*qbar[2, 1]
- (1/(q^2+q+1))*qbar[3]
```

We compute character tables for Hecke algebras, which correspond to the transition matrix from the \bar{q} basis to the Schur basis:

```
sage: qbar.transition_matrix(s, 1)
[1]
sage: qbar.transition_matrix(s, 2)
[ q -1]
[ 1  1]
sage: qbar.transition_matrix(s, 3)
[ q^2  -q  1]
[  q  q - 1  -1]
[  1  2  1]
sage: qbar.transition_matrix(s, 4)
[  q^3  -q^2  0  q  -1]
[  q^2  q^2 - q  -q  -q + 1  1]
[  q^2  q^2 - 2*q  q^2 + 1  -2*q + 1  1]
[  q  2*q - 1  q - 1  q - 2  -1]
[  1  3  2  3  1]
```

We can do computations with a specialized q to a generic element of the base ring. We compute some examples with $q = 2$:

```

sage: qbar = Sym.qbar(q=2)
sage: s = Sym.schur()
sage: qbar(s[2,1])
2/7*qbar[1, 1, 1] + 1/7*qbar[2, 1] - 1/7*qbar[3]
sage: s(qbar[2,1])
-s[1, 1, 1] + s[2, 1] + 2*s[3]

```

REFERENCES:

- [Ram1991]
- [RR1997]

coproduct_on_generators(*r*)

Return the coproduct on the generator \bar{q}_r of `self`.

Define the coproduct on \bar{q}_r by

$$\Delta(\bar{q}_r) = \bar{q}_0 \otimes \bar{q}_r + (q-1) \sum_{j=1}^{r-1} \bar{q}_j \otimes \bar{q}_{r-j} + \bar{q}_r \otimes \bar{q}_0.$$

EXAMPLES:

```

sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character()
sage: s = Sym.s()
sage: qbar[2].coproduct()
qbar[] # qbar[2] + (q-1)*qbar[1] # qbar[1] + qbar[2] # qbar[]

```

5.1.283 Homogeneous symmetric functions

By this we mean the basis formed of the complete homogeneous symmetric functions h_λ , not an arbitrary graded basis.

class `sage.combinat.sf.homogeneous.SymmetricFunctionAlgebra_homogeneous`(*Sym*)

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

A class of methods specific to the homogeneous basis of symmetric functions.

INPUT:

- `self` – a homogeneous basis of symmetric functions
- `Sym` – an instance of the ring of symmetric functions

class `Element`

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

expand(*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the *n* variables labelled by *alphabet*.

EXAMPLES:

```

sage: h = SymmetricFunctions(QQ).h()
sage: h([3]).expand(2)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3
sage: h([1, 1, 1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: h([2, 1]).expand(3)
x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 +
↪ 2*x0*x2^2 + 2*x1*x2^2 + x2^3
sage: h([3]).expand(2, alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
sage: h([3]).expand(2, alphabet='x, y')
x^3 + x^2*y + x*y^2 + y^3
sage: h([3]).expand(3, alphabet='x, y, z')
x^3 + x^2*y + x*y^2 + y^3 + x^2*z + x*y*z + y^2*z + x*z^2 + y*z^2 + z^3
sage: (h([]) + 2*h([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: h([1]).expand(0)
0
sage: (3*h([])).expand(0)
3

```

exponential_specialization(*t=None, q=1*)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q -exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R . It is defined whenever the base ring K is a \mathbf{Q} -algebra and t is an element of R . The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q -exponential specialization is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q -factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n , we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see *principal_specialization()*). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \rightarrow 1$ is ex .

INPUT:

- **t** (default: None) – the value to use for t ; the default is to create a ring of polynomials in **t**.
- **q** (default: 1) – the value to use for q . If **q** is None, then a ring (or fraction field) of polynomials in **q** is created.

EXAMPLES:

```

sage: h = SymmetricFunctions(QQ).h()
sage: x = h[5,3]
sage: x.exponential_specialization()
1/720*t^8
sage: factorial(5)*factorial(3)
720

sage: x = 5*h[1,1,1] + 3*h[2,1] + 1
sage: x.exponential_specialization()
13/2*t^3 + 1

```

We also support the q -exponential_specialization:

```

sage: factor(h[3].exponential_specialization(q=var("q"), t=var("t")))
t^3/((q^2 + q + 1)*(q + 1))

```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'}$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```

sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]

```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the

omega involution. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]
```

`principal_specialization`($n=+$ Infinity, $q=None$)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \dots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R , and we assume that the variables of our symmetric functions are x_1, x_2, x_3, \dots (To be more precise, $ps_{n,q}$ is a K -algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i . This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` (default: `infinity`) – a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` (default: `None`) – the value to use for q ; the default is to create a ring of polynomials in `q` (or a field of rational functions in `q`) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2] (using Gaussian binomial coefficients $\binom{u}{v}_q$):

$$ps_{n,q}(h_\lambda) = \prod_i \binom{n + \lambda_i - 1}{\lambda_i}_q,$$

$$ps_{n,1}(h_\lambda) = \prod_i \binom{n + \lambda_i - 1}{\lambda_i},$$

$$ps_q(h_\lambda) = 1 / \prod_i \prod_{j=1}^{\lambda_i} (1 - q^j).$$

EXAMPLES:

```

sage: h = SymmetricFunctions(QQ).h()
sage: x = h[2,1]
sage: x.principal_specialization(3)
q^6 + 2*q^5 + 4*q^4 + 4*q^3 + 4*q^2 + 2*q + 1
sage: x = 3*h[2] + 2*h[1] + 1
sage: x.principal_specialization(3, q=var("q"))
2*(q^3 - 1)/(q - 1) + 3*(q^4 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1

```

coproduct_on_generators(*i*)

Return the coproduct on h_i .

INPUT:

- `self` – a homogeneous basis of symmetric functions
- `i` – a nonnegative integer

OUTPUT:

- the sum $\sum_{r=0}^i h_r \otimes h_{i-r}$

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: h.coproduct_on_generators(2)
h[] # h[2] + h[1] # h[1] + h[2] # h[]
sage: h.coproduct_on_generators(0)
h[] # h[]

```

5.1.284 Jack Symmetric Functions

Jack's symmetric functions appear in [Ma1995] Chapter VI, section 10. Zonal polynomials are the subject of [Ma1995] Chapter VII. The parameter α in that reference is the parameter t in this implementation in sage.

REFERENCES:

class `sage.combinat.sf.jack.Jack(Sym, t='t')`

Bases: `sage.structure.unique_representation.UniqueRepresentation`

The family of Jack symmetric functions including the P , Q , J , Qp bases. The default parameter is t .

INPUT:

- `self` – the family of Jack symmetric function bases
- `Sym` – a ring of symmetric functions
- `t` – an optional parameter (default : 't')

EXAMPLES:

```

sage: SymmetricFunctions(FractionField(QQ['t'])).jack()
Jack polynomials over Fraction Field of Univariate Polynomial Ring in t over
↪Rational Field
sage: SymmetricFunctions(QQ).jack(1)
Jack polynomials with t=1 over Rational Field

```

J()Returns the algebra of Jack polynomials in the J basis.

INPUT:

- self – the family of Jack symmetric function bases

OUTPUT: the J basis of the Jack symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
Rational Field in the Jack J basis
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-1).J()
Symmetric Functions over Rational Field in the Jack J with t=-1 basis
```

At $t = 1$, the Jack polynomials in the J basis are scalar multiples of the Schur functions with the scalar given by a Partition's `hook_product()` method at 1:

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=1).J()
sage: s = Sym.schur()
sage: p = Partition([3,2,1,1])
sage: s(JJ(p)) == p.hook_product(1)*s(p) # long time (4s on sage.math, 2012)
True
```

At $t = 2$, the Jack polynomials in the J basis are scalar multiples of the zonal polynomials with the scalar given by a Partition's `hook_product()` method at 2.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=2).J()
sage: Z = Sym.zonal()
sage: p = Partition([2,2,1])
sage: Z(JJ(p)) == p.hook_product(2)*Z(p)
True
```

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J()
sage: JP = Sym.jack().P()
sage: JJ(sum(JP(p) for p in Partitions(3)))
1/6*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
```

```
sage: s = Sym.schur()
sage: JJ(s([3])) # indirect doctest
((1/6*t^2-1/2*t+1/3)/(t^2+3*t+2))*JackJ[1, 1, 1] + ((t-1)/(t^2+5/
2*t+1))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
sage: JJ(s([2,1]))
((1/3*t-1/3)/(t+2))*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1]
sage: JJ(s([1,1,1]))
1/6*JackJ[1, 1, 1]
```

P()Returns the algebra of Jack polynomials in the P basis.

INPUT:

- self – the family of Jack symmetric function bases

OUTPUT:

- the P basis of the Jack symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().PC(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Jack P basis
sage: Sym.jack(t=-1).PC()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Jack P with t=-1 basis
```

At $t = 1$, the Jack polynomials in the P basis are the Schur symmetric functions.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=1).PC()
sage: s = Sym.schur()
sage: s(JP([2,2,1]))
s[2, 2, 1]
sage: JP(s([2,2,1]))
JackP[2, 2, 1]
sage: JP([2,1])^2
JackP[2, 2, 1, 1] + JackP[2, 2, 2] + JackP[3, 1, 1, 1] + 2*JackP[3, 2, 1] +
↳JackP[3, 3] + JackP[4, 1, 1] + JackP[4, 2]
```

At $t = 2$, the Jack polynomials in the P basis are the zonal polynomials.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).PC()
sage: Z = Sym.zonal()
sage: Z(JP([2,2,1]))
Z[2, 2, 1]
sage: JP(Z[2, 2, 1])
JackP[2, 2, 1]
sage: JP([2])^2
64/45*JackP[2, 2] + 16/21*JackP[3, 1] + JackP[4]
sage: Z([2])^2
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
```

```
sage: Sym = SymmetricFunctions(QQ['a','b'].fraction_field())
sage: (a,b) = Sym.base_ring().gens()
sage: Jacka = Sym.jack(t=a)
sage: Jackb = Sym.jack(t=b)
sage: m = Sym.monomial()
sage: JPa = Jacka.P()
sage: JPb = Jackb.P()
sage: m(JPa[2,1])
(6/(a+2))*m[1, 1, 1] + m[2, 1]
sage: m(JPb[2,1])
```

(continues on next page)

(continued from previous page)

```

(6/(b+2))*m[1, 1, 1] + m[2, 1]
sage: m(a*JPb([2,1]) + b*JPa([2,1]))
((6*a^2+6*b^2+12*a+12*b)/(a*b+2*a+2*b+4))*m[1, 1, 1] + (a+b)*m[2, 1]
sage: JPa(JPb([2,1]))
((6*a-6*b)/(a*b+2*a+2*b+4))*JackP[1, 1, 1] + JackP[2, 1]

```

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q()
sage: JP = Sym.jack().P()
sage: JJ = Sym.jack().J()

```

```

sage: JP(JQ([2,1]))
((1/2*t+1)/(t^3+1/2*t^2))*JackP[2, 1]
sage: JP(JQ([3]))
((1/3*t^2+1/2*t+1/6)/t^3)*JackP[3]
sage: JP(JQ([1,1,1]))
(6/(t^3+3*t^2+2*t))*JackP[1, 1, 1]

```

```

sage: JP(JJ([3]))
(2*t^2+3*t+1)*JackP[3]
sage: JP(JJ([2,1]))
(t+2)*JackP[2, 1]
sage: JP(JJ([1,1,1]))
6*JackP[1, 1, 1]

```

```

sage: s = Sym.schur()
sage: JP(s([2,1]))
((2*t-2)/(t+2))*JackP[1, 1, 1] + JackP[2, 1]
sage: s(_)
s[2, 1]

```

Q()

Returns the algebra of Jack polynomials in the Q basis.

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT:

- the Q basis of the Jack symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Jack Q basis
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-1).Q()
Symmetric Functions over Rational Field in the Jack Q with t=-1 basis

```

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q()
sage: JP = Sym.jack().P()
sage: JQ(sum(JP(p) for p in Partitions(3)))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^
↪3/(t^2+3/2*t+1/2))*JackQ[3]

```

```

sage: s = Sym.schur()
sage: JQ(s([3])) # indirect doctest
(1/6*t^3-1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3-2*t^2)/(t+2))*JackQ[2, 1] +
↪(3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
sage: JQ(s([2,1]))
(1/3*t^3-1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1]
sage: JQ(s([1,1,1]))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1]

```

Qp()

Returns the algebra of Jack polynomials in the Qp , which is dual to the P basis with respect to the standard scalar product.

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT:

- the Q' basis of the Jack symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪Rational Field in the Jack Qp basis
sage: a = JQp([2])
sage: a.scalar(JP([2]))
1
sage: a.scalar(JP([1,1]))
0
sage: JP(JQp([2])) # todo: missing auto normalization
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
sage: JP._normalize(JP(JQp([2])))
((t-1)/(t+1))*JackP[1, 1] + JackP[2]

```

base_ring()

Returns the base ring of the symmetric functions in which the Jack symmetric functions live

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT:

- the base ring of the symmetric functions ring of `self`

EXAMPLES:

```
sage: J2 = SymmetricFunctions(QQ).jack(t=2)
sage: J2.base_ring()
Rational Field
```

symmetric_function_ring()

Returns the base ring of the symmetric functions of the Jack symmetric function bases

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT:

- the symmetric functions ring of `self`

EXAMPLES:

```
sage: Jacks = SymmetricFunctions(FractionField(QQ['t'])).jack()
sage: Jacks.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪Rational Field
```

class `sage.combinat.sf.jack.JackPolynomials_generic(jack)`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

A class of methods which are common to all Jack bases of the symmetric functions

INPUT:

- `self` – a Jack basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).P(); JP.base_ring()
Rational Field
```

class `Element`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

scalar_jack(x, t=None)

A scalar product where the power sums are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{\text{length}(\mu)}$

INPUT:

- `self` – an element of a Jack basis of the symmetric functions
- `x` – an element of the symmetric functions
- `t` – an optional parameter (default [None uses the parameter from] the basis)

OUTPUT:

- returns the Jack scalar product between `x` and `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQ = Sym.jack().Q()
```

(continues on next page)

(continued from previous page)

```

sage: p = Partitions(3).list()
sage: matrix([[JP(a).scalar_jack(JQ(b)) for a in p] for b in p])
[1 0 0]
[0 1 0]
[0 0 1]

```

c1(part)

Returns the t -Jack scalar product between $J(\text{part})$ and $P(\text{part})$.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `part` – a partition
- `t` – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter t which is equal to the scalar product of $J(\text{part})$ and $P(\text{part})$

EXAMPLES:

```

sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().PC()
sage: JP.c1(Partition([2,1]))
t + 2

```

c2(part)

Returns the t -Jack scalar product between $J(\text{part})$ and $Q(\text{part})$.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `part` – a partition
- **`t` – an optional parameter (default: uses the parameter t from the Jack basis)**

OUTPUT:

- a polynomial in the parameter t which is equal to the scalar product of $J(\text{part})$ and $Q(\text{part})$

EXAMPLES:

```

sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().PC()
sage: JP.c2(Partition([2,1]))
2*t^3 + t^2

```

coproduct_by_coercion(elt)

Returns the coproduct of the element `elt` by coercion to the Schur basis.

INPUT:

- `self` – a Jack symmetric function basis
- `elt` – an instance of this basis

OUTPUT:

- The coproduct acting on `elt`, the result is an element of the tensor squared of the Jack symmetric function basis

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
sage: Sym.jack().PC[2,2].coproduct() #indirect doctest
JackP[] # JackP[2, 2] + (2/(t+1))*JackP[1] # JackP[2, 1] + ((8*t+4)/(t^3+4*t^
↪ 2+5*t+2))*JackP[1, 1] # JackP[1, 1] + JackP[2] # JackP[2] + (2/(t+1))*JackP[2,
↪ 1] # JackP[1] + JackP[2, 2] # JackP[]

```

jack_family()

Returns the family of Jack bases associated to the basis `self`

INPUT:

- `self` – a Jack basis of the symmetric functions

OUTPUT:

- the family of Jack symmetric functions associated to `self`

EXAMPLES:

```

sage: JackP = SymmetricFunctions(QQ).jack(t=2).PC()
sage: JackP.jack_family()
Jack polynomials with t=2 over Rational Field

```

product(left, right)

The product of two Jack symmetric functions is done by multiplying the elements in the P basis and then expressing the elements in the basis `self`.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `left, right` – symmetric function elements

OUTPUT:

the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```

sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().JC()
sage: JJ([1])^2 # indirect doctest
(t/(t+1))*JackJ[1, 1] + (1/(t+1))*JackJ[2]
sage: JJ([2])^2
(t^2/(t^2+3/2*t+1/2))*JackJ[2, 2] + (4/3*t/(t^2+4/3*t+1/3))*JackJ[3, 1] + ((1/
↪ 6*t+1/6)/(t^2+5/6*t+1/6))*JackJ[4]
sage: JQ = SymmetricFunctions(FractionField(QQ['t'])).jack().QC()
sage: JQ([1])^2 # indirect doctest
JackQ[1, 1] + (2/(t+1))*JackQ[2]
sage: JQ([2])^2
JackQ[2, 2] + (2/(t+1))*JackQ[3, 1] + ((t+1)/(t^2+5/6*t+1/6))*JackQ[4]

```

class sage.combinat.sf.jack.JackPolynomials_j(jack)

Bases: `sage.combinat.sf.jack.JackPolynomials_generic`

The J basis is a defined as a normalized form of the P basis

INPUT:

- `self` – an instance of the Jack P basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:

```
sage: J = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: TestSuite(J).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
sage: TestSuite(J).run(elements = [J.t*J[1,1]+J[2], J[1]+(1+J.t)*J[1,1]]) # long_
↪time (3s on sage.math, 2012)
```

class Element

Bases: *sage.combinat.sf.jack.JackPolynomials_generic.Element*

class `sage.combinat.sf.jack.JackPolynomials_p(jack)`

Bases: *sage.combinat.sf.jack.JackPolynomials_generic*

The P basis is uni-triangularly related to the monomial basis and orthogonal with respect to the Jack scalar product.

INPUT:

- `self` – an instance of the Jack P basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:

```
sage: P = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: TestSuite(P).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
sage: TestSuite(P).run(elements = [P.t*P[1,1]+P[2], P[1]+(1+P.t)*P[1,1]])
```

class Element

Bases: *sage.combinat.sf.jack.JackPolynomials_generic.Element*

scalar_jack(x , $t=None$)

The scalar product on the symmetric functions where the power sums are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{\text{length}(\mu)}$ where the t parameter from the Jack symmetric function family.

INPUT:

- `self` – an element of the Jack P basis
- `x` – an element of the P basis

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: l = [JP(p) for p in Partitions(3)]
sage: matrix([[a.scalar_jack(b) for a in l] for b in l])
[3*t^3/(t^2 + 3/2*t + 1/2)      0      ↪
↪ 0]
[      0      (2*t^3 + t^2)/(t + 2)  ↪
↪ 0]
[      0      0  1/6*t^3 + 1/2*t^2 + 1/
↪ 3*t]
```

product(*left*, *right*)

The product of two Jack symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements the basis `self`.

INPUT:

- `self` – a Jack basis of the symmetric functions

- `left, right` – symmetric function elements

OUTPUT:

the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().PC
sage: m = JP.symmetric_function_ring().m()
sage: JP([1])^2 # indirect doctest
(2*t/(t+1))*JackP[1, 1] + JackP[2]
sage: m(_)
2*m[1, 1] + m[2]
sage: JP = SymmetricFunctions(QQ).jack(t=2).PC()
sage: JP([2,1])^2
125/63*JackP[2, 2, 1, 1] + 25/12*JackP[2, 2, 2] + 25/18*JackP[3, 1, 1, 1] + 12/
↪5*JackP[3, 2, 1] + 4/3*JackP[3, 3] + 4/3*JackP[4, 1, 1] + JackP[4, 2]
sage: m(_)
45*m[1, 1, 1, 1, 1, 1] + 51/2*m[2, 1, 1, 1, 1] + 29/2*m[2, 2, 1, 1] + 33/4*m[2, 2,
↪2, 2] + 9*m[3, 1, 1, 1] + 5*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, 2]
```

scalar_jack_basis(*part1*, *part2=*None)

Returns the scalar product of $P(\text{part1})$ and $P(\text{part2})$.

This is equation (10.16) of [Mc1995] on page 380.

INPUT:

- `self` – an instance of the Jack P basis of the symmetric functions
- `part1` – a partition
- `part2` – an optional partition (default : None)

OUTPUT:

- the scalar product between $P(\text{part1})$ and $P(\text{part2})$ (or itself if `part2` is None)

REFERENCES:

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().PC()
sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().JC()
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: JP._normalize_coefficients(JP.scalar_jack_basis(Partition([3,2,1]),
↪Partition([3,2,1])))
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
sage: JJ(JP[3,2,1]).scalar_jack(JP[3,2,1])
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
```

With a single argument, takes $\text{part2} = \text{part1}$:

```
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([2,1]))
(2*t^3 + t^2)/(t + 2)
sage: JJ(JP[2,1]).scalar_jack(JP[2,1])
(2*t^3 + t^2)/(t + 2)
```

class sage.combinat.sf.jack.JackPolynomials_q(*jack*)
 Bases: *sage.combinat.sf.jack.JackPolynomials_generic*

The Q basis is defined as a normalized form of the P basis

INPUT:

- *self* – an instance of the Jack Q basis of the symmetric functions
- *jack* – a family of Jack symmetric function bases

EXAMPLES:

```
sage: Q = SymmetricFunctions(FractionField(QQ['t'])).jack().QC
sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]]) # long_
↪time (3s on sage.math, 2012)
```

class Element

Bases: *sage.combinat.sf.jack.JackPolynomials_generic.Element*

class sage.combinat.sf.jack.JackPolynomials_qp(*jack*)
 Bases: *sage.combinat.sf.jack.JackPolynomials_generic*

The Qp basis is the dual basis to the P basis with respect to the standard scalar product

INPUT:

- *self* – an instance of the Jack Qp basis of the symmetric functions
- *jack* – a family of Jack symmetric function bases

EXAMPLES:

```
sage: Qp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
sage: TestSuite(Qp).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
sage: TestSuite(Qp).run(elements = [Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]]) #_
↪long time (3s on sage.math, 2012)
```

class Element

Bases: *sage.combinat.sf.jack.JackPolynomials_generic.Element*

coproduct_by_coercion(*elt*)

Returns the coproduct of the element *elt* by coercion to the Schur basis.

INPUT:

- *elt* – an instance of the Qp basis

OUTPUT:

- The coproduct acting on *elt*, the result is an element of the tensor squared of the Qp symmetric function basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: JQp = Sym.jack().Qp()
sage: JQp[2,2].coproduct() #indirect doctest
JackQp[] # JackQp[2, 2] + (2*t/(t+1))*JackQp[1] # JackQp[2, 1] + JackQp[1, 1] #_
↪JackQp[1, 1] + ((2*t^3+4*t^2)/(t^3+5/2*t^2+2*t+1/2))*JackQp[2] # JackQp[2] +_
↪(2*t/(t+1))*JackQp[2, 1] # JackQp[1] + JackQp[2, 2] # JackQp[] (continues on next page)
```

(continued from previous page)

product(*left*, *right*)

The product of two Jack symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements the basis *self*.

INPUT:

- *self* – an instance of the Jack Qp basis of the symmetric functions
- *left*, *right* – symmetric function elements

OUTPUT:

the product of *left* and *right* expanded in the basis *self*

EXAMPLES:

```
sage: JQp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
sage: h = JQp.symmetric_function_ring().h()
sage: JQp([1])^2 # indirect doctest
JackQp[1, 1] + (2/(t+1))*JackQp[2]
sage: h(_)
h[1, 1]
sage: JQp = SymmetricFunctions(QQ).jack(t=2).Qp()
sage: h = SymmetricFunctions(QQ).h()
sage: JQp([2,1])^2
JackQp[2, 2, 1, 1] + 2/3*JackQp[2, 2, 2] + 2/3*JackQp[3, 1, 1, 1] + 48/
↪35*JackQp[3, 2, 1] + 28/75*JackQp[3, 3] + 128/225*JackQp[4, 1, 1] + 28/
↪75*JackQp[4, 2]
sage: h(_)
h[2, 2, 1, 1] - 6/5*h[3, 2, 1] + 9/25*h[3, 3]
```

class `sage.combinat.sf.jack.SymmetricFunctionAlgebra_zonal`(*Sym*)

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

Returns the algebra of zonal polynomials.

INPUT:

- *self* – a zonal basis of the symmetric functions
- *Sym* – a ring of the symmetric functions

EXAMPLES:

```
sage: Z = SymmetricFunctions(QQ).zonal()
sage: Z([2])^2
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
sage: Z = SymmetricFunctions(QQ).zonal()
sage: TestSuite(Z).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
sage: TestSuite(Z).run(elements = [Z[1,1]+Z[2], Z[1]+2*Z[1,1]])
```

class `Element`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

scalar_zonal(*x*)

The zonal scalar product has the power sum basis and the zonal symmetric functions are orthogonal. In particular, $\langle p_\mu, p_\mu \rangle = z_\mu^{2^{\text{length}(\mu)}}$.

INPUT:

- `self` – an element of the zonal basis
- `x` – an element of the symmetric function

OUTPUT:

- the scalar product between `self` and `x`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: parts = Partitions(3).list()
sage: matrix([[Z(a).scalar_zonal(Z(b)) for a in parts] for b in parts])
[16/5  0  0]
[  0  5  0]
[  0  0  4]
sage: p = Z.symmetric_function_ring().power()
sage: matrix([[Z(p(a)).scalar_zonal(p(b)) for a in parts] for b in parts])
[ 6  0  0]
[ 0  8  0]
[ 0  0 48]
```

product (*left, right*)

The product of two zonal symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements in the basis `self`.

INPUT:

- `self` – a zonal basis of the symmetric functions
- `left, right` – symmetric function elements

OUTPUT:

the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: JP = Sym.jack(t=1).PC()
sage: Z([2])*Z([3]) # indirect doctest
192/175*Z[3, 2] + 32/45*Z[4, 1] + Z[5]
sage: Z([2])*JP([2])
10/27*Z[2, 1, 1] + 64/45*Z[2, 2] + 23/21*Z[3, 1] + Z[4]
sage: JP = Sym.jack(t=2).PC()
sage: Z([2])*JP([2])
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
```

`sage.combinat.sf.jack.c1` (*part, t*)

Returns the t -Jack scalar product between $J(\text{part})$ and $P(\text{part})$.

INPUT:

- `part` – a partition
- `t` – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter `t` which is equal to the scalar product of $J(\text{part})$ and $P(\text{part})$

EXAMPLES:

```
sage: from sage.combinat.sf.jack import c1
sage: t = QQ['t'].gen()
sage: [c1(p,t) for p in Partitions(3)]
[2*t^2 + 3*t + 1, t + 2, 6]
```

`sage.combinat.sf.jack.c2(part, t)`

Returns the t -Jack scalar product between $J(\text{part})$ and $Q(\text{part})$.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `part` – a partition
- `t` – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter t which is equal to the scalar product of $J(\text{part})$ and $Q(\text{part})$

EXAMPLES:

```
sage: from sage.combinat.sf.jack import c2
sage: t = QQ['t'].gen()
sage: [c2(p,t) for p in Partitions(3)]
[6*t^3, 2*t^3 + t^2, t^3 + 3*t^2 + 2*t]
```

`sage.combinat.sf.jack.normalize_coefficients(self, c)`

If our coefficient ring is the field of fractions over a univariate polynomial ring over the rationals, then we should clear both the numerator and denominator of the denominators of their coefficients.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `c` – a coefficient in the base ring of `self`

OUTPUT:

- divide numerator and denominator by the greatest common divisor

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().PC()
sage: t = JP.base_ring().gen()
sage: a = 2/(1/2*t+1/2)
sage: JP._normalize_coefficients(a)
4/(t + 1)
sage: a = 1/(1/3+1/6*t)
sage: JP._normalize_coefficients(a)
6/(t + 2)
sage: a = 24/(4*t^2 + 12*t + 8)
sage: JP._normalize_coefficients(a)
6/(t^2 + 3*t + 2)
```

`sage.combinat.sf.jack.part_scalar_jack(part1, part2, t)`

Returns the Jack scalar product between $p(\text{part1})$ and $p(\text{part2})$ where p is the power-sum basis.

INPUT:

- part1, part2 – two partitions
- t – a parameter

OUTPUT:

- returns the scalar product between the power sum indexed by part1 and part2

EXAMPLES:

```
sage: Q.<t> = QQ[]
sage: from sage.combinat.sf.jack import part_scalar_jack
sage: matrix([[part_scalar_jack(p1,p2,t) for p1 in Partitions(4)] for p2 in
↪Partitions(4)])
[ 4*t      0      0      0      0]
[  0  3*t^2  0      0      0]
[  0      0  8*t^2  0      0]
[  0      0      0  4*t^3  0]
[  0      0      0      0 24*t^4]
```

5.1.285 Quotient of symmetric function space by ideal generated by Hall-Littlewood symmetric functions

The quotient of symmetric functions by the ideal generated by the Hall-Littlewood P symmetric functions indexed by partitions with first part greater than k . When $t = 1$ this space is the quotient of the symmetric functions by the ideal generated by the monomial symmetric functions indexed by partitions with first part greater than k .

AUTHORS:

- Chris Berg (2012-12-01)
- Mike Zabrocki - k -bounded Hall Littlewood P and dual k -Schur functions (2012-12-02)

class `sage.combinat.sf.k_dual.AffineSchurFunctions`(*kBoundedRing*)

Bases: `sage.combinat.sf.k_dual.KBoundedQuotientBasis`

This basis is dual to the k -Schur functions at $t = 1$. This realization follows the monomial expansion given by Lam [Lam2006].

REFERENCES:

class `sage.combinat.sf.k_dual.DualkSchurFunctions`(*kBoundedRing*)

Bases: `sage.combinat.sf.k_dual.KBoundedQuotientBasis`

This basis is dual to the k -Schur functions. The expansion is given in Section 4.12 of [LLMSSZ]. When $t = 1$ this basis is equal to the `AffineSchurFunctions` and that basis is more efficient in this case.

REFERENCES:

class `sage.combinat.sf.k_dual.KBoundedQuotient`(*Sym, k, t='t'*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Initialization of the ring of Symmetric functions modulo the ideal of monomial symmetric functions which are indexed by partitions whose first part is greater than k .

INPUT:

- `Sym` – an element of class `sage.combinat.sf.sf.SymmetricFunctions`
- `k` – a positive integer

- R – a ring

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: Q
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
sage: km = Q.km()

```

AffineGrothendieckPolynomial(*la, m*)

Returns the affine Grothendieck polynomial indexed by the partition *la*. Because this belongs to the completion of the algebra, and hence is an infinite sum, it computes only up to those symmetric functions of degree at most *m*. See `_AffineGrothendieckPolynomial()` for the code.

INPUT:

- *la* – A *k*-bounded partition
- *m* – An integer

EXAMPLES:

```

sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.AffineGrothendieckPolynomial([2,1],4)
2*m3[1, 1, 1] - 8*m3[1, 1, 1, 1] + m3[2, 1] - 3*m3[2, 1, 1] - m3[2, 2]

```

F()

The affine Schur basis of the *k*-bounded quotient of symmetric functions, indexed by *k*-bounded partitions. This is also equal to the affine Stanley symmetric functions (see `WeylGroups.ElementMethods.stanley_symmetric_function()`) indexed by an affine Grassmannian permutation.

EXAMPLES:

```

sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 2-
↪bounded affine Schur basis

```

a_realization()

Returns a particular realization of `self` (the basis of *k*-bounded monomials if *t* = 1 and the basis of *k*-bounded Hall-Littlewood functions otherwise).

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-
↪bounded monomial basis
sage: Q = Sym.kBoundedQuotient(3,t=2)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=2 in the 3-
↪bounded Hall-Littlewood P basis

```

affineSchur()

The affine Schur basis of the *k*-bounded quotient of symmetric functions, indexed by *k*-bounded partitions. This is also equal to the affine Stanley symmetric functions (see `WeylGroups.ElementMethods.`

`stanley_symmetric_function()` indexed by an affine Grassmannian permutation.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 2-
↳bounded affine Schur basis
```

ambient()

Returns the Symmetric Functions over the same ring as `self`. This is needed to realize our ring as a quotient.

an_element()

Returns an element of the quotient ring of k -bounded symmetric functions. This method is here to make the TestSuite run properly.

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.an_element()
2*m3[] + 2*m3[1] + 3*m3[2]
```

dkS()

The dual k -Schur basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. At $t = 1$ this is also equal to the affine Schur basis and calculations will be faster using elements in the `affineSchur()` basis.

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t']).fraction_field().kBoundedQuotient(2).dual_k_
↳Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↳Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

dual_k_Schur()

The dual k -Schur basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. At $t = 1$ this is also equal to the affine Schur basis and calculations will be faster using elements in the `affineSchur()` basis.

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t']).fraction_field().kBoundedQuotient(2).dual_k_
↳Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↳Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

kHLP()

The Hall-Littlewood P basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. At $t = 1$ this basis is equal to the k -bounded monomial basis and calculations will be faster using elements in the k -bounded monomial basis (see `kmonomial()`).

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t']).fraction_field().kBoundedQuotient(2).
↳kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↳Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P_
↳basis
```

kHallLittlewoodP()

The Hall-Littlewood P basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions. At $t = 1$ this basis is equal to the k -bounded monomial basis and calculations will be faster using elements in the k -bounded monomial basis (see `kmonomial()`).

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t']).fraction_field().kBoundedQuotient(2).
↳kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↳Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P_
↳basis
```

km()

The monomial basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 2-
↳bounded monomial basis
```

kmonomial()

The monomial basis of the k -bounded quotient of symmetric functions, indexed by k -bounded partitions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 2-
↳bounded monomial basis
```

lift(la)

Gives the lift map from the quotient ring of k -bounded symmetric functions to the symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- la – A k -bounded partition

OUTPUT:

- **The monomial element or a Hall-Littlewood P element of the symmetric functions** indexed by the partition la .

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.lift([2,1])
m[2, 1]
sage: Q = SymmetricFunctions(QQ['t']).fraction_field().kBoundedQuotient(3)
sage: Q.lift([2,1])
HLP[2, 1]
```

one()

Returns the unit of the quotient ring of k -bounded symmetric functions. This method is here to make the TestSuite run properly.

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.one()
m3[]
```

realizations()

A list of realizations of the k -bounded quotient.

EXAMPLES:

```
sage: kQ = SymmetricFunctions(QQ['t']).fraction_field().kBoundedQuotient(3)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↳Polynomial Ring in t over Rational Field in the 3-bounded monomial basis, 3-
↳Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
↳Polynomial Ring in t over Rational Field in the 3-bounded Hall-Littlewood P_
↳basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of_
↳Univariate Polynomial Ring in t over Rational Field in the 3-bounded affine_
↳Schur basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of_
↳Univariate Polynomial Ring in t over Rational Field in the dual 3-Schur basis]
sage: HLP = kQ.ambient().hall_littlewood().P()
sage: all( rzn(HLP[3,2,1]).lift() == HLP[3,2,1] for rzn in kQ.realizations())
True
sage: kQ = SymmetricFunctions(QQ).kBoundedQuotient(3,1)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the_
↳3-bounded monomial basis, 3-Bounded Quotient of Symmetric Functions over_
↳Rational Field with t=1 in the 3-bounded Hall-Littlewood P basis, 3-Bounded_
↳Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded_
↳affine Schur basis, 3-Bounded Quotient of Symmetric Functions over Rational_
↳Field with t=1 in the dual 3-Schur basis]
sage: m = kQ.ambient().m()
sage: all( rzn(m[3,2,1]).lift() == m[3,2,1] for rzn in kQ.realizations())
True
```

retract(*la*)

Gives the retract map from the symmetric functions to the quotient ring of k -bounded symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- la – A partition

OUTPUT:

- The monomial element of the k -bounded quotient indexed by la .

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]
```

class sage.combinat.sf.k_dual.KBoundedQuotientBases(*base*)

Bases: sage.categories.realizations.Category_realization_of_parent

The category of bases for the k -bounded subspace of symmetric functions.

class ElementMethods

Bases: object

class ParentMethods

Bases: object

ambient()

Returns the symmetric functions.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.ambient()
Symmetric Functions over Rational Field
```

antipode(element)Return the antipode of *element* via lifting to the symmetric functions and then retracting into the *k*-bounded quotient basis.

INPUT:

- *element* – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks3[3,2].antipode()
-dks3[1, 1, 1, 1, 1]
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km[3,2].antipode()
m3[3, 2]
sage: km.antipode(km[3,2])
m3[3, 2]
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
```

```
sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
↳ km()
sage: km[1,1,1,1].antipode()
(t^3-3*t^2+3*t)*m3[1, 1, 1, 1] + (-t^2+2*t)*m3[2, 1, 1] + t*m3[2, 2] +
↳ t*m3[3, 1]
sage: kHP = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
↳ kHLP()
sage: kHP[2,2].antipode()
(t^9-t^6-t^5+t^2)*HLP3[1, 1, 1, 1] + (t^6-t^3-t^2+t)*HLP3[2, 1, 1] + (t^5-t^
↳ 2+1)*HLP3[2, 2] + (t^4-t)*HLP3[3, 1]
sage: dks = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
↳ dks()
sage: dks[2,2].antipode()
dks3[2, 2]
sage: dks[3,2].antipode()
-t^2*dks3[1, 1, 1, 1, 1] + (t^2-1)*dks3[2, 2, 1] + (-t^5+t)*dks3[3, 2]
```

coproduct(element)Return the coproduct of *element* via lifting to the symmetric functions and then returning to the *k*-bounded quotient basis. This method is implemented for all *t* but is (weakly) conjectured to not be

the correct operation for arbitrary t because the coproduct on dual- k -Schur functions does not have a positive expansion.

INPUT:

- `element` – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Q3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: km = Q3.km()
sage: km[3,2].coproduct()
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
sage: dks3 = Q3.dual_k_Schur()
sage: dks3[2,2].coproduct()
dks3[] # dks3[2, 2] + dks3[1] # dks3[2, 1] + dks3[1, 1] # dks3[1, 1] +
↳dks3[2] # dks3[2] + dks3[2, 1] # dks3[1] + dks3[2, 2] # dks3[]
```

```
sage: Q3t = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3)
sage: km = Q3t.km()
sage: km[3,2].coproduct()
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
sage: dks = Q3t.dks()
sage: dks[2,1,1].coproduct()
dks3[] # dks3[2, 1, 1] + (-t+1)*dks3[1] # dks3[1, 1, 1] + dks3[1] # dks3[2,
↳1] + (-t+1)*dks3[1, 1] # dks3[1, 1] + dks3[1, 1] # dks3[2] + (-
↳t+1)*dks3[1, 1, 1] # dks3[1] + dks3[2] # dks3[1, 1] + dks3[2, 1] #
↳dks3[1] + dks3[2, 1, 1] # dks3[]
sage: kHLP = Q3t.kHLP()
sage: kHLP[2,1].coproduct()
HLP3[] # HLP3[2, 1] + (-t^2+1)*HLP3[1] # HLP3[1, 1] + HLP3[1] # HLP3[2] + (-
↳t^2+1)*HLP3[1, 1] # HLP3[1] + HLP3[2] # HLP3[1] + HLP3[2, 1] # HLP3[]
sage: km.coproduct(km[3,2])
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
```

counit(*element*)

Return the counit of `element`.

The counit is the constant term of `element`.

INPUT:

- `element` – an element in a basis

EXAMPLES:

```
sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
↳km()
sage: f = 2*km[2,1] - 3*km([])
sage: f.counit()
-3
sage: km.counit(f)
-3
```

degree_on_basis(*b*)

Return the degree of the basis element indexed by `b`.

INPUT:

- `b` – a partition

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.degree_on_basis(Partition([3,2]))
5
```

indices()

The set of k -bounded partitions of all non-negative integers.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.indices()
3-Bounded Partitions
```

lift(la)

Implements the lift map from the basis `self` to the monomial basis of symmetric functions.

INPUT:

- la – A k -bounded partition.

OUTPUT:

- A symmetric function in the monomial basis.

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.lift([3,1])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
sage: dks = Sym.kBoundedQuotient(3).dual_k_Schur()
sage: dks.lift([3,1])
t^5*HLP[1, 1, 1, 1] + t^2*HLP[2, 1, 1] + t*HLP[2, 2] + HLP[3, 1]
sage: dks = Sym.kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks.lift([3,1])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
```

one_basis()

Return the basis element indexing 1.

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.one() # indirect doctest
F3[]
```

product(x, y)

Returns the product of two elements x and y .

INPUT:

- x, y – Elements of the k -bounded quotient of symmetric functions.

OUTPUT:

- A k -bounded symmetric function in the dual k -Schur function basis

EXAMPLES:

```
sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks3.product(dks3[2,1],dks3[1,1])
2*dks3[1, 1, 1, 1] + 2*dks3[2, 1, 1, 1] + 2*dks3[2, 2, 1] + dks3[3, 1, ↵
↵1] + dks3[3, 2]
sage: dks3.product(dks3[2,1]+dks3[1,1], dks3[1,1])
```

(continues on next page)

(continued from previous page)

```

dks3[1, 1, 1] + 2*dks3[1, 1, 1, 1, 1] + dks3[2, 1] + 2*dks3[2, 1, 1, 1] +
↳ 2*dks3[2, 2, 1] + dks3[3, 1, 1] + dks3[3, 2]
sage: dks3.product(dks3[2,1]+dks3[1], dks3([]))
dks3[1] + dks3[2, 1]
sage: dks3.product(dks3([]), dks3([]))
dks3[]
sage: dks3.product(dks3([]), dks3([4,1]))

```

retract(*la*)

Gives the retract map from the symmetric functions to the quotient ring of k -bounded symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- la – A partition

OUTPUT:

- The monomial element of the k -bounded quotient indexed by la .

EXAMPLES:

```

sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]

```

super_categories()

The super categories of self.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.k_dual import KBoundedQuotientBases
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: KQB = KBoundedQuotientBases(Q)
sage: KQB.super_categories()
[Category of realizations of 3-Bounded Quotient of Symmetric Functions over
↪ Univariate Polynomial Ring in t over Rational Field with t=1,

class sage.combinat.sf.k_dual.KBoundedQuotientBasis(*kBoundedRing*, *prefix*)

Bases: *sage.combinat.free_module.CombinatorialFreeModule*

Abstract base class for the bases of the k -bounded quotient.

class sage.combinat.sf.k_dual.kMonomial(*kBoundedRing*)

Bases: *sage.combinat.sf.k_dual.KBoundedQuotientBasis*

The basis of monomial symmetric functions indexed by partitions with first part less than or equal to k .

lift(*la*)

Implements the lift function on the monomial basis. Given a k -bounded partition la , the lift will return the corresponding monomial basis element.

INPUT:

- la – A k -bounded partition

OUTPUT:

- A monomial symmetric function.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.lift(Partition([3,1]))
m[3, 1]
sage: km.lift([])
m[]
sage: km.lift(Partition([4,1]))
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-Bounded_
↪Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded_
↪monomial basis)
```

retract(*la*)

Implements the retract function on the monomial basis. Given a partition la , the retract will return the corresponding k -bounded monomial basis element if la is k -bounded; zero otherwise.

INPUT:

- la – A partition

OUTPUT:

- A k -bounded monomial symmetric function in the k -quotient of symmetric functions.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.retract(Partition([3,1]))
m3[3, 1]
sage: km.retract(Partition([4,1]))
0
sage: km.retract([])
```

(continues on next page)

(continued from previous page)

```

m3[]
sage: m = SymmetricFunctions(QQ).m()
sage: km(m[3, 1])
m3[3, 1]
sage: km(m[4, 1])
0

```

```

sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).km()
sage: km.retract(Partition([3,1]))
m3[3, 1]
sage: km.retract(Partition([4,1]))
(t^4+t^3-9*t^2+11*t-4)*m3[1, 1, 1, 1, 1] + (-3*t^2+6*t-3)*m3[2, 1, 1, 1] + (-t^
↳2+3*t-2)*m3[2, 2, 1] + (2*t-2)*m3[3, 1, 1] + (t-1)*m3[3, 2]
sage: m = SymmetricFunctions(FractionField(QQ['t'])).m()
sage: km(m[3, 1])
m3[3, 1]
sage: km(m[4, 1])
(t^4+t^3-9*t^2+11*t-4)*m3[1, 1, 1, 1, 1] + (-3*t^2+6*t-3)*m3[2, 1, 1, 1] + (-t^
↳2+3*t-2)*m3[2, 2, 1] + (2*t-2)*m3[3, 1, 1] + (t-1)*m3[3, 2]

```

```
class sage.combinat.sf.k_dual.kbounded_HallLittlewoodP(kBoundedRing)
```

Bases: `sage.combinat.sf.k_dual.KBoundedQuotientBasis`

The basis of P Hall-Littlewood symmetric functions indexed by partitions with first part less than or equal to k .

lift(la)

Implements the lift function on the Hall-Littlewood P basis. Given a k -bounded partition la , the lift will return the corresponding Hall-Littlewood P basis element.

INPUT:

- la – A k -bounded partition

OUTPUT:

- A Hall-Littlewood symmetric function.

EXAMPLES:

```

sage: kHLP = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3).
↳kHallLittlewoodP()
sage: kHLP.lift(Partition([3,1]))
HLP[3, 1]
sage: kHLP.lift([])
HLP[]
sage: kHLP.lift(Partition([4,1]))
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-Bounded_
↳Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial_
↳Ring in t over Rational Field in the 3-bounded Hall-Littlewood P basis)

```

retract(la)

Implements the retract function on the Hall-Littlewood P basis. Given a partition la , the retract will return the corresponding k -bounded Hall-Littlewood P basis element if la is k -bounded; zero otherwise.

INPUT:

- $1a$ – A partition

OUTPUT:

- A k -bounded Hall-Littlewood P symmetric function in the k -quotient of symmetric functions.

EXAMPLES:

```
sage: kHLP = SymmetricFunctions(QQ['t']).fraction_field().kBoundedQuotient(3).
↳kHallLittlewoodP()
sage: kHLP.retract(Partition([3,1]))
HLP3[3, 1]
sage: kHLP.retract(Partition([4,1]))
0
sage: kHLP.retract([])
HLP3[]
sage: m = kHLP.realization_of().ambient().m()
sage: kHLP(m[2,2])
(t^4-t^3-t+1)*HLP3[1, 1, 1, 1] + (t-1)*HLP3[2, 1, 1] + HLP3[2, 2]
```

5.1.286 Kostka-Foulkes Polynomials

Based on the algorithms in John Stembridge's SF package for Maple which can be found at <http://www.math.lsa.umich.edu/~jrs/maple.html>.

`sage.combinat.sf.kfpoly.KostkaFoulkesPolynomial(mu, nu, t=None)`

Returns the Kostka-Foulkes polynomial $K_{\mu,\nu}(t)$.

INPUT:

- μ, ν – partitions
- t – an optional parameter (default: None)

OUTPUT:

- the Kostka-Foulkes polynomial indexed by partitions μ and ν and evaluated at the parameter t . If t is None the resulting polynomial is in the polynomial ring $\mathbf{Z}[t]$.

EXAMPLES:

```
sage: KostkaFoulkesPolynomial([2,2],[2,2])
1
sage: KostkaFoulkesPolynomial([2,2],[4])
0
sage: KostkaFoulkesPolynomial([2,2],[1,1,1,1])
t^4 + t^2
sage: KostkaFoulkesPolynomial([2,2],[2,1,1])
t
sage: q = PolynomialRing(QQ,'q').gen()
sage: KostkaFoulkesPolynomial([2,2],[2,1,1],q)
q
```

`sage.combinat.sf.kfpoly.compat(n, mu, nu)`

Generate all possible partitions of n that can precede μ, ν in a rigging sequence.

INPUT:

- n – a positive integer

- `mu, nu` – partitions

OUTPUT:

- a list of partitions

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: compat(4, [1], [2,1])
[[1, 1, 1, 1], [2, 1, 1], [2, 2], [3, 1], [4]]
sage: compat(3, [1], [2,1])
[[1, 1, 1], [2, 1], [3]]
sage: compat(2, [1], [])
[[2]]
sage: compat(3, [1], [])
[[2, 1], [3]]
sage: compat(3, [2], [1])
[[3]]
sage: compat(4, [1,1], [])
[[2, 2], [3, 1], [4]]
sage: compat(4, [2], [])
[[4]]
```

`sage.combinat.sf.kfpoly.dom(mu, snu)`

Return True if $\text{sum}(\text{mu}[:i+1]) \geq \text{snu}[i]$ for all $0 \leq i < \text{len}(\text{snu})$; otherwise, it returns False.

INPUT:

- `mup` – a partition conjugate to `mu`
- `snu` – a sequence of positive integers

OUTPUT:

- a boolean value

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: dom([3,2,1], [2,4,5])
True
sage: dom([3,2,1], [2,4,7])
False
sage: dom([3,2,1], [2,6,5])
False
sage: dom([3,2,1], [4,4,4])
False
```

`sage.combinat.sf.kfpoly.kfpoly(mu, nu, t=None)`

Return the Kostka-Foulkes polynomial $K_{\mu,\nu}(t)$ by generating all rigging sequences for the shape μ , and then selecting those of content ν .

INPUT:

- `mu, nu` – partitions
- `t` – an optional parameter (default: None)

OUTPUT:

- the Koska-Foulkes polynomial indexed by partitions μ and ν and evaluated at the parameter t . If t is `None` the resulting polynomial is in the polynomial ring $\mathbf{Z}[t]$.

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import kfpoly
sage: kfpoly([2,2], [2,1,1])
t
sage: kfpoly([4], [2,1,1])
t^3
sage: kfpoly([4], [2,2])
t^2
sage: kfpoly([1,1,1,1], [2,2])
0
```

`sage.combinat.sf.kfpoly.riggings(part)`

Generate all possible rigging sequences for a fixed partition `part`.

INPUT:

- `part` – a partition

OUTPUT:

- a list of riggings associated to the partition `part`

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: riggings([3])
[[[1, 1, 1]], [[2, 1]], [[3]]]
sage: riggings([2,1])
[[[2, 1], [1]], [[3], [1]]]
sage: riggings([1,1,1])
[[[3], [2], [1]]]
sage: riggings([2,2])
[[[2, 2], [1, 1]], [[3, 1], [1, 1]], [[4], [1, 1]], [[4], [2]]]
sage: riggings([2,2,2])
[[[3, 3], [2, 2], [1, 1]],
 [[4, 2], [2, 2], [1, 1]],
 [[5, 1], [2, 2], [1, 1]],
 [[6], [2, 2], [1, 1]],
 [[5, 1], [3, 1], [1, 1]],
 [[6], [3, 1], [1, 1]],
 [[6], [4], [2]]]
```

`sage.combinat.sf.kfpoly.schur_to_hl(mu, t=None)`

Return a dictionary corresponding to s_μ in Hall-Littlewood P basis.

INPUT:

- `mu` – a partition
- `t` – an optional parameter (default: the generator from $\mathbf{Z}[t]$)

OUTPUT:

- a dictionary with the coefficients $K_{\mu\nu}(t)$ for ν smaller in dominance order than μ

EXAMPLES:

```

sage: from sage.combinat.sf.kfpoly import *
sage: schur_to_hl([1,1,1])
{[1, 1, 1]: 1}
sage: a = schur_to_hl([2,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1], t^2 + t)
([2, 1], 1)
sage: a = schur_to_hl([3])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1], t^3)
([2, 1], t)
([3], 1)
sage: a = schur_to_hl([4])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^6)
([2, 1, 1], t^3)
([2, 2], t^2)
([3, 1], t)
([4], 1)
sage: a = schur_to_hl([3,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^5 + t^4 + t^3)
([2, 1, 1], t^2 + t)
([2, 2], t)
([3, 1], 1)
sage: a = schur_to_hl([2,2])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^4 + t^2)
([2, 1, 1], t)
([2, 2], 1)
sage: a = schur_to_hl([2,1,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^3 + t^2 + t)
([2, 1, 1], 1)
sage: a = schur_to_hl([1,1,1,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], 1)
sage: a = schur_to_hl([2,2,2])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1, 1, 1], t^9 + t^7 + t^6 + t^5 + t^3)
([2, 1, 1, 1, 1], t^4 + t^2)
([2, 2, 1, 1], t)
([2, 2, 2], 1)

```

`sage.combinat.sf.kfpoly.weight`(*rg*, *t=None*)

Return the weight of a rigging.

INPUT:

- *rg* – a rigging, a list of partitions
- *t* – an optional parameter, (default: the generator from $\mathbf{Z}[t]$)

OUTPUT:

- a polynomial in the parameter *t*

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import weight
sage: weight([[2,1], [1]])
1
sage: weight([[3], [1]])
t^2 + t
sage: weight([[2,1], [3]])
t^4
sage: weight([[2, 2], [1, 1]])
1
sage: weight([[3, 1], [1, 1]])
t
sage: weight([[4], [1, 1]], 2)
16
sage: weight([[4], [2]], t=2)
4
```

5.1.287 LLT symmetric functions

REFERENCES:

class `sage.combinat.sf.llt.LLT_class`(*Sym, k, t='t'*)
 Bases: `sage.structure.unique_representation.UniqueRepresentation`
 A class for working with LLT symmetric functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3); L3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: HC3 = L3.hcospin(); HC3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the level 3 LLT cospin basis
sage: m = Sym.monomial()
sage: m( HC3[1,1] )
(t+1)*m[1, 1] + m[2]
```

We require that the parameter t must be in the base ring:

```
sage: Symxt = SymmetricFunctions(QQ['x','t'].fraction_field())
sage: (x,t) = Symxt.base_ring().gens()
sage: LLT3x = Symxt.llt(3,t=x)
sage: LLT3 = Symxt.llt(3)
sage: HS3x = LLT3x.hspin()
sage: HS3t = LLT3.hspin()
sage: s = Symxt.schur()
sage: s(HS3x[2,1])
s[2, 1] + x*s[3]
sage: s(HS3t[2,1])
```

(continues on next page)

(continued from previous page)

```

s[2, 1] + t*s[3]
sage: HS3x(HS3t[2, 1])
HSp3[2, 1] + (-x+t)*HSp3[3]
sage: s(HS3x(HS3t[2, 1]))
s[2, 1] + t*s[3]
sage: LLT3t2 = Symxt.llt(3, t=2)
sage: HC3t2 = LLT3t2.hcospin()
sage: HS3x(HC3t2[3, 1])
2*HSp3[3, 1] + (-2*x+1)*HSp3[4]

```

base_ring()

Returns the base ring of `self`.

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT:

- returns the base ring of the symmetric function ring associated to `self`

EXAMPLES:

```

sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field

```

cospin(*skp*)

Calculate a single instance of the cospin symmetric functions.

These are the functions defined in [LLT1997] equation (26).

INPUT:

- `self` – a family of LLT symmetric functions bases
- `skp` – a partition or a list of partitions or a list of skew partitions

OUTPUT:

the monomial expansion of the LLT symmetric function cospin functions indexed by `skp`

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3)
sage: L3.cospin([2, 1])
m[1]
sage: L3.cospin([3, 2, 1])
(t+1)*m[1, 1] + m[2]
sage: s = Sym.schur()
sage: s(L3.cospin([[2], [1], [2]]))
t^4*s[2, 2, 1] + t^3*s[3, 1, 1] + (t^3+t^2)*s[3, 2] + (t^2+t)*s[4, 1] + s[5]

```

hcospin()

Returns the HCospin basis. This basis is defined [LLT1997] equation (27).

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT:

- returns the h-cospin basis of the LLT symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HCosp3 = Sym.llt(3).hcospin(); HCosp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the level 3 LLT cospin basis
sage: HCosp3([1])^2
1/t*HCosp3[1, 1] + ((t-1)/t)*HCosp3[2]

sage: s = Sym.schur()
sage: HCosp3(s([2]))
HCosp3[2]
sage: HCosp3(s([1, 1]))
1/t*HCosp3[1, 1] - 1/t*HCosp3[2]
sage: s(HCosp3([2, 1]))
t*s[2, 1] + s[3]

```

hspin()

Returns the HSpin basis. This basis is defined [LLT1997] equation (28).

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT:

- returns the h-spin basis of the LLT symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HSp3 = Sym.llt(3).hspin(); HSp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the level 3 LLT spin basis
sage: HSp3([1])^2
HSp3[1, 1] + (-t+1)*HSp3[2]

sage: s = Sym.schur()
sage: HSp3(s([2]))
HSp3[2]
sage: HSp3(s([1, 1]))
HSp3[1, 1] - t*HSp3[2]
sage: s(HSp3([2, 1]))
s[2, 1] + t*s[3]

```

level()

Returns the level of `self`.

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT:

- the level is the parameter of k in the basis

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).level()
3
```

spin_square(*skp*)

Calculate a single instance of a spin squared LLT symmetric function associated with a partition, list of partitions, or a list of skew partitions.

This family of symmetric functions is defined in [LT2000] equation (43).

INPUT:

- *self* – a family of LLT symmetric functions bases
- *skp* – a partition of a list of partitions or a list of skew partitions

OUTPUT:

the monomial expansion of the LLT symmetric function spin-square functions indexed by *skp*

EXAMPLES:

```
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.spin_square([2, 1])
t^m[1]
sage: L3.spin_square([3, 2, 1])
(t^3+t)^m[1, 1] + t^3*m[2]
sage: L3.spin_square([[1], [1], [1]])
(t^6+2*t^4+2*t^2+1)*m[1, 1, 1] + (t^6+t^4+t^2)*m[2, 1] + t^6*m[3]
sage: L3.spin_square([[2, 2], [1]], [[2, 1], []])
(2*t^4+3*t^2+1)*m[1, 1, 1, 1] + (t^4+t^2)*m[2, 1, 1] + t^4*m[2, 2]
```

symmetric_function_ring()

The symmetric function algebra associated to the family of LLT symmetric function bases

INPUT:

- *self* – a family of LLT symmetric functions bases

OUTPUT:

- returns the symmetric function ring associated to *self*.

EXAMPLES:

```
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪Rational Field
```

class `sage.combinat.sf.llt.LLT_cospin`(*llt*)

Bases: `sage.combinat.sf.llt.LLT_generic`

A class of methods for the h-cospin LLT basis of the symmetric functions.

INPUT:

- *self* – an instance of the LLT hcospin basis
- *llt* – a family of LLT symmetric function bases

class `Element`

Bases: `sage.combinat.sf.llt.LLT_generic.Element`

class sage.combinat.sf.llt.LLT_generic(*llt, prefix*)

Bases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic*

A class of methods which are common to both the hspin and hcospin of the LLT symmetric functions.

INPUT:

- *self* – an instance of the LLT hspin or hcospin basis
- *llt* – a family of LLT symmetric functions

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the level 3 LLT spin basis
sage: SymmetricFunctions(QQ).llt(3,t=2).hspin()
Symmetric Functions over Rational Field in the level 3 LLT spin with t=2 basis
sage: QQz = FractionField(QQ['z']); z = QQz.gen()
sage: SymmetricFunctions(QQz).llt(3,t=z).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in z over
↳Rational Field in the level 3 LLT spin with t=z basis
```

class Element

Bases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element*

level()

Returns the level of *self*.

INPUT:

- *self* – an instance of the LLT hspin or hcospin basis

OUTPUT:

- returns the level associated to the basis *self*.

EXAMPLES:

```
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.level()
3
```

llt_family()

The family of the llt bases of the symmetric functions.

INPUT:

- *self* – an instance of the LLT hspin or hcospin basis

OUTPUT:

- returns an instance of the family of LLT bases associated to *self*.

EXAMPLES:

```
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.llt_family()
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field
```

product (*left*, *right*)

Convert to the monomial basis, do the multiplication there, and convert back to the basis *self*.

INPUT:

- *self* – an instance of the LLT hspin or hcospin basis
- *left*, *right* – elements of the symmetric functions

OUTPUT:

the product of *left* and *right* expanded in the basis *self*

EXAMPLES:

```
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.product(HSp3([1]), HSp3([2]))
HSp3[2, 1] + (-t+1)*HSp3[3]
sage: HCosp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hcospin()
sage: HCosp3.product(HCosp3([1]), HSp3([2]))
1/t*HCosp3[2, 1] + ((t-1)/t)*HCosp3[3]
```

class `sage.combinat.sf.llt.LLT_spin`(*llt*)

Bases: `sage.combinat.sf.llt.LLT_generic`

A class of methods for the h-spin LLT basis of the symmetric functions.

INPUT:

- *self* – an instance of the LLT hcospin basis
- *llt* – a family of LLT symmetric function bases

class `Element`

Bases: `sage.combinat.sf.llt.LLT_generic.Element`

5.1.288 Macdonald Polynomials

Notation used in the definitions follows mainly [Mac1995].

The integral forms of the bases H and Ht do not appear in Macdonald's book. They correspond to the two bases $H_\mu[X; q, t] = \sum_\nu K_{\nu\mu}(q, t) s_\nu[X]$ and $\tilde{H}_\mu[X; q, t] = t^{n(\mu)} \sum_\nu K_{\nu\mu}(q, 1/t) s_\nu[X]$ where $K_{\mu\nu}(q, t)$ are the Macdonald q, t -Koskta coefficients.

The Ht in this case is short for \tilde{H} and is the basis which is the graded Frobenius image of the Garsia-Haiman modules [GH1993].

REFERENCES:

- [Mac1995]

class `sage.combinat.sf.macdonald.Macdonald`(*Sym*, *q='q'*, *t='t'*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`

Macdonald Symmetric functions including P , Q , J , H , Ht bases also including the S basis which is the plethystic transformation of the Schur basis (that which is dual to the Schur basis with respect to the Macdonald q, t -scalar product)

INPUT:

- *self* – a family of Macdonald symmetric function bases

EXAMPLES:

```

sage: t = QQ['t'].gen(); SymmetricFunctions(QQ['t'].fraction_field()).macdonald(q=t,
↳t=1)
Macdonald polynomials with q=t and t=1 over Fraction Field of Univariate Polynomial
↳Ring in t over Rational Field
sage: Sym = SymmetricFunctions(FractionField(QQ['t'])).macdonald()
Traceback (most recent call last):
...
TypeError: unable to evaluate 'q' in Fraction Field of Univariate Polynomial Ring
↳in t over Rational Field

```

H()

Returns the Macdonald polynomials on the H basis. When the H basis is expanded on the Schur basis, the coefficients are the qt -Kostka numbers.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT:

- returns the H Macdonald basis of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: H = Sym.macdonald().H(); H
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↳over Rational Field in the Macdonald H basis
sage: s = Sym.schur()
sage: s(H([2]))
q*s[1, 1] + s[2]
sage: s(H([1, 1]))
s[1, 1] + t*s[2]

```

Coercions to/from the Schur basis are implemented:

```

sage: H = Sym.macdonald().H()
sage: s = Sym.schur()
sage: H(s([2]))
(q/(q*t-1))*McdH[1, 1] - (1/(q*t-1))*McdH[2]

```

Ht()

Returns the Macdonald polynomials on the Ht basis. The elements of the Ht basis are eigenvectors of the $nabla$ operator. When expanded on the Schur basis, the coefficients are the modified qt -Kostka numbers.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT:

- returns the Ht Macdonald basis of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: Ht = Sym.macdonald().Ht(); Ht
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↳over Rational Field in the Macdonald Ht basis

```

(continues on next page)

(continued from previous page)

```
sage: [Ht(p).nabla() for p in Partitions(3)]
[q^3*McdHt[3], q*t*McdHt[2, 1], t^3*McdHt[1, 1, 1]]
```

```
sage: s = Sym.schur()
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: q,t = Ht.base_ring().gens()
sage: s(Ht([2,1]))
q*t*s[1, 1, 1] + (q+t)*s[2, 1] + s[3]
sage: qt_kostka([1,1,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q*t
sage: qt_kostka([2,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q + t
sage: qt_kostka([3],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
1
```

Coercions to/from the Schur basis are implemented:

```
sage: Ht = Sym.macdonald().Ht()
sage: s = Sym.schur()
sage: Ht(s([2,1]))
(q/(q*t^2-t^3-q^2+q*t))*McdHt[1, 1, 1] + ((-q^2-q*t-t^2)/(q^2*t^2-q^3-t^
↪3+q*t))*McdHt[2, 1] + (t/(-q^3+q^2*t+q*t-t^2))*McdHt[3]
sage: Ht(s([2]))
((-q)/(-q+t))*McdHt[1, 1] + (t/(-q+t))*McdHt[2]
```

J()

Returns the Macdonald polynomials on the J basis also known as the integral form of the Macdonald polynomials. These are scalar multiples of both the P and Q bases. When expressed in the P or Q basis, the scaling coefficients are polynomials in q and t rather than rational functions.

The J basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the S -basis [LLM1998].

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT:

- returns the J Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: J = Sym.macdonald().J(); J
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↪over Rational Field in the Macdonald J basis
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: P(J([2]))
(q*t^2-q*t-t+1)*McdP[2]
sage: P(J([1,1]))
(t^3-t^2-t+1)*McdP[1, 1]
sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]
```

(continues on next page)

(continued from previous page)

```
sage: Q(J([1,1]))
(q^2*t-q*t-q+1)*McdQ[1, 1]
```

Coercions from the Q and J basis (proportional) and to/from the Schur basis are implemented:

```
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()
```

```
sage: J(P([2]))
(1/(q*t^2-q*t-t+1))*McdJ[2]
```

```
sage: J(Q([2]))
(1/(q^3-q^2-q+1))*McdJ[2]
```

```
sage: s(J([2]))
(-q*t+t^2+q-t)*s[1, 1] + (q*t^2-q*t-t+1)*s[2]
sage: J(s([2]))
((q-t)/(q*t^4-q*t^3-q*t^2-t^3+q*t+t^2+t-1))*McdJ[1, 1] + (1/(q*t^2-q*t-
→t+1))*McdJ[2]
```

P()

Returns Macdonald polynomials in P basis. The P basis is defined here as a normalized form of the J basis.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT:

- returns the P Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↳over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
```

The P Macdonald basis is upper triangularly related to the monomial symmetric functions and are orthogonal with respect to the qt -Hall scalar product:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↳over Rational Field in the Macdonald P basis
sage: m = Sym.monomial()
sage: P.transition_matrix(m,2)
[
  1 (q*t - q + t - 1)/(q*t - 1)]
[
  0                                1]
```

(continues on next page)

(continued from previous page)

```

sage: P([1,1]).scalar_qt(P([2]))
0
sage: P([2]).scalar_qt(P([2]))
(-q^3 + q^2 + q - 1)/(-q*t^2 + q*t + t - 1)
sage: P([1,1]).scalar_qt(P([1,1]))
(-q^2*t + q*t + q - 1)/(-t^3 + t^2 + t - 1)

```

When $q = 0$, the Macdonald polynomials on the P basis are the same as the Hall-Littlewood polynomials on the P basis.

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: P = Sym.macdonald(q=0).P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
Rational Field in the Macdonald P with q=0 basis
sage: P([2])^2
(t+1)*McdP[2, 2] + (-t+1)*McdP[3, 1] + McdP[4]
sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])^2
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]

```

Coercions from the Q and J basis (proportional) are implemented:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()

```

```

sage: P(Q([2]))
((q*t^2-q*t-t+1)/(q^3-q^2-q+1))*McdP[2]
sage: P(Q([2,1]))
((-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1)/(-q^4*t+2*q^3*t-q^2*t+q^2-2*q+1))*McdP[2, 1]

```

```

sage: P(J([2]))
(q*t^2-q*t-t+1)*McdP[2]
sage: P(J([2,1]))
(-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1)*McdP[2, 1]

```

By transitivity, one get coercions from the classical bases:

```

sage: P(s([2]))
((q-t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P(s([2,1]))
((q*t-t^2+q-t)/(q*t^2-1))*McdP[1, 1, 1] + McdP[2, 1]

```

```

sage: Sym = SymmetricFunctions(QQ['x', 'y', 'z'].fraction_field())
sage: (x,y,z) = Sym.base_ring().gens()
sage: Macxy = Sym.macdonald(q=x,t=y)
sage: Macyz = Sym.macdonald(q=y,t=z)
sage: Maczx = Sym.macdonald(q=z,t=x)
sage: P1 = Macxy.P()
sage: P2 = Macyz.P()

```

(continues on next page)

(continued from previous page)

```

sage: P3 = Maczx.P()
sage: m(P1[2,1])
((-2*x*y^2+x*y-y^2+x-y+2)/(-x*y^2+1))*m[1, 1] + m[2, 1]
sage: m(P2[2,1])
((-2*y*z^2+y*z-z^2+y-z+2)/(-y*z^2+1))*m[1, 1] + m[2, 1]
sage: m(P1(P2(P3[2,1])))
((-2*x^2*z-x^2+x*z-x+z+2)/(-x^2*z+1))*m[1, 1] + m[2, 1]
sage: P1(P2[2])
((-x*y^2+2*x*y*z-y^2*z-x+2*y-z)/(x*y^2*z-x*y-y*z+1))*McdP[1, 1] + McdP[2]
sage: m(z*P1[2]+x*P2[2])
((x^2*y^2*z+x*y^2*z^2-x^2*y^2+x^2*y*z-x*y*z^2+y^2*z^2-x^2*y-2*x*y*z-y*z^2+x*y-
-y*z+x+z)/(x*y^2*z-x*y-y*z+1))*m[1, 1] + (x+z)*m[2]

```

Q()

Returns the Macdonald polynomials on the Q basis. These are dual to the Macdonald polynomials on the P basis with respect to the qt -Hall scalar product. The Q basis is defined to be a normalized form of the J basis.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT:

- returns the Q Macdonald basis of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
over Rational Field in the Macdonald Q basis
sage: P = Sym.macdonald().P()
sage: Q([2]).scalar_qt(P([2]))
1
sage: Q([2]).scalar_qt(P([1,1]))
0
sage: Q([1,1]).scalar_qt(P([2]))
0
sage: Q([1,1]).scalar_qt(P([1,1]))
1
sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: Q(P([1,1]))
((q^2*t-q*t-q+1)/(t^3-t^2-t+1))*McdQ[1, 1]

```

Coercions from the P and J basis (proportional) are implemented:

```

sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()

```

```

sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]

```

```

sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: P(Q(P([2])))
McdP[2]
sage: Q(P(Q([2])))
McdQ[2]

```

By transitivity, one gets coercions from the classical bases:

```

sage: Q(s([2]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdQ[1, 1] + ((q^3-q^2-q+1)/(q*t^2-q*t-
↪t+1))*McdQ[2]

```

S()

Returns the modified Schur functions defined by the plethystic substitution $S_\mu = s_\mu[X(1-t)/(1-q)]$. When the Macdonald polynomials in the J basis are expressed in terms of the modified Schur functions at $q = 0$, the coefficients are qt -Kostka numbers.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT:

- returns the S Macdonald basis of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: S = Sym.macdonald().S(); S
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t_
↪over Rational Field in the Macdonald S basis
sage: p = Sym.power()
sage: p(S[2,1])
((1/3*t^3-t^2+t-1/3)/(q^3-3*q^2+3*q-1))*p[1, 1, 1] + ((-1/3*t^3+1/3)/(q^3-
↪1))*p[3]
sage: J = Sym.macdonald().J()
sage: S(J([2]))
(q^3-q^2-q+1)*McdS[2]
sage: S(J([1,1]))
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
sage: S = Sym.macdonald(q=0).S()
sage: S(J[1,1])
McdS[1, 1] + t*McdS[2]
sage: S(J[2])
q*McdS[1, 1] + McdS[2]
sage: p(S[2,1])
(-1/3*t^3+t^2-t+1/3)*p[1, 1, 1] + (1/3*t^3-1/3)*p[3]

sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2], [1,1])
t
sage: qt_kostka([1,1], [2])
q

```

Coercions to/from the Schur basis are implemented:

```

sage: S = Sym.macdonald().S()
sage: s = Sym.schur()
sage: S(s([2]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-
↪1))*McdS[2]
sage: s(S([1,1]))
((-q*t^2+q*t+t-1)/(-q^3+q^2+q-1))*s[1, 1] + ((q*t-t^2-q+t)/(-q^3+q^2+q-1))*s[2]

```

base_ring()

Returns the base ring of the symmetric functions where the Macdonald symmetric functions live

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT:

- the base ring associated to the corresponding symmetric function ring

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['q'].fraction_field())
sage: Mac = Sym.macdonald(t=0)
sage: Mac.base_ring()
Fraction Field of Univariate Polynomial Ring in q over Rational Field

```

symmetric_function_ring()

Returns the base ring of the symmetric functions where the Macdonald symmetric functions live

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT:

- the symmetric function ring associated to the Macdonald bases

EXAMPLES:

```

sage: Mac = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0)
sage: Mac.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q over
↪Rational Field

```

class `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`(*macdonald*)

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

A class for methods for one of the Macdonald bases of the symmetric functions

INPUT:

- `self` – a Macdonald basis
- `macdonald` – a family of Macdonald symmetric function bases

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q,t'])); Sym.rename("Sym"); Sym
Sym
sage: Sym.macdonald().P()
Sym in the Macdonald P basis

```

(continues on next page)

(continued from previous page)

```
sage: Sym.macdonald(t=2).P()
Sym in the Macdonald P with t=2 basis
sage: Sym.rename()
```

class ElementBases: *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element***nabla**(*q=None, t=None, power=1*)Return the value of the nabla operator applied to *self*.

The eigenvectors of the nabla operator are the Macdonald polynomials in the *Ht* basis. For more information see: [BGHT1999].

The operator nabla acts on symmetric functions and has the Macdonald *Ht* basis as eigenfunctions and the eigenvalues are $q^{n(\mu')}t^{n(\mu)}$ where $n(\mu) = \sum_i (i-1)\mu_i$ and μ' is the conjugate shape of μ .

If the parameter *power* is an integer then it calculates nabla to that integer. The default value of *power* is 1.

INPUT:

- *self* – an element of a Macdonald basis
- *q, t* – optional parameters to specialize
- *power* – an integer (default: 1)

OUTPUT:

- returns the symmetric function of ∇ acting on *self*

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: P = Sym.macdonald().P()
sage: P([1, 1]).nabla()
((q^2*t+q*t^2-2*t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P([1, 1]).nabla(t=1)
((q^2*t+q*t-t-1)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: H = Sym.macdonald().H()
sage: H([1, 1]).nabla()
t*McdH[1, 1] + (-t^2+1)*McdH[2]
sage: H([1, 1]).nabla(q=1)
((t^2+q-t-1)/(q*t-1))*McdH[1, 1] + ((-t^3+t^2+t-1)/(q*t-1))*McdH[2]
sage: H(0).nabla()
0
sage: H([2, 2, 1]).nabla(t=1/H.t)
((-q^2)/(-t^4))*McdH[2, 2, 1]
sage: H([2, 2, 1]).nabla(t=1/H.t, power=-1)
((-t^4)/(-q^2))*McdH[2, 2, 1]
```

c1(*part*)Returns the *qt*-Hall scalar product between *J*(*part*) and *P*(*part*).

INPUT:

- *self* – a Macdonald basis
- *part* – a partition

OUTPUT:

- returns the *qt*-Hall scalar product between *J*(*part*) and *P*(*part*)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().PC()
sage: P.c1(Partition([2,1]))
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
```

c2(*part*)

Returns the *qt*-Hall scalar product between $J(\text{part})$ and $Q(\text{part})$.

INPUT:

- *self* – a Macdonald basis
- *part* – a partition

OUTPUT:

- returns the *qt*-Hall scalar product between $J(\text{part})$ and $Q(\text{part})$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().PC()
sage: P.c2(Partition([2,1]))
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

macdonald_family()

Returns the family of Macdonald bases associated to the basis *self*

INPUT:

- *self* – a Macdonald basis

OUTPUT:

- the family of Macdonald symmetric functions associated to *self*

EXAMPLES:

```
sage: MacP = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0).PC()
sage: MacP.macdonald_family()
Macdonald polynomials with t=0 over Fraction Field of Univariate Polynomial_
↪Ring in q over Rational Field
```

product(*left*, *right*)

Multiply an element of the Macdonald symmetric function basis *self* and another symmetric function

Convert to the Schur basis, do the multiplication there, and convert back to *self* basis.

INPUT:

- *self* – a Macdonald symmetric function basis
- *left* – an element of the basis *self*
- *right* – another symmetric function

OUTPUT:

the product of *left* and *right* expanded in the basis *self*

EXAMPLES:

```

sage: Mac = SymmetricFunctions(FractionField(QQ['q', 't'])).macdonald()
sage: H = Mac.H()
sage: J = Mac.J()
sage: P = Mac.P()
sage: Q = Mac.Q()
sage: Ht = Mac.Ht()
sage: J([1])^2 #indirect doctest
((q-1)/(q*t-1))*McdJ[1, 1] + ((t-1)/(q*t-1))*McdJ[2]
sage: J.product( J[1], J[2] )
((-q^2+1)/(-q^2*t+1))*McdJ[2, 1] + ((-t+1)/(-q^2*t+1))*McdJ[3]
sage: H.product( H[1], H[2] )
((q^2-1)/(q^2*t-1))*McdH[2, 1] + ((-t+1)/(-q^2*t+1))*McdH[3]
sage: P.product( P[1], P[2] )
((-q^3*t^2+q*t^2+q^2-1)/(-q^3*t^2+q^2*t+q*t-1))*McdP[2, 1] + McdP[3]
sage: Q.product( Q[1], Q[2] )
McdQ[2, 1] + ((q^2*t-q^2+q*t-q+t-1)/(q^2*t-1))*McdQ[3]
sage: Ht.product( Ht[1], Ht[2] )
((q^2-1)/(q^2-t))*McdHt[2, 1] + ((t-1)/(-q^2+t))*McdHt[3]

```

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_h**(*macdonald*)

Bases: *sage.combinat.sf.macdonald.MacdonaldPolynomials_generic*

The H basis is defined as $H_\mu = \sum_\lambda K_{\lambda\mu}(q, t) s_\lambda$ where $K_{\lambda\mu}(q, t)$ are the Macdonald Kostka coefficients.

In this implementation, it is calculated by using the Macdonald Ht basis and substituting $t \rightarrow 1/t$ and multiplying by $t^{n(\mu)}$.

INPUT:

- *self* – a Macdonald H basis
- *macdonald* – a family of Macdonald bases

class **Element**

Bases: *sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element*

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_ht**(*macdonald*)

Bases: *sage.combinat.sf.macdonald.MacdonaldPolynomials_generic*

The Ht basis is defined as $\tilde{H}_\mu = t^{n(\mu)} \sum_\lambda K_{\lambda\mu}(q, t^{-1}) s_\lambda$ where $K_{\lambda\mu}(q, t)$ are the Macdonald (q, t) -Kostka coefficients and $n(\mu) = \sum_i (i-1)\mu_i$.

It is implemented here by using a Pieri formula due to F. Bergeron and M. Haiman [BH2013].

INPUT:

- *self* – a Macdonald Ht basis
- *macdonald* – a family of Macdonald bases

class **Element**

Bases: *sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element*

nabla(*q=None, t=None, power=1*)

Returns the value of the nabla operator applied to *self*. The eigenvectors of the *nabla* operator are the Macdonald polynomials in the Ht basis. For more information see: [BGHT1999].

The operator *nabla* acts on symmetric functions and has the Macdonald Ht basis as eigenfunctions and the eigenvalues are $q^{n(\mu')} t^{n(\mu)}$ where $n(\mu) = \sum_i (i-1)\mu_i$.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `self` – an element of the Macdonald Ht basis
- `q, t` – optional parameters to specialize
- `power` – an integer (default: 1)

OUTPUT:

- returns the symmetric function of ∇ acting on `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Ht = Sym.macdonald().Ht()
sage: t = Ht.t; q = Ht.q
sage: s = Sym.schur()
sage: a = sum(Ht(p) for p in Partitions(3))
sage: Ht(0).nabla()
0
sage: a.nabla() == t^3*Ht([1,1,1])+q*t*Ht([2,1]) + q^3*Ht([3])
True
sage: a.nabla(t=3) == 27*Ht([1,1,1])+3*q*Ht([2,1]) + q^3*Ht([3])
True
sage: a.nabla(q=3) == t^3*Ht([1,1,1])+3*t*Ht([2,1]) + 27*Ht([3])
True
sage: Ht[2,1].nabla(power=-1)
1/(q*t)*McdHt[2, 1]
sage: Ht[2,1].nabla(power=4)
q^4*t^4*McdHt[2, 1]
sage: s(a.nabla(q=3))
(t^6+27*q^3+3*q*t^2)*s[1, 1, 1] + (t^5+t^4+27*q^2+3*q*t+3*t^2+27*q)*s[2, 1]
↪ + (t^3+3*t+27)*s[3]
sage: Ht = Sym.macdonald(q=3).Ht()
sage: a = sum(Ht(p) for p in Partitions(3))
sage: s(a.nabla())
(t^6+9*t^2+729)*s[1, 1, 1] + (t^5+t^4+3*t^2+9*t+324)*s[2, 1] + (t^
↪ 3+3*t+27)*s[3]
```

class `sage.combinat.sf.macdonald.MacdonaldPolynomials_j`(*macdonald*)

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`

The J basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the S -basis.

INPUT:

- `self` – a Macdonald J basis
- `macdonald` – a family of Macdonald bases

class `Element`

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`

class `sage.combinat.sf.macdonald.MacdonaldPolynomials_p`(*macdonald*)

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`

The P basis is defined here as the J basis times a normalizing coefficient c_2 .

INPUT:

- `self` – a Macdonald P basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`

scalar_qt_basis(*part1*, *part2*=None)

Returns the scalar product of $P(\text{part1})$ and $P(\text{part2})$. This scalar product formula is given in equation (4.11) p.323 and (6.19) p.339 of Macdonald's book [Mac1995].

INPUT:

- `self` – a Macdonald P basis
- `part1`, `part2` – partitions

OUTPUT:

- returns the scalar product of $P(\text{part1})$ and $P(\text{part2})$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.scalar_qt_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: f = P.scalar_qt_basis(Partition([3,2,1]), Partition([3,2,1]))
sage: factor(f.numerator())
(q - 1)^3 * (q^2*t - 1)^2 * (q^3*t^2 - 1)
sage: factor(f.denominator())
(t - 1)^3 * (q*t^2 - 1)^2 * (q^2*t^3 - 1)
```

With a single argument, takes $\text{part2} = \text{part1}$:

```
sage: P.scalar_qt_basis(Partition([2,1]), Partition([2,1]))
(-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1)/(-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1)
```

class sage.combinat.sf.macdonald.MacdonaldPolynomials_q(*macdonald*)

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`

The Q basis is defined here as the J basis times a normalizing coefficient.

INPUT:

- `self` – a Macdonald Q basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`

class sage.combinat.sf.macdonald.MacdonaldPolynomials_s(*macdonald*)

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic`

An implementation of the basis $s_\lambda[(1-t)X/(1-q)]$

This is perhaps misnamed as a 'Macdonald' basis for the symmetric functions but is used in the calculation of the Macdonald J basis (see method 'creation' below) but does use both of the two parameters and can be specialized to $s_\lambda[(1-t)X]$ and $s_\lambda[X/(1-t)]$.

INPUT:

- `self` – a Macdonald S basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: `sage.combinat.sf.macdonald.MacdonaldPolynomials_generic.Element`

creation(k)

This function is a creation operator for the J -basis for which the action is known on the ‘Macdonald’ S -basis by formula from [LLM1998].

INPUT:

- `self` – an element of the Macdonald S basis
- `k` – a positive integer

OUTPUT:

- returns the column adding operator on the J basis on `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: S = Sym.macdonald().S()
sage: a = S(1)
sage: a.creation(1)
(-q+1)*McdS[1]
sage: a.creation(2)
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
```

product($left$, $right$)

The multiplication of the modified Schur functions behaves the same as the multiplication of the Schur functions.

INPUT:

- `self` – a Macdonald S basis
- `left`, `right` – a symmetric functions

OUTPUT:

the product of `left` and `right`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: S = Sym.macdonald().S()
sage: S([2])^2 #indirect doctest
McdS[2, 2] + McdS[3, 1] + McdS[4]
```

sage.combinat.sf.macdonald.c1($part$, q , t)

This function returns the qt -Hall scalar product between $J(part)$ and $P(part)$.

This coefficient is c_λ in equation (8.1') p. 352 of Macdonald's book [Mac1995].

INPUT:

- `part` – a partition
- `q`, `t` – parameters

OUTPUT:

- returns a polynomial of the scalar product between the J and P bases

EXAMPLES:

```

sage: from sage.combinat.sf.macdonald import c1
sage: R.<q,t> = QQ[]
sage: c1(Partition([2,1]),q,t)
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
sage: c1(Partition([1,1]),q,t)
q^2*t - q*t - q + 1

```

`sage.combinat.sf.macdonald.c2(part, q, t)`

This function returns the qt-Hall scalar product between $J(\text{part})$ and $Q(\text{part})$.

This coefficient is c_λ in equation (8.1) p. 352 of Macdonald's book [Mac1995].

INPUT:

- `part` – a partition
- `q, t` – parameters

OUTPUT:

- returns a polynomial of the scalar product between the J and P bases

EXAMPLES:

```

sage: from sage.combinat.sf.macdonald import c2
sage: R.<q,t> = QQ[]
sage: c2(Partition([1,1]),q,t)
t^3 - t^2 - t + 1
sage: c2(Partition([2,1]),q,t)
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1

```

`sage.combinat.sf.macdonald.cmunu(mu, nu)`

Return the coefficient of \tilde{H}_ν in $h_r^\perp \tilde{H}_\mu$.

Proposition 5 of F. Bergeron and M. Haiman [BH2013] states

$$c_{\mu\nu} = \sum_{\alpha \leftarrow \nu} c_{\mu\alpha} c_{\alpha\nu} B_{\alpha/\nu} / B_{\mu/\nu}$$

where $c_{\mu\nu}$ is the coefficient of \tilde{H}_ν in $h_r^\perp \tilde{H}_\mu$ and $B_{\mu/\nu}$ is the bi-exponent generator implemented in the function `sage.combinat.sf.macdonald.Bmu()`.

INPUT:

- `mu, nu` – partitions with `nu` contained in `mu`

OUTPUT:

- an element of the fraction field of polynomials in q and t

EXAMPLES:

```

sage: from sage.combinat.sf.macdonald import cmunu
sage: cmunu(Partition([2,1]),Partition([1]))
q + t + 1
sage: cmunu(Partition([2,2]),Partition([1,1]))
(-q^3 - q^2 + q*t + t)/(-q + t)
sage: Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
sage: h = Sym.h()
sage: Ht = Sym.macdonald().Ht()

```

(continues on next page)

(continued from previous page)

```

sage: all(Ht[2,2].skew_by(h[r]).coefficient(nu)
.....:      == cmunu(Partition([2,2]),nu)
.....:      for r in range(1,5) for nu in Partitions(4-r))
True

```

`sage.combinat.sf.macdonald.cmunu1(mu, nu)`

Return the coefficient of \tilde{H}_ν in $h_1^\perp \tilde{H}_\mu$.

INPUT:

- mu, nu – partitions with nu precedes mu

OUTPUT:

- an element of the fraction field of polynomials in q and t

EXAMPLES:

```

sage: from sage.combinat.sf.macdonald import cmunu1
sage: cmunu1(Partition([2,1]),Partition([2]))
(-t^2 + q)/(q - t)
sage: cmunu1(Partition([2,1]),Partition([1,1]))
(-q^2 + t)/(-q + t)
sage: Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
sage: h = Sym.h()
sage: Ht = Sym.macdonald().Ht()
sage: all(Ht[3,2,1].skew_by(h[1]).coefficient(nu)
.....:      == cmunu1(Partition([3,2,1]),nu)
.....:      for nu in Partition([3,2,1]).down_list())
True

```

`sage.combinat.sf.macdonald.qt_kostka(lam, mu)`

Returns the $K_{\lambda\mu}(q, t)$ by computing the change of basis from the Macdonald H basis to the Schurs.

INPUT:

- lam, mu – partitions of the same size

OUTPUT:

- returns the q, t -Kostka polynomial indexed by the partitions lam and mu

EXAMPLES:

```

sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2,1,1],[1,1,1,1])
t^3 + t^2 + t
sage: qt_kostka([1,1,1,1],[2,1,1])
q
sage: qt_kostka([1,1,1,1],[3,1])
q^3
sage: qt_kostka([1,1,1,1],[1,1,1,1])
1
sage: qt_kostka([2,1,1],[2,2])
q^2*t + q*t + q
sage: qt_kostka([2,2],[2,2])
q^2*t^2 + 1

```

(continues on next page)

(continued from previous page)

```

sage: qt_kostka([4],[3,1])
t
sage: qt_kostka([2,2],[3,1])
q^2*t + q
sage: qt_kostka([3,1],[2,1,1])
q*t^3 + t^2 + t
sage: qt_kostka([2,1,1],[2,1,1])
q*t^2 + q*t + 1
sage: qt_kostka([2,1],[1,1,1,1])
0

```

5.1.289 Monomial symmetric functions

class `sage.combinat.sf.monomial.SymmetricFunctionAlgebra_monomial`(*Sym*)
 Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`

A class for methods related to monomial symmetric functions

INPUT:

- `self` – a monomial symmetric function basis
- `Sym` – an instance of the ring of the symmetric functions

class `Element`

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

expand(*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the *n* variables labelled by *alphabet*.

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).m()
sage: m([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: m([1,1,1]).expand(2)
0
sage: m([2,1]).expand(3,alphabet='z')
z0^2*z1 + z0*z1^2 + z0^2*z2 + z1^2*z2 + z0*z2^2 + z1*z2^2
sage: m([2,1]).expand(3,alphabet='x,y,z')
x^2*y + x*y^2 + x^2*z + y^2*z + x*z^2 + y*z^2
sage: m([1]).expand(0)
0
sage: (3*m([])).expand(0)
3

```

exponential_specialization(*t*=None, *q*=1)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q -exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R . It is defined whenever the base ring K is a \mathbf{Q} -algebra and t is an element of R . The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q -exponential specialization is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q -factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n , we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \rightarrow 1$ is ex .

INPUT:

- `t` (default: None) – the value to use for t ; the default is to create a ring of polynomials in `t`.
- `q` (default: 1) – the value to use for q . If `q` is None, then a ring (or fraction field) of polynomials in `q` is created.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: (m[3]+m[2,1]+m[1,1,1]).exponential_specialization()
1/6*t^3
sage: x = 5*m[1,1,1] + 3*m[2,1] + 1
sage: x.exponential_specialization()
5/6*t^3 + 1
```

We also support the `q`-exponential_specialization:

```
sage: factor(m[3].exponential_specialization(q=var("q"), t=var("t")))
(q - 1)^2*t^3/(q^2 + q + 1)
```

principal_specialization($n=+\infty$, $q=None$)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \dots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R , and we assume that the variables of our symmetric functions are x_1, x_2, x_3, \dots . (To be more precise, $ps_{n,q}$ is a K -algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i . This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` (default: `infinity`) – a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` (default: `None`) – the value to use for q ; the default is to create a ring of polynomials in q (or a field of rational functions in q) over the given coefficient ring.

For $q=1$ and finite n we use the formula from Proposition 7.8.3 of [EnumComb2]:

$$ps_{n,1}(m_\lambda) = \binom{n}{\ell(\lambda)} \binom{\ell(\lambda)}{m_1(\lambda), m_2(\lambda), \dots},$$

where $\ell(\lambda)$ denotes the length of λ .

In all other cases, we convert to complete homogeneous symmetric functions.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: x = m[3,1]
sage: x.principal_specialization(3)
q^7 + q^6 + q^5 + q^3 + q^2 + q

sage: x = 5*m[2] + 3*m[1] + 1
sage: x.principal_specialization(3, q=var("q"))
-10*(q^3 - 1)*q/(q - 1) + 5*(q^3 - 1)^2/(q - 1)^2 + 3*(q^3 - 1)/(q - 1) + 1
```

`antipode_by_coercion(element)`

The antipode of `element` via coercion to and from the power-sum basis or the Schur basis (depending on whether the power sums really form a basis over the given ground ring).

INPUT:

- `element` – element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]
```

Todo: Is there a not too difficult way to get the power-sum computations to work over any ring, not just one with coercion from \mathbb{Q} ?

`from_polynomial(f, check=True)`

Return the symmetric function in the monomial basis corresponding to the polynomial `f`.

INPUT:

- `self` – a monomial symmetric function basis

- `f` – a polynomial in finitely many variables over the same base ring as `self`. It is assumed that this polynomial is symmetric.
- `check` – boolean (default: `True`), checks whether the polynomial is indeed symmetric

OUTPUT:

- This function converts a symmetric polynomial f in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: m.from_polynomial(f)
m[1]
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: m.from_polynomial(f)
m[2]
sage: f = x[0]^2+x[1]
sage: m.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a symmetric polynomial
sage: f = (m[2,1]+m[1,1]).expand(3)
sage: m.from_polynomial(f)
m[1, 1] + m[2, 1]
sage: f = (2*m[2,1]+m[1,1]+3*m[3]).expand(3)
sage: m.from_polynomial(f)
m[1, 1] + 2*m[2, 1] + 3*m[3]
```

`from_polynomial_exp(p)`

Conversion from polynomial in exponential notation

INPUT:

- `self` – a monomial symmetric function basis
- `p` – a multivariate polynomial over the same base ring as `self`

OUTPUT:

- This returns a symmetric function by mapping each monomial of p with exponents `exp` into m_λ where λ is the partition with exponential notation `exp`.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 5)
sage: x = P.gens()
```

The exponential notation of the partition $(5, 5, 5, 3, 1, 1)$ is:

```
sage: Partition([5,5,5,3,1,1]).to_exp()
[2, 0, 1, 0, 3]
```

Therefore, the monomial:

```
sage: f = x[0]^2 * x[2] * x[4]^3
```

is mapped to:

```
sage: m.from_polynomial_exp(f)
m[5, 5, 5, 3, 1, 1]
```

Furthermore, this function is linear:

```
sage: f = 3 * x[3] + 2 * x[0]^2 * x[2] * x[4]^3
sage: m.from_polynomial_exp(f)
3*m[4] + 2*m[5, 5, 5, 3, 1, 1]
```

See also:

Partition(), *Partition.to_exp()*

product(*left*, *right*)

Return the product of *left* and *right*.

- *left*, *right* – symmetric functions written in the monomial basis *self*.

OUTPUT:

- the product of *left* and *right*, expanded in the monomial basis, as a dictionary whose keys are partitions and whose values are the coefficients of these partitions (more precisely, their respective monomial symmetric functions) in the product.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: a = m([2, 1])
sage: a^2
4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, ↵
↵2]
```

```
sage: QQx.<x> = QQ['x']
sage: m = SymmetricFunctions(QQx).m()
sage: a = m([2, 1])+x
sage: 2*a # indirect doctest
2*x*m[] + 2*m[2, 1]
sage: a^2
x^2*m[] + 2*x*m[2, 1] + 4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3, ↵
↵3] + 2*m[4, 1, 1] + m[4, 2]
```

5.1.290 Multiplicative symmetric functions

A realization h of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \dots)$ we have $h_\lambda = h_{\lambda_1} h_{\lambda_2} \dots$.

```
class sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative(Sym, ba-
                                                                    sis_name=None,
                                                                    prefix=None,
                                                                    graded=True)
```

Bases: *sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical*

The class of multiplicative bases of the ring of symmetric functions.

A realization q of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \dots)$ we have $q_\lambda = q_{\lambda_1} q_{\lambda_2} \cdots$ (with q_0 meaning 1).

Examples of multiplicative realizations are the elementary symmetric basis, the complete homogeneous basis, the powersum basis (if the base ring is a \mathbf{Q} -algebra), and the Witt basis (but not the Schur basis or the monomial basis).

coproduct_on_basis(*mu*)

Return the coproduct on a basis element for multiplicative bases.

INPUT:

- *mu* – a partition

OUTPUT:

- the image of `self[mu]` under comultiplication; this is an element of the tensor square of `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_basis([2,1])
p[] # p[2, 1] + p[1] # p[2] + p[2] # p[1] + p[2, 1] # p[]

sage: e = Sym.elementary()
sage: e.coproduct_on_basis([3,1])
e[] # e[3, 1] + e[1] # e[2, 1] + e[1] # e[3] + e[1, 1] # e[2] + e[2] # e[1, 1]
↪+ e[2, 1] # e[1] + e[3] # e[1] + e[3, 1] # e[]

sage: h = Sym.homogeneous()
sage: h.coproduct_on_basis([3,1])
h[] # h[3, 1] + h[1] # h[2, 1] + h[1] # h[3] + h[1, 1] # h[2] + h[2] # h[1, 1]
↪+ h[2, 1] # h[1] + h[3] # h[1] + h[3, 1] # h[]
```

product_on_basis(*left*, *right*)

Return the product of *left* and *right*.

INPUT:

- *left*, *right* – partitions

OUTPUT:

- an element of `self`

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: e([2,1])^2 # indirect doctest
e[2, 2, 1, 1]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: h([2,1])^2
h[2, 2, 1, 1]
```

```
sage: p = SymmetricFunctions(QQ).p()
sage: p([2,1])^2
p[2, 2, 1, 1]
```

```
sage: QQx.<x> = QQ[]
sage: p = SymmetricFunctions(QQx).p()
sage: (x*p([2]))^2
x^2*p[2, 2]

sage: TestSuite(p).run() # to silence sage -coverage
```

5.1.291 k -Schur Functions

class `sage.combinat.sf.new_kschur.KBoundedSubspace`(*Sym*, *k*, *t='t'*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

This class implements the subspace of the ring of symmetric functions spanned by $\{s_\lambda[X/(1-t)]\}_{\lambda_1 \leq k} = \{s_\lambda^{(k)}[X;t]\}_{\lambda_1 \leq k}$ over the base ring $\mathbf{Q}[t]$. When $t = 1$, this space is in fact a subring of the ring of symmetric functions generated by the complete homogeneous symmetric functions h_i for $1 \leq i \leq k$.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1

sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↪Field
```

The k -Schur function basis can be constructed as follows:

```
sage: ks = KB.kschur(); ks
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↪Field in the 3-Schur basis
```

K_kschur()

Return the k -bounded basis called the K - k -Schur basis.

See [Morse11] and [LamSchillingShimozono10].

REFERENCES:

EXAMPLES:

```
sage: kB = SymmetricFunctions(QQ).kBoundedSubspace(3,1)
sage: g = kB.K_kschur()
sage: g
3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur
↪basis
sage: kB = SymmetricFunctions(QQ['t']).kBoundedSubspace(3)
sage: g = kB.K_kschur()
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: This basis only exists for t=1
```

khomogeneous()

The homogeneous basis of this algebra.

See also:

[*kHomogeneous\(\)*](#)

EXAMPLES:

```
sage: kh3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).khomogeneous()
sage: TestSuite(kh3).run()
```

kschur()

The k -Schur basis of this algebra.

See also:

[*kSchur\(\)*](#)

EXAMPLES:

```
sage: ks3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).kschur()
sage: TestSuite(ks3).run()
```

ksplit()

The k -split basis of this algebra.

See also:

[*kSplit\(\)*](#)

EXAMPLES:

```
sage: ksp3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).ksplit()
sage: TestSuite(ksp3).run()
```

realizations()

A list of realizations of this algebra.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedSubspace(3,1).realizations()
[3-bounded Symmetric Functions over Rational Field with t=1 in the 3-Schur_
↳basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-split_
↳basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-bounded_
↳homogeneous basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur_
↳basis]
sage: SymmetricFunctions(QQ['t']).kBoundedSubspace(3).realizations()
[3-bounded Symmetric Functions over Univariate Polynomial Ring in t over_
↳Rational Field in the 3-Schur basis,
 3-bounded Symmetric Functions over Univariate Polynomial Ring in t over_
↳Rational Field in the 3-split basis]
```

(continues on next page)

retract(*sym*)

Return the retract of *sym* from the ring of symmetric functions to *self*.

INPUT:

- *sym* – a symmetric function

OUTPUT:

- the analogue of the symmetric function in the *k*-bounded subspace (if possible)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1
sage: KB.retract(s[2]+s[3])
ks3[2] + ks3[3]
sage: KB.retract(s[2,1,1])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1] is not in the image
```

class sage.combinat.sf.new_kschur.**KBoundedSubspaceBases**(*base, t='t'*)

Bases: [sage.categories.realizations.Category_realization_of_parent](#)

The category of bases for the *k*-bounded subspace of symmetric functions.

class **ElementMethods**

Bases: object

expand(**args*, ***kwargs*)

Return the monomial expansion of *self* in *n* variables.

INPUT:

- *n* – positive integer

OUTPUT: monomial expansion of *self* in *n* variables

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[3,1].expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: s = Sym.schur()
sage: ks[3,1].expand(2) == s(ks[3,1]).expand(2)
True

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: f = ks[3,2]-ks[1]
sage: f.expand(2)
t^2*x0^5 + (t^2 + t)*x0^4*x1 + (t^2 + t + 1)*x0^3*x1^2 + (t^2 + t + 1)*x0^
↪ 2*x1^3 + (t^2 + t)*x0*x1^4 + t^2*x1^5 - x0 - x1
```

hl_creation_operator(*nu*, *t=None*)

This is the vertex operator that generalizes Jing's operator.

It is a linear operator that raises the degree by $|\nu|$. This creation operator is a t -analogue of multiplication by $s(\nu)$.

See also:

Proposition 5 in [SZ2001].

INPUT:

- *nu* – a partition or a list of integers
- *t* – (default: None, in which case *t* is used) an element of the base ring

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(4)
sage: s = Sym.schur()
sage: s(ks([3,1,1]).hl_creation_operator([1]))
(t-1)*s[2, 2, 1, 1] + t^2*s[3, 1, 1, 1] + (t^3+t^2-t)*s[3, 2, 1] + (t^3-t^
↪2)*s[3, 3] + (t^4+t^3)*s[4, 1, 1] + t^4*s[4, 2] + t^5*s[5, 1]
sage: ks([3,1,1]).hl_creation_operator([1])
(t-1)*ks4[2, 2, 1, 1] + t^2*ks4[3, 1, 1, 1] + t^3*ks4[3, 2, 1] + (t^3-t^
↪2)*ks4[3, 3] + t^4*ks4[4, 1, 1]

sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(4,t=1)
sage: ks([3,1,1]).hl_creation_operator([1])
ks4[3, 1, 1, 1] + ks4[3, 2, 1] + ks4[4, 1, 1]
```

is_schur_positive(*args, **kwargs)

Return whether *self* is Schur positive.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False
```

omega()

Return the ω operator on *self*.

At $t = 1$, ω maps the k -Schur function $s_{\lambda}^{(k)}$ to $s_{\lambda^{(k)}}^{(k)}$, where $\lambda^{(k)}$ is the k -conjugate of the partition λ .

See also:

[`k_conjugate\(\)`](#).

For generic t , ω sends $s_{\lambda}^{(k)}[X; t]$ to $t^d s_{\lambda}^{(k)}[X; 1/t]$, where d is the size of the core of λ minus the size of λ . Most of the time, this result is not in the k -bounded subspace.

See also:

[`omega_t_inverse\(\)`](#).

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2,2,1,1].omega()
ks3[2, 2, 2]
sage: kh = Sym.khomogeneous(3)
sage: kh[3].omega()
h3[1, 1, 1] - 2*h3[2, 1] + h3[3]

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega()
Traceback (most recent call last):
...
ValueError: t*s[2, 1, 1, 1] + s[3, 1, 1] is not in the image
```

`omega_t_inverse()`

Return the map $t \rightarrow 1/t$ composed with ω on `self`.

Unlike the map [`omega\(\)`](#), the result of [`omega_t_inverse\(\)`](#) lives in the k -bounded subspace and hence will return an element even for generic t . For $t = 1$, [`omega\(\)`](#) and [`omega_t_inverse\(\)`](#) return the same result.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega_t_inverse()
1/t*ks3[2, 1, 1, 1]
sage: ks[3,2].omega_t_inverse()
1/t^2*ks3[1, 1, 1, 1, 1]
```

`scalar(x, zee=None)`

Return standard scalar product between `self` and `x`.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `zee` – an optional function on partitions giving the value for the scalar product between p_{μ} and p_{μ} (default is to use the standard [`zee\(\)`](#) function)

See also:

[`scalar\(\)`](#)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3)
```

(continues on next page)

(continued from previous page)

```

sage: ks3[3,2,1].scalar( ks3[2,2,2] )
t^3 + t
sage: dks3 = Sym.kBoundedQuotient(3).dks()
sage: [ks3[3,2,1].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 1, 0, 0, 0, 0, 0]
sage: dks3 = Sym.kBoundedQuotient(3,t=1).dks()
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, t - 1, 0, 1, 0, 0, 0]
sage: ks3 = Sym.kschur(3,t=1)
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 0, 0, 1, 0, 0, 0]
sage: kH = Sym.khomogeneous(4)
sage: kH([2,2,1]).scalar(ks3[2,2,1])
3

```

class ParentMethods

Bases: object

an_element()

Return an element of self.

EXAMPLES:

```

sage: SymmetricFunctions(QQ['t']).kschur(3).an_element()
2*ks3[] + 2*ks3[1] + 3*ks3[2]

```

antipode(*element*)

Return the antipode on *self* by lifting to the space of symmetric functions, computing the antipode, and then converting to *self.parent()*. This is only the antipode for $t = 1$ and for other values of t the result may not be in the space where the k -Schur functions live.

INPUT:

- *element* – an element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[3,2].antipode()
-ks3[1, 1, 1, 1, 1]
sage: ks3.antipode(ks3[3,2])
-ks3[1, 1, 1, 1, 1]

```

coproduct(*element*)Return the coproduct operation on *element*.

The coproduct is first computed on the homogeneous basis if $t = 1$ and on the Hall-Littlewood Qp basis otherwise. The result is computed then converted to the tensor squared of *self.parent()*.

INPUT:

- *element* – an element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[2,1].coproduct()

```

(continues on next page)

(continued from previous page)

```

ks3[] # ks3[2, 1] + ks3[1] # ks3[1, 1] + ks3[1] # ks3[2] + ks3[1, 1] #
↪ks3[1] + ks3[2] # ks3[1] + ks3[2, 1] # ks3[]
sage: h3 = Sym.khomogeneous(3)
sage: h3[2,1].coproduct()
h3[] # h3[2, 1] + h3[1] # h3[1, 1] + h3[1] # h3[2] + h3[1, 1] # h3[1] +
↪h3[2] # h3[1] + h3[2, 1] # h3[]
sage: ks3t = SymmetricFunctions(FractionField(QQ['t'])).kschur(3)
sage: ks3t[2,1].coproduct()
ks3[] # ks3[2, 1] + ks3[1] # ks3[1, 1] + ks3[1] # ks3[2] + ks3[1, 1] #
↪ks3[1] + ks3[2] # ks3[1] + ks3[2, 1] # ks3[]
sage: ks3t[3,1].coproduct()
ks3[] # ks3[3, 1] + ks3[1] # ks3[2, 1] + (t+1)*ks3[1] # ks3[3] + ks3[1, 1]
↪# ks3[2] + ks3[2] # ks3[1, 1]
+ (t+1)*ks3[2] # ks3[2] + ks3[2, 1] # ks3[1] + (t+1)*ks3[3] # ks3[1] +
↪ks3[3, 1] # ks3[]
sage: h3.coproduct(h3[2,1])
h3[] # h3[2, 1] + h3[1] # h3[1, 1] + h3[1] # h3[2] + h3[1, 1] # h3[1] +
↪h3[2] # h3[1] + h3[2, 1] # h3[]

```

counit(*element*)

Return the counit of *element*.

The counit is the constant term of *element*.

INPUT:

- *element* – an element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: f = 2*ks3[2,1] + 3*ks3[[]]
sage: f.counit()
3
sage: ks3.counit(f)
3

```

degree_on_basis(*b*)

Return the degree of the basis element indexed by *b*.

INPUT:

- *b* – a partition

EXAMPLES:

```

sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.degree_on_basis(Partition([3,2]))
5

```

one_basis()

Return the basis element indexing 1.

EXAMPLES:

```

sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.one() # indirect doctest
ks3[]

```

transition_matrix(*other*, *n*)

Return the degree *n* transition matrix between *self* and *other*.

INPUT:

- *other* – a basis in the ring of symmetric functions
- *n* – a positive integer

The entry in the i^{th} row and j^{th} column is the coefficient obtained by writing the i^{th} element of the basis of *self* in terms of the basis *other*, and extracting the j^{th} coefficient.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ); s = Sym.schur()
sage: ks3 = Sym.kschur(3, 1)
sage: ks3.transition_matrix(s, 5)
[1 1 1 0 0 0 0]
[0 1 0 1 0 0 0]
[0 0 1 0 1 0 0]
[0 0 0 1 0 1 0]
[0 0 0 0 1 1 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: s = Sym.schur()
sage: ks = Sym.kschur(3)
sage: ks.transition_matrix(s, 5)
[t^2  t  1  0  0  0  0]
[ 0  t  0  1  0  0  0]
[ 0  0  t  0  1  0  0]
[ 0  0  0  t  0  1  0]
[ 0  0  0  0  t^2  t  1]
```

super_categories()

The super categories of *self*.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.new_kschur import KBoundedSubspaceBases
sage: KB = Sym.kBoundedSubspace(3)
sage: KBB = KBoundedSubspaceBases(KB); KBB
Category of k bounded subspace bases of 3-bounded Symmetric Functions over
↳Univariate Polynomial Ring in t over Rational Field
sage: KBB.super_categories()
[Category of realizations of 3-bounded Symmetric Functions over Univariate
↳Polynomial Ring in t over Rational Field,
Join of Category of graded coalgebras with basis over Univariate Polynomial
↳Ring in t over Rational Field
and Category of subobjects of filtered modules with basis over Univariate
↳Polynomial Ring in t over Rational Field]
```

class `sage.combinat.sf.new_kschur.K_kSchur`(*kBoundedRing*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

This class implements the basis of the *k*-bounded subspace called the *K-k*-Schur basis.

See [Morse2011], [LamSchillingShimozono2010].

REFERENCES:

K_k_Schur_non_commutative_variables(*la*)

Return the K - k -Schur function, as embedded inside the affine zero Hecke algebra.

INPUT:

- la – A k -bounded Partition

OUTPUT:

- An element of the affine zero Hecke algebra.

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.K_k_Schur_non_commutative_variables([2,1])
T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[0,3,0] + T[2,0,3] +
↪ T[0,3,1] + T[2,3,2] + T[2,3,1] + T[3,1,2] + T[1,2,1] - T[2,0] - T[3,1]
sage: g.K_k_Schur_non_commutative_variables([])
1
sage: g.K_k_Schur_non_commutative_variables([4,1])
Traceback (most recent call last):
...
ValueError: Partition should be 3-bounded
```

homogeneous_basis_noncommutative_variables_zero_Hecke(*la*)

Return the homogeneous basis element indexed by la , viewed as an element inside the affine zero Hecke algebra. For the code, see method `_homogeneous_basis`.

INPUT:

- la – A k -bounded partition

OUTPUT:

- An element of the affine zero Hecke algebra.

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([2,1])
T[2,1,0] + T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[1,0,3] +
↪ T[0,3,0] + T[2,0,3] + T[0,3,2] + T[0,3,1] + T[2,3,2] + T[3,2,1] + T[2,3,1] +
↪ T[3,1,2] + T[1,2,1] - T[1,0] - 2*T[2,0] - T[0,3] - T[3,2] - 2*T[3,1] - T[2,1]
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([])
1
```

lift(*x*)

Return the lift of a k -bounded symmetric function.

INPUT:

- x – An expression in the K - k -Schur basis. Equivalently, x can be a k -bounded partition (then x corresponds to the basis element indexed by x)

OUTPUT:

- A symmetric function.

EXAMPLES:

```

sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.lift([2,1])
h[2] + h[2, 1] - h[3]
sage: g.lift([])
h[]
sage: g.lift([4,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-bounded_
↪Symmetric Functions over Rational Field with t=1 in the K-3-Schur basis)

```

product(x, y)

Return the product of the two K - k -Schur functions.

INPUT:

- x, y – elements of the k -bounded subspace, in the K - k -Schur basis.

OUTPUT:

- An element of the k -bounded subspace, in the K - k -Schur basis

EXAMPLES:

```

sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.product(g([2,1]), g[1])
-2*Kks3[2, 1] + Kks3[2, 1, 1] + Kks3[2, 2]
sage: g.product(g([2,1]), g([]))
Kks3[2, 1]

```

retract(x)

Return the retract of a symmetric function.

INPUT:

- x – A symmetric function.

OUTPUT:

- A k -bounded symmetric function in the K - k -Schur basis.

EXAMPLES:

```

sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: m = SymmetricFunctions(QQ).m()
sage: g.retract(m[2,1])
-2*Kks3[1] + 4*Kks3[1, 1] - 2*Kks3[1, 1, 1] - Kks3[2] + Kks3[2, 1]
sage: g.retract(m([]))
Kks3[]

```

class sage.combinat.sf.new_kschur.**kHomogeneous**($kBoundedRing$)
 Bases: *sage.combinat.free_module.CombinatorialFreeModule*

Space of k -bounded homogeneous symmetric functions.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: kH = Sym.khomogeneous(3)

```

(continues on next page)

(continued from previous page)

```
sage: kH[2]
h3[2]
sage: kH[2].lift()
h[2]
```

class `sage.combinat.sf.new_kschur.kSchur`(*kBoundedRing*)
 Bases: `sage.combinat.free_module.CombinatorialFreeModule`
 Space of k -Schur functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational_
↪Field
```

The k -Schur function basis can be constructed as follows:

```
sage: ks3 = KB.kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational_
↪Field in the 3-Schur basis
```

We can convert to any basis of the ring of symmetric functions and, whenever it makes sense, also the other way round:

```
sage: s = Sym.schur()
sage: s(ks3([3,2,1]))
s[3, 2, 1] + t*s[4, 1, 1] + t*s[4, 2] + t^2*s[5, 1]
sage: t = Sym.base_ring().gen()
sage: ks3(s([3, 2, 1]) + t*s([4, 1, 1]) + t*s([4, 2]) + t^2*s([5, 1]))
ks3[3, 2, 1]
sage: s(ks3[2, 1, 1])
s[2, 1, 1] + t*s[3, 1]
sage: ks3(s[2, 1, 1] + t*s[3, 1])
ks3[2, 1, 1]
```

k -Schur functions are indexed by partitions with first part $\leq k$. Constructing a k -Schur function for a larger partition raises an error:

```
sage: ks3([4,3,2,1]) #
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 3, 2, 1]) an element of self (=3-
↪bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational_
↪Field in the 3-Schur basis)
```

Similarly, attempting to convert a function that is not in the linear span of the k -Schur functions raises an error:

```
sage: ks3(s([4]))
Traceback (most recent call last):
...
ValueError: s[4] is not in the image
```

Note that the product of k -Schur functions is not guaranteed to be in the space spanned by the k -Schurs. In general, we only have that a k -Schur times a j -Schur function is in the $(k+j)$ -bounded subspace. The multiplication of two k -Schur functions thus generally returns the product of the lift of the functions to the ambient symmetric function space. If the result happens to lie in the k -bounded subspace, then the result is cast into the k -Schur basis:

```
sage: ks2 = Sym.kBoundedSubspace(2).kschur()
sage: ks2[1] * ks2[1]
ks2[1, 1] + ks2[2]
sage: ks2[1] * ks2[2]
s[2, 1] + s[3]
```

Because the target space of the product of a k -Schur and a j -Schur has several possibilities, the product of a k -Schur and j -Schur function is not implemented for distinct k and j . Let us show how to get around this ‘manually’:

```
sage: ks3 = Sym.kBoundedSubspace(3).kschur()
sage: ks2([2,1]) * ks3([3,1])
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: '2-bounded Symmetric Functions over
↳Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis' and '3-
↳bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↳Field in the 3-Schur basis'
```

The workaround:

```
sage: f = s(ks2([2,1])) * s(ks3([3,1])); f # Convert to Schur functions first and
↳multiply there.
s[3, 2, 1, 1] + s[3, 2, 2] + (t+1)*s[3, 3, 1] + s[4, 1, 1, 1]
+ (2*t+2)*s[4, 2, 1] + (t^2+t+1)*s[4, 3] + (2*t+1)*s[5, 1, 1]
+ (t^2+2*t+1)*s[5, 2] + (t^2+2*t)*s[6, 1] + t^2*s[7]
```

or:

```
sage: f = ks2[2,1].lift() * ks3[3,1].lift()
sage: ks5 = Sym.kBoundedSubspace(5).kschur()
sage: ks5(f) # The product of a 'ks2' with a 'ks3' is a 'ks5'.
ks5[3, 2, 1, 1] + ks5[3, 2, 2] + (t+1)*ks5[3, 3, 1] + ks5[4, 1, 1, 1]
+ (t+2)*ks5[4, 2, 1] + (t^2+t+1)*ks5[4, 3] + (t+1)*ks5[5, 1, 1] + ks5[5, 2]
```

For other technical reasons, taking powers of k -Schur functions is not implemented, even when the answer is still in the k -bounded subspace:

```
sage: ks2([1])^2
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for ^: '2-bounded Symmetric Functions over
↳Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis' and
↳'Integer Ring'
```

Todo: Get rid of said technical “reasons”.

However, at $t = 1$, the product of k -Schur functions is in the span of the k -Schur functions always. Below are some examples at $t = 1$

```
sage: ks3 = Sym.kBoundedSubspace(3, t=1).kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↪Field with t=1 in the 3-Schur basis
sage: s = SymmetricFunctions(ks3.base_ring()).schur()
sage: ks3(s([3]))
ks3[3]
sage: s(ks3([3,2,1]))
s[3, 2, 1] + s[4, 1, 1] + s[4, 2] + s[5, 1]
sage: ks3([2,1])^2 # taking powers works for t=1
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

product_on_basis(left, right)

Take the product of two k -Schur functions.

If $t \neq 1$, then take the product by lifting to the Schur functions and then retracting back into the k -bounded subspace (if possible).

If $t = 1$, then the product calls `_product_on_basis_via_rectangles()`.

INPUT:

- left, right – partitions

OUTPUT:

- an element of the k -Schur functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3,1)
sage: kH = Sym.khomogeneous(3)
sage: ks3(kH[2,1,1])
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([])*kH[2,1,1]
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([3,3,3,2,2,1,1,1])^2
ks3[3, 3, 3, 3, 3, 3, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1]
sage: ks3([3,3,3,2,2,1,1,1])*ks3([2,2,2,2,2,1,1,1])
ks3[3, 3, 3, 2, 2, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1]
sage: ks3([2,2,1,1,1,1])*ks3([2,2,2,1,1,1])
ks3[2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1] + ks3[2, 2, 2, 2, 2, 2, 1, 1, 1, 1,
↪1, 1]
sage: ks3[2,1]^2
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
sage: ks3 = Sym.kschur(3)
sage: ks3[2,1]*ks3[2,1]
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1,
↪1] + s[4, 2]
```

class sage.combinat.sf.new_kschur.kSplit(*kBoundedRing*)

Bases: *sage.combinat.free_module.CombinatorialFreeModule*

The k -split basis of the space of k -bounded-symmetric functions

Fix k a positive integer and t an element of the base ring.

The k -split functions are a basis for the space of k -bounded symmetric functions that also have the bases

$$\{Q'_\lambda[X; t]\}_{\lambda_1 \leq k} = \{s_\lambda^{(k)}[X; t]\}_{\lambda_1 \leq k}$$

where $Q'_\lambda[X; t]$ are the Hall-Littlewood symmetric functions (using the notation of [MAC]) and $s_\lambda^{(k)}[X; t]$ are the k -Schur functions. If t is not a root of unity, then

$$\{s_\lambda[X/(1-t)]\}_{\lambda_1 \leq k}$$

is also a basis of this space.

The k -split basis has the property that $Q'_\lambda[X; t]$ expands positively in the k -split basis and the k -split basis conjecturally expands positively in the k -Schur functions. See [LLMSSZ] p. 81.

The k -split basis is defined recursively using the Hall-Littlewood creation operator defined in [SZ2001]. If a partition $1a$ is the concatenation (as lists) of a partition μ and ν where μ has maximal hook length equal to k then $\text{ksp}(1a) = \text{ksp}(\nu) \cdot \text{hl_creation_operator}(\mu)$. If the hook length of $1a$ is less than or equal to k , then $\text{ksp}(1a)$ is equal to the Schur function indexed by $1a$.

EXAMPLES:

```
sage: Symt = SymmetricFunctions(QQ['t']).fraction_field()
sage: kBS3 = Symt.kBoundedSubspace(3)
sage: ks3 = kBS3.kschur()
sage: ksp3 = kBS3.ksplit()
sage: ks3(ksp3[2, 1, 1])
ks3[2, 1, 1] + t*ks3[2, 2]
sage: ksp3(ks3[2, 1, 1])
ksp3[2, 1, 1] - t*ksp3[2, 2]
sage: ksp3[2, 1]*ksp3[1]
s[2, 1, 1] + s[2, 2] + s[3, 1]
sage: ksp3[2, 1].hl_creation_operator([1])
t*ksp3[2, 1, 1] + (-t^2+t)*ksp3[2, 2]

sage: Qp = Symt.hall_littlewood().Qp()
sage: ksp3(Qp[3, 2, 1])
ksp3[3, 2, 1] + t*ksp3[3, 3]

sage: kBS4 = Symt.kBoundedSubspace(4)
sage: ksp4 = kBS4.ksplit()
sage: ksp4(ksp3([3, 2, 1]))
ksp4[3, 2, 1] - t*ksp4[3, 3] + t*ksp4[4, 1, 1]
sage: ks4 = kBS4.kschur()
sage: ks4(ksp4[3, 2, 2, 1])
ks4[3, 2, 2, 1] + t*ks4[3, 3, 1, 1] + t*ks4[3, 3, 2]
```

5.1.292 Non-symmetric Macdonald Polynomials

class `sage.combinat.sf.ns_macdonald.AugmentedLatticeDiagramFilling(l, pi=None)`
 Bases: `sage.combinat.combinat.CombinatorialObject`

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a == loads(dumps(a))
True
sage: pi = Permutation([2,3,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]],pi)
sage: a == loads(dumps(a))
True

```

are_attacking(*i, j, ii, jj*)

Return True if the boxes (*i, j*) and (*ii, jj*) in *self* are attacking.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: all( a.are_attacking(i,j,ii,jj) for (i,j),(ii,jj) in a.attacking_boxes())
True
sage: a.are_attacking(1,1,3,2)
False

```

attacking_boxes()

Return a list of pairs of boxes in *self* that are attacking.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.attacking_boxes()[:5]
[((1, 1), (2, 1)),
 ((1, 1), (3, 1)),
 ((1, 1), (6, 1)),
 ((1, 1), (2, 0)),
 ((1, 1), (3, 0))]

```

boxes()

Return a list of the coordinates of the boxes of *self*, including the ‘basement row’.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.boxes()
[(1, 1),
 (1, 2),
 (2, 1),
 (3, 1),
 (3, 2),
 (3, 3),
 (6, 1),
 (6, 2),
 (1, 0),
 (2, 0),
 (3, 0),
 (4, 0),
 (5, 0),
 (6, 0)]

```

coeff(*q, t*)

Return the coefficient in front of *self* in the HHL formula for the expansion of the non-symmetric Mac-

donald polynomial $E(\text{self.shape}())$.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t')
sage: a.coeff(q,t)
(t - 1)^4/((q^2*t^3 - 1)^2*(q*t^2 - 1)^2)
```

coeff_integral(q, t)

Return the coefficient in front of `self` in the HHL formula for the expansion of the integral non-symmetric Macdonald polynomial $E(\text{self.shape}())$

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t')
sage: a.coeff_integral(q,t)
(q^2*t^3 - 1)^2*(q*t^2 - 1)^2*(t - 1)^4
```

coinv()

Return `self`'s co-inversion statistic.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.coinv()
2
```

descents()

Return a list of the descents of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.descents()
[(1, 2), (3, 2)]
```

inv()

Return `self`'s inversion statistic.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.inv()
15
```

inversions()

Return a list of the inversions of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.inversions()[5]
[((6, 2), (3, 2)),
 ((1, 2), (6, 1)),
 ((1, 2), (3, 1)),
```

(continues on next page)

(continued from previous page)

```

((1, 2), (2, 1)),
((6, 1), (3, 1))]
sage: len(a.inversions())
25

```

is_non_attacking()

Return True if self is non-attacking.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.is_non_attacking()
True
sage: a = AugmentedLatticeDiagramFilling([[1, 1, 1], [2, 3], [3]])
sage: a.is_non_attacking()
False
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]])
sage: a.is_non_attacking()
False
sage: pi = Permutation([2,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]],pi)
sage: a.is_non_attacking()
True

```

maj()

Return the major index of self.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.maj()
3

```

permuted_filling(*sigma*)

EXAMPLES:

```

sage: pi=Permutation([2,1,4,3]).to_permutation_group_element()
sage: fill=[[2],[1,2,3],[],[3,1]]
sage: AugmentedLatticeDiagramFilling(fill).permuted_filling(pi)
[[2, 1], [1, 2, 1, 4], [4], [3, 4, 2]]

```

reading_order()

Return a list of coordinates of the boxes in self, starting from the top right, and reading from right to left.

Note that this includes the ‘basement row’ of self.

EXAMPLES:

```

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.reading_order()
[(3, 3),
 (6, 2),
 (3, 2),
 (1, 2),
 (6, 1),

```

(continues on next page)

(continued from previous page)

```
(3, 1),
(2, 1),
(1, 1),
(6, 0),
(5, 0),
(4, 0),
(3, 0),
(2, 0),
(1, 0)]
```

reading_word()

Return the reading word of `self`, obtained by reading the boxes entries of `self` from right to left, starting in the upper right.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.reading_word()
word: 25465321
```

shape()

Return the shape of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.shape()
[2, 1, 3, 0, 0, 2]
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.weight()
[1, 2, 1, 1, 2, 1]
```

`sage.combinat.sf.ns_macdonald.E(mu, q=None, t=None, pi=None)`

Return the non-symmetric Macdonald polynomial in type A corresponding to a shape `mu`, with basement permuted according to `pi`.

Note that if both `q` and `t` are specified, then they must have the same parent.

REFERENCE:

- J. Haglund, M. Haiman, N. Loehr. *A combinatorial formula for non-symmetric Macdonald polynomials*. arXiv math/0601693v3.

See also:

[NonSymmetricMacdonaldPolynomials](#) for a type free implementation where the polynomials are constructed recursively by the application of intertwining operators.

EXAMPLES:

```

sage: from sage.combinat.sf.ns_macdonald import E
sage: E([0,0,0])
1
sage: E([1,0,0])
x0
sage: E([0,1,0])
(t - 1)/(q*t^2 - 1)*x0 + x1
sage: E([0,0,1])
(t - 1)/(q*t - 1)*x0 + (t - 1)/(q*t - 1)*x1 + x2
sage: E([1,1,0])
x0*x1
sage: E([1,0,1])
(t - 1)/(q*t^2 - 1)*x0*x1 + x0*x2
sage: E([0,1,1])
(t - 1)/(q*t - 1)*x0*x1 + (t - 1)/(q*t - 1)*x0*x2 + x1*x2
sage: E([2,0,0])
x0^2 + (q*t - q)/(q*t - 1)*x0*x1 + (q*t - q)/(q*t - 1)*x0*x2
sage: E([0,2,0])
(t - 1)/(q^2*t^2 - 1)*x0^2 + (q^2*t^3 - q^2*t^2 + q*t^2 - 2*q*t + q - t + 1)/(q^3*t^
↪ 3 - q^2*t^2 - q*t + 1)*x0*x1 + x1^2 + (q*t^2 - 2*q*t + q)/(q^3*t^3 - q^2*t^2 -
↪ q*t + 1)*x0*x2 + (q*t - q)/(q*t - 1)*x1*x2

```

`sage.combinat.sf.ns_macdonald.E_integral(mu, q=None, t=None, pi=None)`

Return the integral form for the non-symmetric Macdonald polynomial in type A corresponding to a shape mu.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- J. Haglund, M. Haiman, N. Loehr. *A combinatorial formula for non-symmetric Macdonald polynomials.* arXiv math/0601693v3.

EXAMPLES:

```

sage: from sage.combinat.sf.ns_macdonald import E_integral
sage: E_integral([0,0,0])
1
sage: E_integral([1,0,0])
(-t + 1)*x0
sage: E_integral([0,1,0])
(-q*t^2 + 1)*x0 + (-t + 1)*x1
sage: E_integral([0,0,1])
(-q*t + 1)*x0 + (-q*t + 1)*x1 + (-t + 1)*x2
sage: E_integral([1,1,0])
(t^2 - 2*t + 1)*x0*x1
sage: E_integral([1,0,1])
(q*t^3 - q*t^2 - t + 1)*x0*x1 + (t^2 - 2*t + 1)*x0*x2
sage: E_integral([0,1,1])
(q^2*t^3 + q*t^4 - q*t^3 - q*t^2 - q*t - t^2 + t + 1)*x0*x1 + (q*t^2 - q*t - t +
↪ 1)*x0*x2 + (t^2 - 2*t + 1)*x1*x2
sage: E_integral([2,0,0])
(t^2 - 2*t + 1)*x0^2 + (q^2*t^2 - q^2*t - q*t + q)*x0*x1 + (q^2*t^2 - q^2*t - q*t +
↪ q)*x0*x2
sage: E_integral([0,2,0])
(q^2*t^3 - q^2*t^2 - t + 1)*x0^2 + (q^4*t^3 - q^3*t^2 - q^2*t + q*t^2 - q*t + q - t
↪ + 1)*x0*x1 + (t^2 - 2*t + 1)*x1^2 + (q^4*t^3 - q^3*t^2 - q^2*t + q)*x0*x2 +
↪ 2*t^2 - q^2*t - q*t + q)*x1*x2

```

(continued from previous page)

```
sage.combinat.sf.ns_macdonald.Ht(mu, q=None, t=None, pi=None)
```

Return the symmetric Macdonald polynomial using the Haiman, Haglund, and Loehr formula.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- J. Haglund, M. Haiman, N. Loehr. *A combinatorial formula for non-symmetric Macdonald polynomials.* arXiv math/0601693v3.

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import Ht
sage: HHt = SymmetricFunctions(QQ['q', 't'].fraction_field()).macdonald().Ht()
sage: Ht([0, 0, 1])
x0 + x1 + x2
sage: HHt([1]).expand(3)
x0 + x1 + x2
sage: Ht([0, 0, 2])
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
sage: HHt([2]).expand(3)
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
```

```
class sage.combinat.sf.ns_macdonald.LatticeDiagram(l, copy=True)
```

Bases: `sage.combinat.combinat.CombinatorialObject`

```
a(i, j)
```

Return the length of the arm of the box (i, j) in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3, 1, 2, 4, 3, 0, 4, 2, 3])
sage: a.a(5, 2)
3
```

```
arm(i, j)
```

Return the arm of the box (i, j) in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3, 1, 2, 4, 3, 0, 4, 2, 3])
sage: a.arm(5, 2)
[(1, 2), (3, 2), (8, 1)]
```

```
arm_left(i, j)
```

Return the left arm of the box (i, j) in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3, 1, 2, 4, 3, 0, 4, 2, 3])
sage: a.arm_left(5, 2)
[(1, 2), (3, 2)]
```

```
arm_right(i, j)
```

Return the right arm of the box (i, j) in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_right(5,2)
[(8, 1)]
```

boxes()

EXAMPLES:

```
sage: a = LatticeDiagram([3,0,2])
sage: a.boxes()
[(1, 1), (1, 2), (1, 3), (3, 1), (3, 2)]
sage: a = LatticeDiagram([2, 1, 3, 0, 0, 2])
sage: a.boxes()
[(1, 1), (1, 2), (2, 1), (3, 1), (3, 2), (3, 3), (6, 1), (6, 2)]
```

boxes_same_and_lower_right(*ii, jj*)

Return a list of the boxes of `self` that are in row `jj` but not identical with `(ii, jj)`, or lie in the row `jj - 1` (the row directly below `jj`; this might be the basement) and strictly to the right of `(ii, jj)`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a = a.shape()
sage: a.boxes_same_and_lower_right(1,1)
[(2, 1), (3, 1), (6, 1), (2, 0), (3, 0), (4, 0), (5, 0), (6, 0)]
sage: a.boxes_same_and_lower_right(1,2)
[(3, 2), (6, 2), (2, 1), (3, 1), (6, 1)]
sage: a.boxes_same_and_lower_right(3,3)
[(6, 2)]
sage: a.boxes_same_and_lower_right(2,3)
[(3, 3), (3, 2), (6, 2)]
```

flip()

Return the flip of `self`, where flip is defined as follows. Let $r = \max(\text{self})$. Then `self.flip()[i] = r - self[i]`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,0,2])
sage: a.flip()
[0, 3, 1]
```

l(*i, j*)

Return `self[i] - j`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.l(5,2)
1
```

leg(*i, j*)

Return the leg of the box `(i, j)` in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.leg(5,2)
[(5, 3)]
```

size()

Return the number of boxes in self.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.size()
22
```

class sage.combinat.sf.ns_macdonald.**NonattackingBacktracker**(*shape, pi=None*)

Bases: *sage.combinat.backtrack.GenericBacktracker*

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: n = NonattackingBacktracker(LatticeDiagram([0,1,2]))
sage: n._ending_position
(3, 2)
sage: n._initial_state
(2, 1)
```

get_next_pos(*ii, jj*)

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: n = NonattackingBacktracker(a.shape())
sage: n.get_next_pos(1, 1)
(2, 1)
sage: n.get_next_pos(6, 1)
(1, 2)
sage: n = NonattackingBacktracker(LatticeDiagram([2,2,2]))
sage: n.get_next_pos(3, 1)
(1, 2)
```

sage.combinat.sf.ns_macdonald.**NonattackingFillings**(*shape, pi=None*)

Returning the finite set of nonattacking fillings of a given shape.

EXAMPLES:

```
sage: NonattackingFillings([0,1,2])
Nonattacking fillings of [0, 1, 2]
sage: NonattackingFillings([0,1,2]).list()
[[[1], [2, 1], [3, 2, 1]],
 [[1], [2, 1], [3, 2, 2]],
 [[1], [2, 1], [3, 2, 3]],
 [[1], [2, 1], [3, 3, 1]],
 [[1], [2, 1], [3, 3, 2]],
 [[1], [2, 1], [3, 3, 3]],
 [[1], [2, 2], [3, 1, 1]],
 [[1], [2, 2], [3, 1, 2]],
```

(continues on next page)

(continued from previous page)

```
[[1], [2, 2], [3, 1, 3]],
[[1], [2, 2], [3, 3, 1]],
[[1], [2, 2], [3, 3, 2]],
[[1], [2, 2], [3, 3, 3]]]
```

class `sage.combinat.sf.ns_macdonald.NonattackingFillings_shape`(*shape*, *pi=None*)

Bases: `sage.structure.parent.Parent`, `sage.structure.unique_representation.UniqueRepresentation`

EXAMPLES:

```
sage: n = NonattackingFillings([0,1,2])
sage: n == loads(dumps(n))
True
```

flip()

Return the nonattacking fillings of the flipped shape.

EXAMPLES:

```
sage: NonattackingFillings([0,1,2]).flip()
Nonattacking fillings of [2, 1, 0]
```

5.1.293 Orthogonal Symmetric Functions

AUTHORS:

- Travis Scrimshaw (2013-11-10): Initial version

class `sage.combinat.sf.orthogonal.SymmetricFunctionAlgebra_orthogonal`(*Sym*)

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

The orthogonal symmetric function basis (or orthogonal basis, to be short).

The orthogonal basis $\{o_\lambda\}$ where λ is taken over all partitions is defined by the following change of basis with the Schur functions:

$$s_\lambda = \sum_{\mu} \left(\sum_{\nu \in H} c_{\mu\nu}^\lambda \right) o_\mu$$

where H is the set of all partitions with even-width rows and $c_{\mu\nu}^\lambda$ is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

Note: This is only a filtered basis, not a \mathbf{Z} -graded basis. However this does respect the induced $(\mathbf{Z}/2\mathbf{Z})$ -grading.

INPUT:

- `Sym` – an instance of the ring of the symmetric functions

REFERENCES:

- [ChariKleber2000]
- [KoikeTerada1987]
- [ShimozonoZabrocki2006]

EXAMPLES:

Here are the first few orthogonal symmetric functions, in various bases:

```

sage: Sym = SymmetricFunctions(QQ)
sage: o = Sym.o()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(o([1]))
p[1]
sage: m(o([1]))
m[1]
sage: e(o([1]))
e[1]
sage: h(o([1]))
h[1]
sage: s(o([1]))
s[1]

sage: p(o([2]))
-p[] + 1/2*p[1, 1] + 1/2*p[2]
sage: m(o([2]))
-m[] + m[1, 1] + m[2]
sage: e(o([2]))
-e[] + e[1, 1] - e[2]
sage: h(o([2]))
-h[] + h[2]
sage: s(o([2]))
-s[] + s[2]

sage: p(o([3]))
-p[1] + 1/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3]
sage: m(o([3]))
-m[1] + m[1, 1, 1] + m[2, 1] + m[3]
sage: e(o([3]))
-e[1] + e[1, 1, 1] - 2*e[2, 1] + e[3]
sage: h(o([3]))
-h[1] + h[3]
sage: s(o([3]))
-s[1] + s[3]

sage: Sym = SymmetricFunctions(ZZ)
sage: o = Sym.o()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(o([4]))
-m[1, 1] + m[1, 1, 1, 1] - m[2] + m[2, 1, 1] + m[2, 2] + m[3, 1] + m[4]

```

(continues on next page)

(continued from previous page)

```

sage: e(o([4]))
-e[1, 1] + e[1, 1, 1, 1] + e[2] - 3*e[2, 1, 1] + e[2, 2] + 2*e[3, 1] - e[4]
sage: h(o([4]))
-h[2] + h[4]
sage: s(o([4]))
-s[2] + s[4]

```

Some examples of conversions the other way:

```

sage: o(h[3])
o[1] + o[3]
sage: o(e[3])
o[1, 1, 1]
sage: o(m[2, 1])
o[1] - 2*o[1, 1, 1] + o[2, 1]
sage: o(p[3])
o[1, 1, 1] - o[2, 1] + o[3]

```

Some multiplication:

```

sage: o([2]) * o([1,1])
o[1, 1] + o[2] + o[2, 1, 1] + o[3, 1]
sage: o([2,1,1]) * o([2])
o[1, 1] + o[1, 1, 1, 1] + 2*o[2, 1, 1] + o[2, 2] + o[2, 2, 1, 1]
+ o[3, 1] + o[3, 1, 1, 1] + o[3, 2, 1] + o[4, 1, 1]
sage: o([1,1]) * o([2,1])
o[1] + o[1, 1, 1] + 2*o[2, 1] + o[2, 1, 1, 1] + o[2, 2, 1]
+ o[3] + o[3, 1, 1] + o[3, 2]

```

Examples of the Hopf algebra structure:

```

sage: o([1]).antipode()
-o[1]
sage: o([2]).antipode()
-o[] + o[1, 1]
sage: o([1]).coproduct()
o[] # o[1] + o[1] # o[]
sage: o([2]).coproduct()
o[] # o[] + o[] # o[2] + o[1] # o[1] + o[2] # o[]
sage: o([1]).counit()
0
sage: o.one().counit()
1

```

5.1.294 Symmetric functions defined by orthogonality and triangularity

One characterization of Schur functions is that they are upper triangularly related to the monomial symmetric functions and orthogonal with respect to the Hall scalar product. We can use the class `SymmetricFunctionAlgebra_orthotriang` to obtain the Schur functions from this definition.

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur functions')
sage: s([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2]
```

```
sage: s2 = SymmetricFunctions(QQ).s()
sage: s2([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2]
```

```
class sage.combinat.sf.orthotriang.SymmetricFunctionAlgebra_orthotriang(Sym, base, scalar,
                                                                    prefix, basis_name,
                                                                    leading_coeff=None)
```

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

Initialization of the symmetric function algebra defined via orthotriangular rules.

INPUT:

- `self` – a basis determined by an orthotriangular definition
- `Sym` – ring of symmetric functions
- `base` – an instance of a basis of the ring of symmetric functions (e.g. the Schur functions)
- `scalar` – a function `zee` on partitions. The function `zee` determines the scalar product on the power sum basis with normalization $\langle p_\mu, p_\mu \rangle = zee(\mu)$.
- `prefix` – the prefix used to display the basis
- `basis_name` – the name used for the basis

Note: The base ring is required to be a \mathbb{Q} -algebra for this method to be usable, since the scalar product is defined by its values on the power sum basis.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur'); s
Symmetric Functions over Rational Field in the Schur basis
```

class `Element`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

product(*left*, *right*)

Return `left * right` by converting both to the base and then converting back to `self`.

INPUT:

- `self` – a basis determined by an orthotriangular definition
- `left`, `right` – elements in `self`

OUTPUT:

- the expansion of the product of `left` and `right` in the basis `self`.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_
↳orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur_
↳functions')
sage: s([1])*s([2,1]) #indirect doctest
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

5.1.295 Power sum symmetric functions

class `sage.combinat.sf.powersum.SymmetricFunctionAlgebra_power`(*Sym*)

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

A class for methods associated to the power sum basis of the symmetric functions

INPUT:

- `self` – the power sum basis of the symmetric functions
- `Sym` – an instance of the ring of symmetric functions

class `Element`

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

adams_operation(*n*)

Return the image of the symmetric function `self` under the n -th Frobenius operator.

The n -th Frobenius operator \mathbf{f}_n is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \dots)$ to $P(x_1^n, x_2^n, x_3^n, \dots)$. This operator \mathbf{f}_n is a Hopf algebra endomorphism, and satisfies

$$\mathbf{f}_n m_{(\lambda_1, \lambda_2, \lambda_3, \dots)} = m_{(n\lambda_1, n\lambda_2, n\lambda_3, \dots)}$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \dots)$ (where m means the monomial basis). Moreover, $\mathbf{f}_n(p_r) = p_{nr}$ for every positive integer r (where p_k denotes the k -th powersum symmetric function).

The n -th Frobenius operator is also called the n -th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n -th Frobenius operator is also the n -th Adams operator of the Λ -ring of symmetric functions over the integers.

The n -th Frobenius operator can also be described via plethysm: Every symmetric function P satisfies $\mathbf{f}_n(P) = p_n \circ P = P \circ p_n$, where p_n is the n -th powersum symmetric function, and \circ denotes (outer) plethysm.

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Frobenius operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].frobenius(2)
p[6]
sage: p[4,2,1].frobenius(3)
p[12, 6, 3]
sage: p[[]].frobenius(4)
p[[]]
sage: p[3].frobenius(1)
p[3]
sage: (p([3]) - p([2]) + p([[]])).frobenius(3)
p[[]] - p[6] + p[9]
```

See also:

[plethysm\(\)](#)

eval_at_permutation_roots(*rho*)

Evaluate at eigenvalues of a permutation matrix.

Evaluate an element of the power sum basis at the eigenvalues of a permutation matrix with cycle structure ρ .

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \dots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \dots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure ρ .

INPUT:

- *rho* – a partition or a list of non-negative integers

OUTPUT:

- an element of the base ring

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p([3,3]).eval_at_permutation_roots([6])
0
sage: p([3,3]).eval_at_permutation_roots([3])
9
sage: p([3,3]).eval_at_permutation_roots([1])
```

(continues on next page)

(continued from previous page)

```

1
sage: p([3,3]).eval_at_permutation_roots([3,3])
36
sage: p([3,3]).eval_at_permutation_roots([1,1,1,1,1])
25
sage: (p[1]+p[2]+p[3]).eval_at_permutation_roots([3,2])
5

```

expand(*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the *n* variables labelled by *alphabet*.

EXAMPLES:

```

sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2])
sage: a.expand(2)
x0^2 + x1^2
sage: a.expand(3, alphabet=['a','b','c'])
a^2 + b^2 + c^2
sage: p([2,1,1]).expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: p([7]).expand(4)
x0^7 + x1^7 + x2^7 + x3^7
sage: p([7]).expand(4, alphabet='t')
t0^7 + t1^7 + t2^7 + t3^7
sage: p([7]).expand(4, alphabet='x,y,z,t')
x^7 + y^7 + z^7 + t^7
sage: p(1).expand(4)
1
sage: p(0).expand(4)
0
sage: (p([]) + 2*p([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: p([1]).expand(0)
0
sage: (3*p([])).expand(0)
3

```

exponential_specialization(*t*=None, *q*=1)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q -exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R . It is defined whenever the base ring K is a \mathbb{Q} -algebra and t is an element of R . The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q -exponential specialization is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n / [n]_q!,$$

where $[n]_q!$ is the q -factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n , we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see [principal_specialization\(\)](#)). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \rightarrow 1$ is ex .

INPUT:

- `t` (default: None) – the value to use for t ; the default is to create a ring of polynomials in `t`.
- `q` (default: 1) – the value to use for q . If `q` is None, then a ring (or fraction field) of polynomials in `q` is created.

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: x = p[8,7,3,1]
sage: x.exponential_specialization()
0
sage: x = p[3] + 5*p[1,1] + 2*p[1] + 1
sage: x.exponential_specialization(t=var("t"))
5*t^2 + 2*t + 1
```

We also support the q -exponential_specialization:

```
sage: factor(p[3].exponential_specialization(q=var("q"), t=var("t")))
(q - 1)^2*t^3/(q^2 + q + 1)
```

frobenius(n)

Return the image of the symmetric function `self` under the n -th Frobenius operator.

The n -th Frobenius operator \mathbf{f}_n is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \dots)$ to $P(x_1^n, x_2^n, x_3^n, \dots)$. This operator \mathbf{f}_n is a Hopf algebra endomorphism, and satisfies

$$\mathbf{f}_n m_{(\lambda_1, \lambda_2, \lambda_3, \dots)} = m_{(n\lambda_1, n\lambda_2, n\lambda_3, \dots)}$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \dots)$ (where m means the monomial basis). Moreover, $\mathbf{f}_n(p_r) = p_{nr}$ for every positive integer r (where p_k denotes the k -th powersum symmetric function).

The n -th Frobenius operator is also called the n -th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n -th Frobenius operator is also the n -th Adams operator of the Λ -ring of symmetric functions over the integers.

The n -th Frobenius operator can also be described via plethysm: Every symmetric function P satisfies $\mathbf{f}_n(P) = p_n \circ P = P \circ p_n$, where p_n is the n -th powersum symmetric function, and \circ denotes (outer) plethysm.

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Frobenius operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].frobenius(2)
p[6]
sage: p[4,2,1].frobenius(3)
p[12, 6, 3]
sage: p[[]].frobenius(4)
p[]
sage: p[3].frobenius(1)
p[3]
sage: (p[[3]] - p[[2]] + p[[]]).frobenius(3)
p[] - p[6] + p[9]
```

See also:

[plethysm\(\)](#)

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length ([length\(\)](#)) of the partition λ , where λ' denotes the conjugate partition ([conjugate\(\)](#)) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

[omega_involution\(\)](#) is a synonym for the [omega\(\)](#) method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p[[2,1]]; a
p[2, 1]
sage: a.omega()
-p[2, 1]
sage: p[[]].omega()
p[]
sage: p[0].omega()
0
sage: p = SymmetricFunctions(ZZ).p()
```

(continues on next page)

(continued from previous page)

```
sage: (p([3,1,1]) - 2 * p([2,1])) .omega()
2*p[2, 1] + p[3, 1, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2,1]); a
p[2, 1]
sage: a.omega()
-p[2, 1]
sage: p([]).omega()
p[]
sage: p(0).omega()
0
sage: p = SymmetricFunctions(ZZ).p()
sage: (p([3,1,1]) - 2 * p([2,1])) .omega()
2*p[2, 1] + p[3, 1, 1]
```

principal_specialization(*n*=+ Infinity, *q*=None)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \dots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R , and we assume that the variables of our symmetric functions are x_1, x_2, x_3, \dots . (To be more precise, $ps_{n,q}$ is a K -algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i . This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- **n** (default: `infinity`) – a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.

- q (default: None) – the value to use for q ; the default is to create a ring of polynomials in q (or a field of rational functions in q) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2]:

$$ps_{n,q}(p_\lambda) = \prod_i (1 - q^{n\lambda_i}) / (1 - q^{\lambda_i}),$$

$$ps_{n,1}(p_\lambda) = n^{\ell(\lambda)},$$

$$ps_q(p_\lambda) = 1 / \prod_i (1 - q^{\lambda_i}),$$

where $\ell(\lambda)$ denotes the length of λ , and where the products range from $i = 1$ to $i = \ell(\lambda)$.

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: x = p[8,7,3,1]
sage: x.principal_specialization(3, q=var("q"))
(q^24 - 1)*(q^21 - 1)*(q^9 - 1)/((q^8 - 1)*(q^7 - 1)*(q - 1))

sage: x = 5*p[1,1,1] + 3*p[2,1] + 1
sage: x.principal_specialization(3, q=var("q"))
5*(q^3 - 1)^3/(q - 1)^3 + 3*(q^6 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1
```

By default, we return a rational function in q :

```
sage: x.principal_specialization(3)
8*q^6 + 18*q^5 + 36*q^4 + 38*q^3 + 36*q^2 + 18*q + 9
```

If n is not given we return the stable principal specialization:

```
sage: x.principal_specialization(q=var("q"))
3/((q^2 - 1)*(q - 1)) - 5/(q - 1)^3 + 1
```

scalar(x , $zee=None$)

Return the standard scalar product of `self` and `x`.

INPUT:

- `x` – a power sum symmetric function
- `zee` – (default: uses standard `zee` function) optional input specifying the scalar product on the power sum basis with normalization $\langle p_\mu, p_\mu \rangle = zee(\mu)$. `zee` should be a function on partitions.

Note that the power-sum symmetric functions are orthogonal under this scalar product. With the default value of `zee`, the value of $\langle p_\lambda, p_\lambda \rangle$ is given by the size of the centralizer in S_n of a permutation of cycle type λ .

OUTPUT:

- the standard scalar product between `self` and `x`, or, if the optional parameter `zee` is specified, then the scalar product with respect to the normalization $\langle p_\mu, p_\mu \rangle = zee(\mu)$ with the power sum basis elements being orthogonal

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p4 = Partitions(4)
sage: matrix([ [p(a).scalar(p(b)) for a in p4] for b in p4])
[ 4  0  0  0  0]
[ 0  3  0  0  0]
```

(continues on next page)

(continued from previous page)

```

[ 0 0 8 0 0]
[ 0 0 0 4 0]
[ 0 0 0 0 24]
sage: p(0).scalar(p(1))
0
sage: p(1).scalar(p(2))
2

sage: zee = lambda x : 1
sage: matrix( [[p[la].scalar(p[mu], zee) for la in Partitions(3)] for mu in
↪Partitions(3)])
[1 0 0]
[0 1 0]
[0 0 1]

```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator \mathbf{V}_n is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator \mathbf{V}_n is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].verschiebung(2)
0
sage: p[4].verschiebung(4)
4*p[1]

```

The Verschiebung endomorphisms are multiplicative:

```

sage: all( all( p(lam).verschiebung(2) * p(mu).verschiebung(2)
.....:         == (p(lam) * p(mu)).verschiebung(2)
.....:         for mu in Partitions(4) )
.....:         for lam in Partitions(4) )
True

```

Testing the adjointness between the Frobenius operators f_n and the Verschiebung operators V_n :

```

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: all( all( p(lam).verschiebung(2).scalar(p(mu))
.....:         == p(lam).scalar(p(mu).frobenius(2))
.....:         for mu in Partitions(2) )
.....:         for lam in Partitions(4) )
True

```

antipode_on_basis(*partition*)

Return the antipode of `self[partition]`.

The antipode on the generator p_i (for $i > 0$) is $-p_i$, and the antipode on p_μ is $(-1)^{\text{length}(\mu)} p_\mu$.

INPUT:

- `self` – the power sum basis of the symmetric functions
- `partition` – a partition

OUTPUT:

- the result of the antipode on `self(partition)`

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.antipode_on_basis([2])
-p[2]
sage: p.antipode_on_basis([3])
-p[3]
sage: p.antipode_on_basis([2,2])
p[2, 2]
sage: p.antipode_on_basis([])
p[]

```

bottom_schur_function(*partition*, *degree=None*)

Return the least-degree component of `s[partition]`, where `s` denotes the Schur basis of the symmetric functions, and the grading is not the usual grading on the symmetric functions but rather the grading which gives every p_i degree 1.

This least-degree component has its degree equal to the Frobenius rank of `partition`, while the degree with respect to the usual grading is still the size of `partition`.

This method requires the base ring to be a (commutative) \mathbf{Q} -algebra. This restriction is unavoidable, since the least-degree component (in general) has noninteger coefficients in all classical bases of the symmetric functions.

The optional keyword `degree` allows taking any homogeneous component rather than merely the least-degree one. Specifically, if `degree` is set, then the `degree`-th component will be returned.

REFERENCES:

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.bottom_schur_function([2,2,1])
-1/6*p[3, 2] + 1/4*p[4, 1]
sage: p.bottom_schur_function([2,1])
-1/3*p[3]
sage: p.bottom_schur_function([3])
1/3*p[3]
sage: p.bottom_schur_function([1,1,1])
1/3*p[3]
sage: p.bottom_schur_function(Partition([1,1,1]))
1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=1)
-1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=2)
0
sage: p.bottom_schur_function([2,1], degree=3)
1/3*p[1, 1, 1]
sage: p.bottom_schur_function([2,2,1], degree=3)
1/8*p[2, 2, 1] - 1/6*p[3, 1, 1]
```

coproduct_on_generators(*i*)

Return coproduct on generators for power sums p_i (for $i > 0$).

The elements p_i are primitive elements.

INPUT:

- `self` – the power sum basis of the symmetric functions
- `i` – a positive integer

OUTPUT:

- the result of the coproduct on the generator $p(i)$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_generators(2)
p[] # p[2] + p[2] # p[]
```

eval_at_permutation_roots_on_generators(*k*, *rho*)

Evaluate p_k at eigenvalues of permutation matrix.

This function evaluates a symmetric function $p([k])$ at the eigenvalues of a permutation matrix with cycle structure ρ .

This function evaluates a p_k at the roots of unity

$$\xi_{\rho_1}, \xi_{\rho_2}, \dots, \xi_{\rho_\ell}$$

where

$$\xi_m = 1, \zeta_m, \zeta_m^2, \dots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. This is characterized by $p_k[A, B] = p_k[A] + p_k[B]$ and $p_k[\xi_m] = 0$ unless m divides k and $p_{r/m}[\xi_m] = m$.

INPUT:

- k – a non-negative integer
- ρ – a partition or a list of non-negative integers

OUTPUT:

- an element of the base ring

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p.eval_at_permutation_roots_on_generators(3, [6])
0
sage: p.eval_at_permutation_roots_on_generators(3, [3])
3
sage: p.eval_at_permutation_roots_on_generators(3, [1])
1
sage: p.eval_at_permutation_roots_on_generators(3, [3, 3])
6
sage: p.eval_at_permutation_roots_on_generators(3, [1, 1, 1, 1, 1])
5
```

5.1.296 Schur symmetric functions

class `sage.combinat.sf.schur.SymmetricFunctionAlgebra_schur`(*Sym*)

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical`

A class for methods related to the Schur symmetric function basis

INPUT:

- `self` – a Schur symmetric function basis
- `Sym` – an instance of the ring of the symmetric functions

class `Element`

Bases: `sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical.Element`

expand(*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the n variables labelled by `alphabet`.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: a.expand(2)
x0^2*x1 + x0*x1^2
sage: a.expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: a.expand(4)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + x0^
↪ 2*x3 + 2*x0*x1*x3 + x1^2*x3 + 2*x0*x2*x3 + 2*x1*x2*x3 + x2^2*x3 + x0*x3^2
↪ + x1*x3^2 + x2*x3^2
sage: a.expand(2, alphabet='y')
y0^2*y1 + y0*y1^2
sage: a.expand(2, alphabet=['a','b'])
a^2*b + a*b^2
sage: s([1,1,1,1]).expand(3)
0
sage: (s([]) + 2*s([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: s([1]).expand(0)
0
sage: (3*s([])).expand(0)
3
```

exponential_specialization($t=None$, $q=1$)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q -exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R . It is defined whenever the base ring K is a \mathbf{Q} -algebra and t is an element of R . The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q -exponential specialization is a K -algebra homomorphism from the K -algebra of symmetric functions to another K -algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q -factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n , we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see [principal_specialization\(\)](#)). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \rightarrow 1$ is ex .

INPUT:

- t (default: `None`) – the value to use for t ; the default is to create a ring of polynomials in t .

- q (default: 1) – the value to use for q . If q is None, then a ring (or fraction field) of polynomials in q is created.

We use the formula in the proof of Corollary 7.21.6 of [EnumComb2]

$$ex_q(s_\lambda) = t^{|\lambda|} q^{\sum_i (i-1)\lambda_i} / \prod_{u \in \lambda} (1 + q + q^2 + \dots + q^{h(u)-1})$$

where $h(u)$ is the hook length of a cell u in λ .

As a limit case, we obtain a formula for $q = 1$

$$ex_1(s_\lambda) = f^\lambda t^{|\lambda|} / |\lambda|!$$

where f^λ is the number of standard Young tableaux of shape λ .

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: x = s[5,3]
sage: x.exponential_specialization()
1/1440*t^8

sage: x = 5*s[1,1,1] + 3*s[2,1] + 1
sage: x.exponential_specialization()
11/6*t^3 + 1
```

We also support the q -exponential_specialization:

```
sage: factor(s[3].exponential_specialization(q=var("q"), t=var("t")))
t^3/((q^2 + q + 1)*(q + 1))
```

`omega()`

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'}$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'}$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT:

- the image of `self` under the omega automorphism

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2, 1]).omega()
s[2, 1]
sage: s([2, 1, 1]).omega()
s[3, 1]
```

principal_specialization(n=+ Infinity, q=None)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \dots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R , and we assume that the variables of our symmetric functions are x_1, x_2, x_3, \dots (To be more precise, $ps_{n,q}$ is a K -algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i . This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` (default: `infinity`) – a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` (default: `None`) – the value to use for q ; the default is to create a ring of polynomials in `q` (or a field of rational functions in `q`) over the given coefficient ring.

For $q = 1$ we use the formula from Corollary 7.21.4 of [EnumComb2]:

$$ps_{n,1}(s_\lambda) = \prod_{u \in \lambda} (n + c(u))/h(u),$$

where $h(u)$ is the hook length of a cell u in λ , and where $c(u)$ is the content of a cell u in λ .

For $n = \text{infinity}$ we use the formula from Corollary 7.21.3 of [EnumComb2]

$$ps_q(s_\lambda) = q^{\sum_i (i-1)\lambda_i} / \prod_{u \in \lambda} (1 - q^{h(u)}).$$

Otherwise, we use the formula from Theorem 7.21.2 of [EnumComb2],

$$ps_{n,q}(s_\lambda) = q^{\sum_i (i-1)\lambda_i} \prod_{u \in \lambda} (1 - q^{n+c(u)}) / (1 - q^{h(u)}).$$

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: x = s[2]
sage: x.principal_specialization(3)
q^4 + q^3 + 2*q^2 + q + 1

sage: x = 3*s[2,2] + 2*s[1] + 1
sage: x.principal_specialization(3, q=var("q"))
3*(q^4 - 1)*(q^3 - 1)*q^2/((q^2 - 1)*(q - 1)) + 2*(q^3 - 1)/(q - 1) + 1

sage: x.principal_specialization(q=var("q"))
-2/(q - 1) + 3*q^2/((q^3 - 1)*(q^2 - 1)^2*(q - 1)) + 1
```

scalar(*x*, *zee=None*)

Return the standard scalar product between **self** and *x*.

Note that the Schur functions are self-dual with respect to this scalar product. They are also lower-triangularly related to the monomial symmetric functions with respect to this scalar product.

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as **self**
- *zee* – an optional function on partitions giving the value for the scalar product between the power-sum symmetric function p_μ and itself (the default value is the standard `zee()` function)

OUTPUT:

- the scalar product between **self** and *x*

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: b = s([1,1,1])
sage: c = 2*s([1,1,1])
sage: d = a + b
sage: a.scalar(a)
1
sage: b.scalar(b)
1
sage: b.scalar(a)
0
sage: b.scalar(c)
2
sage: c.scalar(c)
4
sage: d.scalar(a)
1
sage: d.scalar(b)
1
sage: d.scalar(c)
2
```

```

sage: m = SymmetricFunctions(ZZ).monomial()
sage: p4 = Partitions(4)
sage: l = [ [s(p).scalar(m(q)) for q in p4] for p in p4]
sage: matrix(l)
[ 1  0  0  0  0]
[-1  1  0  0  0]
[ 0 -1  1  0  0]
[ 1 -1 -1  1  0]
[-1  2  1 -3  1]

```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator \mathbf{V}_n is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator \mathbf{V}_n is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: s[5].verschiebung(2)
0

```

(continues on next page)

(continued from previous page)

```

sage: s[6].verschiebung(6)
s[1]
sage: s[6,3].verschiebung(3)
s[2, 1] + s[3]
sage: s[6,3,1].verschiebung(2)
-s[3, 2]
sage: s[3,2,1].verschiebung(1)
s[3, 2, 1]
sage: s[[]].verschiebung(1)
s[]
sage: s[[]].verschiebung(4)
s[]

```

coproduct_on_basis(*mu*)

Returns the coproduct of `self(mu)`.

Here `self` is the basis of Schur functions in the ring of symmetric functions.

INPUT:

- `self` – a Schur symmetric function basis
- `mu` – a partition

OUTPUT:

- the image of the `mu`-th Schur function under the comultiplication of the Hopf algebra of symmetric functions; this is an element of the tensor square of the Schur basis

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s.coproduct_on_basis([2])
s[] # s[2] + s[1] # s[1] + s[2] # s[]

```

product_on_basis(*left*, *right*)

Return the product of `left` and `right`.

INPUT:

- `self` – a Schur symmetric function basis
- `left`, `right` – partitions

OUTPUT:

- an element of the Schur basis, the product of `left` and `right`

5.1.297 Symplectic Symmetric Functions

AUTHORS:

- Travis Scrimshaw (2013-11-10): Initial version

class `sage.combinat.sf.symplectic.SymmetricFunctionAlgebra_symplectic(Sym)`

Bases: `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic`

The symplectic symmetric function basis (or symplectic basis, to be short).

The symplectic basis $\{sp_\lambda\}$ where λ is taken over all partitions is defined by the following change of basis with the Schur functions:

$$s_\lambda = \sum_{\mu} \left(\sum_{\nu \in V} c_{\mu\nu}^\lambda \right) sp_\mu$$

where V is the set of all partitions with even-height columns and $c_{\mu\nu}^\lambda$ is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

Note: This is only a filtered basis, not a \mathbf{Z} -graded basis. However this does respect the induced $(\mathbf{Z}/2\mathbf{Z})$ -grading.

INPUT:

- `Sym` – an instance of the ring of the symmetric functions

REFERENCES:

EXAMPLES:

Here are the first few symplectic symmetric functions, in various bases:

```
sage: Sym = SymmetricFunctions(QQ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(sp([1]))
p[1]
sage: m(sp([1]))
m[1]
sage: e(sp([1]))
e[1]
sage: h(sp([1]))
h[1]
sage: s(sp([1]))
s[1]

sage: p(sp([2]))
1/2*p[1, 1] + 1/2*p[2]
sage: m(sp([2]))
m[1, 1] + m[2]
sage: e(sp([2]))
```

(continues on next page)

(continued from previous page)

```

e[1, 1] - e[2]
sage: h(sp([2]))
h[2]
sage: s(sp([2]))
s[2]

sage: p(sp([3]))
1/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3]
sage: m(sp([3]))
m[1, 1, 1] + m[2, 1] + m[3]
sage: e(sp([3]))
e[1, 1, 1] - 2*e[2, 1] + e[3]
sage: h(sp([3]))
h[3]
sage: s(sp([3]))
s[3]

sage: Sym = SymmetricFunctions(ZZ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(sp([4]))
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1] + m[4]
sage: e(sp([4]))
e[1, 1, 1, 1] - 3*e[2, 1, 1] + e[2, 2] + 2*e[3, 1] - e[4]
sage: h(sp([4]))
h[4]
sage: s(sp([4]))
s[4]

```

Some examples of conversions the other way:

```

sage: sp(h[3])
sp[3]
sage: sp(e[3])
sp[1] + sp[1, 1, 1]
sage: sp(m[2,1])
-sp[1] - 2*sp[1, 1, 1] + sp[2, 1]
sage: sp(p[3])
sp[1, 1, 1] - sp[2, 1] + sp[3]

```

Some multiplication:

```

sage: sp([2]) * sp([1,1])
sp[1, 1] + sp[2] + sp[2, 1, 1] + sp[3, 1]
sage: sp([2,1,1]) * sp([2])
sp[1, 1] + sp[1, 1, 1, 1] + 2*sp[2, 1, 1] + sp[2, 2] + sp[2, 2, 1, 1]
+ sp[3, 1] + sp[3, 1, 1, 1] + sp[3, 2, 1] + sp[4, 1, 1]
sage: sp([1,1]) * sp([2,1])

```

(continues on next page)

(continued from previous page)

```
sp[1] + sp[1, 1, 1] + 2*sp[2, 1] + sp[2, 1, 1, 1] + sp[2, 2, 1]
+ sp[3] + sp[3, 1, 1] + sp[3, 2]
```

Examples of the Hopf algebra structure:

```
sage: sp([1]).antipode()
-sp[1]
sage: sp([2]).antipode()
sp[] + sp[1, 1]
sage: sp([1]).coproduct()
sp[] # sp[1] + sp[1] # sp[]
sage: sp([2]).coproduct()
sp[] # sp[2] + sp[1] # sp[1] + sp[2] # sp[]
sage: sp([1]).counit()
0
sage: sp.one().counit()
1
```

5.1.298 Symmetric functions, with their multiple realizations

class sage.combinat.sf.sf.SymmetricFunctions(*R*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The abstract algebra of commutative symmetric functions

Symmetric Functions in Sage

Author: Jason Bandlow, Anne Schilling, Nicolas M. Thiery, Mike Zabrocki

This document is an introduction to working with symmetric function theory in Sage. It is not intended to be an introduction to the theory of symmetric functions ([MAC] and [STA], Chapter 7, are two excellent references.) The reader is also expected to be familiar with Sage.

The algebra of symmetric functions

The algebra of symmetric functions is the unique free commutative graded connected algebra over the given ring, with one generator in each degree. It can also be thought of as the inverse limit (in the category of graded algebras) of the algebra of symmetric polynomials in n variables as $n \rightarrow \infty$. Sage allows us to construct the algebra of symmetric functions over any ring. We will use a base ring of rational numbers in these first examples:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym
Symmetric Functions over Rational Field
```

Sage knows certain categorical information about this algebra:

```
sage: Sym.category()
Join of Category of hopf algebras over Rational Field
and Category of graded algebras over Rational Field
and Category of commutative algebras over Rational Field
```

(continues on next page)

(continued from previous page)

```

and Category of monoids with realizations
and Category of graded coalgebras over Rational Field
and Category of coalgebras over Rational Field with realizations
and Category of cocommutative coalgebras over Rational Field

```

Notice that `Sym` is an *abstract* algebra. This reflects the fact that there are multiple natural bases. To work with specific elements, we need a *realization* of this algebra. In practice, this means we need to specify a basis.

An example basis - power sums

Here is an example of how one might use the power sum realization:

```

sage: p = Sym.powersum()
sage: p
Symmetric Functions over Rational Field in the powersum basis

```

`p` now represents the realization of the symmetric function algebra on the power sum basis. The basis itself is accessible through:

```

sage: p.basis()
Lazy family (Term map from Partitions to Symmetric Functions over Rational Field in
↳the powersum basis(i))_{i in Partitions}
sage: p.basis().keys()
Partitions

```

This last line means that `p.basis()` is an association between the set of Partitions and the basis elements of the algebra `p`. To construct a specific element one can therefore do:

```

sage: p.basis()[Partition([2,1,1])]
p[2, 1, 1]

```

As this is rather cumbersome, realizations of the symmetric function algebra allow for the following abuses of notation:

```

sage: p[Partition([2, 1, 1])]
p[2, 1, 1]
sage: p[[2, 1, 1]]
p[2, 1, 1]
sage: p[2, 1, 1]
p[2, 1, 1]

```

or even:

```

sage: p[(i for i in [2, 1, 1])]
p[2, 1, 1]

```

In the special case of the empty partition, due to a limitation in Python syntax, one cannot use:

```

sage: p[]      # todo: not implemented

```

Please use instead:

```
sage: p[[]]
p[]
```

Note: When elements are constructed using the `p[something]` syntax, an error will be raised if the input cannot be interpreted as a partition. This is *not* the case when `p.basis()` is used:

```
sage: p['something']
Traceback (most recent call last):
...
ValueError: all parts of 'something' should be nonnegative integers
sage: p.basis()['something']
p'something'
```

Elements of `p` are linear combinations of such compositions:

```
sage: p.an_element()
2*p[] + 2*p[1] + 3*p[2]
```

Algebra structure

Algebraic combinations of basis elements can be entered in a natural way:

```
sage: p[2,1,1] + 2 * p[1] * (p[4] + p[2,1])
3*p[2, 1, 1] + 2*p[4, 1]
```

Let us explore the other operations of `p`. We can ask for the mathematical properties of `p`:

```
sage: p.categories()
[Category of graded bases of Symmetric Functions over Rational Field,
Category of filtered bases of Symmetric Functions over Rational Field,
Category of bases of Symmetric Functions over Rational Field,
Category of graded hopf algebras with basis over Rational Field,
...]
```

To start with, `p` is a graded algebra, the grading being induced by the size of the partitions. Due to this, the one is the basis element indexed by the empty partition:

```
sage: p.one()
p[]
```

The `p` basis is multiplicative; that is, multiplication is induced by linearity from the (nonincreasingly sorted) concatenation of partitions:

```
sage: p[3,1] * p[2,1]
p[3, 2, 1, 1]

sage: (p.one() + 2 * p[3,1]) * p[4, 2]
p[4, 2] + 2*p[4, 3, 2, 1]
```

The classical bases

In addition to the power sum basis, other classical bases of the symmetric function algebra include the elementary, complete homogeneous, monomial, and Schur bases:

```
sage: e = Sym.elementary()
sage: h = Sym.homogeneous()
sage: m = Sym.monomial()
sage: s = Sym.schur()
```

These and others can be defined all at once with the single command:

```
sage: Sym.inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the
↳elementary basis
Defining f as shorthand for Symmetric Functions over Rational Field in the
↳forgotten basis
Defining h as shorthand for Symmetric Functions over Rational Field in the
↳homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial
↳basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum
↳basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur
↳basis
```

We can then do conversions from one basis to another:

```
sage: s(p[2,1])
-s[1, 1, 1] + s[3]

sage: m(p[3])
m[3]
sage: m(p[3,2])
m[3, 2] + m[5]
```

For computations which mix bases, Sage will return a result with respect to a single (not necessarily predictable) basis:

```
sage: p[2] * s[2] - m[4]
1/2*p[2, 1, 1] + 1/2*p[2, 2] - p[4]

sage: p( m[1] * ( e[3]*s[2] + 1 ))
p[1] + 1/12*p[1, 1, 1, 1, 1, 1] - 1/6*p[2, 1, 1, 1, 1] - 1/4*p[2, 2, 1, 1] + 1/
↳6*p[3, 1, 1, 1] + 1/6*p[3, 2, 1]
```

The one for different bases such as the power sum and Schur function is the same:

```
sage: s.one() == p.one()
True
```

Basic computations

In this section, we explore some of the many methods that can be applied to an arbitrary symmetric function:

```
sage: f = s[2]^2; f
s[2, 2] + s[3, 1] + s[4]
```

For more methods than discussed here, create a symmetric function as above, and use `f.<tab>`.

Representation theory of the symmetric group

The Schur functions s_λ can also be interpreted as irreducible characters of the symmetric group S_n , where n is the size of the partition λ . Since the Schur functions of degree n form a basis of the symmetric functions of degree n , it follows that an arbitrary symmetric function (homogeneous of degree n) may be interpreted as a function on the symmetric group. In this interpretation the power sum symmetric function p_λ is the characteristic function of the conjugacy class with shape λ , multiplied by the order of the centralizer of an element. Hence the irreducible characters can be computed as follows:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: p = Sym.power()
sage: P = Partitions(5).list()
sage: P = [P[i] for i in range(len(P)-1,-1,-1)]
sage: M = matrix([[s[P[i]].scalar(p[P[j]]) for j in range(len(P))] for i in
->range(len(P))])
sage: M
[ 1 -1  1  1 -1 -1  1]
[ 4 -2  0  1  1  0 -1]
[ 5 -1  1 -1 -1  1  0]
[ 6  0 -2  0  0  0  1]
[ 5  1  1 -1  1 -1  0]
[ 4  2  0  1 -1  0 -1]
[ 1  1  1  1  1  1  1]
```

We can indeed check that this agrees with the character table of S_5 :

```
sage: SymmetricGroup(5).character_table() == M
True
```

In this interpretation of symmetric functions as characters on the symmetric group, the multiplication and comultiplication are interpreted as induction (from $S_n \times S_m$ to S_{n+m}) and restriction, respectively. The Schur functions can also be interpreted as characters of GL_n , see [Partitions and Schur functions](#).

The omega involution

The ω involution is the linear extension of the map which sends e_λ to h_λ :

```
sage: h(f)
h[2, 2]
sage: e(f.omega())
e[2, 2]
```

The Hall scalar product

The Hall scalar product on the algebra of symmetric functions makes the Schur functions into an orthonormal basis:

```
sage: f.scalar(f)
3
```

Skewing

Skewing is the adjoint operation to multiplication with respect to this scalar product:

```
sage: f.skew_by(s[1])
2*s[2, 1] + 2*s[3]
```

In general, `s[1a].skew_by(s[mu])` is the symmetric function typically denoted $s_{\lambda \setminus \mu}$ or $s_{\lambda/\mu}$.

Expanding into variables

We can expand a symmetric function into a symmetric polynomial in a specified number of variables:

```
sage: f.expand(2)
x0^4 + 2*x0^3*x1 + 3*x0^2*x1^2 + 2*x0*x1^3 + x1^4
```

See the documentation for `expand` for more examples.

The Kronecker product

As in the section on the *Representation theory of the symmetric group*, a symmetric function may be considered as a class function on the symmetric group where the elements p_μ/z_μ are the indicators of a permutation having cycle structure μ . The Kronecker product of two symmetric functions corresponds to the pointwise product of these class functions.

Since the Schur functions are the irreducible characters of the symmetric group under this identification, the Kronecker product of two Schur functions corresponds to the internal tensor product of two irreducible symmetric group representations.

Under this identification, the Kronecker product of p_μ/z_μ and p_ν/z_ν is p_μ/z_μ if $\mu = \nu$, and the result is equal to 0 otherwise.

`internal_product`, `kroncker_product`, `inner_tensor` and `itensor` are different names for the same function.

```
sage: f.kronecker_product(f)
s[1, 1, 1, 1] + 3*s[2, 1, 1] + 4*s[2, 2] + 5*s[3, 1] + 3*s[4]
```

Plethysm

The *plethysm* of symmetric functions is the operation corresponding to composition of representations of the general linear group. See [STA] Chapter 7, Appendix 2 for details.

```
sage: s[2].plethysm(s[2])
s[2, 2] + s[4]
```

Plethysm can also be written as a composition of functions:

```
sage: s[2]( s[2] )
s[2, 2] + s[4]
```

If the coefficient ring contains degree 1 elements, these are handled properly by plethysm:

```
sage: R.<t> = QQ[]; s = SymmetricFunctions(R).schur()
sage: s[2]( (1-t)*s[1] )
(t^2-t)*s[1, 1] + (-t+1)*s[2]
```

See the documentation for `plethysm` for more information.

Inner plethysm

The operation of inner plethysm `f.inner_plethysm(g)` models the composition of the S_n representation represented by g with the GL_m representation whose character is f . See the documentation of `inner_plethysm`, [ST94] or [STA], exercise 7.74 solutions for more information:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: f = s[2]^2
sage: f.inner_plethysm(s[2])
s[2]
```

Hopf algebra structure

The ring of symmetric functions is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; the power sum generators are primitive:

```
sage: p[1].coproduct()
p[] # p[1] + p[1] # p[]
sage: p[2].coproduct()
p[] # p[2] + p[2] # p[]
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```
sage: p[2, 1].coproduct()
p[] # p[2, 1] + p[1] # p[2] + p[2] # p[1] + p[2, 1] # p[]
```

This coproduct, along with the counit which sends every symmetric function to its 0-th homogeneous component, makes the ring of symmetric functions into a graded connected bialgebra. It is known that every graded connected bialgebra has an antipode. For the ring of symmetric functions, the antipode can be characterized explicitly: The antipode is an anti-algebra morphism (thus an algebra morphism, since our algebra is commutative) which sends p_λ to $(-1)^{\text{length}(\lambda)} p_\lambda$ for every partition λ . Thus, in particular, it sends the generators on the p basis to their opposites:

```
sage: p[3].antipode()
-p[3]
sage: p[3,2,1].antipode()
-p[3, 2, 1]
```

The graded connected bialgebra of symmetric functions over a \mathbf{Q} -algebra has a rather simply-understood structure: It is (isomorphic to) the symmetric algebra of its space of primitives (which is spanned by the power-sum symmetric functions).

Here are further examples:

```
sage: f = s[2]^2
sage: f.antipode()
s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2]
sage: f.coproduct()
s[] # s[2, 2] + s[] # s[3, 1] + s[] # s[4] + 2*s[1] # s[2, 1] + 2*s[1] # s[3] + s[1,
↪ 1] # s[1, 1]
+ s[1, 1] # s[2] + s[2] # s[1, 1] + 3*s[2] # s[2] + 2*s[2, 1] # s[1] + s[2, 2] #
↪ s[] + 2*s[3] # s[1]
+ s[3, 1] # s[] + s[4] # s[]
sage: f.coproduct().apply_multilinear_morphism( lambda x,y: x*y.antipode() )
0
```

Transformations of symmetric functions

There are many methods in Sage which make it easy to manipulate symmetric functions. For example, if we have some function which acts on partitions (say, conjugation), it is a simple matter to apply it to the support of a symmetric function. Here is an example:

```
sage: conj = lambda mu: mu.conjugate()
sage: f = h[4] + 2*h[3,1]
sage: f.map_support(conj)
h[1, 1, 1, 1] + 2*h[2, 1, 1]
```

We can also easily modify the coefficients:

```
sage: def foo(mu, coeff): return mu.conjugate(), -coeff
sage: f.map_item(foo)
-h[1, 1, 1, 1] - 2*h[2, 1, 1]
```

See also `map_coefficients`.

There are also methods for building functions directly:

```
sage: s.sum_of_monomials(mu for mu in Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]
sage: s.sum_of_monomials(Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]
sage: s.sum_of_terms( (mu, mu[0]) for mu in Partitions(3))
s[1, 1, 1] + 2*s[2, 1] + 3*s[3]
```

These are the preferred way to build elements within a program; the result will usually be faster than using `sum()`. It also guarantees that empty sums yields the zero of `s` (see also `s.sum`).

Note also that it is a good idea to use:

```
sage: s.one()
s[]
sage: s.zero()
0
```

instead of $s(1)$ and $s(0)$ within programs where speed is important, in order to prevent unnecessary coercions.

Different base rings

Depending on the base ring, the different realizations of the symmetric function algebra may not span the same space:

```
sage: SZ = SymmetricFunctions(ZZ)
sage: p = SZ.power(); s = SZ.schur()
sage: p(s[1,1,1])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

Because of this, some functions may not behave as expected when working over the integers, even though they make mathematical sense:

```
sage: s[1,1,1].plethysm(s[1,1,1])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

It is possible to work over different base rings simultaneously:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: p = SymmetricFunctions(QQ).power()
sage: sz = SymmetricFunctions(ZZ).schur(); sz._prefix = 'sz'
sage: pz = SymmetricFunctions(ZZ).power(); pz._prefix = 'pz'
sage: p(sz[1,1,1])
1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3]
sage: sz( 1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3] )
sz[1, 1, 1]
```

As shown in this example, if you are working over multiple base rings simultaneously, it is a good idea to change the prefix in some cases, so that you can tell from the output which realization your result is in.

Let us change the notation back for the remainder of this tutorial:

```
sage: sz._prefix = 's'
sage: pz._prefix = 'p'
```

One can also use the Sage standard renaming idiom to get shorter outputs:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.rename("Sym")
sage: Sym
Sym
sage: Sym.rename()
```

And we name it back:

```
sage: Sym.rename("Symmetric Functions over Rational Field"); Sym
Symmetric Functions over Rational Field
```

Other bases

There are two additional basis of the symmetric functions which are not considered as classical bases:

- forgotten basis
- Witt basis

The forgotten basis is the dual basis of the elementary symmetric functions basis with respect to the Hall scalar product. The Witt basis can be constructed by

$$\prod_{d=1}^{\infty} (1 - w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n$$

where t is a formal variable.

There are further bases of the ring of symmetric functions, in general over fields with parameters such as q and t :

- Hall-Littlewood bases
- Jack bases
- Macdonald bases
- k -Schur functions
- Hecke character basis

We briefly demonstrate how to access these bases. For more information, see the documentation of the individual bases.

The *Jack polynomials* can be obtained as:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Jack = Sym.jack()
sage: P = Jack.P(); J = Jack.J(); Q = Jack.Q()
sage: J(P[2, 1])
(1/(t+2))*JackJ[2, 1]
```

The parameter t can be specialized as follows:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Jack = Sym.jack(t = 1)
sage: P = Jack.P(); J = Jack.J(); Q = Jack.Q()
sage: J(P[2, 1])
1/3*JackJ[2, 1]
```

Similarly one can access the Hall-Littlewood and Macdonald polynomials, etc:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: Mcd = Sym.macdonald()
sage: P = Mcd.P(); J = Mcd.J(); Q = Mcd.Q()
```

(continues on next page)

(continued from previous page)

```
sage: J(P[2, 1])
(1/(-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1))*McdJ[2, 1]
```

We can also construct the \bar{q} basis that can be used to determine character tables for Hecke algebras (with quadratic relation $T_i^2 = (1 - q)T_i + q$):

```
sage: Sym = SymmetricFunctions(ZZ['q'].fraction_field())
sage: qbar = Sym.hecke_character()
sage: s = Sym.s()
sage: s(qbar[2, 1])
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
```

k -Schur functions

The k -Schur functions live in the k -bounded subspace of the ring of symmetric functions. It is possible to compute in the k -bounded subspace directly:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3, 1)
sage: f = ks[2, 1]*ks[2, 1]; f
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

or to lift to the ring of symmetric functions:

```
sage: f.lift()
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] +
↪s[4, 2]
```

However, it is not always possible to convert a symmetric function to the k -bounded subspace:

```
sage: s = Sym.schur()
sage: ks(s[2, 1, 1])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1] is not in the image
```

The k -Schur functions are more generally defined with a parameter t and they are a basis of the subspace spanned by the Hall-Littlewood Q_p symmetric functions indexed by partitions whose first part is less than or equal to k :

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: SymS3 = Sym.kBoundedSubspace(3) # default t='t'
sage: ks = SymS3.kschur()
sage: Qp = Sym.hall_littlewood().Qp()
sage: ks(Qp[2, 1, 1, 1])
ks3[2, 1, 1, 1] + (t^2+t)*ks3[2, 2, 1] + (t^3+t^2)*ks3[3, 1, 1] + t^4*ks3[3, 2]
```

The subspace spanned by the k -Schur functions with a parameter t are not known to form a natural algebra. However it is known that the product of a k -Schur function and an ℓ -Schur function is in the linear span of the $k + \ell$ -Schur functions:

```
sage: ks(ks[2, 1]*ks[1, 1])
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```

...
ValueError: s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] is not in the image
sage: ks[2,1]*ks[1,1]
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2]
sage: ks6 = Sym.kBoundedSubspace(6).kschur()
sage: ks6(ks[3,1,1]*ks[3])
ks6[3, 3, 1, 1] + ks6[4, 2, 1, 1] + (t+1)*ks6[4, 3, 1] + t*ks6[4, 4]
+ ks6[5, 1, 1, 1] + ks6[5, 2, 1] + t*ks6[5, 3] + ks6[6, 1, 1]

```

The k -split basis is a second basis of the ring spanned by the k -Schur functions with a parameter t . The k -split basis has the property that $Q'_\lambda[X; t]$ expands positively in the k -split basis and the k -split basis conjecturally expands positively in the k -Schur functions. The definition can be found in [LLMSSZ] p. 81.:

```

sage: ksp3 = SymS3.ksplit()
sage: ksp3(Qp[2,1,1,1])
ksp3[2, 1, 1, 1] + t^2*ksp3[2, 2, 1] + (t^3+t^2)*ksp3[3, 1, 1] + t^4*ksp3[3, 2]
sage: [ks(ksp3(la)) for la in sorted(ksp3(Qp[2,1,1,1]).support())]
[ks[2, 1, 1, 1] + t*ks[2, 2, 1], ks[2, 2, 1], ks[3, 1, 1], ks[3, 2]]

```

dual k -Schur functions

The dual space to the subspace spanned by the k -Schur functions is most naturally realized as a quotient of the ring of symmetric functions by an ideal. When $t = 1$ the ideal is generated by the monomial symmetric functions indexed by partitions whose first part is greater than k .

```

sage: Sym = SymmetricFunctions(QQ)
sage: SymQ3 = Sym.kBoundedQuotient(3,t=1)
sage: km = SymQ3.kmonomial()
sage: km[2,1]*km[2,1]
4*m3[2, 2, 1, 1] + 6*m3[2, 2, 2] + 2*m3[3, 2, 1] + 2*m3[3, 3]
sage: F = SymQ3.affineSchur()
sage: F[2,1]*F[2,1]
2*F3[1, 1, 1, 1, 1, 1] + 4*F3[2, 1, 1, 1, 1] + 4*F3[2, 2, 1, 1] + 4*F3[2, 2, 2]
+ 2*F3[3, 1, 1, 1] + 4*F3[3, 2, 1] + 2*F3[3, 3]

```

When t is not equal to 1, the subspace spanned by the k -Schur functions is realized as a quotient of the ring of symmetric functions by the ideal generated by the Hall-Littlewood symmetric functions in the P basis indexed by partitions with first part greater than k .

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: SymQ3 = Sym.kBoundedQuotient(3)
sage: kHLP = SymQ3.kHallLittlewoodP()
sage: kHLP[2,1]*kHLP[2,1]
(t^2+2*t+1)*HLP3[2, 2, 1, 1] + (t^3+2*t^2+2*t+1)*HLP3[2, 2, 2]
+ (-t^4-t^3+t+1)*HLP3[3, 1, 1, 1] + (-t^2+t+2)*HLP3[3, 2, 1] + (t+1)*HLP3[3, 3]
sage: HLP = Sym.hall_littlewood().P()
sage: kHLP(HLP[3,1])
HLP3[3, 1]
sage: kHLP(HLP[4])
0

```

In this space, the basis which is dual to the k -Schur functions conjecturally expands positively in the k -bounded Hall-Littlewood functions and has positive structure coefficients.:

```
sage: dks = SymQ3.dual_k_Schur()
sage: kHLP(dks[2,2])
(t^4+t^2)*HLP3[1, 1, 1, 1] + t*HLP3[2, 1, 1] + HLP3[2, 2]
sage: dks[2,1]*dks[1,1]
(t^2+t)*dks3[1, 1, 1, 1, 1] + (t+1)*dks3[2, 1, 1, 1] + (t+1)*dks3[2, 2, 1]
+ dks3[3, 1, 1] + dks3[3, 2]
```

At $t = 1$ the k -bounded Hall-Littlewood basis is equal to the k -bounded monomial basis and the dual k -Schur elements are equal to the affine Schur basis. The k -bounded monomial basis and affine Schur functions are faster and should be used instead of the k -bounded Hall-Littlewood P basis and dual k -Schur functions when $t = 1$.

```
sage: SymQ3 = Sym.kBoundedQuotient(3,t=1)
sage: dks = SymQ3.dual_k_Schur()
sage: F = SymQ3.affineSchur()
sage: F[3,1]==dks[3,1]
True
```

Implementing new bases

In order to implement a new symmetric function basis, Sage will need to know at a minimum how to change back and forth between at least one other basis (although they do not necessarily have to be the same basis). All of the standard functions associated with the basis will have a default implementation (although a more specific implementation may be more efficient).

To present an idea of how this is done, we will create here the example of how to implement the basis $s_\mu[X(1-t)]$.

To begin, we import the class `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic()`. Our new basis will inherit all of the default methods from this class:

```
sage: from sage.combinat.sf.sfa import SymmetricFunctionAlgebra_generic as SFA_
->generic
```

Now the basis we are creating has a parameter t which is possible to specialize. In this example we will convert to and from the Schur basis. For this we implement methods `_self_to_s` and `_s_to_self`. By registering these two functions as coercions, Sage then knows automatically how it possible to change between any two bases for which there is a path of changes of bases.

```
sage: from sage.categories.morphism import SetMorphism
sage: class SFA_st(SFA_generic):
.....:     def __init__(self, Sym, t):
.....:         SFA_generic.__init__(self, Sym, basis_name=
.....:             "Schur functions with a plethystic substitution of X -> X(1-t)",
.....:             prefix='st')
.....:         self._s = Sym.s()
.....:         self.t = Sym.base_ring()(t)
.....:         cat = HopfAlgebras(Sym.base_ring()).WithBasis()
.....:         self.register_coercion(
.....:             SetMorphism(Hom(self._s, self, cat), self._s_to_self))
.....:         self._s.register_coercion(
.....:             SetMorphism(Hom(self, self._s, cat), self._self_to_s))
.....:     def _s_to_self(self, f):
```

(continues on next page)

(continued from previous page)

```

.....:         # f is a Schur function and the output is in the st basis
.....:         return self._from_dict(f.theta_qt(0,self.t)._monomial_coefficients)
.....:     def _self_to_s(self, f):
.....:         # f is in the st basis and the output is in the Schur basis
.....:         return self._s.sum(cmu*self._s(mu).theta_qt(self.t,0) for mu,cmu in f)
.....:     class Element(SFA_generic.Element):
.....:         pass

```

An instance of this basis is created by calling it with a symmetric function ring `Sym` and a parameter `t` which is in the base ring of `Sym`. The `Element` class inherits all of the methods from `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`.

In the reference [MAC] on page 354, this basis is denoted $S_\lambda(x;t)$ and the change of basis coefficients of the Macdonald J basis are the coefficients $K_{\lambda\mu}(q,t)$. Here is an example of its use:

```

sage: QQqt = QQ['q','t'].fraction_field()
sage: (q,t) = QQqt.gens()
sage: st = SFA_st(SymmetricFunctions(QQqt),t)
sage: st
Symmetric Functions over Fraction Field of Multivariate Polynomial
Ring in q, t over Rational Field in the Schur functions with a
plethystic substitution of X -> X(1-t) basis
sage: st[2,1] * st[1]
st[2, 1, 1] + st[2, 2] + st[3, 1]
sage: st([2]).coproduct()
st[] # st[2] + st[1] # st[1] + st[2] # st[]
sage: J = st.symmetric_function_ring().macdonald().J()
sage: st(J[2,1])
q*st[1, 1, 1] + (q*t+1)*st[2, 1] + t*st[3]

```

Acknowledgements

The design is heavily inspired from the implementation of symmetric functions in MuPAD-Combinat (see [HT04] and [FD06]).

REFERENCES:

Further tests

Todo:

- Introduce fields with degree 1 elements as in MuPAD-Combinat, to get proper plethysm.
- Use `UniqueRepresentation` to get rid of all the manual cache handling for the bases
- Devise a mechanism so that pickling bases of symmetric functions pickles the coercions which have a cache.

Schur()

The Schur basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

Witt(*coerce_h=True, coerce_e=False, coerce_p=False*)

The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
```

a_realization()

Return a particular realization of `self` (the Schur basis).

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.a_realization()
Symmetric Functions over Rational Field in the Schur basis
```

complete()

The complete basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

e()

The elementary basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
```

elementary()

The elementary basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
```

f()

The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

EXAMPLES:

```
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

forgotten()

The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

EXAMPLES:

```
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

from_polynomial(f)

Converts a symmetric polynomial f to a symmetric function.

INPUT:

- f – a symmetric polynomial

This function converts a symmetric polynomial f in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

EXAMPLES:

```
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: S = SymmetricFunctions(QQ)
sage: S.from_polynomial(f)
m[1]

sage: f = x[0] + 2*x[1] + x[2]
sage: S.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0 + 2*x1 + x2 is not a symmetric polynomial
```

h()

The complete basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

hall_littlewood($t='t'$)

Returns the entry point for the various Hall-Littlewood bases.

INPUT:

- t – parameter

Hall-Littlewood symmetric functions including bases P , Q , Qp . The Hall-Littlewood P and Q functions at $t = -1$ are the Schur- P and Schur- Q functions when indexed by strict partitions.

The parameter t must be in the base ring of parent.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: P = Sym.hall_littlewood().P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪ Rational Field in the Hall-Littlewood P basis
```

(continues on next page)

(continued from previous page)

```

sage: P[2]
HLP[2]
sage: Q = Sym.hall_littlewood().Q(); Q
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Hall-Littlewood Q basis
sage: Q[2]
HLQ[2]
sage: Qp = Sym.hall_littlewood().Qp(); Qp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Hall-Littlewood Qp basis
sage: Qp[2]
HLQp[2]

```

hecke_character($q='q'$)

The basis of symmetric functions that determines the character tables for Hecke algebras.

EXAMPLES:

```

sage: SymmetricFunctions(ZZ['q']).fraction_field().hecke_character()
Symmetric Functions over
  Fraction Field of Univariate Polynomial Ring in q over Integer Ring
  in the Hecke character with q=q basis
sage: SymmetricFunctions(QQ).hecke_character(1/2)
Symmetric Functions over Rational Field in the Hecke character with q=1/2 basis

```

homogeneous()

The complete basis of the Symmetric Functions

EXAMPLES:

```

sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis

```

ht()

The induced trivial character basis of the Symmetric Functions.

The trivial character of

$$S_{n-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell(\lambda)}$$

induced to the group S_n is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the coefficient $\langle h_{(n-|\lambda|,\lambda)}, p_\rho \rangle$.

In terms of methods that are implemented in Sage, if n is a sufficiently large integer, then `ht(lam).character_to_frobenius_image(n)` is equal the complete function indexed by $[n-\text{sum}(lam)]+lam$.

This basis is introduced in [OZ2015].

See also:

`character_to_frobenius_image()`, `eval_at_permutation_roots()`

EXAMPLES:

```

sage: SymmetricFunctions(QQ).induced_trivial_character()
Symmetric Functions over Rational Field in the induced trivial symmetric group
↳character basis
sage: ht = SymmetricFunctions(QQ).ht()
sage: h = SymmetricFunctions(QQ).h()
sage: h(ht([3,2]).character_to_frobenius_image(9))
h[4, 3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(7))
h[3, 2, 2]
sage: h(ht([3,2]).character_to_frobenius_image(5))
h[3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(4))
0
sage: p = SymmetricFunctions(QQ).p()
sage: [h([4,1]).scalar(p(rho)) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
sage: [ht([1]).eval_at_permutation_roots(rho) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]

```

induced_trivial_character()

The induced trivial character basis of the Symmetric Functions.

The trivial character of

$$S_{n-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell(\lambda)}$$

induced to the group S_n is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the coefficient $\langle h_{(n-|\lambda|,\lambda)}, p_\rho \rangle$.

In terms of methods that are implemented in Sage, if n is a sufficiently large integer, then `ht(lam).character_to_frobenius_image(n)` is equal the complete function indexed by `[n-sum(lam)]+lam`.

This basis is introduced in [OZ2015].

See also:

[`character_to_frobenius_image\(\)`](#), [`eval_at_permutation_roots\(\)`](#)

EXAMPLES:

```

sage: SymmetricFunctions(QQ).induced_trivial_character()
Symmetric Functions over Rational Field in the induced trivial symmetric group
↳character basis
sage: ht = SymmetricFunctions(QQ).ht()
sage: h = SymmetricFunctions(QQ).h()
sage: h(ht([3,2]).character_to_frobenius_image(9))
h[4, 3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(7))
h[3, 2, 2]
sage: h(ht([3,2]).character_to_frobenius_image(5))
h[3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(4))
0
sage: p = SymmetricFunctions(QQ).p()

```

(continues on next page)

(continued from previous page)

```

sage: [h([4,1]).scalar(p(rho)) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
sage: [ht([1]).eval_at_permutation_roots(rho) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]

```

irreducible_symmetric_group_character()

The irreducible S_n character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the irreducible character $\chi^{(|\rho|-|\lambda|,\lambda)}(\rho)$.

In terms of methods that are implemented in Sage, if n is a sufficiently large integer, then `st(lam).character_to_frobenius_image(n)` is equal the Schur function indexed by `[n-sum(lam)]+lam`.

This basis is introduced in [OZ2015].

See also:

`character_to_frobenius_image()`, `eval_at_permutation_roots()`

EXAMPLES:

```

sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group
↳ character basis
sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))
0
sage: s(st([3,2]).character_to_frobenius_image(6))
-s[2, 2, 2]
sage: list(SymmetricGroup(5).character_table()[-2])
[4, 2, 0, 1, -1, 0, -1]
sage: list(reversed([st([1]).eval_at_permutation_roots(rho)
.....: for rho in Partitions(5)]))
[4, 2, 0, 1, -1, 0, -1]

```

jack($t='t'$)

Returns the entry point for the various Jack bases.

INPUT:

- t – parameter

Jack symmetric functions including bases P , Q , Qp .

The parameter t must be in the base ring of parent.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳ Rational Field in the Jack P basis
sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳ Rational Field in the Jack Q basis

```

(continues on next page)

(continued from previous page)

```

sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Jack J basis
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the Jack Qp basis

```

kBoundedQuotient($k, t='t'$)Returns the k -bounded quotient space of the ring of symmetric functions.

INPUT:

- k - a positive integer

The quotient of the ring of symmetric functions ...

See also:

[`sage.combinat.sf.k_dual.KBoundedQuotient\(\)`](#)

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: KQ = Sym.kBoundedQuotient(3); KQ
Traceback (most recent call last):
...
TypeError: unable to convert 't' to a rational
sage: KQ = Sym.kBoundedQuotient(3,t=1); KQ
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
sage: KQ = Sym.kBoundedQuotient(3); KQ
3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate
↳Polynomial Ring in t over Rational Field

```

kBoundedSubspace($k, t='t'$)Return the k -bounded subspace of the ring of symmetric functions.

INPUT:

- k - a positive integer
- t a formal parameter; $t = 1$ yields a subring

The subspace of the ring of symmetric functions spanned by $\{s_\lambda[X/(1-t)]\}_{\lambda_1 \leq k} = \{s_\lambda^{(k)}[X, t]\}_{\lambda_1 \leq k}$ over the base ring $\mathbb{Q}[t]$. When $t = 1$, this space is in fact a subalgebra of the ring of symmetric functions generated by the complete homogeneous symmetric functions h_i for $1 \leq i \leq k$.

See also:

[`sage.combinat.sf.new_kschur.KBoundedSubspace\(\)`](#)

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1
sage: Sym = SymmetricFunctions(QQ['t'])
sage: Sym.kBoundedSubspace(3)

```

(continues on next page)

(continued from previous page)

```

3-bounded Symmetric Functions over Univariate Polynomial Ring in t over
↳Rational Field

sage: Sym = SymmetricFunctions(QQ['z'])
sage: z = Sym.base_ring().gens()[0]
sage: Sym.kBoundedSubspace(3,t=z)
3-bounded Symmetric Functions over Univariate Polynomial Ring in z over
↳Rational Field with t=z

```

khomogeneous(*k*)Returns the homogeneous symmetric functions in the *k*-bounded subspace.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: kh = Sym.khomogeneous(4)
sage: kh[3]*kh[4]
h4[4, 3]
sage: kh[4].lift()
h[4]

```

kschur(*k*, *t='t'*)Returns the *k*-Schur functions.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2]*ks[2]
ks3[2, 2] + ks3[3, 1]
sage: ks[2,1,1].lift()
s[2, 1, 1] + s[3, 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: ks[2,2,1].lift()
s[2, 2, 1] + t*s[3, 2]

```

ksplit(*k*, *t='t'*)Return the *k*-split basis of the *k*-bounded subspace.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: ksp = Sym.ksplit(3,1)
sage: ksp[2]*ksp[2]
ksp3[2, 2] + ksp3[3, 1]
sage: ksp[2,1,1].lift()
s[2, 1, 1] + s[2, 2] + s[3, 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ksp = Sym.ksplit(3)
sage: ksp[2,1,1].lift()
s[2, 1, 1] + t*s[2, 2] + t*s[3, 1]

```

llt($k, t='t'$)

The LLT symmetric functions.

INPUT:

- k – a positive integer indicating the level
- t – a parameter (default: t)

LLT polynomials in *hspin* and *hcospin* bases.

EXAMPLES:

```

sage: llt3 = SymmetricFunctions(QQ['t']).fraction_field().llt(3); llt3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t
↳over Rational Field
sage: llt3.hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the level 3 LLT spin basis
sage: llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the level 3 LLT cospin basis
sage: llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↳Rational Field in the level 3 LLT cospin basis

```

m()

The monomial basis of the Symmetric Functions

EXAMPLES:

```

sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis

```

macdonald($q='q', t='t'$)

Returns the entry point for the various Macdonald bases.

INPUT:

- q, t – parameters

Macdonald symmetric functions including bases P, Q, J, H, Ht . This also contains the S basis which is dual to the Schur basis with respect to the q, t scalar product.The parameters q and t must be in the `base_ring` of parent.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↳over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
↳over Rational Field in the Macdonald Q basis
sage: S = Sym.macdonald().S()
sage: s = Sym.schur()

```

(continues on next page)

(continued from previous page)

```

sage: matrix([[S(la).scalar_qt(s(mu)) for la in Partitions(3)] for mu in
↳Partitions(3)])
[1 0 0]
[0 1 0]
[0 0 1]
sage: H = Sym.macdonald().H()
sage: s(H[2,2])
q^2*s[1, 1, 1, 1] + (q^2*t+q*t+q)*s[2, 1, 1] + (q^2*t^2+1)*s[2, 2] + (q*t^2+
↳2+q*t+t)*s[3, 1] + t^2*s[4]

sage: Sym = SymmetricFunctions(QQ['z','q'].fraction_field())
sage: (z,q) = Sym.base_ring().gens()
sage: Hzq = Sym.macdonald(q=z,t=q).H()
sage: H1z = Sym.macdonald(q=1,t=z).H()
sage: s = Sym.schur()
sage: s(H1z([2,2]))
s[1, 1, 1, 1] + (2*z+1)*s[2, 1, 1] + (z^2+1)*s[2, 2] + (z^2+2*z)*s[3, 1] + z^
↳2*s[4]
sage: s(Hzq[2,2])
z^2*s[1, 1, 1, 1] + (z^2*q+z*q+z)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^2+
↳2+z*q+q)*s[3, 1] + q^2*s[4]
sage: s(H1z(Hzq[2,2]))
z^2*s[1, 1, 1, 1] + (z^2*q+z*q+z)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^2+
↳2+z*q+q)*s[3, 1] + q^2*s[4]

```

monomial()

The monomial basis of the Symmetric Functions

EXAMPLES:

```

sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis

```

o()

The orthogonal basis of the symmetric functions.

See also:[*SymmetricFunctionAlgebra_orthogonal*](#)

EXAMPLES:

```

sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis

```

orthogonal()

The orthogonal basis of the symmetric functions.

See also:[*SymmetricFunctionAlgebra_orthogonal*](#)

EXAMPLES:

```

sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis

```

p()

The power sum basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

power()

The power sum basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

powersum()

The power sum basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

qbar($q='q'$)

The basis of symmetric functions that determines the character tables for Hecke algebras.

EXAMPLES:

```
sage: SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Symmetric Functions over
Fraction Field of Univariate Polynomial Ring in q over Integer Ring
in the Hecke character with q=q basis
sage: SymmetricFunctions(QQ).hecke_character(1/2)
Symmetric Functions over Rational Field in the Hecke character with q=1/2 basis
```

register_isomorphism(*morphism*, *only_conversion=False*)Register an isomorphism between two bases of `self`, as a canonical coercion (unless the optional keyword `only_conversion` is set to `True`, in which case the isomorphism is registered as conversion only).

EXAMPLES:

We override the canonical coercion from the Schur basis to the powersum basis by a (stupid!) map $s_\lambda \mapsto 2p_\lambda$.

```
sage: Sym = SymmetricFunctions(QQ['zorglub']) # make sure we are not going to
↪ screw up later tests
sage: s = Sym.s(); p = Sym.p().dual_basis()
sage: phi = s.module_morphism(diagonal = lambda t: 2, codomain = p)
sage: phi(s[2, 1])
2*d_p[2, 1]
sage: Sym.register_isomorphism(phi)
sage: p(s[2,1])
2*d_p[2, 1]
```

The map is supposed to implement the canonical isomorphism between the two bases. Otherwise, the results will be mathematically wrong, as above. Use with care!

s()

The Schur basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

schur()

The Schur basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

sp()

The symplectic basis of the symmetric functions.

See also:*SymmetricFunctionAlgebra_symplectic*

EXAMPLES:

```
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

st()The irreducible S_n character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the irreducible character $\chi^{(|\rho|-\lambda, \lambda)}(\rho)$.

In terms of methods that are implemented in Sage, if n is a sufficiently large integer, then `st(lam).character_to_frobenius_image(n)` is equal the Schur function indexed by $[n-\text{sum}(lam)]+\text{lam}$.

This basis is introduced in [OZ2015].

See also:*character_to_frobenius_image(), eval_at_permutation_roots()*

EXAMPLES:

```
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group
↳ character basis
sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))
0
sage: s(st([3,2]).character_to_frobenius_image(6))
-s[2, 2, 2]
sage: list(SymmetricGroup(5).character_table()[-2])
[4, 2, 0, 1, -1, 0, -1]
sage: list(reversed([st([1]).eval_at_permutation_roots(rho)
```

(continues on next page)

(continued from previous page)

```
.....: for rho in Partitions(5)])
[4, 2, 0, 1, -1, 0, -1]
```

symplectic()

The symplectic basis of the symmetric functions.

See also:

SymmetricFunctionAlgebra_symplectic

EXAMPLES:

```
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

w(*coerce_h=True, coerce_e=False, coerce_p=False*)

The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
```

witt(*coerce_h=True, coerce_e=False, coerce_p=False*)

The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
sage: SymmetricFunctions(QQ).witt(coerce_h=False, coerce_e=True, coerce_p=True)
Symmetric Functions over Rational Field in the Witt basis
```

zonal()

The zonal basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).zonal()
Symmetric Functions over Rational Field in the zonal basis
```

class `sage.combinat.sf.sf.SymmetricaConversionOnBasis`(*t, domain, codomain*)

Bases: object

Initialization of self.

INPUT:

- **t** – a function taking a monomial in `CombinatorialFreeModule(QQ, Partitions())`, and returning a (partition, coefficient) list.
- `domain, codomain` – parents

Construct a function mapping a partition to an element of codomain.

This is a temporary quick hack to wrap around the existing symmetrica conversions, without changing their specs.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['x'])
sage: p = Sym.p(); s = Sym.s()
sage: def t(x) : [(p,c)] = x; return [ (p,2*c), (p.conjugate(), c) ]
sage: f = sage.combinat.sf.sf.SymmetricaConversionOnBasis(t, p, s)
sage: f(Partition([3,1]))
s[2, 1, 1] + 2*s[3, 1]
```

5.1.299 Symmetric Functions

For a comprehensive tutorial on how to use symmetric functions in Sage

See also:

[SymmetricFunctions\(\)](#)

We define the algebra of symmetric functions in the Schur and elementary bases:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: e = SymmetricFunctions(QQ).elementary()
```

Each is actually a graded Hopf algebra whose basis is indexed by integer partitions:

```
sage: s.category()
Category of graded bases of Symmetric Functions over Rational Field
sage: s.basis().keys()
Partitions
```

Let us compute with some elements in different bases:

```
sage: f1 = s([2,1]); f1
s[2, 1]
sage: f2 = e(f1); f2 # basis conversion
e[2, 1] - e[3]
sage: f1 == f2
True
sage: f1.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
sage: f2.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: m([3,1])
m[3, 1]
sage: m(4) # This is the constant 4, not the partition 4.
4*m[]
sage: m([4]) # This is the partition 4.
m[4]
```

(continues on next page)

(continued from previous page)

```
sage: 3*m([3,1])-1/2*m([4])
3*m[3, 1] - 1/2*m[4]
```

```
sage: p = SymmetricFunctions(QQ).power()
sage: f = p(3)
sage: f
3*p[]
sage: f.parent()
Symmetric Functions over Rational Field in the powersum basis
sage: f + p([3,2])
3*p[] + p[3, 2]
```

One can convert symmetric functions to symmetric polynomials and vice versa:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: h = Sym.homogeneous()
sage: f = h[2,1] + 2*p[3,1]
sage: poly = f.expand(3); poly
2*x0^4 + 2*x0^3*x1 + 2*x0*x1^3 + 2*x1^4 + 2*x0^3*x2 + 2*x1^3*x2 + 2*x0*x2^3 + 2*x1*x2^3
↪ + 2*x2^4
+ x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + 2*x0*x2^2
↪ + 2*x1*x2^2 + x2^3
sage: Sym.from_polynomial(poly)
3*m[1, 1, 1] + 2*m[2, 1] + m[3] + 2*m[3, 1] + 2*m[4]
sage: Sym.from_polynomial(poly) == f
True
sage: g = h[1,1,1,1]
sage: poly = g.expand(3)
sage: Sym.from_polynomial(poly) == g
False
```

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: p = Sym.p()
sage: e = Sym.e()
sage: m = Sym.m()
sage: a = s([3,1])
sage: s(a)
s[3, 1]
sage: h(a)
h[3, 1] - h[4]
sage: p(a)
1/8*p[1, 1, 1, 1] + 1/4*p[2, 1, 1] - 1/8*p[2, 2] - 1/4*p[4]
sage: e(a)
e[2, 1, 1] - e[2, 2] - e[3, 1] + e[4]
sage: m(a)
3*m[1, 1, 1, 1] + 2*m[2, 1, 1] + m[2, 2] + m[3, 1]
sage: a.expand(4)
x0^3*x1 + x0^2*x1^2 + x0*x1^3 + x0^3*x2 + 2*x0^2*x1*x2 + 2*x0*x1^2*x2 + x1^3*x2 + x0^
↪ 2*x2^2 + 2*x0*x1^2*x3 + x1^3*x3 + 2*x0^2*x2*x3 + 3*x0*x1*x2*x3 + 2*x1^2*x2*x3 + 2*x0
↪ 2*x0*x1^2*x3 + x1^3*x3 + 2*x0^2*x2*x3 + 3*x0*x1*x2*x3 + 2*x1^2*x2*x3 + 2*x0*x2^2*x3
↪ 2*x1*x2^2*x3 + x2^3*x3 + x0^2*x3^2 + 2*x0*x1*x3^2 + x1^2*x3^2 + 2*x0*x2*x3^2
↪ 2*x1*x2*x3^2 + x2^2*x3^2 + x0*x3^3 + x1*x3^3 + x2*x3^3
```

(continued from previous page)

Here are further examples:

```
sage: h(m([1]))
h[1]
sage: h( m([2]) +m([1,1]) )
h[2]
sage: h( m([3]) + m([2,1]) + m([1,1,1]) )
h[3]
sage: h( m([4]) + m([3,1]) + m([2,2]) + m([2,1,1]) + m([1,1,1,1]) )
h[4]
sage: k = 5
sage: h( sum([ m(part) for part in Partitions(k)]) )
h[5]
sage: k = 10
sage: h( sum([ m(part) for part in Partitions(k)]) )
h[10]
```

```
sage: P3 = Partitions(3)
sage: P3.list()
[[3], [2, 1], [1, 1, 1]]
sage: m = SymmetricFunctions(QQ).monomial()
sage: f = sum([m(p) for p in P3])
sage: m.get_print_style()
'lex'
sage: f
m[1, 1, 1] + m[2, 1] + m[3]
sage: m.set_print_style('length')
sage: f
m[3] + m[2, 1] + m[1, 1, 1]
sage: m.set_print_style('maximal_part')
sage: f
m[1, 1, 1] + m[2, 1] + m[3]
sage: m.set_print_style('lex')
```

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: m = Sym.m()
sage: m([3])*s([2,1])
2*m[3, 1, 1, 1] + m[3, 2, 1] + 2*m[4, 1, 1] + m[4, 2] + m[5, 1]
sage: s(m([3])*s([2,1]))
s[2, 1, 1, 1, 1] - s[2, 2, 2] - s[3, 3] + s[5, 1]
sage: s(s([2,1])*m([3]))
s[2, 1, 1, 1, 1] - s[2, 2, 2] - s[3, 3] + s[5, 1]
sage: e = Sym.e()
sage: e([4])*e([3])*e([1])
e[4, 3, 1]
```

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([2,1]) + s([1,1,1])
sage: z.coefficient([2,1])
```

(continues on next page)

(continued from previous page)

```

1
sage: z.length()
2
sage: sorted(z.support())
[[1, 1, 1], [2, 1]]
sage: z.degree()
3

```

- Darij Grinberg (2013) Sym over rings that are not characteristic 0

```

class sage.combinat.sf.sfa.FilteredSymmetricFunctionsBases(parent_with_realization)
Bases: sage.categories.realizations.Category_realization_of_parent

```

The category of filtered bases of the ring of symmetric functions.

```

super_categories()
The super categories of self.

```

EXAMPLES:

```

sage: from sage.combinat.sf.sfa import FilteredSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = FilteredSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of bases of Symmetric Functions over Rational Field,
Category of commutative filtered hopf algebras with basis over Rational Field]

```

```

class sage.combinat.sf.sfa.GradedSymmetricFunctionsBases(parent_with_realization)
Bases: sage.categories.realizations.Category_realization_of_parent

```

The category of graded bases of the ring of symmetric functions.

These are further required to have the property that the basis element indexed by the empty partition is 1.

```

class ElementMethods
Bases: object

```

```

degree_negation()
Return the image of self under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree  $k$  by  $(-1)^k$  (for all  $k$ ).

```

Calling `degree_negation(self)` is equivalent to calling `self.parent().degree_negation(self)`.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[[]]
sage: f.degree_negation()

```

(continues on next page)

(continued from previous page)

```

-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
sage: x = m.zero().degree_negation(); x
0
sage: parent(x) is m
True

```

degree_zero_coefficient()

Return the degree zero coefficient of self.

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 3*m[[]]
sage: f.degree_zero_coefficient()
3

```

class ParentMethods

Bases: object

antipode_by_coercion(*element*)

The antipode of element.

INPUT:

- element – element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: s = Sym.s()
sage: e = Sym.e()
sage: h = Sym.h()
sage: (h([]) + h([1])).antipode() # indirect doctest
h[] - h[1]
sage: (s([]) + s([1]) + s[2]).antipode()
s[] - s[1] + s[1, 1]
sage: (p([2]) + p([3])).antipode()
-p[2] - p[3]
sage: (e([2]) + e([3])).antipode()
e[1, 1] - e[1, 1, 1] - e[2] + 2*e[2, 1] - e[3]
sage: f = Sym.f()
sage: f([3,2,1]).antipode()
-f[3, 2, 1] - 4*f[3, 3] - 2*f[4, 2] - 2*f[5, 1] - 6*f[6]

```

The antipode is an involution:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: all( s[u].antipode().antipode() == s[u] for u in Partitions(4) )
True

```

The antipode is an algebra homomorphism:

```

sage: Sym = SymmetricFunctions(FiniteField(23))
sage: h = Sym.h()
sage: all( all( (s[u] * s[v]).antipode() == s[u].antipode() * s[v].
↪antipode()
.....:         for u in Partitions(3) )
.....:         for v in Partitions(3) )
True

```

counit(*element*)

Return the counit of *element*.

The counit is the constant term of *element*.

INPUT:

- *element* – element in a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 3*m[[]]
sage: f.counit()
3

```

degree_negation(*element*)

Return the image of *element* under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

INPUT:

- *element* – symmetric function written in *self*

EXAMPLES:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[[]]
sage: m.degree_negation(f)
-3*m[[]] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]

```

super_categories()

The super categories of *self*.

EXAMPLES:

```

sage: from sage.combinat.sf.sfa import GradedSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = GradedSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of filtered bases of Symmetric Functions over Rational Field,
Category of commutative graded hopf algebras with basis over Rational Field]

```

```

class sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic(Sym, basis_name=None, prefix=None,
                                                             graded=True)

```

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

Abstract base class for symmetric function algebras.

Todo: Most of the methods in this class are generic (manipulations of morphisms, ...) and should be generalized (or removed)

Element

alias of *SymmetricFunctionAlgebra_generic_Element*

basis_name()

Return the name of the basis of *self*.

This is used for output and, for the classical bases of symmetric functions, to connect this basis with Symmetrca.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: s.basis_name()
'Schur'
sage: p = Sym.p()
sage: p.basis_name()
'powersum'
sage: h = Sym.h()
sage: h.basis_name()
'homogeneous'
sage: e = Sym.e()
sage: e.basis_name()
'elementary'
sage: m = Sym.m()
sage: m.basis_name()
'monomial'
sage: f = Sym.f()
sage: f.basis_name()
'forgotten'
```

coproduct_by_coercion(elt)

Return the coproduct of the element *elt* by coercion to the Schur basis.

INPUT:

- *elt* – an instance of this basis

OUTPUT:

- The image of *elt* under the comultiplication (=coproduct) of the coalgebra of symmetric functions. The result is an element of the tensor squared of the basis *self*.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,1,1].coproduct()
m[] # m[3, 1, 1] + m[1] # m[3, 1] + m[1, 1] # m[3] + m[3] # m[1, 1] + m[3, 1] #
↪m[1] + m[3, 1, 1] # m[]
sage: m.coproduct_by_coercion(m[2,1])
m[] # m[2, 1] + m[1] # m[2] + m[2] # m[1] + m[2, 1] # m[]
sage: m.coproduct_by_coercion(m[2,1]) == m([2,1]).coproduct()
True
```

(continues on next page)

(continued from previous page)

```

sage: McdH = SymmetricFunctions(QQ['q','t']).fraction_field().macdonald().H()
sage: McdH[2,1].coproduct()
McdH[] # McdH[2, 1] + ((q^2*t-1)/(q*t-1))*McdH[1] # McdH[1, 1] + ((q*t^2-1)/
↳(q*t-1))*McdH[1] # McdH[2] + ((q^2*t-1)/(q*t-1))*McdH[1, 1] # McdH[1] + ((q*t^
↳2-1)/(q*t-1))*McdH[2] # McdH[1] + McdH[2, 1] # McdH[]
sage: HLQp = SymmetricFunctions(QQ['t']).fraction_field().hall_littlewood().Qp()
sage: HLQp[2,1].coproduct()
HLQp[] # HLQp[2, 1] + HLQp[1] # HLQp[1, 1] + HLQp[1] # HLQp[2] + HLQp[1, 1] #
↳HLQp[1] + HLQp[2] # HLQp[1] + HLQp[2, 1] # HLQp[]
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: LLT = Sym.llt(3)
sage: LLT.cospin([3,2,1]).coproduct()
(t+1)*m[] # m[1, 1] + m[] # m[2] + (t+1)*m[1] # m[1] + (t+1)*m[1, 1] # m[] +
↳m[2] # m[]
sage: f = SymmetricFunctions(ZZ).f()
sage: f[3].coproduct()
f[] # f[3] + f[3] # f[]
sage: f[3,2,1].coproduct()
f[] # f[3, 2, 1] + f[1] # f[3, 2] + f[2] # f[3, 1] + f[2, 1] # f[3] + f[3] #
↳f[2, 1] + f[3, 1] # f[2] + f[3, 2] # f[1] + f[3, 2, 1] # f[]

```

dual_basis(*scalar=None, scalar_name="", basis_name=None, prefix=None*)

Return the dual basis of `self` with respect to the scalar product `scalar`.

INPUT:

- `scalar` – A function `zee` from partitions to the base ring which specifies the scalar product by $\langle p_\lambda, p_\lambda \rangle = zee(\lambda)$. (Independently on the function chosen, the power sum basis will always be orthogonal; the function `scalar` only determines the norms of the basis elements.) If `scalar` is `None`, then the standard (Hall) scalar product is used.
- `scalar_name` – name of the scalar function
- `prefix` – prefix used to display the basis

EXAMPLES:

The duals of the elementary symmetric functions with respect to the Hall scalar product are the forgotten symmetric functions.

```

sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(prefix='f'); f
Dual basis to Symmetric Functions over Rational Field in the elementary basis
↳with respect to the Hall scalar product
sage: f([2,1])^2
4*f[2, 2, 1, 1] + 6*f[2, 2, 2] + 2*f[3, 2, 1] + 2*f[3, 3] + 2*f[4, 1, 1] + f[4,
↳2]
sage: f([2,1]).scalar(e([2,1]))
1
sage: f([2,1]).scalar(e([1,1,1]))
0

```

Since the power-sum symmetric functions are orthogonal, their duals with respect to the Hall scalar product are scalar multiples of themselves.

```

sage: p = SymmetricFunctions(QQ).p()
sage: q = p.dual_basis(prefix='q'); q
Dual basis to Symmetric Functions over Rational Field in the powersum basis
↳with respect to the Hall scalar product
sage: q([2,1])^2
4*q[2, 2, 1, 1]
sage: p([2,1]).scalar(q([2,1]))
1
sage: p([2,1]).scalar(q([1,1,1]))
0

```

from_polynomial(*poly*, *check=True*)

Convert polynomial to a symmetric function in the monomial basis and then to the basis `self`.

INPUT:

- `poly` – a symmetric polynomial
- `check` – (default: `True`) boolean, specifies whether the computation checks that the polynomial is indeed symmetric

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: f = (h([]) + h([2,1]) + h([3])).expand(3)
sage: h.from_polynomial(f)
h[] + h[2, 1] + h[3]
sage: s = Sym.s()
sage: g = (s([]) + s([2,1])).expand(3); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + 1
sage: s.from_polynomial(g)
s[] + s[2, 1]

```

get_print_style()

Return the value of the current print style for `self`.

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')

```

prefix()

Return the prefix on the elements of `self`.

EXAMPLES:

```

sage: schur = SymmetricFunctions(QQ).schur()
sage: schur([3,2,1])
s[3, 2, 1]
sage: schur.prefix()
's'

```

product_by_coercion(*left*, *right*)

Return the product of elements *left* and *right* by coercion to the Schur basis.

INPUT:

- *left*, *right* – instances of this basis

OUTPUT:

- the product of *left* and *right* expressed in the basis *self*

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p.product_by_coercion(p[3,1,1], p[2,2])
p[3, 2, 2, 1, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: m.product_by_coercion(m[2,1], m[1,1]) == m[2,1]*m[1,1]
True
```

set_print_style(*ps*)

Set the value of the current print style to *ps*.

INPUT:

- *ps* – a string specifying the printing style

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')
```

symmetric_function_ring()

Return the family of symmetric functions associated to the basis *self*.

OUTPUT:

- returns an instance of the ring of symmetric functions

EXAMPLES:

```
sage: schur = SymmetricFunctions(QQ).schur()
sage: schur.symmetric_function_ring()
Symmetric Functions over Rational Field
sage: power = SymmetricFunctions(QQ['t']).power()
sage: power.symmetric_function_ring()
Symmetric Functions over Univariate Polynomial Ring in t over Rational Field
```

transition_matrix(*basis*, *n*)

Return the transition matrix between *self* and *basis* for the homogeneous component of degree *n*.

INPUT:

- *basis* – a basis of the ring of symmetric functions
- *n* – a nonnegative integer

OUTPUT:

- a matrix of coefficients giving the expansion of the homogeneous degree- n elements of `self` in the degree- n elements of `basis`

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: m = SymmetricFunctions(QQ).m()
sage: s.transition_matrix(m,5)
[1 1 1 1 1 1]
[0 1 1 2 2 3 4]
[0 0 1 1 2 3 5]
[0 0 0 1 1 3 6]
[0 0 0 0 1 2 5]
[0 0 0 0 0 1 4]
[0 0 0 0 0 0 1]
sage: s.transition_matrix(m,1)
[1]
sage: s.transition_matrix(m,0)
[1]
```

```
sage: p = SymmetricFunctions(QQ).p()
sage: s.transition_matrix(p, 4)
[ 1/4  1/3  1/8  1/4  1/24]
[-1/4   0 -1/8  1/4  1/8]
[  0 -1/3  1/4   0  1/12]
[ 1/4   0 -1/8 -1/4  1/8]
[-1/4  1/3  1/8 -1/4  1/24]
sage: StoP = s.transition_matrix(p,4)
sage: a = s([3,1])+5*s([1,1,1,1])-s([4])
sage: a
5*s[1, 1, 1, 1] + s[3, 1] - s[4]
sage: mon = sorted(a.support())
sage: coeffs = [a[i] for i in mon]
sage: coeffs
[5, 1, -1]
sage: mon
[[1, 1, 1, 1], [3, 1], [4]]
sage: cm = matrix([[ -1, 1, 0, 0, 5]])
sage: cm * StoP
[-7/4  4/3  3/8 -5/4  7/24]
sage: p(a)
7/24*p[1, 1, 1, 1] - 5/4*p[2, 1, 1] + 3/8*p[2, 2] + 4/3*p[3, 1] - 7/4*p[4]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: e = SymmetricFunctions(QQ).e()
sage: s.transition_matrix(m,7) == h.transition_matrix(s,7).transpose()
True
```

```
sage: h.transition_matrix(m, 7) == h.transition_matrix(m, 7).transpose()
True
```

```
sage: h.transition_matrix(e, 7) == e.transition_matrix(h, 7)
True
```

```
sage: p.transition_matrix(s, 5)
[ 1 -1  0  1  0 -1  1]
[ 1  0 -1  0  1  0 -1]
[ 1 -1  1  0 -1  1 -1]
[ 1  1 -1  0 -1  1  1]
[ 1  0  1 -2  1  0  1]
[ 1  2  1  0 -1 -2 -1]
[ 1  4  5  6  5  4  1]
```

```
sage: e.transition_matrix(m,7) == e.transition_matrix(m,7).transpose()
True
```

class sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element

Bases: sage.modules.with_basis.indexed_element.IndexedFreeModuleElement

Class of generic elements for the symmetric function algebra.

arithmetic_product(*x*)

Return the arithmetic product of `self` and `x` in the basis of `self`.

The arithmetic product is a binary operation \square on the ring of symmetric functions which is bilinear in its two arguments and satisfies

$$p_\lambda \square p_\mu = \prod_{i \geq 1, j \geq 1} p_{\text{lcm}(\lambda_i, \mu_j)}^{\text{gcd}(\lambda_i, \mu_j)}$$

for any two partitions $\lambda = (\lambda_1, \lambda_2, \lambda_3, \dots)$ and $\mu = (\mu_1, \mu_2, \mu_3, \dots)$ (where p_ν denotes the power-sum symmetric function indexed by the partition ν , and p_i denotes the i -th power-sum symmetric function). This is enough to define the arithmetic product if the base ring is torsion-free as a \mathbf{Z} -module; for all other cases the arithmetic product is uniquely determined by requiring it to be functorial in the base ring. See <http://mathoverflow.net/questions/138148/> for a discussion of this arithmetic product.

If f and g are two symmetric functions which are homogeneous of degrees a and b , respectively, then $f \square g$ is homogeneous of degree ab .

The arithmetic product is commutative and associative and has unity $e_1 = p_1 = h_1$.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

Arithmetic product of `self` with `x`; this is a symmetric function over the same base ring as `self`.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2]).arithmetic_product(s([2]))
s[1, 1, 1, 1] + 2*s[2, 2] + s[4]
sage: s([2]).arithmetic_product(s([1,1]))
s[2, 1, 1] + s[3, 1]
```

The symmetric function `e[1]` is the unity for the arithmetic product:

```
sage: e = SymmetricFunctions(ZZ).e()
sage: all( e([1]).arithmetic_product(e(q)) == e(q) for q in Partitions(4) )
True
```

The arithmetic product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).arithmetic_product(m(q)) == m(q).arithmetic_product(e(p))
↳# long time (26s on sage.math, 2013)
.....:         for q in Partitions(4) )
.....:         for p in Partitions(4) )
True
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \mathbf{Q} -algebra (in which case the arithmetic product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \mathbf{Q} (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

`bernstein_creation_operator`(n)

Return the image of `self` under the n -th Bernstein creation operator.

Let n be an integer. The n -th Bernstein creation operator \mathbf{B}_n is defined as the endomorphism of the space Sym of symmetric functions which sends every f to

$$\sum_{i \geq 0} (-1)^i h_{n+i} e_i^\perp,$$

where usual notations are in place (h stands for the complete homogeneous symmetric functions, e for the elementary ones, and e_i^\perp means skewing (`skew_by()`) by e_i).

This has been studied in [BBSSZ2012], section 2.2, where the following rule is given for computing \mathbf{B}_n on a Schur function: If $(\alpha_1, \alpha_2, \dots, \alpha_n)$ is an n -tuple of integers (positive or not), then

$$\mathbf{B}_n s_{(\alpha_1, \alpha_2, \dots, \alpha_n)} = s_{(n, \alpha_1, \alpha_2, \dots, \alpha_n)}.$$

Here, $s_{(\alpha_1, \alpha_2, \dots, \alpha_n)}$ is the “Schur function” associated to the n -tuple $(\alpha_1, \alpha_2, \dots, \alpha_n)$, and defined by literally applying the Jacobi-Trudi identity, i.e., by

$$s_{(\alpha_1, \alpha_2, \dots, \alpha_n)} = \det((h_{\alpha_i - i + j})_{i,j=1,2,\dots,n}).$$

This notion of a Schur function clearly extends the classical notion of Schur function corresponding to a partition, but is easily reduced to the latter (in fact, for any n -tuple α of integers, one easily sees that s_α is either 0 or minus-plus a Schur function corresponding to a partition; and it is easy to determine which of these is the case and find the partition by a combinatorial algorithm).

EXAMPLES:

Let us check that what this method computes agrees with the definition:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
```

(continues on next page)

(continued from previous page)

```

sage: h = Sym.h()
sage: s = Sym.s()
sage: def bernstein_creation_by_def(n, f):
.....:     # `n`-th Bernstein creation operator applied to `f`
.....:     # computed according to its definition.
.....:     res = f.parent().zero()
.....:     if not f:
.....:         return res
.....:     max_degree = max(sum(m) for m, c in f)
.....:     for i in range(max_degree + 1):
.....:         if n + i >= 0:
.....:             res += (-1) ** i * h[n + i] * f.skew_by(e[i])
.....:     return res
sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_
↳operator(n)
.....:     for n in range(-2, 3) for l in Partitions(4) )
True
sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_
↳operator(n)
.....:     for n in range(-3, 4) for l in Partitions(3) )
True
sage: all( bernstein_creation_by_def(n, e[l]) == e[l].bernstein_creation_
↳operator(n)
.....:     for n in range(-3, 4) for k in range(3) for l in Partitions(k) )
True

```

Some examples:

```

sage: s[3,2].bernstein_creation_operator(3)
s[3, 3, 2]
sage: s[3,2].bernstein_creation_operator(1)
-s[2, 2, 2]
sage: h[3,2].bernstein_creation_operator(-2)
h[2, 1]
sage: h[3,2].bernstein_creation_operator(-1)
h[2, 1, 1] - h[2, 2] - h[3, 1]
sage: h[3,2].bernstein_creation_operator(0)
-h[3, 1, 1] + h[3, 2]
sage: h[3,2].bernstein_creation_operator(1)
-h[2, 2, 2] + h[3, 2, 1]
sage: h[3,2].bernstein_creation_operator(2)
-h[3, 3, 1] + h[4, 2, 1]

```

character_to_frobenius_image(*n*)

Interpret `self` as a GL_n character and then take the Frobenius image of this character of the permutation matrices S_n which naturally sit inside of GL_n .

To know the value of this character at a permutation of cycle structure ρ the symmetric function `self` is evaluated at the eigenvalues of a permutation of cycle structure ρ . The Frobenius image is then defined as $\sum_{\rho \vdash n} f[\Xi_\rho] p_\rho / z_\rho$.

See also:

`eval_at_permutation_roots()`

INPUT:

- n – a non-negative integer to interpret `self` as a character of GL_n

OUTPUT:

- a symmetric function of degree n

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([1,1]).character_to_frobenius_image(5)
s[3, 1, 1] + s[4, 1]
sage: s([2,1]).character_to_frobenius_image(5)
s[2, 2, 1] + 2*s[3, 1, 1] + 2*s[3, 2] + 3*s[4, 1] + s[5]
sage: s([2,2,2]).character_to_frobenius_image(3)
s[3]
sage: s([2,2,2]).character_to_frobenius_image(4)
s[2, 2] + 2*s[3, 1] + 2*s[4]
sage: s([2,2,2]).character_to_frobenius_image(5)
2*s[2, 2, 1] + s[3, 1, 1] + 4*s[3, 2] + 3*s[4, 1] + 2*s[5]
```

degree()

Return the degree of `self` (which is defined to be 0 for the zero element).

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1]) + 3
sage: z.degree()
4
sage: s(1).degree()
0
sage: s(0).degree()
0
```

derivative_with_respect_to_p1($n=1$)

Return the symmetric function obtained by taking the derivative of `self` with respect to the power-sum symmetric function p_1 when the expansion of `self` in the power-sum basis is considered as a polynomial in p_k 's (with $k \geq 1$).

This is the same as skewing `self` by the first power-sum symmetric function p_1 .

INPUT:

- n – (default: 1) nonnegative integer which determines which power of the derivative is taken

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([1,1,1])
sage: a.derivative_with_respect_to_p1()
3*p[1, 1]
sage: a.derivative_with_respect_to_p1(1)
3*p[1, 1]
sage: a.derivative_with_respect_to_p1(2)
6*p[1]
sage: a.derivative_with_respect_to_p1(3)
6*p[]
```

```

sage: s = SymmetricFunctions(QQ).s()
sage: s([3]).derivative_with_respect_to_p1()
s[2]
sage: s([2,1]).derivative_with_respect_to_p1()
s[1, 1] + s[2]
sage: s([1,1,1]).derivative_with_respect_to_p1()
s[1, 1]
sage: s(0).derivative_with_respect_to_p1()
0
sage: s(1).derivative_with_respect_to_p1()
0
sage: s([1]).derivative_with_respect_to_p1()
s[]

```

Let us check that taking the derivative with respect to $p[1]$ is equivalent to skewing by $p[1]$:

```

sage: p1 = s([1])
sage: all( s(lam).derivative_with_respect_to_p1()
.....:      == s(lam).skew_by(p1) for lam in Partitions(4) )
True

```

`eval_at_permutation_roots`(*rho*)

Evaluate at eigenvalues of a permutation matrix.

Evaluate a symmetric function at the eigenvalues of a permutation matrix whose cycle structure is ρ . This computation is computed by coercing to the power sum basis where the value may be computed on the generators.

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \dots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \dots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure ρ .

INPUT:

- ρ – a partition or a list of non-negative integers

OUTPUT:

- an element of the base ring

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s([3,3]).eval_at_permutation_roots([6])
0
sage: s([3,3]).eval_at_permutation_roots([3])
1
sage: s([3,3]).eval_at_permutation_roots([1])
0
sage: s([3,3]).eval_at_permutation_roots([3,3])

```

(continues on next page)

(continued from previous page)

```

4
sage: s([3,3]).eval_at_permutation_roots([1,1,1,1,1])
175
sage: (s[1]+s[2]+s[3]).eval_at_permutation_roots([3,2])
2

```

expand(*n*, *alphabet*='x')

Expand the symmetric function `self` as a symmetric polynomial in *n* variables.

INPUT:

- *n* – a nonnegative integer
- *alphabet* – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the *n* variables labelled x_0, x_1, \dots, x_{n-1} (or just *x* if *n* = 1), where *x* is *alphabet*.

EXAMPLES:

```

sage: J = SymmetricFunctions(QQ).jack(t=2).J()
sage: J([2,1]).expand(3)
4*x0^2*x1 + 4*x0*x1^2 + 4*x0^2*x2 + 6*x0*x1*x2 + 4*x1^2*x2 + 4*x0*x2^2 +
↪ 4*x1*x2^2
sage: (2*J([2])).expand(0)
0
sage: (3*J([])).expand(0)
3

```

exponential_specialization(*t*=None, *q*=1)

Return the exponential specialization of a symmetric function (when *q* = 1), or the *q*-exponential specialization (when *q* ≠ 1).

The *exponential specialization* ex at *t* is a *K*-algebra homomorphism from the *K*-algebra of symmetric functions to another *K*-algebra *R*. It is defined whenever the base ring *K* is a **Q**-algebra and *t* is an element of *R*. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the *q*-exponential specialization is a *K*-algebra homomorphism from the *K*-algebra of symmetric functions to another *K*-algebra *R* that depends on two elements *t* and *q* of *R* for which the elements $1 - q^i$ for all positive integers *i* are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the *q*-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function *f* of degree *n*, we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of *f* (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \rightarrow 1$ is ex .

INPUT:

- t (default: None) – the value to use for t ; the default is to create a ring of polynomials in t .
- q (default: 1) – the value to use for q . If q is None, then a ring (or fraction field) of polynomials in q is created.

EXAMPLES:

```

sage: m = SymmetricFunctions(QQ).m()
sage: (m[2,1]+m[1,1]).exponential_specialization()
1/2*t^2
sage: (m[2,1]+m[1,1]).exponential_specialization(q=1)
1/2*t^2
sage: m[1,1].exponential_specialization(q=None)
(q/(q + 1))*t^2
sage: Qq = PolynomialRing(QQ, "q"); q = Qq.gen()
sage: m[1,1].exponential_specialization(q=q)
(q/(q + 1))*t^2
sage: Qt = PolynomialRing(QQ, "t"); t = Qt.gen()
sage: m[1,1].exponential_specialization(t=t)
1/2*t^2
sage: Qqt = PolynomialRing(QQ, ["q", "t"]); q, t = Qqt.gens()
sage: m[1,1].exponential_specialization(q=q, t=t)
q*t^2/(q + 1)

sage: x = m[3]+m[2,1]+m[1,1,1]
sage: d = x.homogeneous_degree()
sage: var("q t")
(q, t)
sage: factor((x.principal_specialization()*(1-q)^d*t^d))
t^3/((q^2 + q + 1)*(q + 1))
sage: factor(x.exponential_specialization(q=q, t=t))
t^3/((q^2 + q + 1)*(q + 1))

```

frobenius(n)

Return the image of the symmetric function `self` under the n -th Frobenius operator.

The n -th Frobenius operator f_n is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \dots)$ to $P(x_1^n, x_2^n, x_3^n, \dots)$. This operator f_n is a Hopf algebra endomorphism, and satisfies

$$f_n m_{(\lambda_1, \lambda_2, \lambda_3, \dots)} = m_{(n\lambda_1, n\lambda_2, n\lambda_3, \dots)}$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \dots)$ (where m means the monomial basis). Moreover, $f_n(p_r) = p_{nr}$ for every positive integer r (where p_k denotes the k -th powersum symmetric function).

The n -th Frobenius operator is also called the n -th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n -th Frobenius operator is also the n -th Adams operator of the Λ -ring of symmetric functions over the integers.

The n -th Frobenius operator can also be described via plethysm: Every symmetric function P satisfies $f_n(P) = p_n \circ P = P \circ p_n$, where p_n is the n -th powersum symmetric function, and \circ denotes (outer) plethysm.

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Frobenius operator (on the ring of symmetric functions) to self.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].frobenius(2)
-s[3, 3] + s[4, 2] - s[5, 1] + s[6]
sage: m[4,2,1].frobenius(3)
m[12, 6, 3]
sage: p[4,2,1].frobenius(3)
p[12, 6, 3]
sage: h[4].frobenius(2)
h[4, 4] - 2*h[5, 3] + 2*h[6, 2] - 2*h[7, 1] + 2*h[8]
```

The Frobenius endomorphisms are multiplicative:

```
sage: all( all( s(lam).frobenius(3) * s(mu).frobenius(3) # long time
.....:      == (s(lam) * s(mu)).frobenius(3)
.....:      for mu in Partitions(3) )
.....:      for lam in Partitions(3) )
True
sage: all( all( m(lam).frobenius(2) * m(mu).frobenius(2)
.....:      == (m(lam) * m(mu)).frobenius(2)
.....:      for mu in Partitions(4) )
.....:      for lam in Partitions(4) )
True
sage: all( all( p(lam).frobenius(2) * p(mu).frobenius(2)
.....:      == (p(lam) * p(mu)).frobenius(2)
.....:      for mu in Partitions(3) )
.....:      for lam in Partitions(4) )
True
```

Being Hopf algebra endomorphisms, the Frobenius operators commute with the antipode:

```
sage: all( p(lam).frobenius(4).antipode()
.....:      == p(lam).antipode().frobenius(4)
.....:      for lam in Partitions(3) )
True
```

Testing the $f_n(P) = p_n \circ P = P \circ p_n$ equality (over \mathbf{Q} , since plethysm is currently not defined over \mathbf{Z} in Sage):

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: p = Sym.p()
sage: all( s(lam).frobenius(3) == s(lam).plethysm(p[3])
.....:      == s(p[3].plethysm(s(lam)))
.....:      for lam in Partitions(4) )
True
```

By Exercise 7.61 in Stanley's EC2 [STA] (see the errata on his website), $f_n(h_m)$ is a linear combination of Schur polynomials (of straight shapes) using coefficients 0, 1 and -1 only; moreover, all partitions whose Schur polynomials occur with coefficient $\neq 0$ in this combination have empty n -cores. Let us check this on examples:

```
sage: all( all( all( (coeff == -1 or coeff == 1)
.....:         and lam.core(n) == Partition([])
.....:         for lam, coeff in s([m]).frobenius(n) )
.....:     for n in range(2, 4) )
.....: for m in range(4) )
True
```

See also:

[*plethysm\(\)*](#)

Todo: This method is fast on the monomial and the powersum bases, while all other bases get converted to the monomial basis. For most bases, this is probably the quickest way to do, but at least the Schur basis should have a better option. (Quoting from Stanley's EC2 [STA]: "D. G. Duncan, J. London Math. Soc. 27 (1952), 235-236, or Y. M. Chen, A. M. Garsia, and J. B. Remmel, Contemp. Math. 34 (1984), 109-153".)

hl_creation_operator(*nu*, *t=None*)

This is the vertex operator that generalizes Jing's operator.

It is a linear operator that raises the degree by $|\nu|$. This creation operator is a t -analogue of multiplication by $s(\text{nu})$.

See also:

Proposition 5 in [SZ2001].

INPUT:

- nu – a partition or a list of integers
- t – (default: None, in which case t is used) an element of the base ring

inner_plethysm(*x*)

Return the inner plethysm of `self` with `x`.

Whenever R is a \mathbf{Q} -algebra, and f and g are two symmetric functions over R such that the constant term of f is zero, the inner plethysm of f with g is a symmetric function over R , and the degree of this symmetric function is the same as the degree of g . We will denote the inner plethysm of f with g by $f\{g\}$ (in contrast to the notation of outer plethysm which is generally denoted $f[g]$); in Sage syntax, it is `f.inner_plethysm(g)`.

First we describe the axiomatic definition of the operation; see below for a representation-theoretic interpretation. In the following equations, we denote the outer product (i.e., the standard product on the ring of symmetric functions, `product()`) by \cdot and the Kronecker product (`itensor()`) by $*$.

$$\begin{aligned} (f + g)\{h\} &= f\{h\} + g\{h\} \\ (f \cdot g)\{h\} &= (f\{h\}) * (g\{h\}) \\ p_k\{f + g\} &= p_k\{f\} + p_k\{g\} \end{aligned}$$

where p_k is the k -th power-sum symmetric function for every $k > 0$.

Let σ be a permutation of cycle type μ and let μ^k be the cycle type of σ^k . Then,

$$p_k\{p_\mu/z_\mu\} = \sum_{\nu:\nu^k=\mu} p_\nu/z_\nu$$

Since $(p_\mu/z_\mu)_\mu$ is a basis for the symmetric functions, these four formulas define the symmetric function operation $f\{g\}$ for any symmetric functions f and g (where f has constant term 0) by expanding f in the power sum basis and g in the dual basis p_μ/z_μ .

See also:

`itensor()`, `partition_power()`, `plethysm()`

This operation admits a representation-theoretic interpretation in the case where f is a Schur function s_λ and g is a homogeneous degree n symmetric function with nonnegative integral coefficients in the Schur basis. The symmetric function $f\{g\}$ is the Frobenius image of the S_n -representation constructed as follows.

The assumptions on g imply that g is the Frobenius image of a representation ρ of the symmetric group S_n :

$$\rho : S_n \rightarrow GL_N.$$

If the degree N of this representation is greater than or equal to the number of parts of λ , then f , which denotes s_λ , corresponds to the character of some irreducible GL_N -representation, say

$$\sigma : GL_N \rightarrow GL_M.$$

The composition $\sigma \circ \rho : S_n \rightarrow GL_M$ is a representation of S_n whose Frobenius image is precisely $f\{g\}$.

If N is less than the number of parts of λ , then $f\{g\}$ is 0 by definition.

When f is a symmetric function with constant term $\neq 0$, the inner plethysm $f\{g\}$ isn't well-defined in the ring of symmetric functions. Indeed, it is not clear how to define $1\{g\}$. The most sensible way to get around this probably is defining it as the infinite sum $h_0 + h_1 + h_2 + \dots$ (where h_i means the i -th complete homogeneous symmetric function) in the completion of this ring with respect to its grading. This is how [SchaThi1994] defines $1\{g\}$. The present method, however, sets it to be the sum of h_i over all i for which the i -th homogeneous component of g is nonzero. This is rather a hack than a reasonable definition. Use with caution!

Note: If a symmetric function g is written in the form $g = g_0 + g_1 + g_2 + \dots$ with each g_i homogeneous of degree i , then $f\{g\} = f\{g_0\} + f\{g_1\} + f\{g_2\} + \dots$ for every f with constant term 0. But in general, inner plethysm is not linear in the second variable.

REFERENCES:

INPUT:

- x – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- an element of symmetric functions in the parent of `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()

1/24*p[1, 1, 1, 1] + 1/4*p[2, 1, 1] + 1/8*p[2, 2] + 1/4*p[4]
sage: p[3,3].inner_plethysm(p[1,1,1])
6*p[1, 1, 1] + 12*p[3]
```

inner_tensor(x)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see [scalar\(\)](#)).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods [itensor\(\)](#), [internal_product\(\)](#), [kronecker_product\(\)](#), [inner_tensor\(\)](#) are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
```

(continues on next page)

(continued from previous page)

```
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
+ 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
+ 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n -th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is f :

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function s_λ with the n -th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) )
↪)
.....: for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) # long time
.....: for r in Partitions(4) )
.....: for p in Partitions(3) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, [arXiv hep-th/9407124](https://arxiv.org/abs/hep-th/9407124), for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes \mu((u \otimes v) * \Delta(w)) with
.....: # * meaning Kronecker product and \mu meaning
↪the
.....: # usual multiplication.
.....: result = w.parent().zero()
.....: for partition_pair, coeff in w.coproduct():
.....: result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
```

(continues on next page)

(continued from previous page)

```

.....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])    # long time
.....:         == (e[u] * s[v]).itensor(m[w])
.....:         for w in Partitions(5) )
.....:         for v in Partitions(2) )
.....:         for u in Partitions(3) )
True

```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” arXiv 0907.4652:

```

sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1] +
↪s[6]

```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```

sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]

```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \mathbf{Q} -algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \mathbf{Q} (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

`internal_coproduct()`

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism Δ^\times from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,$$

where $\lambda \vdash n$ means λ is a partition of n , and n is any nonnegative integer. It also satisfies

$$\Delta^\times(p_n) = p_n \otimes p_n$$

for any positive integer n . If the base ring is a \mathbf{Q} -algebra, it also satisfies

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda \otimes p_\lambda,$$

where

$$z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!$$

with $m_i(\lambda)$ meaning the number of appearances of i in λ (see `zee()`).

The method `kronecker_coproduct()` is a synonym of `internal_coproduct()`.

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: a.internal_coproduct()
s[1, 1, 1] # s[2, 1] + s[2, 1] # s[1, 1, 1] + s[2, 1] # s[2, 1] + s[2, 1] #
↪s[3] + s[3] # s[2, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
sage: b.internal_coproduct()
e[1, 1] # e[2] + e[2] # e[1, 1] - 2*e[2] # e[2]
```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions f, g and h satisfy $\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle$, where we write $\Delta^\times(h)$ as $\sum_i h'_i \otimes h''_i$. Let us check this in degree 4:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_incopr(f, g, h): # computes \sum_i \left\langle f, h'_i \right\rangle \left\langle
↪\left\langle g, h''_i \right\rangle
.....:     result = h.base_ring().zero()
.....:     for partition_pair, coeff in h.internal_coproduct():
.....:         result += coeff * h.parent()(f).scalar(partition_pair[0]) * h.
↪parent()(g).scalar(partition_pair[1])
.....:     return result
sage: all( all( all( tensor_incopr(e[u], s[v], m[w]) == (e[u].itensor(s[v])).
↪scalar(m[w]) # long time (10s on sage.math, 2013)
.....:         for w in Partitions(5) )
.....:         for v in Partitions(2) )
.....:         for u in Partitions(3) )
True
```

Let us check the formulas for $\Delta^\times(h_n)$ and $\Delta^\times(p_n)$ given in the description of this method:

```
sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)]) for
↪lam in Partitions(n)])
.....:     for n in range(6) )
True
sage: all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))]) for
↪lam in Partitions(n)])
.....:     for n in range(6) )
```

(continues on next page)

(continued from previous page)

```

True
sage: all( factorial(n) * h([n]).internal_coproduct()
.....:      == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
.....:              for lam in Partitions(n)])
.....:      for n in range(6) )
True

```

internal_product(x)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
+ 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
+ 3*s[4, 2] + 2*s[5, 1] + s[6]

```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n -th complete homogeneous symmetric function $h[n]$ (a.k.a. `s[n]`) is f :

```

sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True

```

The Kronecker product of a Schur function s_λ with the n -th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) )
↪)
.....:     for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) # long time
.....:     for r in Partitions(4) )
.....:     for p in Partitions(3) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, [arXiv hep-th/9407124](https://arxiv.org/abs/hep-th/9407124), for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes \mu ((u \otimes v) * \Delta(w)) with
.....:     # * meaning Kronecker product and \mu meaning
↪the
.....:     # usual multiplication.
.....:     result = w.parent().zero()
.....:     for partition_pair, coeff in w.coproduct():
.....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
.....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w]) # long time
.....:     == (e[u] * s[v]).itensor(m[w])
.....:     for w in Partitions(5) )
.....:     for v in Partitions(2) )
.....:     for u in Partitions(3) )
True
```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” [arXiv 0907.4652](https://arxiv.org/abs/0907.4652):

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
```

(continues on next page)

(continued from previous page)

```

sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1] +
↪s[6]

```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```

sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]

```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \mathbb{Q} -algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \mathbb{Q} (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

`is_schur_positive()`

Return True if and only if `self` is Schur positive.

If `s` is the space of Schur functions over `self`'s base ring, then this is the same as `self._is_positive(s)`.

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1]) + s([3])
sage: a.is_schur_positive()
True
sage: a = s([2,1]) - s([3])
sage: a.is_schur_positive()
False

```

```

sage: QQx = QQ['x']
sage: s = SymmetricFunctions(QQx).s()
sage: x = QQx.gen()
sage: a = (1+x)*s([2,1])
sage: a.is_schur_positive()
True
sage: a = (1-x)*s([2,1])
sage: a.is_schur_positive()
False
sage: s(0).is_schur_positive()
True
sage: s(1+x).is_schur_positive()
True

```

`itensor(x)`

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu =$

$\delta_{\lambda,\mu} z_{\lambda} p_{\lambda}$, where $z_{\lambda} = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see [scalar\(\)](#)).

INPUT:

- x – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with x (an element of the ring of symmetric functions in the same basis as `self`)

The methods [itensor\(\)](#), [internal_product\(\)](#), [kronecker_product\(\)](#), [inner_tensor\(\)](#) are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
+ 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
+ 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n -th complete homogeneous symmetric function $h[n]$ (a.k.a. `s[n]`) is f :

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function s_{λ} with the n -th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```

sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) )
↪)
.....:     for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) # long time
.....:     for r in Partitions(4) )
.....:     for p in Partitions(3) )
True

```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, [arXiv hep-th/9407124](https://arxiv.org/abs/hep-th/9407124), for $r = 2$:

```

sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes \mu ((u \otimes v) * \Delta(w)) with
.....:     # * meaning Kronecker product and \mu meaning
↪the
.....:     # usual multiplication.
.....:     result = w.parent().zero()
.....:     for partition_pair, coeff in w.coproduct():
.....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
.....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w]) # long time
.....:     == (e[u] * s[v]).itensor(m[w])
.....:     for w in Partitions(5) )
.....:     for v in Partitions(2) )
.....:     for u in Partitions(3) )
True

```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” [arXiv 0907.4652](https://arxiv.org/abs/0907.4652):

```

sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1] +
↪s[6]

```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```

sage: s = SymmetricFunctions(QQbar).s()

```

(continues on next page)

(continued from previous page)

```
sage: s[2, 1].itensor(s[2, 1])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \mathbf{Q} -algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \mathbf{Q} (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

`kronecker_coproduct()`

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism Δ^\times from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,$$

where $\lambda \vdash n$ means λ is a partition of n , and n is any nonnegative integer. It also satisfies

$$\Delta^\times(p_n) = p_n \otimes p_n$$

for any positive integer n . If the base ring is a \mathbf{Q} -algebra, it also satisfies

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda \otimes p_\lambda,$$

where

$$z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!$$

with $m_i(\lambda)$ meaning the number of appearances of i in λ (see `zee()`).

The method `kronecker_coproduct()` is a synonym of `internal_coproduct()`.

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2, 1])
sage: a.internal_coproduct()
s[1, 1, 1] # s[2, 1] + s[2, 1] # s[1, 1, 1] + s[2, 1] # s[2, 1] + s[2, 1] #
↪ s[3] + s[3] # s[2, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
sage: b.internal_coproduct()
e[1, 1] # e[2] + e[2] # e[1, 1] - 2*e[2] # e[2]
```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions f, g and h satisfy $\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle$, where we write $\Delta^\times(h)$ as $\sum_i h'_i \otimes h''_i$. Let us check this in degree 4:

```

sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_incopr(f, g, h): # computes \sum_i \left\langle f, h'_i \right\rangle \left\langle
↪ g, h''_i \right\rangle
.....:     result = h.base_ring().zero()
.....:     for partition_pair, coeff in h.internal_coproduct():
.....:         result += coeff * h.parent()(f).scalar(partition_pair[0]) * h.
↪ parent()(g).scalar(partition_pair[1])
.....:     return result
sage: all( all( all( tensor_incopr(e[u], s[v], m[w]) == (e[u].itensor(s[v])).
↪ scalar(m[w]) # long time (10s on sage.math, 2013)
.....:         for w in Partitions(5) )
.....:         for v in Partitions(2) )
.....:         for u in Partitions(3) )
True

```

Let us check the formulas for $\Delta^\times(h_n)$ and $\Delta^\times(p_n)$ given in the description of this method:

```

sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)]) for
↪ lam in Partitions(n)])
.....:     for n in range(6) )
True
sage: all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))]) for
↪ lam in Partitions(n)])
.....:     for n in range(6) )
True
sage: all( factorial(n) * h([n]).internal_coproduct()
.....:     == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
.....:         for lam in Partitions(n)])
.....:     for n in range(6) )
True

```

kronecker_product(x)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda, \mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

INPUT:

- x – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with x (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
+ 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
+ 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n -th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is f :

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function s_λ with the n -th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) )
↪ )
.....:         for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().QC()
sage: mh = SymmetricFunctions(F).macdonald().HC()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) # long time
.....:         for r in Partitions(4) )
```

(continues on next page)

(continued from previous page)

```
.....:     for p in Partitions(3) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Non-commutative symmetric functions”, arXiv hep-th/9407124, for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes \mu ((u \otimes v) * \Delta(w)) with
.....:                          # * meaning Kronecker product and \mu meaning
↪the
.....:                          # usual multiplication.
.....:     result = w.parent().zero()
.....:     for partition_pair, coeff in w.coproduct():
.....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
.....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w]) # long time
.....:                          == (e[u] * s[v]).itensor(m[w])
.....:                          for w in Partitions(5) )
.....:                          for v in Partitions(2) )
.....:     for u in Partitions(3) )
True
```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” arXiv 0907.4652:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1] +
↪s[6]
```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \mathbb{Q} -algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \mathbb{Q} (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

left_padded_kronecker_product(x)

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the Kronecker product (`itensor()`) on the space of symmetric functions. For any partitions α, β, γ , let $g_{\alpha, \beta}^{\gamma}$ denote the coefficient of the complete homogeneous symmetric function h_{γ} in the Kronecker product $h_{\alpha} * h_{\beta}$. For every partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \dots)$ and every integer $n > |\lambda| + \lambda_1$, let $\lambda[n]$ denote the n -completion of λ (this is the partition $(n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \dots)$; see `t_completion()`). Then, for any partitions α and β and every integer $n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1$, we can write the Kronecker product $h_{\alpha[n]} * h_{\beta[n]}$ in the form

$$h_{\alpha[n]} * h_{\beta[n]} = \sum_{\gamma} g_{\alpha[n], \beta[n]}^{\gamma[n]} h_{\gamma[n]}$$

with γ ranging over all partitions. The coefficients $g_{\alpha[n], \beta[n]}^{\gamma[n]}$ are independent on n . These coefficients $g_{\alpha[n], \beta[n]}^{\gamma[n]}$ are denoted by $\bar{g}_{\alpha, \beta}^{\gamma}$, and the symmetric function

$$\sum_{\gamma} \bar{g}_{\alpha, \beta}^{\gamma} h_{\gamma}$$

is said to be the *left-padded Kronecker product* of h_{α} and h_{β} . By bilinearity, this extends to a definition of a left-padded Kronecker product of any two symmetric functions.

This notion of left-padded Kronecker product can be lifted to the non-commutative symmetric functions (`left_padded_kronecker_product()`).

Warning: Do not mistake this product for the reduced Kronecker product (`reduced_kronecker_product()`), which uses the Schur functions instead of the complete homogeneous functions in its definition.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the left-padded Kronecker product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.h()
sage: h[2, 1].left_padded_kronecker_product(h[3])
h[1, 1, 1, 1] + h[2, 1] + h[2, 1, 1] + h[2, 1, 1, 1] + h[2, 2, 1] + h[3, 2, 1]
sage: h[2, 1].left_padded_kronecker_product(h[1])
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]
sage: h[1].left_padded_kronecker_product(h[2, 1])
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]
sage: h[1, 1].left_padded_kronecker_product(h[2])
h[1, 1] + 2*h[1, 1, 1] + h[2, 1, 1]
sage: h[1].left_padded_kronecker_product(h[2, 1, 1])
h[1, 1, 1, 1] + 2*h[2, 1, 1] + h[2, 1, 1, 1]
sage: h[2].left_padded_kronecker_product(h[3])
h[2, 1] + h[2, 1, 1] + h[3, 2]
```

Taking the left-padded Kronecker product with $1 = h_{\emptyset}$ is the identity map on the ring of symmetric functions:

```
sage: all( h[Partition([])].left_padded_kronecker_product(h[lam])
.....:     == h[lam] for i in range(4)
.....:     for lam in Partitions(i) )
True
```

Here is a rule for the left-padded Kronecker product of h_1 (this is the same as $h_{(1)}$) with any complete homogeneous function: Let λ be a partition. Then, the left-padded Kronecker product of h_1 and h_λ is $\sum_{\mu} a_{\mu} h_{\mu}$, where the sum runs over all partitions μ , and the coefficient a_{μ} is defined as the number of ways to obtain μ from λ by one of the following two operations:

- Insert a 1 into λ .
- Subtract 1 from one of the entries of λ (and remove the entry if it thus becomes 0), and insert a 1 into λ .

We check this for partitions of size ≤ 4 :

```
sage: def mults1(I):
.....:     # Left-padded Kronecker multiplication by h[1].
.....:     res = h[I[:] + [1]]
.....:     for k in range(len(I)):
.....:         I2 = I[:]
.....:         if I2[k] == 1:
.....:             I2 = I2[:k] + I2[k+1:]
.....:         else:
.....:             I2[k] -= 1
.....:         res += h[sorted(I2 + [1], reverse=True)]
.....:     return res
sage: all( mults1(I) == h[1].left_padded_kronecker_product(h[I])
.....:       == h[I].left_padded_kronecker_product(h[1])
.....:       for i in range(5) for I in Partitions(i) )
True
```

The left-padded Kronecker product is commutative:

```
sage: all( h[lam].left_padded_kronecker_product(h[mu])
.....:     == h[mu].left_padded_kronecker_product(h[lam])
.....:     for lam in Partitions(3) for mu in Partitions(3) )
True
```

nabla($q=None, t=None, power=1$)

Return the value of the nabla operator applied to self.

The eigenvectors of the nabla operator are the Macdonald polynomials in the Ht basis.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `q, t` – optional parameters (default: `None`, in which case `q` and `t` are used)
- `power` – (default: 1) an integer indicating how many times to apply the operator ∇ . Negative values of `power` indicate powers of ∇^{-1} .

EXAMPLES:

```

sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: p = Sym.power()
sage: p([1,1]).nabla()
(-1/2*q*t+1/2*q+1/2*t+1/2)*p[1, 1] + (1/2*q*t-1/2*q-1/2*t+1/2)*p[2]
sage: p([2,1]).nabla(q=1)
(-t-1)*p[1, 1, 1] + t*p[2, 1]
sage: p([2]).nabla(q=1)*p([1]).nabla(q=1)
(-t-1)*p[1, 1, 1] + t*p[2, 1]
sage: s = Sym.schur()
sage: s([2,1]).nabla()
(-q^3*t-q^2*t^2-q*t^3)*s[1, 1, 1] + (-q^2*t-q*t^2)*s[2, 1]
sage: s([1,1,1]).nabla()
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: s([1,1,1]).nabla(t=1)
(q^3+q^2+2*q+1)*s[1, 1, 1] + (q^2+2*q+2)*s[2, 1] + s[3]
sage: s(0).nabla()
0
sage: s(1).nabla()
s[]
sage: s([2,1]).nabla(power=-1)
((-q-t)/(q^2*t^2))*s[2, 1] + ((q^2+q*t+t^2)/(-q^3*t^3))*s[3]
sage: (s([2])+s([3])).nabla()
(-q*t)*s[1, 1] + (q^3*t^2+q^2*t^3)*s[1, 1, 1] + q^2*t^2*s[2, 1]

```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'}$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```

sage: J = SymmetricFunctions(QQ).jack(t=1).PC()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
JackP[2, 1] + JackP[3]
sage: J(0).omega()
0
sage: J(1).omega()
JackP[]

```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True

```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k -th elementary symmetric function, and h_k stands for the k -th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k .

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ , where λ' denotes the conjugate partition (`conjugate()`) of λ , and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```

sage: J = SymmetricFunctions(QQ).jack(t=1).PC
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
JackP[2, 1] + JackP[3]
sage: J(0).omega()
0
sage: J(1).omega()
JackP[]

```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True

```

omega_qt(q=None, t=None)

Return the image of `self` under the q, t -deformed omega automorphism which sends p_k to $(-1)^{k-1} \cdot \frac{1-q^k}{1-t^k} \cdot p_k$ for all positive integers k .

In general, this is well-defined outside of the powersum basis only if the base ring is a \mathbf{Q} -algebra.

If $q = t$, then this is the omega automorphism (`omega()`).

INPUT:

- q, t – parameters (default: None, in which case 'q' and 't' are used)

EXAMPLES:

```

sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p[5].omega_qt()
((-q^5+1)/(-t^5+1))*p[5]
sage: p[5].omega_qt(q,t)
((-q^5+1)/(-t^5+1))*p[5]
sage: p[[2]].omega_qt(q,t)
((q^2-1)/(-t^2+1))*p[2]
sage: p[[2,1]].omega_qt(q,t)
((-q^3+q^2+q-1)/(t^3-t^2-t+1))*p[2, 1]
sage: p[[3,2]].omega_qt(5,q)
-(2976/(q^5-q^3-q^2+1))*p[3, 2]
sage: p[()].omega_qt()
0
sage: p(1).omega_qt()
p[]
sage: H = SymmetricFunctions(QQqt).macdonald().H()
sage: H[[1,1]].omega_qt()
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H[[1,1]].omega_qt(q,t)
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H[[1,1]].omega_qt(t,q)
((-t^3+t^2+t-1)/(-q^3+q^2+q-1))*McdH[2]
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: S[[1,1]].omega_qt()
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-1))*McdS[2]
sage: s = Sym.schur()
sage: s(S[[1,1]].omega_qt())
s[2]

```

plethysm(x , *include=None*, *exclude=None*)

Return the outer plethysm of `self` with x .

This is implemented only over base rings which are \mathbf{Q} -algebras. (To compute outer plethysms over general binomial rings, change bases to the fraction field.)

The outer plethysm of f with g is commonly denoted by $f[g]$ or by $f \circ g$. It is an algebra map in f , but not (generally) in g .

By default, the degree one elements are taken to be the generators for the `self`'s base ring. This setting can be modified by specifying the `include` and `exclude` keywords.

INPUT:

- x – a symmetric function over the same base ring as `self`
- `include` – a list of variables to be treated as degree one elements instead of the default degree one elements
- `exclude` – a list of variables to be excluded from the default degree one elements

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: s ( h([3])( h([2]) ) )
s[2, 2, 2] + s[4, 2] + s[6]
sage: p = Sym.p()
sage: p([3])( s([2,1]) )
1/3*p[3, 3, 3] - 1/3*p[9]
sage: e = Sym.e()
sage: e([3])( e([2]) )
e[3, 3] + e[4, 1, 1] - 2*e[4, 2] - e[5, 1] + e[6]
```

```
sage: R.<t> = QQ[]
sage: s = SymmetricFunctions(R).s()
sage: a = s([3])
sage: f = t*s([2])
sage: a(f)
t^3*s[2, 2, 2] + t^3*s[4, 2] + t^3*s[6]
sage: f(a)
t*s[4, 2] + t*s[6]
sage: s(0).plethysm(s[1])
0
sage: s(1).plethysm(s[1])
s[]
sage: s(1).plethysm(s(0))
s[]
```

Sage also handles plethysm of tensor products of symmetric functions:

```
sage: s = SymmetricFunctions(QQ).s()
sage: X = tensor([s[1],s[[]]])
sage: Y = tensor([s[[]],s[1]])
sage: s[1,1,1](X+Y)
s[] # s[1, 1, 1] + s[1] # s[1, 1] + s[1, 1] # s[1] + s[1, 1, 1] # s[]
sage: s[1,1,1](X*Y)
s[1, 1, 1] # s[3] + s[2, 1] # s[2, 1] + s[3] # s[1, 1, 1]
```

One can use this to work with symmetric functions in two sets of commuting variables. For example, we verify the Cauchy identities (in degree 5):

```
sage: m = SymmetricFunctions(QQ).m()
sage: P5 = Partitions(5)
sage: sum(s[mu](X)*s[mu](Y) for mu in P5) == sum(m[mu](X)*h[mu](Y) for mu in P5)
True
sage: sum(s[mu](X)*s[mu.conjugate()](Y) for mu in P5) == sum(m[mu](X)*e[mu](Y)
↪ for mu in P5)
True
```

[*frobenius\(\)*](#)

principal_specialization($n=+$ Infinity, $q=None$)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \dots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R , and we assume that the variables of our symmetric functions are x_1, x_2, x_3, \dots . (To be more precise, $ps_{n,q}$ is a K -algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i . This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- **n** (default: `infinity`) – a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order **n** or the stable principal specialization.
- **q** (default: `None`) – the value to use for q ; the default is to create a ring of polynomials in **q** (or a field of rational functions in **q**) over the given coefficient ring.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: x = m[1,1]
sage: x.principal_specialization(3)
q^3 + q^2 + q
```

By default we return a rational function in q . Sometimes it is better to obtain an element of the symbolic ring:

```
sage: h = SymmetricFunctions(QQ).h()
sage: (h[3]+h[2]).principal_specialization(q=var("q"))
1/((q^2 - 1)*(q - 1)) - 1/((q^3 - 1)*(q^2 - 1)*(q - 1))
```

In case q is in the base ring, it must be passed explicitly:

```
sage: R = QQ['q,t']
sage: Ht = SymmetricFunctions(R).macdonald().Ht()
sage: Ht[2].principal_specialization()
Traceback (most recent call last):
...
ValueError: the variable q is in the base ring, pass it explicitly

sage: Ht[2].principal_specialization(q=R("q"))
(q^2 + 1)/(q^3 - q^2 - q + 1)
```

Note that the principal specialization can be obtained as a plethysm:

```
sage: R = QQ['q'].fraction_field()
sage: s = SymmetricFunctions(R).s()
sage: one = s.one()
sage: q = R("q")
sage: f = s[3,2,2]
sage: f.principal_specialization(q=q) == f(one/(1-q)).coefficient([])
True
```

(continues on next page)

(continued from previous page)

```
sage: f.principal_specialization(n=4, q=q) == f(one*(1-q^4)/(1-q)).
↪ coefficient([])
True
```

reduced_kronecker_product(x)

Return the reduced Kronecker product of `self` and `x` in the basis of `self`.

The reduced Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the Kronecker product (*itensor()*) on the space of symmetric functions. For any partitions α, β, γ , let $g_{\alpha, \beta}^{\gamma}$ denote the coefficient of the Schur function s_{γ} in the Kronecker product $s_{\alpha} * s_{\beta}$ (this is called a Kronecker coefficient). For every partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \dots)$ and every integer $n > |\lambda| + \lambda_1$, let $\lambda[n]$ denote the n -completion of λ (this is the partition $(n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \dots)$; see *t_completion()*). Then, Theorem 1.2 of [BOR2009] shows that for any partitions α and β and every integer $n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1$, we can write the Kronecker product $s_{\alpha[n]} * s_{\beta[n]}$ in the form

$$s_{\alpha[n]} * s_{\beta[n]} = \sum_{\gamma} g_{\alpha[n], \beta[n]}^{\gamma[n]} s_{\gamma[n]}$$

with γ ranging over all partitions. The coefficients $g_{\alpha[n], \beta[n]}^{\gamma[n]}$ are independent on n . These coefficients $g_{\alpha[n], \beta[n]}^{\gamma[n]}$ are denoted by $\bar{g}_{\alpha, \beta}^{\gamma}$, and the symmetric function

$$\sum_{\gamma} \bar{g}_{\alpha, \beta}^{\gamma} s_{\gamma}$$

is said to be the *reduced Kronecker product* of s_{α} and s_{β} . By bilinearity, this extends to a definition of a reduced Kronecker product of any two symmetric functions.

The definition of the reduced Kronecker product goes back to Murnaghan, and has recently been studied in [BOR2009], [BdVO2012] and other places (our notation $\bar{g}_{\alpha, \beta}^{\gamma}$ appears in these two sources).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the reduced Kronecker product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

EXAMPLES:

The example from page 2 of [BOR2009]:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s[2].reduced_kronecker_product(s[2])
s[] + s[1] + s[1, 1] + s[1, 1, 1] + 2*s[2] + 2*s[2, 1] + s[2, 2] + s[3] + s[3, ↪
↪1] + s[4]
```

Taking the reduced Kronecker product with $1 = s_{\emptyset}$ is the identity map on the ring of symmetric functions:

```
sage: all( s[Partition([])].reduced_kronecker_product(s[lam])
.....:      == s[lam] for i in range(4)
.....:      for lam in Partitions(i) )
True
```

While reduced Kronecker products are hard to compute in general, there is a rule for taking reduced Kronecker products with s_1 . Namely, for every partition λ , the reduced Kronecker product of s_λ with s_1 is $\sum_{\mu} a_{\mu} s_{\mu}$, where the sum runs over all partitions μ , and the coefficient a_{μ} is defined as the number of ways to obtain μ from λ by one of the following three operations:

- Add an addable cell (`addable_cells()`) to λ .
- Remove a removable cell (`removable_cells()`) from λ .
- First remove a removable cell from λ , then add an addable cell to the resulting Young diagram.

This is, in fact, Proposition 5.15 of [CO2010] in an elementary wording. We check this for partitions of size ≤ 4 :

```
sage: def mults1(lam):
.....:     # Reduced Kronecker multiplication by s[1], according
.....:     # to [CO2010]_.
.....:     res = s.zero()
.....:     for mu in lam.up_list():
.....:         res += s(mu)
.....:     for mu in lam.down_list():
.....:         res += s(mu)
.....:         for nu in mu.up_list():
.....:             res += s(nu)
.....:     return res
sage: all( mults1(lam) == s[1].reduced_kronecker_product(s[lam])
.....:     for i in range(5) for lam in Partitions(i) )
True
```

Here is the example on page 3 of Christian Gutschwager’s [arXiv 0912.4411v3](#):

```
sage: s[1,1].reduced_kronecker_product(s[2])
s[1] + 2*s[1, 1] + s[1, 1, 1] + s[2] + 2*s[2, 1] + s[2, 1, 1] + s[3] + s[3, 1]
```

Example 39 from F. D. Murnaghan, “The analysis of the Kronecker product of irreducible representations of the symmetric group”, *American Journal of Mathematics*, Vol. 60, No. 3, Jul. 1938:

```
sage: s[3].reduced_kronecker_product(s[2,1])
s[1] + 2*s[1, 1] + 2*s[1, 1, 1] + s[1, 1, 1, 1] + 2*s[2] + 5*s[2, 1] + 4*s[2, 1,
↪ 1]
+ s[2, 1, 1, 1] + 3*s[2, 2] + 2*s[2, 2, 1] + 2*s[3] + 5*s[3, 1] + 3*s[3, 1, 1]
+ 3*s[3, 2] + s[3, 2, 1] + 2*s[4] + 3*s[4, 1] + s[4, 1, 1] + s[4, 2] + s[5]
+ s[5, 1]
```

Todo: This implementation of the reduced Kronecker product is painfully slow.

restrict_degree(*d*, *exact=True*)

Return the degree *d* component of `self`.

INPUT:

- *d* – positive integer, degree of the terms to be returned
- *exact* – boolean, if `True`, returns the terms of degree exactly *d*, otherwise returns all terms of degree less than or equal to *d*

OUTPUT:

- the homogeneous component of `self` of degree `d`

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_degree(2)
0
sage: z.restrict_degree(1)
s[1]
sage: z.restrict_degree(3)
s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(3, exact=False)
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(0)
0
```

restrict_partition_lengths(*l*, *exact=True*)

Return the terms of `self` labelled by partitions of length `l`.

INPUT:

- `l` – nonnegative integer
- `exact` – boolean, defaulting to `True`

OUTPUT:

- if `True`, returns the terms labelled by partitions of length precisely `l`; otherwise returns all terms labelled by partitions of length less than or equal to `l`

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_partition_lengths(2)
s[2, 1]
sage: z.restrict_partition_lengths(0)
0
sage: z.restrict_partition_lengths(2, exact = False)
s[1] + s[2, 1] + s[4]
```

restrict_parts(*n*)

Return the terms of `self` labelled by partitions λ with $\lambda_1 \leq n$.

INPUT:

- `n` – positive integer, to restrict the parts of the partitions of the terms to be returned

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_parts(2)
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_parts(1)
s[1] + s[1, 1, 1]
```

scalar(*x*, *zee=None*)

Return the standard scalar product between `self` and `x`.

This is also known as the “Hall inner product” or the “Hall scalar product”.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `zee` – an optional function on partitions giving the value for the scalar product between p_μ and p_μ (default is to use the standard `zee()` function)

This is the default implementation that converts both `self` and `x` into either Schur functions (if `zee` is not specified) or power-sum functions (if `zee` is specified) and performs the scalar product in that basis.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: h = SymmetricFunctions(QQ).h()
sage: m = SymmetricFunctions(QQ).m()
sage: p4 = Partitions(4)
sage: matrix([ [e(a).scalar(h(b)) for a in p4] for b in p4])
[ 0 0 0 0 1]
[ 0 0 0 1 4]
[ 0 0 1 2 6]
[ 0 1 2 5 12]
[ 1 4 6 12 24]
sage: matrix([ [h(a).scalar(e(b)) for a in p4] for b in p4])
[ 0 0 0 0 1]
[ 0 0 0 1 4]
[ 0 0 1 2 6]
[ 0 1 2 5 12]
[ 1 4 6 12 24]
sage: matrix([ [m(a).scalar(e(b)) for a in p4] for b in p4])
[-1 2 1 -3 1]
[ 0 1 0 -2 1]
[ 0 0 1 -2 1]
[ 0 0 0 -1 1]
[ 0 0 0 0 1]
sage: matrix([ [m(a).scalar(h(b)) for a in p4] for b in p4])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: p = SymmetricFunctions(QQ).p()
sage: m(p[3,2]).scalar(p[3,2], zee=lambda mu: 2**mu.length())
4
sage: m(p[3,2]).scalar(p[2,2,1], lambda mu: 1)
0
sage: m[3,2].scalar(h[3,2], zee=lambda mu: 2**mu.length())
2/3
```

scalar_hl(`x`, `t=None`)

Return the t -deformed standard Hall-Littlewood scalar product of `self` and `x`.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

- t – parameter (default: None, in which case t is used)

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

scalar_jack($x, t=None$)

Return the Jack-scalar product between **self** and x .

This scalar product is defined so that the power sum elements p_μ are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{\ell(\mu)}$, where $\ell(\mu)$ denotes the length of μ .

INPUT:

- x – element of the ring of symmetric functions over the same base ring as **self**
- t – an optional parameter (default: None in which case t is used)

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ['t']).power()
sage: matrix([[p(mu).scalar_jack(p(nu)) for nu in Partitions(4)] for mu in
↳Partitions(4)])
[ 4*t      0      0      0      0]
[  0  3*t^2    0      0      0]
[  0      0  8*t^2    0      0]
[  0      0      0  4*t^3    0]
[  0      0      0      0 24*t^4]
sage: matrix([[p(mu).scalar_jack(p(nu),2) for nu in Partitions(4)] for mu in
↳Partitions(4)])
[ 8  0  0  0  0]
[ 0 12  0  0  0]
[ 0  0 32  0  0]
[ 0  0  0 32  0]
[ 0  0  0  0 384]
sage: JQ = SymmetricFunctions(QQ['t'].fraction_field()).jack().Q()
sage: matrix([[JQ(mu).scalar_jack(JQ(nu)) for nu in Partitions(3)] for mu in
↳Partitions(3)])
[(1/3*t^2 + 1/2*t + 1/6)/t^3      0      0]
↳ 0]
[      0      0 (1/2*t + 1)/(t^3 + 1/2*t^2)      0]
↳ 0]
[      0      0      0      0      6/(t^3 + 3*t^2 +
↳2*t)]
```

scalar_qt($x, q=None, t=None$)

Return the q, t -deformed standard Hall-Littlewood scalar product of **self** and x .

INPUT:

- x – element of the ring of symmetric functions over the same base ring as **self**
- q, t – parameters (default: None in which case q and t are used)

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_qt(a); factor(sp)
(t - 1)^-3 * (q - 1) * (t^2 + t + 1)^-1 * (q^2*t^2 - q*t^2 + q^2 - 2*q*t + t^2 -
↪ q + 1)
sage: sp.parent()
Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field
sage: a.scalar_qt(a,q=0)
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: a.scalar_qt(a,t=0)
-q^3 + 2*q^2 - 2*q + 1
sage: a.scalar_qt(a,5,7) # q=5 and t=7
490/1539
sage: (x,y) = var('x,y')
sage: a.scalar_qt(a,q=x,t=y)
1/3*(x^3 - 1)/(y^3 - 1) + 2/3*(x - 1)^3/(y - 1)^3
sage: Rn = QQ['q','t','y','z'].fraction_field()
sage: (q,t,y,z) = Rn.gens()
sage: Mac = SymmetricFunctions(Rn).macdonald(q=y,t=z)
sage: a = Mac._sym.schur([2,1])
sage: factor(Mac.P()(a).scalar_qt(Mac.Q()(a),q,t))
(t - 1)^-3 * (q - 1) * (t^2 + t + 1)^-1 * (q^2*t^2 - q*t^2 + q^2 - 2*q*t + t^2 -
↪ q + 1)
sage: factor(Mac.P()(a).scalar_qt(Mac.Q()(a)))
(z - 1)^-3 * (y - 1) * (z^2 + z + 1)^-1 * (y^2*z^2 - y*z^2 + y^2 - 2*y*z + z^2 -
↪ y + 1)

```

scalar_t(*x*, *t=None*)Return the *t*-deformed standard Hall-Littlewood scalar product of *self* and *x*.

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as *self*
- *t* – parameter (default: None, in which case *t* is used)

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field

```

skew_by(*x*)Return the result of skewing *self* by *x*. (Skewing by *x* is the endomorphism (as additive group) of the ring of symmetric functions adjoint to multiplication by *x* with respect to the Hall inner product.)

INPUT:

- *x* – element of the ring of symmetric functions over the same base ring as *self*

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s([3,2]).skew_by(s([2]))
s[2, 1] + s[3]
sage: s([3,2]).skew_by(s([1,1,1]))
0
sage: s([3,2,1]).skew_by(s([2,1]))
s[1, 1, 1] + 2*s[2, 1] + s[3]

```

```

sage: p = SymmetricFunctions(QQ).powersum()
sage: p([4,3,3,2,2,1]).skew_by(p([2,1]))
4*p[4, 3, 3, 2]
sage: zee = sage.combinat.sf.sfa.zee
sage: zee([4,3,3,2,2,1])/zee([4,3,3,2])
4
sage: s(0).skew_by(s([1]))
0
sage: s(1).skew_by(s([1]))
0
sage: s([]).skew_by(s([]))
s[]
sage: s([]).skew_by(s[1])
0

```

theta(a)

Return the image of `self` under the theta endomorphism which sends p_k to $a \cdot p_k$ for every positive integer k .

In general, this is well-defined outside of the powersum basis only if the base ring is a \mathbf{Q} -algebra.

INPUT:

- a – an element of the base ring

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).theta(2)
2*s[1, 1, 1] + 6*s[2, 1] + 2*s[3]
sage: p = SymmetricFunctions(QQ).p()
sage: p([2]).theta(2)
2*p[2]
sage: p(0).theta(2)
0
sage: p(1).theta(2)
p[]

```

theta_qt(q=None, t=None)

Return the image of `self` under the q, t -deformed theta endomorphism which sends p_k to $\frac{1-q^k}{1-t^k} \cdot p_k$ for all positive integers k .

In general, this is well-defined outside of the powersum basis only if the base ring is a \mathbf{Q} -algebra.

INPUT:

- q, t – parameters (default: None, in which case ‘q’ and ‘t’ are used)

EXAMPLES:

```

sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p([2]).theta_qt(q,t)
((-q^2+1)/(-t^2+1))*p[2]
sage: p([2,1]).theta_qt(q,t)
((q^3-q^2-q+1)/(t^3-t^2-t+1))*p[2, 1]
sage: p(0).theta_qt(q=1,t=3)
0
sage: p([2,1]).theta_qt(q=2,t=3)
3/16*p[2, 1]
sage: s = p.realization_of().schur()
sage: s([3]).theta_qt(q=0)*(1-t)*(1-t^2)*(1-t^3)
t^3*s[1, 1, 1] + (t^2+t)*s[2, 1] + s[3]
sage: p(1).theta_qt()
p[]

```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator \mathbf{V}_n is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator \mathbf{V}_n is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see [frobenius\(\)](#) for its definition) with respect to the Hall scalar product ([scalar\(\)](#)).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to self.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].verschiebung(2)
0
sage: s[3].verschiebung(3)
s[1]
sage: p[3].verschiebung(3)
3*p[1]
sage: m[3,2,1].verschiebung(3)
-18*m[1, 1] - 3*m[2]
sage: p[3,2,1].verschiebung(3)
0
sage: h[4].verschiebung(2)
h[2]
sage: p[2].verschiebung(2)
2*p[1]
sage: m[3,2,1].verschiebung(6)
12*m[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( s(lam).verschiebung(2) * s(mu).verschiebung(2)
.....:      == (s(lam) * s(mu)).verschiebung(2)
.....:      for mu in Partitions(4) )
.....:      for lam in Partitions(4) )
True
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```
sage: all( p(lam).verschiebung(3).antipode()
.....:      == p(lam).antipode().verschiebung(3)
.....:      for lam in Partitions(6) )
True
```

Testing the adjointness between the Frobenius operators f_n and the Verschiebung operators V_n :

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: p = Sym.p()
sage: all( all( s(lam).verschiebung(2).scalar(p(mu))
.....:      == s(lam).scalar(p(mu)).frobenius(2)
.....:      for mu in Partitions(3) )
.....:      for lam in Partitions(6) )
True
```

```
class sage.combinat.sf.sfa.SymmetricFunctionsBases(parent_with_realization)
    Bases: sage.categories.realizations.Category_realization_of_parent
```

The category of bases of the ring of symmetric functions.

INPUT:

- `self` – a category of bases for the symmetric functions
- `base` – ring of symmetric functions

class ParentMethods

Bases: object

Eulerian($n, j, k=None$)

Return the Eulerian symmetric function $Q_{n,j}$ (with n either an integer or a partition) or $Q_{n,j,k}$ (if the optional argument k is specified) in terms of the basis `self`.

It is known that the Eulerian quasisymmetric functions are in fact symmetric functions [SW2010]. For more information, see *QuasiSymmetricFunctions.Fundamental.Eulerian()*, which accepts the same syntax as this method.

INPUT:

- n – the nonnegative integer n or a partition
- j – the number of excedances
- k – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: m.Eulerian(3, 1)
4*m[1, 1, 1] + 3*m[2, 1] + 2*m[3]
sage: h = Sym.h()
sage: h.Eulerian(4, 2)
h[2, 2] + h[3, 1] + h[4]
sage: s = Sym.s()
sage: s.Eulerian(5, 2)
s[2, 2, 1] + s[3, 1, 1] + 5*s[3, 2] + 6*s[4, 1] + 6*s[5]
sage: s.Eulerian([2,2,1], 2)
s[2, 2, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s.Eulerian(5, 2, 2)
s[3, 2] + s[4, 1] + s[5]
```

We check Equation (5.4) in [SW2010]:

```
sage: h.Eulerian([6], 3)
h[3, 2, 1] - h[4, 1, 1] + 2*h[4, 2] + h[5, 1]
sage: s.Eulerian([6], 3)
s[3, 2, 1] + s[3, 3] + 3*s[4, 2] + 3*s[5, 1] + 3*s[6]
```

carlitz_shareshian_wachs($n, d, s, comparison=None$)

Return the Carlitz-Shareshian-Wachs symmetric function $X_{n,d,s}$ (if `comparison` is `None`), or $U_{n,d,s}$ (if `comparison` is `-1`), or $V_{n,d,s}$ (if `comparison` is `0`), or $W_{n,d,s}$ (if `comparison` is `1`) written in the basis `self`. These functions are defined below.

The Carlitz-Shareshian-Wachs symmetric functions have been introduced in [GriRei18], Exercise 2.9.11, as refinements of a certain particular case of chromatic quasisymmetric functions defined by Shareshian and Wachs. Their definitions are as follows:

Let n , d and s be three nonnegative integers. Let $W(n, d, s)$ denote the set of all n -tuples (w_1, w_2, \dots, w_n) of positive integers having the property that there exist precisely d elements i of $\{1, 2, \dots, n-1\}$ satisfying $w_i > w_{i+1}$, and precisely s elements i of $\{1, 2, \dots, n-1\}$ satisfying

$w_i = w_{i+1}$. For every $w = (w_1, w_2, \dots, w_n) \in W(n, d, s)$, let x_w be the monomial $x_{w_1} x_{w_2} \cdots x_{w_n}$. We then define the power series $X_{n,d,s}$ by

$$X_{n,d,s} = \sum_{w \in W(n,d,s)} x_w.$$

This is a symmetric function (according to [GriRei18], Exercise 2.9.11(b)), and for $s = 0$ equals the t^d -coefficient of the descent enumerator of Smirnov words of length n (an example of a chromatic quasisymmetric function which happens to be symmetric – see [ShaWach2014], Example 2.5).

Assume that $n > 0$. Then, we can define three further power series as follows:

$$U_{n,d,s} = \sum_{w_1 < w_n} x_w; \quad V_{n,d,s} = \sum_{w_1 = w_n} x_w; \quad W_{n,d,s} = \sum_{w_1 > w_n} x_w,$$

where all three sums range over $w = (w_1, w_2, \dots, w_n) \in W(n, d, s)$. These three power series $U_{n,d,s}$, $V_{n,d,s}$ and $W_{n,d,s}$ are symmetric functions as well ([GriRei18], Exercise 2.9.11(c)). Their sum is $X_{n,d,s}$.

REFERENCES:

INPUT:

- n – a nonnegative integer
- d – a nonnegative integer
- s – a nonnegative integer
- `comparison` (default: `None`) – a variable which can take the forms `None`, `-1`, `0` and `1`

OUTPUT:

The Carlitz-Shareshian-Wachs symmetric function $X_{n,d,s}$ (if `comparison` is `None`), or $U_{n,d,s}$ (if `comparison` is `-1`), or $V_{n,d,s}$ (if `comparison` is `0`), or $W_{n,d,s}$ (if `comparison` is `1`) written in the basis `self`.

EXAMPLES:

The power series $X_{n,d,s}$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: m.carlitz_shareshian_wachs(3, 2, 1)
0
sage: m.carlitz_shareshian_wachs(3, 1, 1)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 2, 0)
m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 2)
m[3]
sage: m.carlitz_shareshian_wachs(3, 1, 0)
4*m[1, 1, 1] + m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 1)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 0)
m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(5, 2, 2)
m[2, 2, 1] + m[3, 1, 1]
sage: m.carlitz_shareshian_wachs(1, 0, 0)
m[1]
sage: m.carlitz_shareshian_wachs(0, 0, 0)
m[]
```

The power series $U_{n,d,s}$:

```
sage: m.carlitz_shareshian_wachs(3, 2, 1, comparison=-1)
0
sage: m.carlitz_shareshian_wachs(3, 1, 1, comparison=-1)
0
sage: m.carlitz_shareshian_wachs(3, 2, 0, comparison=-1)
0
sage: m.carlitz_shareshian_wachs(3, 0, 2, comparison=-1)
0
sage: m.carlitz_shareshian_wachs(3, 1, 0, comparison=-1)
2*m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 1, comparison=-1)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 0, comparison=-1)
m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(5, 2, 2, comparison=-1)
0
sage: m.carlitz_shareshian_wachs(4, 2, 0, comparison=-1)
3*m[1, 1, 1, 1]
sage: m.carlitz_shareshian_wachs(1, 0, 0, comparison=-1)
0
```

The power series $V_{n,d,s}$:

```
sage: m.carlitz_shareshian_wachs(3, 2, 1, comparison=0)
0
sage: m.carlitz_shareshian_wachs(3, 1, 1, comparison=0)
0
sage: m.carlitz_shareshian_wachs(3, 2, 0, comparison=0)
0
sage: m.carlitz_shareshian_wachs(3, 0, 2, comparison=0)
m[3]
sage: m.carlitz_shareshian_wachs(3, 1, 0, comparison=0)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 1, comparison=0)
0
sage: m.carlitz_shareshian_wachs(3, 0, 0, comparison=0)
0
sage: m.carlitz_shareshian_wachs(5, 2, 2, comparison=0)
0
sage: m.carlitz_shareshian_wachs(4, 2, 0, comparison=0)
m[2, 1, 1]
sage: m.carlitz_shareshian_wachs(1, 0, 0, comparison=0)
m[1]
```

The power series $W_{n,d,s}$:

```
sage: m.carlitz_shareshian_wachs(3, 2, 1, comparison=1)
0
sage: m.carlitz_shareshian_wachs(3, 1, 1, comparison=1)
m[2, 1]
sage: m.carlitz_shareshian_wachs(3, 2, 0, comparison=1)
m[1, 1, 1]
```

(continues on next page)

(continued from previous page)

```

sage: m.carlitz_shareshian_wachs(3, 0, 2, comparison=1)
0
sage: m.carlitz_shareshian_wachs(3, 1, 0, comparison=1)
2*m[1, 1, 1]
sage: m.carlitz_shareshian_wachs(3, 0, 1, comparison=1)
0
sage: m.carlitz_shareshian_wachs(3, 0, 0, comparison=1)
0
sage: m.carlitz_shareshian_wachs(5, 2, 2, comparison=1)
m[2, 2, 1] + m[3, 1, 1]
sage: m.carlitz_shareshian_wachs(4, 2, 0, comparison=1)
8*m[1, 1, 1, 1] + 2*m[2, 1, 1] + m[2, 2]
sage: m.carlitz_shareshian_wachs(1, 0, 0, comparison=1)
0

```

corresponding_basis_over(*R*)

Return the realization of symmetric functions corresponding to `self` but over the base ring *R*. Only works when `self` is one of the classical bases, not one of the *q*, *t*-dependent ones. In the latter case, `None` is returned instead.

INPUT:

- *R* – a commutative ring

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m.corresponding_basis_over(ZZ)
Symmetric Functions over Integer Ring in the monomial basis

sage: Sym = SymmetricFunctions(CyclotomicField())
sage: s = Sym.schur()
sage: s.corresponding_basis_over(Integers(13))
Symmetric Functions over Ring of integers modulo 13 in the Schur basis

sage: P = ZZ['q', 't']
sage: Sym = SymmetricFunctions(P)
sage: mj = Sym.macdonald().J()
sage: mj.corresponding_basis_over(Integers(13))

```

Todo: This function is an ugly hack using strings. It should be rewritten as soon as the bases of `SymmetricFunctions` are put on a more robust and systematic footing.

degree_on_basis(*b*)

Return the degree of the basis element indexed by *b*.

INPUT:

- `self` – a basis of the symmetric functions
- *b* – a partition

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['q,t'].fraction_field())
sage: m = Sym.monomial()

```

(continues on next page)

(continued from previous page)

```

sage: m.degree_on_basis(Partition([3,2]))
5
sage: P = Sym.macdonald().P()
sage: P.degree_on_basis(Partition([]))
0

```

formal_series_ring()

Return the completion of all formal linear combinations of `self` with finite linear combinations in each homogeneous degree (computed lazily).

EXAMPLES:

```

sage: s = SymmetricFunctions(ZZ).s()
sage: L = s.formal_series_ring()
sage: L
Lazy completion of Symmetric Functions over Integer Ring in the Schur basis

```

gessel_reutenauer(*lam*)

Return the Gessel-Reutenauer symmetric function corresponding to the partition `lam` written in the basis `self`.

Let λ be a partition. The *Gessel-Reutenauer symmetric function* \mathbf{GR}_λ corresponding to λ is the symmetric function denoted L_λ in [GR1993] and in Exercise 7.89 of [STA] and denoted \mathbf{GR}_λ in Definition 6.6.34 of [GriRei18]. It is also called the *higher Lie character*, for instance in [Sch2003b]. It can be defined in several ways:

- It is the sum of the monomials \mathbf{x}_w over all words w over the alphabet $\{1, 2, 3, \dots\}$ which have CFL type λ . Here, the monomial \mathbf{x}_w for a word $w = (w_1, w_2, \dots, w_k)$ is defined as $x_{w_1} x_{w_2} \cdots x_{w_k}$, and the *CFL type* of a word w is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization (`lyndon_factorization()`) of w . The fact that this power series \mathbf{GR}_λ is symmetric is not obvious.
- It is the sum of the fundamental quasisymmetric functions $F_{\text{Des } \sigma}$ over all permutations σ that have cycle type λ . See `sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions.Fundamental` for the definition of fundamental quasisymmetric functions, and `cycle_type()` for that of cycle type. For a permutation σ , we use $\text{Des } \sigma$ to denote the descent composition (`descents_composition()`) of σ . Again, this definition does not make the symmetry of \mathbf{GR}_λ obvious.
- For every positive integer n , we have

$$\mathbf{GR}_{(n)} = \frac{1}{n} \sum_{d|n} \mu(d) p_d^{n/d},$$

where p_d denotes the d -th power-sum symmetric function. This $\mathbf{GR}_{(n)}$ is also denoted by L_n , and is called the Lie character. Now, the higher Lie character \mathbf{GR}_λ is defined as the product:

$$h_{m_1} [L_1] \cdot h_{m_2} [L_2] \cdot h_{m_3} [L_3] \cdots,$$

where m_i denotes the multiplicity of the part i in λ , and where the square brackets stand for plethysm (`plethysm()`). This definition makes the symmetry (but not the integrality!) of \mathbf{GR}_λ obvious.

The equivalences of these three definitions are proven in [GR1993] Sections 2-3. (See also [GriRei18] Subsection 6.6.2 for the equivalence of the first two definitions and further formulas.)

\mathbf{GR}_λ has further significance in representations afforded by the tensor algebra $T(V)$ of a finite dimensional vector space. The Poincaré-Birkhoff-Witt theorem describes the universal enveloping algebra of a Lie algebra. It gives a decomposition of the degree- n component $T_n(V)$ of $T(V)$ into $GL(V)$

representations indexed by partitions. The higher Lie characters are the symmetric group S_n characters corresponding to this decomposition via Schur-Weyl duality.

Another important question, *Thrall's problem* (see e.g. [Sch2003b]) asks, for λ a partition of n , can we combinatorially interpret the coefficients α_μ^λ in the Schur-expansion of \mathbf{GR}_λ :

$$\mathbf{GR}_\lambda = \sum_{\mu \vdash n} \alpha_\mu^\lambda s_\mu.$$

INPUT:

- `lam` – a partition or a positive integer (in the latter case, it is understood to mean the partition `[lam]`)

OUTPUT:

The Gessel-Reutenauer symmetric function \mathbf{GR}_λ , where λ is `lam`, expanded in the basis `self`.

EXAMPLES:

The first few values of $\mathbf{GR}_{(n)} = L_n$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)
h[1, 1] - h[2]
sage: h.gessel_reutenauer(3)
h[2, 1] - h[3]
sage: h.gessel_reutenauer(4)
h[2, 1, 1] - h[2, 2]
sage: h.gessel_reutenauer(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
sage: h.gessel_reutenauer(6)
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
- 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
- h[4, 2] - h[5, 1] + h[6]
```

Gessel-Reutenauer functions indexed by partitions:

```
sage: h.gessel_reutenauer([2, 1])
h[1, 1, 1] - h[2, 1]
sage: h.gessel_reutenauer([2, 2])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 2*h[2, 2] + h[3, 1] - h[4]
```

The Gessel-Reutenauer functions are Schur-positive:

```
sage: s = Sym.s()
sage: s.gessel_reutenauer([2, 1])
s[1, 1, 1] + s[2, 1]
sage: s.gessel_reutenauer([2, 2, 1])
s[1, 1, 1, 1, 1] + s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 2]
```

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

```
sage: s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1])
True
```

They also go by the name *higher Lie character*:

```
sage: s.higher_lie_character([2, 2, 1]) == s.gessel_reutenauer([2, 2, 1])
True
```

Of the above three equivalent definitions of \mathbf{GR}_λ , we use the third one for computations. Let us check that the second one gives the same results:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F() # fundamental basis
sage: def GR_def2(lam): #  $\mathbf{GR}_\lambda$ 
.....:     n = lam.size()
.....:     r = F.sum_of_monomials([sigma.descents_composition()
.....:                             for sigma in Permutations(n)
.....:                             if sigma.cycle_type() == lam])
.....:     return r.to_symmetric_function()
sage: all( GR_def2(lam) == h.gessel_reutenauer(lam)
.....:         for n in range(5) for lam in Partitions(n) )
True
```

And the first one, too (assuming symmetry):

```
sage: m = Sym.m()
sage: def GR_def1(lam): #  $\mathbf{GR}_\lambda$ 
.....:     n = lam.size()
.....:     Permuset = sage.combinat.permutation.Permutations_mset
.....:     def coeff_of_m_mu_in_result(mu):
.....:         words_to_check = Permuset([i for (i, l) in enumerate(mu)
.....:                                     for _ in range(l)])
.....:         return sum((1 for w in words_to_check if
.....:                     Partition(list(reversed(sorted([len(v) for v in
.....: Word(w).lyndon_factorization()])))
.....:                     == lam))
.....:     r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
.....:                         for mu in Partitions(n)],
.....:                         distinct=True)
.....:     return r
sage: all( GR_def1(lam) == h.gessel_reutenauer(lam)
.....:         for n in range(5) for lam in Partitions(n) )
True
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \mathbf{Q} -algebra from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \mathbf{Q} (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

`higher_lie_character`(*lam*)

Return the Gessel-Reutenauer symmetric function corresponding to the partition *lam* written in the basis `self`.

Let λ be a partition. The *Gessel-Reutenauer symmetric function* \mathbf{GR}_λ corresponding to λ is the symmetric function denoted L_λ in [GR1993] and in Exercise 7.89 of [STA] and denoted \mathbf{GR}_λ in Definition

6.6.34 of [GriRei18]. It is also called the *higher Lie character*, for instance in [Sch2003b]. It can be defined in several ways:

- It is the sum of the monomials \mathbf{x}_w over all words w over the alphabet $\{1, 2, 3, \dots\}$ which have CFL type λ . Here, the monomial \mathbf{x}_w for a word $w = (w_1, w_2, \dots, w_k)$ is defined as $x_{w_1}x_{w_2} \cdots x_{w_k}$, and the *CFL type* of a word w is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization (`lyndon_factorization()`) of w . The fact that this power series \mathbf{GR}_λ is symmetric is not obvious.
- It is the sum of the fundamental quasisymmetric functions $F_{\text{Des } \sigma}$ over all permutations σ that have cycle type λ . See `sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions.Fundamental` for the definition of fundamental quasisymmetric functions, and `cycle_type()` for that of cycle type. For a permutation σ , we use $\text{Des } \sigma$ to denote the descent composition (`descents_composition()`) of σ . Again, this definition does not make the symmetry of \mathbf{GR}_λ obvious.
- For every positive integer n , we have

$$\mathbf{GR}_{(n)} = \frac{1}{n} \sum_{d|n} \mu(d) p_d^{n/d},$$

where p_d denotes the d -th power-sum symmetric function. This $\mathbf{GR}_{(n)}$ is also denoted by L_n , and is called the Lie character. Now, the higher Lie character \mathbf{GR}_λ is defined as the product:

$$h_{m_1}[L_1] \cdot h_{m_2}[L_2] \cdot h_{m_3}[L_3] \cdots,$$

where m_i denotes the multiplicity of the part i in λ , and where the square brackets stand for plethysm (`plethysm()`). This definition makes the symmetry (but not the integrality!) of \mathbf{GR}_λ obvious.

The equivalences of these three definitions are proven in [GR1993] Sections 2-3. (See also [GriRei18] Subsection 6.6.2 for the equivalence of the first two definitions and further formulas.)

\mathbf{GR}_λ has further significance in representations afforded by the tensor algebra $T(V)$ of a finite dimensional vector space. The Poincaré-Birkhoff-Witt theorem describes the universal enveloping algebra of a Lie algebra. It gives a decomposition of the degree- n component $T_n(V)$ of $T(V)$ into $GL(V)$ representations indexed by partitions. The higher Lie characters are the symmetric group S_n characters corresponding to this decomposition via Schur-Weyl duality.

Another important question, *Thrall's problem* (see e.g. [Sch2003b]) asks, for λ a partition of n , can we combinatorially interpret the coefficients α_μ^λ in the Schur-expansion of \mathbf{GR}_λ :

$$\mathbf{GR}_\lambda = \sum_{\mu \vdash n} \alpha_\mu^\lambda s_\mu.$$

INPUT:

- `lam` – a partition or a positive integer (in the latter case, it is understood to mean the partition `[lam]`)

OUTPUT:

The Gessel-Reutenauer symmetric function \mathbf{GR}_λ , where λ is `lam`, expanded in the basis `self`.

EXAMPLES:

The first few values of $\mathbf{GR}_{(n)} = L_n$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)
```

(continues on next page)

(continued from previous page)

```

h[1, 1] - h[2]
sage: h.gessel_reutenauer(3)
h[2, 1] - h[3]
sage: h.gessel_reutenauer(4)
h[2, 1, 1] - h[2, 2]
sage: h.gessel_reutenauer(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
sage: h.gessel_reutenauer(6)
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
- 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
- h[4, 2] - h[5, 1] + h[6]

```

Gessel-Reutenauer functions indexed by partitions:

```

sage: h.gessel_reutenauer([2, 1])
h[1, 1, 1] - h[2, 1]
sage: h.gessel_reutenauer([2, 2])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 2*h[2, 2] + h[3, 1] - h[4]

```

The Gessel-Reutenauer functions are Schur-positive:

```

sage: s = Sym.s()
sage: s.gessel_reutenauer([2, 1])
s[1, 1, 1] + s[2, 1]
sage: s.gessel_reutenauer([2, 2, 1])
s[1, 1, 1, 1, 1] + s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 2]

```

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

```

sage: s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1])
True

```

They also go by the name *higher Lie character*:

```

sage: s.higher_lie_character([2, 2, 1]) == s.gessel_reutenauer([2, 2, 1])
True

```

Of the above three equivalent definitions of \mathbf{GR}_λ , we use the third one for computations. Let us check that the second one gives the same results:

```

sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F() # fundamental basis
sage: def GR_def2(lam): #  $\mathbf{GR}_\lambda$ 
.....:     n = lam.size()
.....:     r = F.sum_of_monomials([sigma.descents_composition()
.....:                             for sigma in Permutations(n)
.....:                             if sigma.cycle_type() == lam])
.....:     return r.to_symmetric_function()
sage: all( GR_def2(lam) == h.gessel_reutenauer(lam)
.....:         for n in range(5) for lam in Partitions(n) )
True

```

And the first one, too (assuming symmetry):

```

sage: m = Sym.m()
sage: def GR_def1(lam): #  $\mathbf{GR}_{\lambda}$ 
.....:     n = lam.size()
.....:     Permuset = sage.combinat.permutation.Permutations_mset
.....:     def coeff_of_m_mu_in_result(mu):
.....:         words_to_check = Permuset([i for (i, l) in enumerate(mu)
.....:                                     for _ in range(l)])
.....:         return sum((1 for w in words_to_check if
.....:                     Partition(list(reversed(sorted([len(v) for v in
.....: Word(w).lyndon_factorization()])))
.....:                               == lam))
.....:                    (mu, coeff_of_m_mu_in_result(mu))
.....:                    for mu in Partitions(n)],
.....:                    distinct=True)
.....:     return r
sage: all( GR_def1(lam) == h.gessel_reutenauer(lam)
.....:       for n in range(5) for lam in Partitions(n) )
True

```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \mathbf{Q} -algebra from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \mathbf{Q} (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

`is_commutative()`

Return whether this symmetric function algebra is commutative.

INPUT:

- `self` – a basis of the symmetric functions

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s.is_commutative()
True

```

`is_field(proof=True)`

Return whether `self` is a field. (It is not.)

INPUT:

- `self` – a basis of the symmetric functions
- `proof` – an optional argument (default value: `True`)

EXAMPLES:

```

sage: s = SymmetricFunctions(QQ).s()
sage: s.is_field()
False

```

`is_integral_domain(proof=True)`

Return whether `self` is an integral domain. (It is if and only if the base ring is an integral domain.)

INPUT:

- `self` – a basis of the symmetric functions

- `proof` – an optional argument (default value: `True`)

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_integral_domain()
True
```

The following doctest is disabled pending [trac ticket #15475](#):

```
sage: s = SymmetricFunctions(Zmod(14)).s() # not tested
sage: s.is_integral_domain() # not tested
False
```

`lehrer_solomon(lam)`

Return the Lehrer-Solomon symmetric function (also known as the Whitney homology character) corresponding to the partition `lam` written in the basis `self`.

Let $\lambda \vdash n$ be a partition. The *Lehrer-Solomon symmetric function* \mathbf{LS}_λ corresponding to λ is the Frobenius characteristic of the representation denoted $\text{Ind}_{Z_\lambda}^{S_n}(\xi_\lambda)$ in Theorem 4.5 of [LS1986] or W_λ in Theorem 2.7 of [HR2017]. It was first computed as a symmetric function in [Sun1994].

It is the symmetric group representation corresponding to a summand of the Whitney homology of the set partition lattice. The summand comes from the orbit of set partitions with block sizes corresponding to λ (after reordering appropriately).

It can be computed using Sundaram's plethystic formula (see [Sun1994] Theorem 1.8):

$$\mathbf{LS}_\lambda = \prod_{\text{odd } j \geq 1} h_{m_j}[\pi_j] \prod_{\text{even } j \geq 2} e_{m_j}[\pi_j],$$

where h_{m_j} are complete homogeneous symmetric functions, e_{m_j} are elementary symmetric functions, and π_j are the images of the Gessel-Reutenauer symmetric function $\mathbf{GR}_{(j)}$ (see `gessel_reutenauer()`) under the involution ω (i.e. `omega_involution()`):

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: pi_2 = (s.gessel_reutenauer(2)).omega_involution()
sage: pi_1 = (s.gessel_reutenauer(1)).omega_involution()
sage: s.lehrer_solomon([2,1]) == pi_2 * pi_1 # since h_1, e_1 are
↪plethystic identities
True
```

Note that this also gives the S_n -equivariant structure of the Orlik-Solomon algebra of the braid arrangement (also known as the type- A reflection arrangement).

The representation corresponding to \mathbf{LS}_λ exhibits representation stability [Chu2012], and a sharp bound is given in [HR2017].

INPUT:

- `lam` – a partition or a positive integer (in the latter case, it is understood to mean the partition `[lam]`)

OUTPUT:

The Lehrer-Solomon symmetric function \mathbf{LS}_λ , where λ is `lam`, expanded in the basis `self`.

EXAMPLES:

The first few values of $\mathbf{LS}_{(n)}$:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.lehrer_solomon(1)
h[1]
sage: h.lehrer_solomon(2)
h[2]
sage: h.lehrer_solomon(3)
h[2, 1] - h[3]
sage: h.lehrer_solomon(4)
h[2, 1, 1] - h[2, 2]
sage: h.lehrer_solomon(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]

```

The `whitney_homology_character()` method is an alias:

```

sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.schur()
sage: s.lehrer_solomon([2, 2, 1]) == s.whitney_homology_character([2, 2, 1])
True

```

Lehrer-Solomon functions indexed by partitions:

```

sage: h.lehrer_solomon([2, 1])
h[2, 1]
sage: h.lehrer_solomon([2, 2])
h[3, 1] - h[4]

```

The Lehrer-Solomon functions are Schur-positive:

```

sage: s = Sym.s()
sage: s.lehrer_solomon([2, 1])
s[2, 1] + s[3]
sage: s.lehrer_solomon([2, 2, 1])
s[3, 1, 1] + s[3, 2] + s[4, 1]
sage: s.lehrer_solomon([4, 1])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]

```

`one_basis()`

Return the empty partition, as per `AlgebrasWithBasis.ParentMethods.one_basis`

INPUT:

- `self` – a basis of the ring of symmetric functions

EXAMPLES:

```

sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: s = Sym.s()
sage: s.one_basis()
[]
sage: Q = Sym.hall_littlewood().QC()
sage: Q.one_basis()
[]

```

Todo: generalize to `Modules.Graded.Connected.ParentMethods`

skew_schur(*x*)

Return the skew Schur function indexed by *x* in *self*.

INPUT:

- *x* – a skew partition

EXAMPLES:

```
sage: sp = SkewPartition([[5,3,3,1], [3,2,1]])
sage: s = SymmetricFunctions(QQ).s()
sage: s.skew_schur(sp)
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 3*s[3, 2, 1]
+ s[3, 3] + 2*s[4, 1, 1] + 2*s[4, 2] + s[5, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: ess = e.skew_schur(sp); ess
e[2, 1, 1, 1, 1] - e[2, 2, 1, 1] - e[3, 1, 1, 1] + e[3, 2, 1]
sage: ess == e(s.skew_schur(sp))
True
```

whitney_homology_character(*lam*)

Return the Lehrer-Solomon symmetric function (also known as the Whitney homology character) corresponding to the partition *lam* written in the basis *self*.

Let $\lambda \vdash n$ be a partition. The *Lehrer-Solomon symmetric function* \mathbf{LS}_λ corresponding to λ is the Frobenius characteristic of the representation denoted $\text{Ind}_{Z_\lambda}^{S_n}(\xi_\lambda)$ in Theorem 4.5 of [LS1986] or W_λ in Theorem 2.7 of [HR2017]. It was first computed as a symmetric function in [Sun1994].

It is the symmetric group representation corresponding to a summand of the Whitney homology of the set partition lattice. The summand comes from the orbit of set partitions with block sizes corresponding to λ (after reordering appropriately).

It can be computed using Sundaram's plethystic formula (see [Sun1994] Theorem 1.8):

$$\mathbf{LS}_\lambda = \prod_{\text{odd } j \geq 1} h_{m_j}[\pi_j] \prod_{\text{even } j \geq 2} e_{m_j}[\pi_j],$$

where h_{m_j} are complete homogeneous symmetric functions, e_{m_j} are elementary symmetric functions, and π_j are the images of the Gessel-Reutenauer symmetric function $\mathbf{GR}_{(j)}$ (see `gessel_reutenauer()`) under the involution ω (i.e. `omega_involution()`):

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: pi_2 = (s.gessel_reutenauer(2)).omega_involution()
sage: pi_1 = (s.gessel_reutenauer(1)).omega_involution()
sage: s.lehrer_solomon([2,1]) == pi_2 * pi_1 # since h_1, e_1 are
↪plethystic identities
True
```

Note that this also gives the S_n -equivariant structure of the Orlik-Solomon algebra of the braid arrangement (also known as the type- A reflection arrangement).

The representation corresponding to \mathbf{LS}_λ exhibits representation stability [Chu2012], and a sharp bound is given in [HR2017].

INPUT:

- *lam* – a partition or a positive integer (in the latter case, it is understood to mean the partition [*lam*])

OUTPUT:

The Lehrer-Solomon symmetric function LS_λ , where λ is lam, expanded in the basis self.

EXAMPLES:

The first few values of $LS_{(n)}$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.lehrer_solomon(1)
h[1]
sage: h.lehrer_solomon(2)
h[2]
sage: h.lehrer_solomon(3)
h[2, 1] - h[3]
sage: h.lehrer_solomon(4)
h[2, 1, 1] - h[2, 2]
sage: h.lehrer_solomon(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
```

The `whitney_homology_character()` method is an alias:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.schur()
sage: s.lehrer_solomon([2, 2, 1]) == s.whitney_homology_character([2, 2, 1])
True
```

Lehrer-Solomon functions indexed by partitions:

```
sage: h.lehrer_solomon([2, 1])
h[2, 1]
sage: h.lehrer_solomon([2, 2])
h[3, 1] - h[4]
```

The Lehrer-Solomon functions are Schur-positive:

```
sage: s = Sym.s()
sage: s.lehrer_solomon([2, 1])
s[2, 1] + s[3]
sage: s.lehrer_solomon([2, 2, 1])
s[3, 1, 1] + s[3, 2] + s[4, 1]
sage: s.lehrer_solomon([4, 1])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
```

super_categories()

The super categories of self.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import SymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = SymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of realizations of Symmetric Functions over Rational Field,
Category of commutative hopf algebras with basis over Rational Field,
```

(continues on next page)

(continued from previous page)

Join of Category of realizations of hopf algebras over Rational Field
 and Category of graded algebras over Rational Field
 and Category of graded coalgebras over Rational Field]

`sage.combinat.sf.sfa.is_SymmetricFunction(x)`

Checks whether `x` is a symmetric function.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import is_SymmetricFunction
sage: s = SymmetricFunctions(QQ).s()
sage: is_SymmetricFunction(2)
False
sage: is_SymmetricFunction(s(2))
True
sage: is_SymmetricFunction(s([2,1]))
True
```

`sage.combinat.sf.sfa.is_SymmetricFunctionAlgebra(x)`

Checks whether `x` is a symmetric function algebra.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import is_SymmetricFunctionAlgebra
sage: is_SymmetricFunctionAlgebra(5)
False
sage: is_SymmetricFunctionAlgebra(ZZ)
False
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(ZZ).schur())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).e())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).macdonald(q=1,t=1).P())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(FractionField(QQ['q','t'])).
↪macdonald().P())
True
```

`sage.combinat.sf.sfa.zee(part)`

Return the size of the centralizer of any permutation of cycle type `part`.

Note that the size of the centralizer is the inner product between `p(part)` and itself, where `p` is the power-sum symmetric functions.

INPUT:

- `part` – an integer partition (for example, `[2, 1, 1]`)

OUTPUT:

- the integer $\prod_i i^{m_i(part)} m_i(part)!$ where $m_i(part)$ is the number of parts in the partition `part` equal to i

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: zee([2,1,1])
4
```

5.1.300 Witt symmetric functions

`class sage.combinat.sf.witt.SymmetricFunctionAlgebra_witt(Sym, coerce_h=True, coerce_e=False, coerce_p=False)`

Bases: `sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative`

The Witt symmetric function basis (or Witt basis, to be short).

The Witt basis of the ring of symmetric functions is denoted by (x_λ) in [HazWitt1], section 9.63, and by (q_λ) in [DoranIV1996]. We will denote this basis by (w_λ) (which is precisely how it is denoted in [GriRei18], Exercise 2.9.3(d)). It is a multiplicative basis (meaning that $w_\emptyset = 1$ and that every partition λ satisfies $w_\lambda = w_{\lambda_1} w_{\lambda_2} w_{\lambda_3} \cdots$, where w_i means $w_{(i)}$ for every nonnegative integer i).

This basis can be defined in various ways. Probably the most well-known one is using the equation

$$\prod_{d=1}^{\infty} (1 - w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n$$

where t is a formal variable and h_n are the complete homogeneous symmetric functions, extended to 0 by $h_0 = 1$. This equation allows one to uniquely determine the functions w_1, w_2, w_3, \dots by recursion; one consequently extends the definition to all w_λ by requiring multiplicativity.

A way to rewrite the above equation without power series is:

$$h_n = \sum_{\lambda \vdash n} w_\lambda$$

for all nonnegative integers n , where $\lambda \vdash n$ means that λ is a partition of n .

A similar equation (which is easily seen to be equivalent to the former) is

$$e_n = \sum_{\lambda} (-1)^{n-\ell(\lambda)} w_\lambda,$$

with the sum running only over *strict* partitions λ of n this time. This equation can also be used to recursively define the w_n . Furthermore, every positive integer n satisfies

$$p_n = \sum_{d|n} d w_d^{n/d},$$

and this can be used to define the w_n recursively over any ring which is torsion-free as a \mathbf{Z} -module. While these equations all yield easy formulas for classical bases of the ring of symmetric functions in terms of the Witt symmetric functions, it seems difficult to obtain explicit formulas in the other direction.

The Witt symmetric functions owe their name to the fact that the ring of symmetric functions can be viewed as the coordinate ring of the group scheme of Witt vectors, and the Witt symmetric functions are the functions that send a Witt vector to its components (whereas the powersum symmetric functions send a Witt vector to its ghost components). Details can be found in [HazWitt1] or section 3.2 of [BorWi2004].

INPUT:

- `Sym` – an instance of the ring of the symmetric functions.
- `coerce_h` – (default: `True`) a boolean that determines whether the transition maps between the Witt basis and the complete homogeneous basis will be cached and registered as coercions.
- `coerce_e` – (default: `False`) a boolean that determines whether the transition maps between the Witt basis and the elementary symmetric basis will be cached and registered as coercions.
- `coerce_p` – (default: `False`) a boolean that determines whether the transition maps between the Witt basis and the powersum basis will be cached and registered as coercions (or conversions, if the base ring is not a \mathbf{Q} -algebra).

REFERENCES:

EXAMPLES:

Here are the first few Witt symmetric functions, in various bases:

```

sage: Sym = SymmetricFunctions(QQ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(w([1]))
p[1]
sage: m(w([1]))
m[1]
sage: e(w([1]))
e[1]
sage: h(w([1]))
h[1]
sage: s(w([1]))
s[1]

sage: p(w([2]))
-1/2*p[1, 1] + 1/2*p[2]
sage: m(w([2]))
-m[1, 1]
sage: e(w([2]))
-e[2]
sage: h(w([2]))
-h[1, 1] + h[2]
sage: s(w([2]))
-s[1, 1]

sage: p(w([3]))
-1/3*p[1, 1, 1] + 1/3*p[3]
sage: m(w([3]))
-2*m[1, 1, 1] - m[2, 1]
sage: e(w([3]))
-e[2, 1] + e[3]
sage: h(w([3]))
-h[2, 1] + h[3]
sage: s(w([3]))
-s[2, 1]

sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()

```

(continues on next page)

(continued from previous page)

```

sage: m(w([4]))
-9*m[1, 1, 1, 1] - 4*m[2, 1, 1] - 2*m[2, 2] - m[3, 1]
sage: e(w([4]))
-e[2, 1, 1] + e[3, 1] - e[4]
sage: h(w([4]))
-h[1, 1, 1, 1] + 2*h[2, 1, 1] - h[2, 2] - h[3, 1] + h[4]
sage: s(w([4]))
-s[1, 1, 1, 1] - s[2, 1, 1] - s[2, 2] - s[3, 1]

```

Some examples of conversions the other way:

```

sage: w(h[3])
w[1, 1, 1] + w[2, 1] + w[3]
sage: w(e[3])
-w[2, 1] + w[3]
sage: w(m[2, 1])
2*w[2, 1] - 3*w[3]
sage: w(p[3])
w[1, 1, 1] + 3*w[3]

```

Antipodes:

```

sage: w([1]).antipode()
-w[1]
sage: w([2]).antipode()
-w[1, 1] - w[2]

```

The following holds for all odd i and is easily proven by induction:

```

sage: all( w([i]).antipode() == -w([i]) for i in range(1, 10, 2) )
True

```

The Witt basis does not allow for simple expressions for comultiplication and antipode in general (this is related to the fact that the sum of two Witt vectors isn't easily described in terms of the components). Therefore, most computations with Witt symmetric functions, as well as conversions and coercions, pass through the complete homogeneous symmetric functions by default. However, one can also use the elementary symmetric functions instead, or (if the base ring is a \mathbf{Q} -algebra) the powersum symmetric functions. This is what the optional keyword variables `coerce_e`, `coerce_h` and `coerce_p` are for. These variables do not affect the results of the (non-underscored) methods of `self`, but they affect the speed of the computations (the more of these variables are set to `True`, the faster these are) and the size of the cache (the more of these variables are set to `True`, the bigger the cache). Let us check that the results are the same no matter to what the variables are set:

```

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: wh = Sym.w()
sage: we = Sym.w(coerce_h=False, coerce_e=True)
sage: wp = Sym.w(coerce_h=False, coerce_p=True)
sage: all( p(wh(lam)) == p(we(lam)) == p(wp(lam)) for lam in Partitions(4) )
True
sage: all ( wh(p(lam)).monomial_coefficients()
.....:      == we(p(lam)).monomial_coefficients()
.....:      == wp(p(lam)).monomial_coefficients() for lam in Partitions(4) )
True

```

coproduct(*elt*)

Return the coproduct of the element *elt*.

INPUT:

- *elt* – a symmetric function written in this basis

OUTPUT:

- The coproduct acting on *elt*; the result is an element of the tensor squared of the basis *self*

EXAMPLES:

```
sage: w = SymmetricFunctions(QQ).w()
sage: w[2].coproduct()
w[] # w[2] - w[1] # w[1] + w[2] # w[]
sage: w.coproduct(w[2])
w[] # w[2] - w[1] # w[1] + w[2] # w[]
sage: w[2,1].coproduct()
w[] # w[2, 1] - w[1] # w[1, 1] + w[1] # w[2] - w[1, 1] # w[1] + w[2] # w[1] +
↪w[2, 1] # w[]
sage: w.coproduct(w[2,1])
w[] # w[2, 1] - w[1] # w[1, 1] + w[1] # w[2] - w[1, 1] # w[1] + w[2] # w[1] +
↪w[2, 1] # w[]
```

from_other_uncached(*u*)

Return an element *u* of another basis of the ring of symmetric functions, expanded in the Witt basis *self*. The result is the same as *self*(*u*), but the *from_other_uncached* method does not precompute a cache with transition matrices. Thus, *from_other_uncached* is faster when *u* is sparse.

INPUT:

- *u* – an element of *self*.*realization_of*()

OUTPUT:

- the expansion of *u* in the Witt basis *self*

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: w = Sym.w()
sage: a = p([3,2]) - p([4,1]) + 27 * p([3])
sage: w.from_other_uncached(a) == w(a)
True
```

Here's a verification of an obvious fact that would take long with regular coercion:

```
sage: foc = w.from_other_uncached
sage: foc(p([15]))
w[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1] + 3*w[3, 3, 3, 3, 3] + 5*w[5, 5,
↪5] + 15*w[15]
sage: foc(p([15])) * foc(p([14])) == foc(p([15, 14]))
True
```

Other bases:

```

sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: all( foc(e(lam)) == w(e(lam)) for lam in Partitions(5) )
True
sage: all( foc(h(lam)) == w(h(lam)) for lam in Partitions(5) )
True
sage: all( foc(p(lam)) == w(p(lam)) for lam in Partitions(5) )
True
sage: all( foc(s(lam)) == w(s(lam)) for lam in Partitions(5) )
True

```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n -th Verschiebung operator.

The n -th Verschiebung operator \mathbf{V}_n is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n , and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n . This operator \mathbf{V}_n is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}, \quad \mathbf{V}_n(w_r) = w_{r/n},$$

(where h is the complete homogeneous basis, p is the powersum basis, e is the elementary basis, and w is the Witt basis). For every nonnegative integer r with $n \nmid r$, it satisfies

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = \mathbf{V}_n(w_r) = 0.$$

The n -th Verschiebung operator is also called the n -th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n -th Verschiebung operator is adjoint to the n -th Frobenius operator (see `frobenius()`) for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n -th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n -core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \dots, \lambda_{ns})$ for some nonnegative integer s . (If n does not divide the length of λ , then this is achieved by adding trailing zeroes to λ .) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \dots, ns\}$. Then, $(\beta_1, \beta_2, \dots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n . Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \dots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n . (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \dots, \lambda^{(n-1)})$ is the n -quotient of λ .

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n -th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: w[3].verschiebung(2)
0
sage: w[4].verschiebung(4)
w[1]
```

5.1.301 Shard intersection order

This file builds a combinatorial version of the shard intersection order of type A (in the classification of finite Coxeter groups). This is a lattice on the set of permutations, closely related to noncrossing partitions and the weak order.

For technical reasons, the elements of the posets are not permutations, but can be easily converted from and to permutations:

```
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

See also:

A general implementation for all finite Coxeter groups is available as `shard_poset()`

REFERENCES:

class `sage.combinat.shard_order.ShardPosetElement(p)`

Bases: `tuple`

An element of the shard poset.

This is basically a permutation with extra stored arguments:

- `p` – the permutation itself as a tuple
- `runs` – the decreasing runs as a tuple of tuples
- `run_indices` – a list integer \rightarrow index of the run
- `dpg` – the transitive closure of the shard preorder graph
- `spg` – the transitive reduction of the shard preorder graph

These elements can easily be converted from and to permutations:

```
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

`sage.combinat.shard_order.shard_poset(n)`

Return the shard intersection order on permutations of size *n*.

This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the descending runs and their relative positions.

The shard intersection order is given by the implication (or refinement) order on the set of pre-orders defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension n . The shard poset is given by the inclusion of these cones.

See also:

[`shard_preorder_graph\(\)`](#)

EXAMPLES:

```
sage: P = posets.ShardPoset(4); P # indirect doctest
Finite poset containing 24 elements
sage: P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
sage: P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
sage: P.is_self_dual()
False
```

`sage.combinat.shard_order.shard_preorder_graph(runs)`

Return the preorder attached to a tuple of decreasing runs.

This is a directed graph, whose vertices correspond to the runs.

There is an edge from a run R to a run S if R is before S in the list of runs and the two intervals defined by the initial and final indices of R and S overlap.

This only depends on the initial and final indices of the runs. For this reason, this input can also be given in that shorten way.

INPUT:

- a tuple of tuples, the runs of a permutation, or
- a tuple of pairs (i, j) , each one standing for a run from i to j .

OUTPUT:

a directed graph, with vertices labelled by integers

EXAMPLES:

```
sage: from sage.combinat.shard_order import shard_preorder_graph
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
sage: def cut(lr):
.....:     return tuple((r[0], r[-1]) for r in lr)
sage: shard_preorder_graph(cut(s.decreasing_runs()))
Digraph on 5 vertices
sage: s = Permutation([9,4,3,2,8,6,5,1,7])
sage: P = shard_preorder_graph(s.decreasing_runs())
sage: P.is_isomorphic(digraphs.TransitiveTournament(3))
True
```

5.1.302 Shifted primed tableaux

AUTHORS:

- Kirill Paramonov (2017-08-18): initial implementation
- Chaman Agrawal (2019-08-12): add parameter to allow primed diagonal entry

```
class sage.combinat.shifted_primed_tableau.CrystalElementShiftedPrimedTableau(parent, T,
                                                                              skew=None,
                                                                              check=True,
                                                                              prepro-
                                                                              cessed=False)
```

Bases: `sage.combinat.shifted_primed_tableau.ShiftedPrimedTableau`

Class for elements of `crystals.ShiftedPrimedTableau`.

e(*ind*)

Compute the action of the crystal operator e_i on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

- *ind* – an element in the index set of the crystal

OUTPUT:

Primed tableau or None.

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,'2p','3p'], [2,'3p',3,3],[3,4]])
sage: t.pp()
1 1 1 2' 3'
  2 3' 3 3
  3 4
sage: s = t.e(2)
sage: s.pp()
1 1 1 2' 3'
  2 2 3 3
  3 4
sage: t == s.f(2)
True

sage: SPT = ShiftedPrimedTableaux([2,1])
sage: t = SPT([[2,'3p'],[3]])
sage: t.e(-1).pp()
1 3'
  3
sage: t.e(1).pp()
1 3'
  3
sage: t.e(2).pp()
2 2
  3
sage: r = SPT([[2, 2],[3]])
```

(continues on next page)

(continued from previous page)

```

sage: r.e(-1).pp()
1 2
  3
sage: r.e(1).pp()
1 2
  3
sage: r.e(2) is None
True
sage: r = SPT([[1, '3p'], [3]])
sage: r.e(-1) is None
True
sage: r.e(1) is None
True
sage: r.e(2).pp()
1 2'
  3
sage: r = SPT([[1, '2p'], [3]])
sage: r.e(-1).pp()
1 1
  3
sage: r.e(1) is None
True
sage: r.e(2).pp()
1 2'
  2
sage: t = SPT([[2, '3p'], [3]])
sage: t.e(-1).e(2).e(2).e(-1) == t.e(2).e(1).e(1).e(2)
True
sage: t.e(-1).e(2).e(2).e(-1).pp()
1 1
  2
sage: all(t.e(-1).e(2).e(2).e(-1).e(i) is None for i in {-1, 1, 2})
True
sage: SPT = ShiftedPrimedTableaux([4])
sage: t = SPT([[2, 2, 2, 2]])
sage: t.e(-1).pp()
1 2 2 2

1 2 2 2
sage: t.e(-1).e(-1) is None
True
sage: t.e(1).e(1).pp()
1 1 2 2

```

f(ind)

Compute the action of the crystal operator f_i on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

- ind – element in the index set of the crystal

OUTPUT:

Primed tableau or None.

EXAMPLES:

```

sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,1,'3p'],[2,2,2,'3p'],[3,3]])
sage: t.pp()
1 1 1 1 3'
  2 2 2 3'
    3 3
sage: s = t.f(2)
sage: s is None
True

sage: t = SPT([[1,1,1,'2p','3p'],[2,2,3,3],[3,4]])
sage: t.pp()
1 1 1 2' 3'
  2 2 3 3
    3 4
sage: s = t.f(2)
sage: s.pp()
1 1 1 2' 3'
  2 3' 3 3
    3 4

sage: SPT = ShiftedPrimedTableaux([2,1])
sage: t = SPT([[1,1],[2]])
sage: t.f(-1).pp()

sage: r.f(1).pp()
1 2

```

(continues on next page)

(continued from previous page)

```

3
sage: r.f(2) is None
True
sage: r = SPT([[1,2],[3]])
sage: r.f(-1).pp()
2 2
3
sage: r.f(1).pp()
2 2
3
sage: r.f(2) is None
True
sage: t = SPT([[1,1],[2]])
sage: t.f(-1).f(2).f(2).f(-1) == t.f(2).f(1).f(-1).f(2)
True
sage: t.f(-1).f(2).f(2).f(-1).pp()
2 3'
3
sage: all(t.f(-1).f(2).f(2).f(-1).f(i) is None for i in {-1, 1, 2})
True
sage: SPT = ShiftedPrimedTableaux([4])
sage: t = SPT([[1,1,1,1]])
sage: t.f(-1).pp()
1 1 1 2'
sage: t.f(1).pp()
1 1 1 2
sage: t.f(-1).f(-1) is None
True
sage: t.f(1).f(-1).pp()
1 1 2' 2
sage: t.f(1).f(1).pp()
1 1 2 2
sage: t.f(1).f(1).f(-1).pp()
1 2' 2 2
sage: t.f(1).f(1).f(1).pp()
1 2 2 2
sage: t.f(1).f(1).f(1).f(-1).pp()
2 2 2 2
sage: t.f(1).f(1).f(1).f(1).pp()
2 2 2 2
sage: t.f(1).f(1).f(1).f(1).f(-1) is None
True

```

is_highest_weight(*index_set=None*)

Return whether `self` is a highest weight element of the crystal.

An element is highest weight if it vanishes under all crystal operators e_i .

EXAMPLES:

```

sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([(1, 1, 1, 1, 1), (2, 2, 2, "3p"), (3, 3)])
sage: t.is_highest_weight()
True

sage: SPT = ShiftedPrimedTableaux([5,4])
sage: s = SPT([(1, 1, 1, 1, 1), (2, 2, "3p", 3)])
sage: s.is_highest_weight(index_set=[1])
True

```

reading_word()

Return the reading word of `self`.

The reading word of a shifted primed tableau is constructed as follows:

1. List all primed entries in the tableau, column by column, in decreasing order within each column, moving from the rightmost column to the left, and with all the primes removed (i.e. all entries are increased by half a unit).
2. Then list all unprimed entries, row by row, in increasing order within each row, moving from the bottommost row to the top.

EXAMPLES:

```

sage: SPT = ShiftedPrimedTableaux([4,2])
sage: t = SPT([[1, '2p', 2, 2], [2, '3p']])
sage: t.reading_word()
[3, 2, 2, 1, 2, 2]

```

weight()

Return the weight of `self`.

The weight of a shifted primed tableau is defined to be the vector with i -th component equal to the number of entries i and i' in the tableau.

EXAMPLES:

```

sage: t = ShiftedPrimedTableau([[1, '2p', 2, 2], [2, '3p']])
sage: t.weight()
(1, 4, 1)

```

class `sage.combinat.shifted_primed_tableau.PrimedEntry`(*entry=None, double=None*)

Bases: `sage.structure.sage_object.SageObject`

The class of entries in shifted primed tableaux.

An entry in a shifted primed tableau is an element in the alphabet $\{1' < 1 < 2' < 2 < \dots < n' < n\}$. The difference between two elements i and $i - 1$ counts as a whole unit, whereas the difference between i and i' counts as half a unit. Internally, we represent an unprimed element x as $2x$ and the primed elements as the corresponding odd integer that respects the total order.

INPUT:

- `entry` – a half integer or a string of an integer possibly ending in `p` or `'`
- `double` – the doubled value

decrease_half()

Decrease `self` by half a unit.

decrease_one()
Decrease `self` by one unit.

increase_half()
Increase `self` by half a unit.

increase_one()
Increase `self` by one unit.

integer()
Return the corresponding integer i for primed entries of the form i or i' .

is_primed()
Checks if `self` is a primed element.

is_unprimed()
Checks if `self` is an unprimed element.

primed()
Prime `self` if it is an unprimed element.

unprimed()
Unprime `self` if it is a primed element.

class `sage.combinat.shifted_primed_tableau.ShiftedPrimedTableau`(*parent*, *T*, *skew=None*,
check=True,
preprocessed=False)

Bases: `sage.structure.list_clone.ClonableArray`

A shifted primed tableau.

A primed tableau is a tableau of shifted shape in the alphabet $X' = \{1' < 1 < 2' < 2 < \dots < n' < n\}$ such that

1. the entries are weakly increasing along rows and columns;
2. a row cannot have two repeated primed elements, and a column cannot have two repeated non-primed elements;

Skew shape of the shifted primed tableaux is specified either with an optional argument `skew` or with `None` entries.

Primed entries in the main diagonal can be allowed with the optional boolean parameter `primed_diagonal` (default: `False`).

EXAMPLES:

```
sage: T = ShiftedPrimedTableaux([4,2])
sage: T([[1,"2'", "3'",3],[2,"3'"]])[1]
(2, 3')
```

```
sage: t = ShiftedPrimedTableau([[1,"2p",2.5,3],[2,2.5]])
sage: t[1]
(2, 3')
```

```
sage: ShiftedPrimedTableau([["2p",2,3],[ "2p","3p"],[2]], skew=[2,1])
[(None, None, 2', 2, 3), (None, 2', 3'), (2,)]
```

```
sage: ShiftedPrimedTableau([["None, None, "2p"], ["None, "2p"]])
[(None, None, 2'), (None, 2')]
```

```
sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: T([[1,"2'", "3'",3],[ "2'", "3'"]])[1] # With primed diagonal entry
(2', 3')
```

check()

Check that `self` is a valid primed tableau.

EXAMPLES:

```
sage: T = ShiftedPrimedTableaux([4,2])
sage: t = T([[1,'2p',2,2],[2,'3p']])
sage: t.check()
sage: s = ShiftedPrimedTableau(["2p",2,3],["2p"],[2],skew=[2,1])
sage: s.check()
sage: t = T(['1p','2p',2,2],[2,'3p'])
Traceback (most recent call last):
...
ValueError: [['1p', '2p', 2, 2], [2, '3p']] is not an element of
  Shifted Primed Tableaux of shape [4, 2]

sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: t = T(['1p','2p',2,2],[2,'3p']) # primed_diagonal allowed
sage: t.check()
sage: t = T(['1p','1p',2,2],[2,'3p'])
Traceback (most recent call last):
...
ValueError: [['1p', '1p', 2, 2], [2, '3p']] is not an element of
  Shifted Primed Tableaux of shape [4, 2] and maximum entry 6
```

is_standard()

Return True if the entries of `self` are in bijection with positive primed integers $1', 1, 2', \dots, n$.

EXAMPLES:

```
sage: ShiftedPrimedTableau(["1'", 1, "2'", [2, "3'"]],
.....:                      primed_diagonal=True).is_standard()
True
sage: ShiftedPrimedTableau(["1'", 1, 2], ["2'", "3'"]],
.....:                      primed_diagonal=True).is_standard()
True
sage: ShiftedPrimedTableau(["1'", 1, 1], ["2'", 2]),
.....:                      primed_diagonal=True).is_standard()
False
sage: ShiftedPrimedTableau([1, "2'"], [2]).is_standard()
False
sage: s = ShiftedPrimedTableau([None, None, "1p", "2p", 2], [None, "1"])
sage: s.is_standard()
True
```

max_entry()

Return the minimum unprimed letter $x > y$ for all y in `self`.

EXAMPLES:

```
sage: Tab = ShiftedPrimedTableau([(1,1,'2p','3p'),(2,2)])
sage: Tab.max_entry()
3
```

pp()

Pretty print `self`.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1, '2p', 2, 2], [2, '3p']])
sage: t.pp()
1  2' 2  2
   2  3'

sage: t = ShiftedPrimedTableau([[10, '11p', 11, 11], [11, '12']])
sage: t.pp()
10 11' 11 11
    11 12

sage: s = ShiftedPrimedTableau(['2p', 2, 3], ['2p'], skew=[2, 1])
sage: s.pp()
.  .  2' 2  3
.  .  2'
```

restrict(n)

Return the restriction of the shifted tableau to all the numbers less than or equal to n .

Note: If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method `restriction_outer_shape()` is preferred. Similarly if only the skew shape is needed, use `restriction_shape()`.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1, '2p', 2, 2], [2, '3p']])
sage: t.restrict(2).pp()
1  2' 2  2
   2

sage: t.restrict("2p").pp()
1  2'

sage: s = ShiftedPrimedTableau(["2p", 2, 3], ["2p"], skew=[2, 1])
sage: s.restrict(2).pp()
.  .  2' 2
.  .  2'

sage: s.restrict(1.5).pp()
.  .  2'
.  .  2'
```

restriction_outer_shape(n)

Return the outer shape of the restriction of the shifted tableau `self` to n .

If T is a (skew) shifted tableau and n is a half-integer, then the restriction of T to n is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than n from T .

This method computes merely the outer shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```
sage: s = ShiftedPrimedTableau(["2p", 2, 3], ["2p"], skew=[2, 1])
sage: s.pp()
.  .  2' 2  3
.  .  2'
```

(continues on next page)

(continued from previous page)

```

sage: s.restriction_outer_shape(2)
[4, 2]
sage: s.restriction_outer_shape("2p")
[3, 2]

```

restriction_shape(*n*)

Return the skew shape of the restriction of the skew tableau `self` to `n`.

If T is a shifted tableau and n is a half-integer, then the restriction of T to n is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than n from T .

This method computes merely the skew shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```

sage: s = ShiftedPrimedTableau(["2p", 2, 3], ["2p"], skew=[2, 1])
sage: s.pp()
. . 2' 2 3
. 2'

sage: s.restriction_shape(2)
[4, 2] / [2, 1]

```

shape()

Return the shape of the underlying partition of `self`.

EXAMPLES:

```

sage: t = ShiftedPrimedTableau([[1, '2p', 2, 2], [2, '3p']])
sage: t.shape()
[4, 2]
sage: s = ShiftedPrimedTableau(["2p", 2, 3], ["2p"], skew=[2, 1])
sage: s.shape()
[5, 2] / [2, 1]

```

to_chain()

Return the chain of partitions corresponding to the (skew) shifted tableau `self`, interlaced by one of the colours 1 is the added cell is on the diagonal, 2 if an ordinary entry is added and 3 if a primed entry is added.

EXAMPLES:

```

sage: s = ShiftedPrimedTableau([(1, 2, 3.5, 5, 6.5), (3, 5.5)])
sage: s.pp()
1 2 4' 5 7'
3 6'

sage: s.to_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]

sage: s = ShiftedPrimedTableau([(1, 3.5), (2.5,)], (6,)], skew=[2, 1])
sage: s.pp()
. . 1 4'
. 3'

```

(continues on next page)

(continued from previous page)

6

```
sage: s.to_chain()
[[2, 1], 2, [3, 1], 0, [3, 1], 3, [3, 2], 3, [4, 2], 0, [4, 2], 1, [4, 2, 1]]
```

weight()

Return the weight of `self`.

The weight of a shifted primed tableau is defined to be the vector with i -th component equal to the number of entries i and i' in the tableau.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[ '2p', 2, 2 ], [ 2, '3p' ]], skew=[1])
sage: t.weight()
(0, 4, 1)
```

```
class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux(skew=None,
                                                                primed_diagonal=False)
```

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Returns the combinatorial class of shifted primed tableaux subject to the constraints given by the arguments.

A primed tableau is a tableau of shifted shape on the alphabet $X' = \{1' < 1 < 2' < 2 < \dots < n' < n\}$ such that

1. the entries are weakly increasing along rows and columns
2. a row cannot have two repeated primed entries, and a column cannot have two repeated non-primed entries

INPUT:

Valid optional keywords:

- `shape` – the (outer skew) shape of tableaux
- `weight` – the weight of tableaux
- `max_entry` – the maximum entry of tableaux
- `skew` – the inner skew shape of tableaux
- `primed_diagonal` – allow primed entries in main diagonal of tableaux

The weight of a tableau is defined to be the vector with i -th component equal to the number of entries i and i' in the tableau. The sum of the coordinates in the weight vector must be equal to the number of entries in the partition.

The shape and skew must be strictly decreasing partitions. The `primed_diagonal` is a boolean (default: `False`).

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2]); SPT
Shifted Primed Tableaux of weight (1, 2, 2) and shape [3, 2]
sage: SPT.list()
[[ (1, 2, 2), (3, 3) ],
 [ (1, 2', 3'), (2, 3) ],
 [ (1, 2', 3'), (2, 3') ],
```

(continues on next page)

```

[(1, 2', 2), (3, 3)]
sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2],
.....:                               primed_diagonal=True); SPT
Shifted Primed Tableaux of weight (1, 2, 2) and shape [3, 2]
sage: SPT.list()
[[ (1, 2, 2), (3, 3) ],
 [ (1, 2, 2), (3', 3) ],
 [ (1, 2', 3'), (2, 3) ],
 [ (1, 2', 3'), (2, 3') ],
 [ (1, 2', 3'), (2', 3) ],
 [ (1, 2', 3'), (2', 3') ],
 [ (1, 2', 2), (3, 3) ],
 [ (1, 2', 2), (3', 3) ],
 [ (1', 2, 2), (3, 3) ],
 [ (1', 2, 2), (3', 3) ],
 [ (1', 2', 3'), (2, 3) ],
 [ (1', 2', 3'), (2, 3') ],
 [ (1', 2', 3'), (2', 3) ],
 [ (1', 2', 3'), (2', 3') ],
 [ (1', 2', 2), (3, 3) ],
 [ (1', 2', 2), (3', 3) ]]
sage: SPT = ShiftedPrimedTableaux(weight=(1,2)); SPT
Shifted Primed Tableaux of weight (1, 2)
sage: list(SPT)
[[ (1, 2, 2) ], [ (1, 2', 2) ], [ (1, 2'), (2,) ]]
sage: SPT = ShiftedPrimedTableaux(weight=(1,2), primed_diagonal=True)
sage: list(SPT)
[[ (1, 2, 2) ],
 [ (1, 2', 2) ],
 [ (1', 2, 2) ],
 [ (1', 2', 2) ],
 [ (1, 2'), (2,) ],
 [ (1, 2'), (2',) ],
 [ (1', 2'), (2,) ],
 [ (1', 2'), (2',) ]]
sage: SPT = ShiftedPrimedTableaux([3,2], max_entry=2); SPT
Shifted Primed Tableaux of shape [3, 2] and maximum entry 2
sage: list(SPT)
[[ (1, 1, 1), (2, 2) ], [ (1, 1, 2'), (2, 2) ]]
sage: SPT = ShiftedPrimedTableaux([3,2], max_entry=2,
.....:                               primed_diagonal=True)
sage: list(SPT)
[[ (1, 1, 1), (2, 2) ],
 [ (1, 1, 1), (2', 2) ],
 [ (1', 1, 1), (2, 2) ],
 [ (1', 1, 1), (2', 2) ],
 [ (1, 1, 2'), (2, 2) ],
 [ (1, 1, 2'), (2', 2) ],
 [ (1', 1, 2'), (2, 2) ],
 [ (1', 1, 2'), (2', 2) ]]

```

See also:

- *ShiftedPrimedTableau*

Element

alias of *ShiftedPrimedTableau*

options(*get_value, **set_value)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- `ascii_art` – (default: `repr`) Controls the ascii art output for tableaux
 - `compact` – minimal length ascii art
 - `repr` – display using the diagram string representation
 - `table` – display as a table
- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
 - `English` – use the English convention
 - `French` – use the French convention
- `display` – (default: `list`) Controls the way in which tableaux are printed
 - `array` – alias for `diagram`
 - `compact` – minimal length string representation
 - `diagram` – display as Young diagram (similar to `pp()`)
 - `ferrers_diagram` – alias for `diagram`
 - `list` – print tableaux as lists
 - `young_diagram` – alias for `diagram`
- `latex` – (default: `diagram`) Controls the way in which tableaux are latexed
 - `array` – alias for `diagram`
 - `diagram` – as a Young diagram
 - `ferrers_diagram` – alias for `diagram`
 - `list` – as a list
 - `young_diagram` – alias for `diagram`
- `notation` – alternative name for `convention`

Note: Changing the `convention` for tableaux also changes the `convention` for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
```

(continues on next page)

(continued from previous page)

```

1 2 3
4 5
sage: Tableaux.options.convention="french"
sage: T
4 5
1 2 3

```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```

sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
*
sage: T
1 2 3
4 5

```

The ASCII art can also be changed:

```

sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
1 2 3
4 5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+-----+
| 1 | 2 | 3 |
+-----+
| 4 | 5 |
+-----+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
sage: Tableaux.options._reset()

```

See [GlobalOptions](#) for more features of these options.

```

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_all(skew=None,
                                                                    primed_diagonal=False)

```

Bases: *sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux*

The class of all shifted primed tableaux.

```

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_shape(shape,
                                                                    max_entry=None,
                                                                    skew=None,
                                                                    primed_diagonal=False)

```

Bases: *sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux*

Shifted primed tableaux of a fixed shape.

Shifted primed tableaux admit a type A_n classical crystal structure with highest weights corresponding to a given shape.

The list of module generators consists of all elements of the crystal with nonincreasing weight entries.

The crystal is constructed following operations described in [HPS2017] and [AO2018].

The optional `primed_diagonal` allows primed entries in the main diagonal of all the Shifted primed tableaux of a fixed shape. If the `max_entry` is `None` then `max_entry` is set to the total number of entries in the tableau if `primed_diagonal` is `True`.

EXAMPLES:

```
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4).cardinality()
384
```

We compute some of the crystal structure:

```
sage: SPTC = crystals.ShiftedPrimedTableaux([3,2], 3)
sage: T = SPTC.module_generators[-1]
sage: T
[(1, 1, 2'), (2, 3')]
sage: T.f(2)
[(1, 1, 3'), (2, 3')]
sage: len(SPTC.module_generators)
7
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
24
```

We compare this implementation with the $q(n)$ -crystal on (tensor products) of letters:

```
sage: tableau_crystal = crystals.ShiftedPrimedTableaux([4,1], 3)
sage: tableau_digraph = tableau_crystal.digraph()
sage: c = crystals.Letters(['Q', 3])
sage: tensor_crystal = tensor([c]*5)
sage: u = tensor_crystal(c(1), c(1), c(1), c(2), c(1))
sage: subcrystal = tensor_crystal.subcrystal(generators=[u],
.....:                                     index_set=[1,2,-1])
sage: tensor_digraph = subcrystal.digraph()
sage: tensor_digraph.is_isomorphic(tableau_digraph, edge_labels=True)
True
```

If we allow primed entries in the main diagonal:

```
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4,
.....:                       primed_diagonal=True)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4,
.....:                       primed_diagonal=True).cardinality()
3072
```

(continues on next page)

(continued from previous page)

```

sage: SPTC = ShiftedPrimedTableaux([3,2], max_entry=3,
.....:                             primed_diagonal=True)
sage: T = SPTC[-1]
sage: T
[(1', 2', 2), (3', 3)]
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
96

```

module_generators()

Return the generators of self as a crystal.

shape()

Return the shape of the shifted tableaux self.

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_weight**(*weight, skew=None, primed_diagonal=False*)

Bases: *sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux*

Shifted primed tableaux of fixed weight.

EXAMPLES:

```

sage: ShiftedPrimedTableaux(weight=(2,3,1))
Shifted Primed Tableaux of weight (2, 3, 1)
sage: ShiftedPrimedTableaux(weight=(2,3,1)).cardinality()
17
sage: SPT = ShiftedPrimedTableaux(weight=(2,3,1), primed_diagonal=True)
sage: SPT.cardinality()
64
sage: T = ShiftedPrimedTableaux(weight=(3,2), primed_diagonal=True)
sage: T[:5]
[[ (1, 1, 1, 2, 2) ],
 [ (1, 1, 1, 2', 2) ],
 [ (1', 1, 1, 2, 2) ],
 [ (1', 1, 1, 2', 2) ],
 [ (1, 1, 1, 2), (2,) ]]
sage: T.cardinality()
16

```

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_weight_shape**(*weight, shape, skew=None, primed_diagonal=False*)

Bases: *sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux*

Shifted primed tableaux of the fixed weight and shape.

EXAMPLES:

```

sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2))
Shifted Primed Tableaux of weight (2, 3, 2) and shape [4, 2, 1]
sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2)).cardinality()
4
sage: T = ShiftedPrimedTableaux([4,2,1], weight=(2,3,2),

```

(continues on next page)

(continued from previous page)

```

.....:          primed_diagonal=True)
sage: T[:6]
[[ (1, 1, 2, 2), (2, 3'), (3,) ],
 [ (1, 1, 2, 2), (2, 3'), (3',) ],
 [ (1, 1, 2, 2), (2', 3'), (3,) ],
 [ (1, 1, 2, 2), (2', 3'), (3',) ],
 [ (1, 1, 2', 3), (2, 2), (3,) ],
 [ (1, 1, 2', 3), (2, 2), (3',) ]]
sage: T.cardinality()
32

```

5.1.303 Shuffle product of iterables

The shuffle product of two sequences of lengths m and n is a sum over the $\binom{m+n}{n}$ ways of interleaving the two sequences. That could be defined inductively by:

$$(a_n)_{n \geq 0} \uplus (b_m)_{m \geq 0} = a_0 \cdot ((a_n)_{n \geq 1} \uplus (b_m)_{m \geq 0}) + b_0 \cdot ((a_n)_{n \geq 0} \uplus (b_m)_{m \geq 1})$$

with (a_n) and (b_m) two non-empty sequences and if one of them is empty then the product is equals to the other.

The shuffle product has been introduced by S. Eilenberg and S. Mac Lane in 1953 [EilLan53].

EXAMPLES:

```

sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct([1,2], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'],
 ['a', 1, 2, 'b', 'c'],
 [1, 'a', 2, 'b', 'c'],
 ['a', 'b', 1, 2, 'c'],
 ['a', 1, 'b', 2, 'c'],
 [1, 'a', 'b', 2, 'c'],
 ['a', 'b', 'c', 1, 2],
 ['a', 'b', 1, 'c', 2],
 ['a', 1, 'b', 'c', 2],
 [1, 'a', 'b', 'c', 2]]

```

class `sage.combinat.shuffle.SetShuffleProduct`(*l1*, *l2*, *element_constructor=None*)

Bases: `sage.combinat.shuffle.ShuffleProduct_abstract`

The union of all possible shuffle products of two sets of iterables.

EXAMPLES:

```

sage: from sage.combinat.shuffle import SetShuffleProduct
sage: sorted(SetShuffleProduct({(1,)}, {(2,3)}, {(4,5), (6,)}))
[[1, 4, 5],
 [1, 6],

```

(continues on next page)

(continued from previous page)

```
[2, 3, 4, 5],
[2, 3, 6],
[2, 4, 3, 5],
[2, 4, 5, 3],
[2, 6, 3],
[4, 1, 5],
[4, 2, 3, 5],
[4, 2, 5, 3],
[4, 5, 1],
[4, 5, 2, 3],
[6, 1],
[6, 2, 3]]
```

cardinality()

The cardinality is defined by the sum of the cardinality of all shuffles. That means by a sum of binomials.

```
class sage.combinat.shuffle.ShuffleProduct(l1, l2, element_constructor=None)
```

Bases: `sage.combinat.shuffle.ShuffleProduct_abstract`

Shuffle product of two iterables.

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct("abc", "de", element_constructor="".join))
['abcde',
'adbce',
'dabce',
'abdce',
'adebc',
'daebc',
'deabc',
'adbec',
'dabec',
'abdec']
sage: list(ShuffleProduct("", "de", element_constructor="".join))
['de']
```

cardinality()

Return the number of shuffles of l_1 and l_2 , respectively of lengths m and n , which is $\binom{m+n}{n}$.

```
class sage.combinat.shuffle.ShuffleProduct_abstract(l1, l2, element_constructor=None)
```

Bases: `sage.structure.parent.Parent`

Abstract base class for shuffle products.

```
class sage.combinat.shuffle.ShuffleProduct_overlapping(w1, w2, element_constructor=None,
add=<built-in function add>)
```

Bases: `sage.combinat.shuffle.ShuffleProduct_abstract`

The overlapping shuffle product of the two words w_1 and w_2 .

If u and v are two words whose letters belong to an additive monoid or to another kind of alphabet on which addition is well-defined, then the *overlapping shuffle product* of u and v is a certain multiset of words defined as follows: Let a and b be the lengths of u and v , respectively. Let A be the set $\{(0, 1), (0, 2), \dots, (0, a)\}$, and let B be the set $\{(1, 1), (1, 2), \dots, (1, b)\}$. Notice that the sets A and B are disjoint. We can make A and B into posets by setting $(k, i) \leq (k, j)$ for all $k \in \{0, 1\}$ and $i \leq j$. Then, $A \cup B$ becomes a poset by disjoint union

(we don't set $(0, i) \leq (1, i)$). Let p be the map from $A \cup B$ to the set of all letters which sends every $(0, i)$ to the i -th letter of u , and every $(1, j)$ to the j -th letter of v . For every nonnegative integer c and every surjective map $f : A \cup B \rightarrow \{1, 2, \dots, c\}$ for which both restrictions $f|_A$ and $f|_B$ are strictly increasing, let $w(f)$ be the length- c word such that for every $1 \leq k \leq c$, the k -th letter of $w(f)$ equals $\sum_{j \in f^{-1}(k)} p(j)$ (this sum always has either one or two addends). The overlapping shuffle product of u and v is then the multiset of all $w(f)$ with c ranging over all nonnegative integers and f ranging over the surjective maps $f : A \cup B \rightarrow \{1, 2, \dots, c\}$ for which both restrictions $f|_A$ and $f|_B$ are strictly increasing.

If one restricts c to a particular fixed nonnegative integer, then the multiset is instead called the *overlapping shuffle product with precisely $a + b - c$ overlaps*. This is nonempty only if $\max\{a, b\} \leq c \leq a + b$.

If $c = a + b$, then the overlapping shuffle product with precisely $a + b - c$ overlaps is plainly the shuffle product (`ShuffleProduct_w1w2`).

INPUT:

- `w1, w2` – iterables
- `element_constructor` – (default: the parent of `w1`) the function used to construct the output
- `add` – (default: `+`) the addition function

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct_overlapping
sage: w, u = [[2, 9], [9, 1]]
sage: S = ShuffleProduct_overlapping(w, u)
sage: sorted(S)
[[2, 9, 1, 9],
 [2, 9, 9, 1],
 [2, 9, 9, 1],
 [2, 9, 10],
 [2, 18, 1],
 [9, 1, 2, 9],
 [9, 2, 1, 9],
 [9, 2, 9, 1],
 [9, 2, 10],
 [9, 3, 9],
 [11, 1, 9],
 [11, 9, 1],
 [11, 10]]
sage: A = [{1,2}, {3,4}]
sage: B = [{2,3}, {4,5,6}]
sage: S = ShuffleProduct_overlapping(A, B, add=lambda X,Y: X.union(Y))
sage: list(S)
[{{1, 2}, {3, 4}, {2, 3}, {4, 5, 6}},
 {{1, 2}, {2, 3}, {3, 4}, {4, 5, 6}},
 {{1, 2}, {2, 3}, {4, 5, 6}, {3, 4}},
 {{2, 3}, {1, 2}, {3, 4}, {4, 5, 6}},
 {{2, 3}, {1, 2}, {4, 5, 6}, {3, 4}},
 {{2, 3}, {4, 5, 6}, {1, 2}, {3, 4}},
 {{1, 2, 3}, {3, 4}, {4, 5, 6}},
 {{1, 2}, {2, 3, 4}, {4, 5, 6}},
 {{1, 2, 3}, {4, 5, 6}, {3, 4}},
 {{1, 2}, {2, 3}, {3, 4, 5, 6}},
 {{2, 3}, {1, 2, 4, 5, 6}, {3, 4}},
```

(continues on next page)

(continued from previous page)

```
[{2, 3}, {1, 2}, {3, 4, 5, 6}],
[{1, 2, 3}, {3, 4, 5, 6}]]
```

class sage.combinat.shuffle.ShuffleProduct_overlapping_r(*w1, w2, r, element_constructor=None, add=<built-in function add>*)

Bases: *sage.combinat.shuffle.ShuffleProduct_abstract*

The overlapping shuffle product of the two words *w1* and *w2* with precisely *r* overlaps.

See *ShuffleProduct_overlapping* for a definition.

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct_overlapping_r
sage: w, u = map(Words(range(20)), [[2, 9], [9, 1]])
sage: S = ShuffleProduct_overlapping_r(w, u, 1)
sage: list(S)
[word: 11, 9, 1,
 word: 2, 18, 1,
 word: 11, 1, 9,
 word: 2, 9, 10,
 word: 939,
 word: 9, 2, 10]
```

5.1.304 Sidon sets and their generalizations, Sidon g -sets

AUTHORS:

- Martin Raum (07-25-2011)

sage.combinat.sidon_sets.sidon_sets(*N, g=1*)

Return the set of all Sidon- g sets that have elements less than or equal to N .

A Sidon- g set is a set of positive integers $A \subset [1, N]$ such that any integer M can be obtain at most g times as sums of unordered pairs of elements of A (the two elements are not necessary distinct):

$$\#\{(a_i, a_j) | a_i, a_j \in A, a_i + a_j = M, a_i \leq a_j\} \leq g$$

INPUT:

- N – A positive integer.
- g – A positive integer (default: 1).

OUTPUT:

- A Sage set with categories whose element are also set of integers.

EXAMPLES:

```
sage: S = sidon_sets(3, 2)
sage: sorted(S, key=str)
[{1, 2, 3}, {1, 2}, {1, 3}, {1}, {2, 3}, {2}, {3}, {}]
sage: S.cardinality()
8
sage: S.category()
Category of finite enumerated sets
```

(continues on next page)

(continued from previous page)

```

sage: sid = S.an_element()
sage: sid
{2}
sage: sid.category()
Category of finite enumerated sets

```

`sage.combinat.sidon_sets.sidon_sets_rec(N, g=1)`

Return the set of all Sidon- g sets that have elements less than or equal to N without checking the arguments. This internal function should not be call directly by user.

5.1.305 Similarity class types of matrices with entries in a finite field

The notion of a matrix conjugacy class type was introduced by J. A. Green in [Green55], in the context of computing the irreducible characters of finite general linear groups. The class types are equivalence classes of similarity classes of square matrices with entries in a finite field which, roughly speaking, have the same qualitative properties.

For example, all similarity classes of the same class type have centralizers of the same cardinality and the same degrees of elementary divisors. Qualitative properties of similarity classes such as semisimplicity and regularity descend to class types.

The most important feature of similarity class types is that, for any n , the number of similarity class types of $n \times n$ matrices is independent of q . This makes it possible to perform many combinatorial calculations treating q as a formal variable.

In order to define similarity class types, recall that similarity classes of $n \times n$ matrices with entries in \mathbf{F}_q correspond to functions

$$c : \text{Irr}\mathbf{F}_{q[t]} \rightarrow \Lambda$$

such that

$$\sum_{f \in \text{Irr}\mathbf{F}_{q[t]}} |c(f)| \deg f = n,$$

where we denote the set of irreducible monic polynomials in $\mathbf{F}_{q[t]}$ by $\text{Irr}\mathbf{F}_{q[t]}$, the set of all partitions by Λ , and the size of $\lambda \in \Lambda$ by $|\lambda|$.

Similarity classes indexed by functions c_1 and c_2 as above are said to be of the same type if there exists a degree-preserving self-bijection σ of $\text{Irr}\mathbf{F}_{q[t]}$ such that $c_2 = c_1 \circ \sigma$. Thus, the type of c remembers only the degrees of the polynomials (and not the polynomials themselves) for which c takes a certain value λ . Replacing each irreducible polynomial of degree d for which c takes a non-trivial value λ by the pair (d, λ) , we obtain a multiset of such pairs. Clearly, c_1 and c_2 have the same type if and only if these multisets are equal. Thus a similarity class type may be viewed as a multiset of pairs of the form (d, λ) .

For 2×2 matrices there are four types:

```

sage: for tau in SimilarityClassTypes(2):
.....:     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]

```

These four types correspond to the regular split semisimple matrices, the non-semisimple matrices, the central matrices and the irreducible matrices respectively.

For any matrix A in a given similarity class type, it is possible to calculate the number elements in the similarity class of A , the dimension of the algebra of matrices in $M_n(A)$ that commute with A , and the cardinality of the subgroup of $GL_n(\mathbf{F}_q)$ that commute with A . For each similarity class type, it is also possible to compute the number of classes of that type (and hence, the total number of matrices of that type). All these calculations treat the cardinality q of the finite field as a formal variable:

```
sage: M = SimilarityClassType([[1, [1]], [1, [1]]])
sage: M.class_card()
q^2 + q
sage: M.centralizer_algebra_dim()
2
sage: M.centralizer_group_card()
q^2 - 2*q + 1
sage: M.number_of_classes()
1/2*q^2 - 1/2*q
sage: M.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

We now describe two applications of similarity class types.

We say that an $n \times n$ matrix has rational canonical form type λ for some partition λ of n if the diagonal blocks in the rational canonical form have sizes given by the parts of λ . Thus the matrices with rational canonical type (n) are the regular ones, while the matrices with rational canonical type (1^n) are the central ones.

Using similarity class types, it becomes easy to get a formula for the number of matrices with a given rational canonical type:

```
sage: def matrices_with_rcf(la):
.....:     return sum([tau.number_of_matrices() for tau in filter(lambda tau:tau.rcf()==la,
↳ SimilarityClassTypes(la.size()))])
sage: matrices_with_rcf(Partition([2,1]))
q^6 + q^5 + q^4 - q^3 - q^2 - q
```

Similarity class types can also be used to calculate the number of simultaneous similarity classes of k -tuples of $n \times n$ matrices with entries in \mathbf{F}_q by using Burnside's lemma:

```
sage: from sage.combinat.similarity_class_type import order_of_general_linear_group,
↳ centralizer_algebra_dim
sage: q = ZZ['q'].gen()
sage: def simultaneous_similarity_classes(n,k):
.....:     return SimilarityClassTypes(n).sum(lambda la: q**(k*centralizer_algebra_
↳ dim(la)), invertible = True)/order_of_general_linear_group(n)
sage: simultaneous_similarity_classes(3, 2)
q^10 + q^8 + 2*q^7 + 2*q^6 + 2*q^5 + q^4
```

Similarity class types can be used to compute the coefficients of generating functions coming from the cycle index type techniques of Kung and Stong (see Morrison [Morrison06]).

They can also be used to compute the number of invariant subspaces for a matrix over a finite field of any given dimension. For this we use the elegant recursive formula of Ramaré [R17] (see also [PR22]).

Along with the results of [PSS13], similarity class types can be used to calculate the number of similarity classes of matrices of order n with entries in a principal ideal local ring of length two with residue field of cardinality q with centralizer of any given cardinality up to $n = 4$. Among these, the classes which are selftranspose can also be counted:

```

sage: from sage.combinat.similarity_class_type import matrix_centralizer_cardinalities_
↪length_two
sage: list(matrix_centralizer_cardinalities_length_two(3))
[(q^6 - 3*q^5 + 3*q^4 - q^3, 1/6*q^6 - 1/2*q^5 + 1/3*q^4),
 (q^6 - 2*q^5 + q^4, q^5 - q^4),
 (q^8 - 3*q^7 + 3*q^6 - q^5, 1/2*q^5 - q^4 + 1/2*q^3),
 (q^8 - 2*q^7 + q^6, q^4 - q^3),
 (q^10 - 2*q^9 + 2*q^7 - q^6, q^4 - q^3),
 (q^8 - q^7 - q^6 + q^5, 1/2*q^5 - q^4 + 1/2*q^3),
 (q^6 - q^5 - q^4 + q^3, 1/2*q^6 - 1/2*q^5),
 (q^6 - q^5, q^4),
 (q^10 - 2*q^9 + q^8, q^3),
 (q^8 - 2*q^7 + q^6, q^4 - q^3),
 (q^8 - q^7, q^3 + q^2),
 (q^12 - 3*q^11 + 3*q^10 - q^9, 1/6*q^4 - 1/2*q^3 + 1/3*q^2),
 (q^12 - 2*q^11 + q^10, q^3 - q^2),
 (q^14 - 2*q^13 + 2*q^11 - q^10, q^3 - q^2),
 (q^12 - q^11 - q^10 + q^9, 1/2*q^4 - 1/2*q^3),
 (q^12 - q^11, q^2),
 (q^14 - 2*q^13 + q^12, q^2),
 (q^18 - q^17 - q^16 + q^14 + q^13 - q^12, q^2),
 (q^12 - q^9, 1/3*q^4 - 1/3*q^2),
 (q^6 - q^3, 1/3*q^6 - 1/3*q^4)]

```

class `sage.combinat.similarity_class_type.PrimarySimilarityClassType`(*parent, deg, par*)
 Bases: `sage.structure.element.Element`

A primary similarity class type is a pair consisting of a partition and a positive integer.

For a partition λ and a positive integer d , the primary similarity class type (d, λ) represents similarity classes of square matrices of order $|\lambda| \cdot d$ with entries in a finite field of order q which correspond to the $\mathbf{F}_{q[t]}$ -module

$$\frac{\mathbf{F}_{q[t]}}{p(t)^{\lambda_1}} \oplus \frac{\mathbf{F}_{q[t]}}{p(t)^{\lambda_2}} \oplus \dots$$

for some irreducible polynomial $p(t)$ of degree d .

centralizer_algebra_dim()

Return the dimension of the algebra of matrices which commute with a matrix of type `self`.

For a partition (d, λ) this dimension is given by $d(\lambda_1 + 3\lambda_2 + 5\lambda_3 + \dots)$.

EXAMPLES:

```

sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.centralizer_algebra_dim()
28

```

centralizer_group_card(*q=None*)

Return the cardinality of the centralizer group of a matrix of type `self` in a field of order q .

INPUT:

- q – an integer or an indeterminate

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(1, [])
sage: PT.centralizer_group_card()
1
sage: PT = PrimarySimilarityClassType(2, [1, 1])
sage: PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2
```

degree()

Return degree of `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.degree()
2
```

invariant_subspace_generating_function(*q=None, t=None*)

Return the invariant subspace generating function of `self`.

INPUT:

- q – (optional) an integer or an indeterminate
- t – (optional) an indeterminate

EXAMPLES:

```
sage: PrimarySimilarityClassType(1, [2, 2]).invariant_subspace_generating_
↪function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

partition()

Return partition corresponding to `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.partition()
[3, 2, 1]
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.size()
12
```

statistic(*func, q=None*)

Return $n_\lambda(q^d)$ where n_λ is the value returned by `func` upon input λ , if `self` is (d, λ) .

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 1])
sage: q = ZZ['q'].gen()
sage: PT.statistic(lambda la:q**la.size(), q = q)
q^8
```

class sage.combinat.similarity_class_type.**PrimarySimilarityClassTypes**(*n*, *min*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

All primary similarity class types of size *n* whose degree is greater than that of *min* or whose degree is that of *min* and whose partition is less than of *min* in lexicographic order.

A primary similarity class type of size *n* is a pair (λ, d) consisting of a partition λ and a positive integer d such that $|\lambda|d = n$.

INPUT:

- *n* – a positive integer
- *min* – a primary matrix type of size *n*

EXAMPLES:

If *min* is not specified, then the class of all primary similarity class types of size *n* is created:

```
sage: PTC = PrimarySimilarityClassTypes(2)
sage: for PT in PTC:
.....:     print(PT)
[1, [2]]
[1, [1, 1]]
[2, [1]]
```

If *min* is specified, then the class consists of only those primary similarity class types whose degree is greater than that of *min* or whose degree is that of *min* and whose partition is less than of *min* in lexicographic order:

```
sage: PTC = PrimarySimilarityClassTypes(2, min = PrimarySimilarityClassType(1, [1, 1]))
sage: for PT in PTC:
.....:     print(PT)
[1, [1, 1]]
[2, [1]]
```

Element

alias of *PrimarySimilarityClassType*

size()

Return size of elements of self.

The size of a primary similarity class type (d, λ) is $d|\lambda|$.

EXAMPLES:

```
sage: PTC = PrimarySimilarityClassTypes(2)
sage: PTC.size()
2
```

class sage.combinat.similarity_class_type.**SimilarityClassType**(*parent*, *tau*)

Bases: sage.combinat.combinat.CombinatorialElement

A similarity class type.

A matrix type is a multiset of primary similarity class types.

INPUT:

- τ – a list of primary similarity class types or a square matrix over a finite field

EXAMPLES:

```
sage: tau1 = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]]); tau1
[[2, [2, 1]], [3, [3, 2, 1]]]

sage: SimilarityClassType(Matrix(GF(2), [[1,1],[0,1]]))
[[1, [2]]]
```

as_partition_dictionary()

Return a dictionary whose keys are the partitions of types occurring in `self` and the value at the key λ is the partition formed by sorting the degrees of primary types with partition λ .

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.as_partition_dictionary()
{[1]: [1, 1]}
```

centralizer_algebra_dim()

Return the dimension of the algebra of matrices which commute with a matrix of type `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_algebra_dim()
2
```

centralizer_group_card($q=None$)

Return the cardinality of the group of matrices in $GL_n(\mathbf{F}_q)$ which commute with a matrix of type `self`.

INPUT:

- q – an integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_group_card()
q^2 - 2*q + 1
```

class_card($q=None$)

Return the number of matrices in each similarity class of type `self`.

INPUT:

- q – an integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1, 1, 1, 1]]])
sage: tau.class_card()
1
```

(continues on next page)

(continued from previous page)

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.class_card()
q^2 + q
```

invariant_subspace_generating_function(*q=None, t=None*)

Return the invariant subspace generating function of `self`.

The invariant subspace generating function is the function is the polynomial

$$\sum_{j \geq 0} a_j(q)t^j,$$

where $a_j(q)$ denotes the number of j -dimensional invariant subspaces of dimension a_j for any matrix with the similarity class type `self` with entries in a field of order q .

EXAMPLES:

```
sage: SimilarityClassType([[1, [2, 2]]]).invariant_subspace_generating_
↪ function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
sage: A = Matrix(GF(2),[(0, 1, 0, 0), (0, 1, 1, 1), (1, 0, 1, 0), (1, 1, 0, 0)])
sage: SimilarityClassType(A).invariant_subspace_generating_function()
t^4 + 1
```

is_regular()

Return True if every primary type in `self` has partition with one part.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1]], [1, [3]]])
sage: tau.is_regular()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [3]]])
sage: tau.is_regular()
False
```

is_semisimple()

Return True if every primary similarity class type in `self` has all parts equal to 1.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [1]]])
sage: tau.is_semisimple()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [2]]])
sage: tau.is_semisimple()
False
```

number_of_classes(*invertible=False, q=None*)

Return the number of similarity classes of matrices of type `self`.

INPUT:

- `invertible` – Boolean; return number of invertible classes if set to `True`
- `q` – An integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_classes()
1/2*q^2 - 1/2*q
```

number_of_matrices(*invertible=False, q=None*)

Return the number of matrices of type `self`.

INPUT:

- `invertible` – A boolean; return the number of invertible matrices if set

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]]])
sage: tau.number_of_matrices()
q
sage: tau.number_of_matrices(invertible = True)
q - 1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

rcf()

Return the partition corresponding to the rational canonical form of a matrix of type `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1, 1, 1]], [1, [3, 2]]])
sage: tau.rcf()
[5, 4, 2]
```

size()

Return the sum of the sizes of the primary parts of `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.size()
24
```

statistic(*func, q=None*)

Return

$$\prod_{(d,\lambda)\in\tau} n_\lambda(q^d)$$

where $n_\lambda(q)$ is the value returned by `func` on the input λ .

INPUT:

- `func` – a function that takes a partition to a polynomial in q
- `q` – an integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [2, 1]], [2, [1, 1]]])
sage: from sage.combinat.similarity_class_type import fq
```

(continues on next page)

(continued from previous page)

```

sage: tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()]))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
sage: q = ZZ['q'].gen()
sage: tau.statistic(lambda la: q**la.size(), q = q)
q^8

```

class sage.combinat.similarity_class_type.SimilarityClassTypes(*n*, *min*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Class of all similarity class types of size *n* with all primary matrix types greater than or equal to the primary matrix type *min*.

A similarity class type is a multiset of primary matrix types.

INPUT:

- *n* – a non-negative integer
- *min* – a primary similarity class type

EXAMPLES:

If *min* is not specified, then the class of all matrix types of size *n* is constructed:

```

sage: M = SimilarityClassTypes(2)
sage: for tau in M:
.....:     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]

```

If *min* is specified, then the class consists of only those similarity class types which are multisets of primary matrix types which either have size greater than that of *min*, or if they have size equal to that of *min*, then they occur after *min* in the iterator for PrimarySimilarityClassTypes(*n*), where *n* is the size of *min*:

```

sage: M = SimilarityClassTypes(2, min = [1, [1, 1]])
sage: for tau in M:
.....:     print(tau)
[[1, [1, 1]]]
[[2, [1]]]

```

Element

alias of *SimilarityClassType*

size()

Return size of *self*.

EXAMPLES:

```

sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.parent().size()
24

```

sum(*stat*, *sumover*='matrices', *invertible*=False, *q*=None)

Return the sum of a local statistic over all types.

Given a set of functions $n_\lambda(q)$ (these could be polynomials or rational functions in q , for each similarity class type τ define

$$n_\tau(q) = \prod_{(d,\lambda) \in \tau} n_\lambda(q^d).$$

This function returns

$$\sum n_{\tau(g)}(q)$$

where $\tau(g)$ denotes the type of a matrix g , and the sum is over all $n \times n$ matrices if `sumover` is set to "matrices", is over all $n \times n$ similarity classes if `sumover` is set to "classes", and over all $n \times n$ types if `sumover` is set to "types". If `invertible` is set to `True`, then the sum is only over invertible matrices or classes.

INPUT:

- `stat` – a function which takes partitions and returns a function of q
- `sumover` – can be one of the following:
 - "matrices"
 - "classes"
 - "types"
- `q` – an integer or an indeterminate

OUTPUT:

A function of q .

EXAMPLES:

```
sage: M = SimilarityClassTypes(2)
sage: M.sum(lambda la:1)
q^4
sage: M.sum(lambda la:1, invertible = True)
q^4 - q^3 - q^2 + q
sage: M.sum(lambda la:1, sumover = "classes")
q^2 + q
sage: M.sum(lambda la:1, sumover = "classes", invertible = True)
q^2 - 1
```

Burside's lemma can be used to calculate the number of similarity classes of matrices:

```
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim, \
order_of_general_linear_group
sage: q = ZZ['q'].gen()
sage: M.sum(lambda la:q**centralizer_algebra_dim(la), invertible = True)/order_
of_general_linear_group(2)
q^2 + q
```

`sage.combinat.similarity_class_type.centralizer_algebra_dim(la)`

Return the dimension of the centralizer algebra in $M_n(\mathbb{F}_q)$ of a nilpotent matrix whose Jordan blocks are given by `la`.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim
sage: centralizer_algebra_dim(Partition([2, 1]))
5
```

Note: If it is a list, `la` is expected to be sorted in decreasing order.

`sage.combinat.similarity_class_type.centralizer_group_cardinality`(*la*, *q=None*)

Return the cardinality of the centralizer group in $GL_n(\mathbb{F}_q)$ of a nilpotent matrix whose Jordan blocks are given by *la*.

INPUT:

- *lambda* – a partition
- *q* – an integer or an indeterminate

OUTPUT:

A polynomial function of *q*.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import centralizer_group_cardinality
sage: q = ZZ['q'].gen()
sage: centralizer_group_cardinality(Partition([2, 1]))
q^5 - 2*q^4 + q^3
```

`sage.combinat.similarity_class_type.dictionary_from_generator`(*gen*)

Given a generator for a list of pairs (c, f) , construct a dictionary whose keys are the distinct values for *c* and whose value at *c* is the sum of *f* over all pairs of the form (c', f) such that $c = c'$.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import dictionary_from_generator
sage: dictionary_from_generator(((x // 2, x) for x in range(10)))
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

It also works with lists:

```
sage: dictionary_from_generator([(x // 2, x) for x in range(10)])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

Note: Since the generator is first converted to a list, memory usage could be high.

`sage.combinat.similarity_class_type.ext_orbit_centralizers`(*input_data*, *q=None*, *selftranspose=False*)

Generate pairs consisting of centralizer cardinalities of orbits in $\text{Ext}^1(M, M)$ for the action of $\text{Aut}(M, M)$, where *M* is the $\mathbb{F}_{q[t]}$ -module constructed from *input* and their frequencies.

INPUT:

- *input_data* – input for `input_parsing()`
- *q* – (default: *q*) an integer or an indeterminate
- *selftranspose* – (default: `False`) boolean stating if we only want selftranspose type

`sage.combinat.similarity_class_type.ext_orbits(input_data, q=None, selftranspose=False)`
 Return the number of orbits in $\text{Ext}^1(M, M)$ for the action of $\text{Aut}(M, M)$, where M is the $\mathbf{F}_{q[t]}$ -module constructed from `input_data`.

INPUT:

- `input_data` – input for `input_parsing()`
- `q` – (default: q) an integer or an indeterminate
- `selftranspose` – (default: `False`) boolean stating if we only want selftranspose type

`sage.combinat.similarity_class_type.fq(n, q=None)`
 Return $(1 - q^{-1})(1 - q^{-2}) \cdots (1 - q^{-n})$.

INPUT:

- `n` – a non-negative integer
- `q` – an integer or an indeterminate

OUTPUT:

A rational function in q .

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import fq
sage: fq(0)
1
sage: fq(3)
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6
```

`sage.combinat.similarity_class_type.input_parsing(data)`
 Recognize and return the intended type of `input`.

`sage.combinat.similarity_class_type.invariant_subspace_generating_function(la, q=None, t=None)`

Return the invariant subspace generating function of a nilpotent matrix with Jordan block sizes given by `la`.

INPUT:

- `la` – a partition
- `q` – (optional) an integer or an indeterminate
- `t` – (optional) an indeterminate

OUTPUT:

A polynomial in t whose coefficients are polynomials in q .

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import invariant_subspace_generating_
↪function
sage: invariant_subspace_generating_function([2,2])
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

`sage.combinat.similarity_class_type.matrix_centralizer_cardinalities(n, q=None, invertible=False)`

Generate pairs consisting of centralizer cardinalities of matrices over a finite field and their frequencies.

```
sage.combinat.similarity_class_type.matrix_centralizer_cardinalities_length_two(n, q=None,
                                                                              selftrans-
                                                                              pose=False,
                                                                              invert-
                                                                              ible=False)
```

Generate pairs consisting of centralizer cardinalities of matrices over a principal ideal local ring of length two with residue field of order q and their frequencies.

INPUT:

- n – the order
- q – (default: q) an integer or an indeterminate
- `selftranspose` – (default: `False`) boolean stating if we only want selftranspose type
- `invertible` – (default: `False`) boolean stating if we only want invertible type

```
sage.combinat.similarity_class_type.matrix_similarity_classes(n, q=None, invertible=False)
Return the number of matrix similarity classes over a finite field of order  $q$ .
```

```
sage.combinat.similarity_class_type.matrix_similarity_classes_length_two(n, q=None,
                                                                           selftranspose=False,
                                                                           invertible=False)
```

Return the number of similarity classes of matrices of order n with entries in a principal ideal local ring of length two.

INPUT:

- n – the order
- q – (default: q) an integer or an indeterminate
- `selftranspose` – (default: `False`) boolean stating if we only want selftranspose type
- `invertible` – (default: `False`) boolean stating if we only want invertible type

EXAMPLES:

We can generate Table 6 of [PSS13]:

```
sage: from sage.combinat.similarity_class_type import matrix_similarity_classes_
      ↪length_two
sage: matrix_similarity_classes_length_two(2)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, invertible = True)
q^4 - q
sage: matrix_similarity_classes_length_two(3)
q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
sage: matrix_similarity_classes_length_two(3, invertible = true)
q^6 - q^3 + 2*q^2 - 2*q
sage: matrix_similarity_classes_length_two(4)
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
sage: matrix_similarity_classes_length_two(4, invertible = True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q
```

And also Table 7:

```
sage: matrix_similarity_classes_length_two(2, selftranspose = True)
q^4 + q^3 + q^2
```

(continues on next page)

(continued from previous page)

```

sage: matrix_similarity_classes_length_two(2, selftranspose = True, invertible =
↳ True)
q^4 - q
sage: matrix_similarity_classes_length_two(3, selftranspose = True)
q^6 + q^5 + 2*q^4 + q^3
sage: matrix_similarity_classes_length_two(3, selftranspose = True, invertible =
↳ True)
q^6 - q^3
sage: matrix_similarity_classes_length_two(4, selftranspose = True)
q^8 + q^7 + 3*q^6 + 3*q^5 + 3*q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(4, selftranspose = True, invertible =
↳ True)
q^8 + q^6 - q^5 - q

```

`sage.combinat.similarity_class_type.order_of_general_linear_group(n, q=None)`

Return the cardinality of the group of $n \times n$ invertible matrices with entries in a field of order q .

INPUT:

- n – a non-negative integer
- q – an integer or an indeterminate

EXAMPLES:

```

sage: from sage.combinat.similarity_class_type import order_of_general_linear_group
sage: order_of_general_linear_group(0)
1
sage: order_of_general_linear_group(2)
q^4 - q^3 - q^2 + q

```

`sage.combinat.similarity_class_type.primitives(n, invertible=False, q=None)`

Return the number of similarity classes of simple matrices of order n with entries in a finite field of order q . This is the same as the number of irreducible polynomials of degree d .

If `invertible` is `True`, then only the number of similarity classes of invertible matrices is returned.

Note: All primitive classes are invertible unless n is 1.

INPUT:

- n – a positive integer
- `invertible` – boolean; if set, only number of non-zero classes is returned
- q – an integer or an indeterminate

OUTPUT:

- a rational function of the variable q

EXAMPLES:

```

sage: from sage.combinat.similarity_class_type import primitives
sage: primitives(1)
q
sage: primitives(1, invertible = True)

```

(continues on next page)

(continued from previous page)

```

q - 1
sage: primitives(4)
1/4*q^4 - 1/4*q^2
sage: primitives(4, invertible = True)
1/4*q^4 - 1/4*q^2

```

5.1.306 sine-Gordon Y-system plotter

This class builds the triangulations associated to sine-Gordon and reduced sine-Gordon Y-systems as constructed in [NS].

AUTHORS:

- Salvatore Stella (2014-07-18): initial version

EXAMPLES:

A reduced sine-Gordon example with 3 generations:

```

sage: Y = SineGordonYsystem('A', (6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.plot()      #not tested

```

The same integer tuple but for the non-reduced case:

```

sage: Y = SineGordonYsystem('D', (6,4,3)); Y
A sine-Gordon Y-system of type D with defining integer tuple (6, 4, 3)
sage: Y.plot()      #not tested

```

Todo: The code for plotting is extremely slow.

REFERENCES:

class sage.combinat.sine_gordon.**SineGordonYsystem**(*X*, *na*)
 Bases: sage.structure.sage_object.SageObject

A class to model a (reduced) sine-Gordon Y-system

Note that the generations, together with all integer tuples, in this implementation are numbered from 0 while in [NS] they are numbered from 1

INPUT:

- *X* – the type of the Y-system to construct (either 'A' or 'D')
- *na* – the tuple of positive integers defining the Y-system with $na[0] > 2$

See [NS]

EXAMPLES:

```

sage: Y = SineGordonYsystem('A', (6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.intervals()
(((0, 0, 'R'),),
 ((0, 17, 'L'),

```

(continues on next page)

(continued from previous page)

```

(17, 34, 'L'),
...
(104, 105, 'R'),
(105, 0, 'R'))))
sage: Y.triangulation()
((17, 89),
(17, 72),
(34, 72),
...
(102, 105),
(103, 105))
sage: Y.plot()      #not tested

```

F()

Return the number of generations in `self`.

EXAMPLES:

```

sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.F()
3

```

intervals()

Return, divided by generation, the list of intervals used to construct the initial triangulation.

Each such interval is a triple (p, q, X) where p and q are the two extremal vertices of the interval and X is the type of the interval (one of 'L', 'R', 'NL', 'NR').

ALGORITHM:

The algorithm used here is the one described in section 5.1 of [NS]. The only difference is that we get rid of the special case of the first generation by treating the whole disk as a type 'R' interval.

EXAMPLES:

```

sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.intervals()
(((0, 0, 'R'),),
((0, 17, 'L'),
(17, 34, 'L'),
...
(104, 105, 'R'),
(105, 0, 'R'))))

```

na()

Return the sequence of the integers n_a defining `self`.

EXAMPLES:

```

sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.na()
(6, 4, 3)

```

pa()

Return the sequence of integers p_a , i.e. the total number of intervals of types 'NL' and 'NR' in the $(a+1)$ -th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.pa()
(1, 6, 25)
```

plot(***kws*)

Plot the initial triangulation associated to *self*.

INPUT:

- *radius* - the radius of the disk; by default the length of the circle is the number of vertices
- *points_color* - the color of the vertices; default 'black'
- *points_size* - the size of the vertices; default 7
- *triangulation_color* - the color of the arcs; default 'black'
- *triangulation_thickness* - the thickness of the arcs; default 0.5
- *shading_color* - the color of the shading used on neuter intervals; default 'lightgray'
- *reflections_color* - the color of the reflection axes; default 'blue'
- *reflections_thickness* - the thickness of the reflection axes; default 1

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.plot() # long time 2s
Graphics object consisting of 219 graphics primitives
```

qa()

Return the sequence of integers q_a , i.e. the total number of intervals of types 'L' and 'R' in the $(a+1)$ -th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.qa()
(6, 25, 81)
```

r()

Return the number of vertices in the polygon realizing *self*.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.r()
106
```

rk()

Return the sequence of integers $r^{\{k\}}$, i.e. the width of an interval of type 'L' or 'R' in the k -th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.rk()
(106, 17, 4)
```

triangulation()

Return the initial triangulation of the polygon realizing `self` as a tuple of pairs of vertices.

Warning: In type 'D' the returned triangulation does NOT contain the two radii.

ALGORITHM:

We implement the four cases described by Figure 14 in [NS].

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.triangulation()
((17, 89),
 (17, 72),
 ...
 (102, 105),
 (103, 105))
```

type()

Return the type of `self`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.type()
'A'
```

vertices()

Return the vertices of the polygon realizing `self` as the ring of integers modulo `self.r()`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3))
sage: Y.vertices()
Ring of integers modulo 106
```

5.1.307 Six Vertex Model

class `sage.combinat.six_vertex_model.SixVertexConfiguration`

Bases: `sage.structure.list_clone.ClonableArray`

A configuration in the six vertex model.

check()

Check if `self` is a valid 6 vertex configuration.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M[0].check()
```

energy(*epsilon*)

Return the energy of the configuration.

The energy of a configuration ν is defined as

$$E(\nu) = n_0\epsilon_0 + n_1\epsilon_1 + \cdots + n_5\epsilon_5$$

where n_i is the number of vertices of type i and ϵ_i is the i -th energy constant.

Note: We number our configurations as:

0. LR
1. LU
2. LD
3. UD
4. UR
5. RD

which differs from [Wikipedia article Ice-type_model](#).

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: nu = M[2]; nu
      ^   ^   ^
      |   |   |
--> # -> # <- # <--
      ^   |   ^
      |   V   |
--> # <- # -> # <--
      |   ^   |
      V   |   V
--> # -> # <- # <--
      |   |   |
      V   V   V
sage: nu.energy([1,2,1,2,1,2])
15
```

A KDP energy:

```
sage: nu.energy([1,1,0,1,0,1])
7
```

A Rys F energy:

```
sage: nu.energy([0,1,1,0,1,1])
4
```

The zero field assumption:

```
sage: nu.energy([1,2,3,1,3,2])
15
```

plot(color='sign')

Return a plot of self.

INPUT:

- color – can be any of the following:
 - 4 - use 4 colors: black, red, blue, and green with each corresponding to up, right, down, and left respectively
 - 2 - use 2 colors: red for horizontal, blue for vertical arrows
 - 'sign' - use red for right and down arrows, blue for left and up arrows
 - a list of 4 colors for each direction
 - a function which takes a direction and a boolean corresponding to the sign

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: print(M[0].plot().description())
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
Arrow from (1.0,1.0) to (1.0,2.0)
Arrow from (2.0,0.0) to (1.0,0.0)
Arrow from (2.0,1.0) to (1.0,1.0)
```

to_signed_matrix()

Return the signed matrix of `self`.

The signed matrix corresponding to a six vertex configuration is given by 0 if there is a cross flow, a 1 if the outward arrows are vertical and -1 if the outward arrows are horizontal.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: [x.to_signed_matrix() for x in M]
[
[1 0 0] [1 0 0] [ 0 1 0] [0 1 0] [0 1 0] [0 0 1] [0 0 1]
[0 1 0] [0 0 1] [ 1 -1 1] [1 0 0] [0 0 1] [1 0 0] [0 1 0]
[0 0 1], [0 1 0], [ 0 1 0], [0 0 1], [1 0 0], [0 1 0], [1 0 0]
]
```

class `sage.combinat.six_vertex_model.SixVertexModel`(*n*, *m*, *boundary_conditions*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The six vertex model.

We model a configuration by indicating which configuration by the following six configurations which are determined by the two outgoing arrows in the Up, Right, Down, Left directions:

1. LR:

v

(continues on next page)

(continued from previous page)

```

<-- # -->
  ^
  |

```

2. LU:

```

  ^
  |
<-- # <--
  ^
  |

```

3. LD:

```

  |
  V
<-- # <--
  |
  V

```

4. UD:

```

  ^
  |
--> # <--
  |
  V

```

5. UR:

```

  ^
  |
--> # -->
  ^
  |

```

6. RD:

```

  |
  V
--> # -->
  |
  V

```

INPUT:

- n – the number of rows
- m – (optional) the number of columns, if not specified, then the number of columns is the number of rows
- `boundary_conditions` – (optional) a quadruple of tuples whose entries are either:
 - True for an inward arrow,
 - False for an outward arrow, or
 - None for no boundary condition.

There are also the following predefined boundary conditions:

- 'ice' - The top and bottom boundary conditions are outward and the left and right boundary conditions are inward; this gives the square ice model. Also called domain wall boundary conditions.
- 'domain wall' - Same as 'ice'.
- 'alternating' - The boundary conditions alternate between inward and outward.
- 'free' - There are no boundary conditions.

EXAMPLES:

Here are the six types of vertices that can be created:

```
sage: M = SixVertexModel(1)
sage: list(M)
[
  |      ^      |      ^      ^      |
  v      |      v      |      |      v
<-- # --> <-- # <-- <-- # <-- --> # <-- --> # --> --> # -->
  ^      ^      |      |      ^      |
  |      ,      |      ,      v      ,      v      ,      |      ,      v
]
```

When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```
sage: M = SixVertexModel(1, boundary_conditions='ice')
sage: len(M)
1
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: len(M)
42
sage: all(len(SixVertexModel(n, boundary_conditions='ice'))
.....:      == AlternatingSignMatrices(n).cardinality() for n in range(1, 7))
True
```

An example with a specified non-standard boundary condition and non-rectangular shape:

```
sage: M = SixVertexModel(2, 1, [[None], [True, True], [None], [None, None]])
sage: list(M)
[
  ^      ^      |      ^
  |      |      v      |
<-- # <-- <-- # <-- <-- # <-- --> # <--
  ^      ^      |      |
  |      |      v      v
<-- # <-- --> # <-- <-- # <-- <-- # <--
  ^      |      |      |
  |      ,      v      ,      v      ,      v
]
```

- [Wikipedia article Vertex_model](#)
- [Wikipedia article Ice-type_model](#)

Element

alias of `SixVertexConfiguration`

boundary_conditions()

Return the boundary conditions of `self`.

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

partition_function(beta, epsilon)

Return the partition function of `self`.

The partition function of a 6 vertex model is defined by:

$$Z = \sum_{\nu} e^{-\beta E(\nu)}$$

where we sum over all configurations and E is the energy function. The constant β is known as the *inverse temperature* and is equal to $1/k_B T$ where k_B is Boltzmann's constant and T is the system's temperature.

INPUT:

- `beta` – the inverse temperature constant β
- `epsilon` – the energy constants, see `energy()`

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M.partition_function(2, [1,2,1,2,1,2])
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```

class `sage.combinat.six_vertex_model.SquareIceModel(n)`

Bases: `sage.combinat.six_vertex_model.SixVertexModel`

The square ice model.

The square ice model is a 6 vertex model on an $n \times n$ grid with the boundary conditions that the top and bottom boundaries are pointing outward and the left and right boundaries are pointing inward. These boundary conditions are also called domain wall boundary conditions.

Configurations of the 6 vertex model with domain wall boundary conditions are in bijection with alternating sign matrices.

class Element

Bases: `sage.combinat.six_vertex_model.SixVertexConfiguration`

An element in the square ice model.

to_alternating_sign_matrix()

Return an alternating sign matrix of `self`.

See also:

`to_signed_matrix()`

EXAMPLES:

```

sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: M[6].to_alternating_sign_matrix()
[1 0 0 0]
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]
sage: M[7].to_alternating_sign_matrix()
[ 0 1 0 0]
[ 1 -1 1 0]
[ 0 1 -1 1]
[ 0 0 1 0]

```

from_alternating_sign_matrix(*asm*)

Return a configuration from the alternating sign matrix *asm*.

EXAMPLES:

```

sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
sage: M.from_alternating_sign_matrix(asm)

  V   V   V

```

5.1.308 Skew Partitions

A skew partition *skp* of size n is a pair of partitions $[p_1, p_2]$ where p_1 is a partition of the integer n_1 , p_2 is a partition of the integer n_2 , p_2 is an inner partition of p_1 , and $n = n_1 - n_2$. We say that p_1 and p_2 are respectively the *inner* and *outer* partitions of *skp*.

A skew partition can be depicted by a diagram made of rows of cells, in the same way as a partition. Only the cells of the outer partition p_1 which are not in the inner partition p_2 appear in the picture. For example, this is the diagram of the skew partition $[[5,4,3,1],[3,3,1]]$.

```

sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).diagram())
**
*
**
*

```

A skew partition can be *connected*, which can easily be described in graphic terms: for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge. This is the diagram of the connected skew partition $[[5,4,3,1],[3,1]]$:

```
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
**
***
***
*
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

The first example of a skew partition is not a connected one.

Applying a reflection with respect to the main diagonal yields the diagram of the *conjugate skew partition*, here $[[4, 3, 3, 2, 1], [3, 3, 2]]$:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).conjugate()
[4, 3, 3, 2, 1] / [3, 2, 2]
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).conjugate().diagram())
*
*
*
**
*
```

The *outer corners* of a skew partition are the corners of its outer partition. The *inner corners* are the internal corners of the outer partition when the inner partition is taken off. Shown below are the coordinates of the inner and outer corners.

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).outer_corners()
[(0, 4), (1, 3), (2, 2), (3, 0)]
sage: SkewPartition([[5,4,3,1],[3,3,1]]).inner_corners()
[(0, 3), (2, 1), (3, 0)]
```

EXAMPLES:

There are 9 skew partitions of size 3, with no empty row nor empty column:

```
sage: SkewPartitions(3).cardinality()
9
sage: SkewPartitions(3).list()
[[3] / [],
 [2, 1] / [],
 [3, 1] / [1],
 [2, 2] / [1],
 [3, 2] / [2],
 [1, 1, 1] / [],
 [2, 2, 1] / [1, 1],
 [2, 1, 1] / [1],
 [3, 2, 1] / [2, 1]]
```

There are 4 connected skew partitions of size 3:

```
sage: SkewPartitions(3, overlap=1).cardinality()
4
sage: SkewPartitions(3, overlap=1).list()
[[3] / [], [2, 1] / [], [2, 2] / [1], [1, 1, 1] / []]
```

This is the conjugate of the skew partition $[[4, 3, 1], [2]]$

```
sage: SkewPartition([[4,3,1], [2]]).conjugate()
[3, 2, 2, 1] / [1, 1]
```

Geometrically, we just applied a reflection with respect to the main diagonal on the diagram of the partition. Of course, this operation is an involution:

```
sage: SkewPartition([[4,3,1],[2]]).conjugate().conjugate()
[4, 3, 1] / [2]
```

The `jacobi_trudi()` method computes the Jacobi-Trudi matrix. See [Mac1995] for a definition and discussion.

```
sage: SkewPartition([[4,3,1],[2]]).jacobi_trudi()
[h[2] h[] 0]
[h[5] h[3] h[]]
[h[6] h[4] h[1]]
```

This example shows how to compute the corners of a skew partition.

```
sage: SkewPartition([[4,3,1],[2]]).inner_corners()
[(0, 2), (1, 0)]
sage: SkewPartition([[4,3,1],[2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

AUTHORS:

- Mike Hansen: Initial version
- Travis Scrimshaw (2013-02-11): Factored out `CombinatorialClass`

class `sage.combinat.skew_partition.SkewPartition`(*parent*, *skp*)
 Bases: `sage.combinat.combinat.CombinatorialElement`

A skew partition.

A skew partition of shape λ/μ is the Young diagram from the partition λ and removing the partition μ from the upper-left corner in English convention.

cell_poset(*orientation='SE'*)

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to "SE"). Concretely, `orientation` has to be specified to one of the strings "NW", "NE", "SW", and "SE", standing for "northwest", "northeast", "southwest" and "southeast", respectively. If `orientation` is "SE", then the order relation of the poset is such that a cell u is greater or equal to a cell v in the poset if and only if u lies weakly southeast of v (this means that u can be reached from v by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of `self`, written as tuples of zero-based coordinates (so that (3, 7) stands for the 8-th cell of the 4-th row, etc.).

EXAMPLES:

```
sage: p = SkewPartition([[3,3,1], [2,1]])
sage: Q = p.cell_poset(); Q
Finite poset containing 4 elements
```

(continues on next page)

(continued from previous page)

```

sage: sorted(Q)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: sorted(Q.minimal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(Q.upper_covers((1, 1)))
[(1, 2)]
sage: sorted(Q.upper_covers((0, 2)))
[(1, 2)]

sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 4 elements
sage: sorted(P)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: sorted(P.maximal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]

sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 4 elements
sage: sorted(R)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: R.upper_covers((2, 0))
[(1, 1)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1]

```

cells()

Return the coordinates of the cells of `self`. Coordinates are given as (row-index, column-index) and are 0 based.

EXAMPLES:

```

sage: SkewPartition([[4, 3, 1], [2]]).cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[4, 3, 1], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[2], []]).cells()
[(0, 0), (0, 1)]

```

column_lengths()

Return the column lengths of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).column_lengths()
[1, 2, 1]
sage: SkewPartition([[5,2,2,2],[2,1]]).column_lengths()
[2, 3, 1, 1, 1]
```

columns_intersection_set()

Return the set of cells in the columns of the outer shape of `self` which columns intersect the skew diagram of `self`.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([(0,0), (0,1), (0,2), (1,0), (1,1), (2,0)])
sage: skp.columns_intersection_set() == cells
True
```

conjugate()

Return the conjugate of the skew partition `skp`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2]]).conjugate()
[3, 2, 1] / [1, 1]
```

diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
**
*
**
*
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
***
***
*
sage: SkewPartitions.options(diagram_str='#', convention="French")
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
#
###
###
##
sage: SkewPartitions.options._reset()
```

ferrers_diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
**
*
```

(continues on next page)

(continued from previous page)

```

**
*
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
**
***
***
*
sage: SkewPartitions.options(diagram_str='#', convention="French")
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
#
###
###
##
sage: SkewPartitions.options._reset()

```

frobenius_rank()

Return the Frobenius rank of the skew partition `self`.

The Frobenius rank of a skew partition λ/μ can be defined in various ways. The quickest one is probably the following: Writing λ as $(\lambda_1, \lambda_2, \dots, \lambda_N)$, and writing μ as $(\mu_1, \mu_2, \dots, \mu_N)$, we define the Frobenius rank of λ/μ to be the number of all $1 \leq i \leq N$ such that

$$\lambda_i - i \notin \{\mu_1 - 1, \mu_2 - 2, \dots, \mu_N - N\}.$$

In other words, the Frobenius rank of λ/μ is the number of rows in the Jacobi-Trudi matrix of λ/μ which don't contain h_0 . Further definitions have been considered in [Sta2002] (where Frobenius rank is just being called rank).

If μ is the empty shape, then the Frobenius rank of λ/μ is just the usual Frobenius rank of the partition λ (see `frobenius_rank()`).

EXAMPLES:

```

sage: SkewPartition([[8,8,7,4], [4,1,1]]).frobenius_rank()
4
sage: SkewPartition([[2,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1,1]]).frobenius_rank()
2
sage: SkewPartition([[5,4,3,2], [2,1,1]]).frobenius_rank()
3
sage: SkewPartition([[4,2,1], [3,1,1]]).frobenius_rank()
2
sage: SkewPartition([[4,2,1], [3,2,1]]).frobenius_rank()
1

```

If the inner shape is empty, then the Frobenius rank of the skew partition is just the standard Frobenius rank of the partition:

```

sage: all( SkewPartition([lam, Partition([])]).frobenius_rank()
.....:    == lam.frobenius_rank() for i in range(6)
.....:    for lam in Partitions(i) )
True

```

If the inner and outer shapes are equal, then the Frobenius rank is zero:

```
sage: all( SkewPartition([lam, lam]).frobenius_rank() == 0
.....:      for i in range(6) for lam in Partitions(i) )
True
```

inner()

Return the inner partition of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).inner()
[1, 1]
```

inner_corners()

Return a list of the inner corners of `self`.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).inner_corners()
[(0, 2), (1, 0)]
sage: SkewPartition([[4, 3, 1], []]).inner_corners()
[(0, 0)]
```

is_connected()

Return True if `self` is a connected skew partition.

A skew partition is said to be *connected* if for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge.

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).is_connected()
False
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

is_overlap(*n*)

Return True if the overlap of `self` is at most *n*.

See also:

[*overlap\(\)*](#)

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,1]]).is_overlap(1)
True
```

is_ribbon()

Return True if and only if `self` is a ribbon.

This means that if it has exactly one cell in each of *q* consecutive diagonals for some nonnegative integer *q*.

EXAMPLES:

```
sage: P = SkewPartition([[4,4,3,3],[3,2,2]])
sage: P.pp()
*
```

(continues on next page)

(continued from previous page)

```

**
*
***
sage: P.is_ribbon()
True

sage: P = SkewPartition([[4,3,3],[1,1]])
sage: P.pp()
***
**
***
sage: P.is_ribbon()
False

sage: P = SkewPartition([[4,4,3,2],[3,2,2]])
sage: P.pp()
*
**
*
**
sage: P.is_ribbon()
False

sage: P = SkewPartition([[4,4,3,3],[4,2,2,1]])
sage: P.pp()

**
*
**
sage: P.is_ribbon()
True

sage: P = SkewPartition([[4,4,3,3],[4,2,2]])
sage: P.pp()

**
*
***
sage: P.is_ribbon()
True

sage: SkewPartition([[2,2,1],[2,2,1])).is_ribbon()
True

```

jacobi_trudi()Return the Jacobi-Trudi matrix of `self`.

EXAMPLES:

```

sage: SkewPartition([[3,2,1],[2,1])).jacobi_trudi()
[h[1]  0  0]
[h[3] h[1]  0]
[h[5] h[3] h[1]]

```

(continues on next page)

(continued from previous page)

```

sage: SkewPartition([[4,3,2],[2,1]]).jacobi_trudi()
[h[2] h[] 0]
[h[4] h[2] h[]]
[h[6] h[4] h[2]]

```

k_conjugate(k)

Return the k -conjugate of the skew partition.

EXAMPLES:

```

sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(3)
[2, 1, 1, 1, 1] / [2, 1]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(4)
[2, 2, 1, 1] / [2, 1]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(5)
[3, 2, 1] / [2, 1]

```

outer()

Return the outer partition of `self`.

EXAMPLES:

```

sage: SkewPartition([[3,2,1],[1,1]]).outer()
[3, 2, 1]

```

outer_corners()

Return a list of the outer corners of `self`.

EXAMPLES:

```

sage: SkewPartition([[4, 3, 1], [2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]

```

overlap()

Return the overlap of `self`.

The overlap of two consecutive rows in a skew partition is the number of pairs of cells (one in each row) that share a common edge. This number can be positive, zero, or negative.

The overlap of a skew partition is the minimum of the overlap of the consecutive rows, or infinity in the case of at most one row. If the overlap is positive, then the skew partition is called *connected*.

EXAMPLES:

```

sage: SkewPartition([], []).overlap()
+Infinity
sage: SkewPartition([[1], []]).overlap()
+Infinity
sage: SkewPartition([[10], []]).overlap()
+Infinity
sage: SkewPartition([[10], [2]]).overlap()
+Infinity
sage: SkewPartition([[10, 1], [2]]).overlap()
-1
sage: SkewPartition([[10, 10], [1]]).overlap()
9

```

per_i_macdonald_coeffs()

Computation of the coefficients which appear in the Pieri formula for Macdonald polynomials given in his book (Chapter 6.6 formula 6.24(ii))

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).per_i_macdonald_coeffs()
1
sage: SkewPartition([[3,2,1],[2,2]]).per_i_macdonald_coeffs()
(q^2*t^3 - q^2*t - t^2 + 1)/(q^2*t^3 - q*t^2 - q*t + 1)
sage: SkewPartition([[3,2,1],[2,2,1]]).per_i_macdonald_coeffs()
(q^6*t^8 - q^6*t^6 - q^4*t^7 - q^5*t^5 + q^4*t^5 - q^3*t^6 + q^5*t^3 + 2*q^3*t^4 + q*t^5 - q^3*t^2 + q^2*t^3 - q*t^3 - q^2*t - t^2 + 1)/(q^6*t^8 - q^5*t^7 - q^5*t^6 - q^4*t^6 + q^3*t^5 + 2*q^3*t^4 + q^3*t^3 - q^2*t^2 - q*t + 1)
sage: SkewPartition([[3,3,2,2],[3,2,2,1]]).per_i_macdonald_coeffs()
(q^5*t^6 - q^5*t^5 + q^4*t^6 - q^4*t^5 - q^4*t^3 + q^4*t^2 - q^3*t^3 - q^2*t^4 + q^3*t^2 + q^2*t^3 - q*t^4 + q*t^3 + q*t - q + t - 1)/(q^5*t^6 - q^4*t^5 - q^3*t^4 - q^3*t^3 + q^2*t^3 + q^2*t^2 + q*t - 1)
```

pp()

Pretty-print self.

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).pp()
**
*
**
*
```

quotient(k)

The quotient map extended to skew partitions.

EXAMPLES:

```
sage: SkewPartition([[3, 3, 2, 1], [2, 1]]).quotient(2)
[[3] / [], [] / []]
```

row_lengths()

Return the row lengths of self.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).row_lengths()
[2, 1, 1]
```

rows_intersection_set()

Return the set of cells in the rows of the outer shape of self which rows intersect the skew diagram of self.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([(0,0), (0,1), (0,2), (1,0), (1,1), (2,0)])
sage: skp.rows_intersection_set() == cells
True
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).size()
4
```

to_dag(*format='string'*)

Return a directed acyclic graph corresponding to the skew partition `self`.

The directed acyclic graph corresponding to a skew partition p is the digraph whose vertices are the cells of p , and whose edges go from each cell to its lower and right neighbors (in English notation).

INPUT:

- `format` – either 'string' or 'tuple' (default: 'string'); determines whether the vertices of the resulting dag will be strings or 2-tuples of coordinates

EXAMPLES:

```
sage: dag = SkewPartition([[3, 3, 1], [1, 1]]).to_dag()
sage: dag.edges(sort=True)
[('0,1', '0,2', None),
 ('0,1', '1,1', None),
 ('0,2', '1,2', None),
 ('1,1', '1,2', None)]
sage: dag.vertices(sort=True)
['0,1', '0,2', '1,1', '1,2', '2,0']
sage: dag = SkewPartition([[3, 2, 1], [1, 1]]).to_dag(format="tuple")
sage: dag.edges(sort=True)
[((0, 1), (0, 2), None), ((0, 1), (1, 1), None)]
sage: dag.vertices(sort=True)
[(0, 1), (0, 2), (1, 1), (2, 0)]
```

to_list()

Return `self` as a list of lists.

EXAMPLES:

```
sage: s = SkewPartition([[4,3,1],[2]])
sage: s.to_list()
[[4, 3, 1], [2]]
sage: type(s.to_list())
<class 'list'>
```

class `sage.combinat.skew_partition.SkewPartitions`(*is_infinite=False*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Skew partitions.

Warning: The iterator of this class only yields skew partitions which are reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column.

EXAMPLES:

```

sage: SkewPartitions(4)
Skew partitions of 4
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(row_lengths=[2,1,2])
Skew partitions with row lengths [2, 1, 2]
sage: SkewPartitions(4, overlap=2)
Skew partitions of 4 with a minimum overlap of 2
sage: SkewPartitions(4, overlap=2).list()
[[4] / [], [2, 2] / []]

```

Element

alias of *SkewPartition*

from_row_and_column_length(rowL, colL)

Construct a partition from its row lengths and column lengths.

INPUT:

- rowL – A composition or a list of positive integers
- colL – A composition or a list of positive integers

OUTPUT:

- If it exists the unique skew-partitions with row lengths rowL and column lengths colL.
- Raise a ValueError if rowL and colL are not compatible.

EXAMPLES:

```

sage: S = SkewPartitions()
sage: print(S.from_row_and_column_length([3,1,2,2],[2,3,1,1,1]).diagram())
***
*
**
**
sage: S.from_row_and_column_length([],[])
[] / []
sage: S.from_row_and_column_length([1],[1])
[1] / []
sage: S.from_row_and_column_length([2,1],[2,1])
[2, 1] / []
sage: S.from_row_and_column_length([1,2],[1,2])
[2, 2] / [1]
sage: S.from_row_and_column_length([1,2],[1,3])
Traceback (most recent call last):
...
ValueError: Sum mismatch : [1, 2] and [1, 3]
sage: S.from_row_and_column_length([3,2,1,2],[2,3,1,1,1])
Traceback (most recent call last):
...
ValueError: Incompatible row and column length : [3, 2, 1, 2] and [2, 3, 1, 1,
↪1]

```

Warning: If some rows and columns have length zero, there is no way to retrieve unambiguously the skew partition. We therefore raise a `ValueError`. For examples here are two skew partitions with the same row and column lengths:

```
sage: skp1 = SkewPartition([[2,2],[2,2]])
sage: skp2 = SkewPartition([[2,1],[2,1]])
sage: skp1.row_lengths(), skp1.column_lengths()
([0, 0], [0, 0])
sage: skp2.row_lengths(), skp2.column_lengths()
([0, 0], [0, 0])
sage: SkewPartitions().from_row_and_column_length([0,0], [0,0])
Traceback (most recent call last):
...
ValueError: row and column length must be positive
```

options(*get_value, **set_value)

Sets and displays the options for elements of the skew partition classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to skew partitions can be accessed as the method `SkewPartitions.options` of `SkewPartitions` and related parent classes.

OPTIONS:

- **convention** – (default: `English`) Sets the convention used for displaying tableaux and partitions
 - `English` – use the English convention
 - `French` – use the French convention
- **diagram_str** – (default: `*`) The character used for the cells when printing Ferrers diagrams
- **display** – (default: `quotient`) Specifies how skew partitions should be printed
 - `array` – alias for `diagram`
 - `diagram` – as a skew Ferrers diagram
 - `ferrers_diagram` – alias for `diagram`
 - `lists` – displayed as a pair of lists
 - `pair` – alias for `lists`
 - `quotient` – displayed as a quotient of partitions
 - `young_diagram` – alias for `diagram`
- **latex** – (default: `young_diagram`) Specifies how skew partitions should be latexed
 - `array` – alias for `diagram`
 - `diagram` – latex as a skew Ferrers diagram
 - `ferrers_diagram` – alias for `diagram`
 - `marked` – latex as a partition where the skew shape is marked
 - `young_diagram` – latex as a skew Young diagram
- **latex_diagram_str** – (default: `\ast`) The character used for the cells when latexing Ferrers diagrams

- `latex_marking_str` – (default: X) The character used to marked the deleted cells when latexing marked partitions
- `notation` – alternative name for convention

EXAMPLES:

```
sage: SP = SkewPartition([[4,2,2,1], [3, 1, 1]])
sage: SP
[4, 2, 2, 1] / [3, 1, 1]
sage: SkewPartitions.options.display="lists"
sage: SP
[[4, 2, 2, 1], [3, 1, 1]]
```

Changing the convention for skew partitions also changes the convention option for partitions and tableaux and vice versa:

```
sage: SkewPartitions.options(display="diagram", convention='French')
sage: SP
*
*
*
*
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
 4 5
 1 2 3
sage: P = Partition([4, 2, 2, 1])
sage: P.pp()
*
**
**
****
sage: Tableaux.options.convention="english"
sage: SP
*
*
*
sage: T.pp()
 1 2 3
 4 5
sage: SkewPartitions.options._reset()
```

See [GlobalOptions](#) for more features of these options.

```
class sage.combinat.skew_partition.SkewPartitions_all
    Bases: sage.combinat.skew_partition.SkewPartitions
```

Class of all skew partitions.

```
class sage.combinat.skew_partition.SkewPartitions_n(n, overlap)
    Bases: sage.combinat.skew_partition.SkewPartitions
```

The set of skew partitions of n with overlap at least `overlap` and no empty row.

INPUT:

- n – a non-negative integer
- `overlap` – an integer (default: 0)

Caveat: this set is stable under conjugation only for `overlap` equal to 0 or 1. What exactly happens for negative overlaps is not yet well specified and subject to change (we may want to introduce vertical overlap constraints as well).

Todo: As is, this set is essentially the composition of `Compositions(n)` (which give the row lengths) and `SkewPartition(n, row_lengths=...)`, and one would want to “inherit” list and cardinality from this composition.

`cardinality()`

Return the number of skew partitions of the integer n (with given `overlap`, if specified; and with no empty rows before the last row).

EXAMPLES:

```
sage: SkewPartitions(0).cardinality()
1
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(5).cardinality()
87
sage: SkewPartitions(4, overlap=1).cardinality()
9
sage: SkewPartitions(5, overlap=1).cardinality()
20
sage: s = SkewPartitions(5, overlap=-1)
sage: s.cardinality() == len(s.list())
True
```

class `sage.combinat.skew_partition.SkewPartitions_rowlengths(co, overlap)`

Bases: `sage.combinat.skew_partition.SkewPartitions`

All skew partitions with given row lengths.

`sage.combinat.skew_partition.row_lengths_aux(skp)`

EXAMPLES:

```
sage: from sage.combinat.skew_partition import row_lengths_aux
sage: row_lengths_aux([[5,4,3,1],[3,3,1]])
[2, 1, 2]
sage: row_lengths_aux([[5,4,3,1],[3,1]])
[2, 3]
```

5.1.309 Skew Tableaux

AUTHORS:

- Mike Hansen: Initial version
- Travis Scrimshaw, Arthur Lubovsky (2013-02-11): Factored out `CombinatorialClass`

class `sage.combinat.skew_tableau.SemistandardSkewTableaux`(*category=None*)

Bases: `sage.combinat.skew_tableau.SkewTableaux`

Semistandard skew tableaux.

This class can be initialized with several optional variables: the size of the skew tableaux (as a nameless integer variable), their shape (as a nameless skew partition variable), their weight (`weight()`), as a nameless second variable after either the size or the shape) and their maximum entry (as an optional keyword variable called `max_entry`, unless the weight has been specified). If neither the weight nor the maximum entry is specified, the maximum entry defaults to the size of the tableau.

Note that “maximum entry” does not literally mean the highest entry; instead it is just an upper bound that no entry is allowed to surpass.

EXAMPLES:

The (infinite) class of all semistandard skew tableaux:

```
sage: SemistandardSkewTableaux()
Semistandard skew tableaux
```

The (still infinite) class of all semistandard skew tableaux with maximum entry 2:

```
sage: SemistandardSkewTableaux(max_entry=2)
Semistandard skew tableaux with maximum entry 2
```

The class of all semistandard skew tableaux of given size 3 and maximum entry 3:

```
sage: SemistandardSkewTableaux(3)
Semistandard skew tableaux of size 3 and maximum entry 3
```

To set a different maximum entry:

```
sage: SemistandardSkewTableaux(3, max_entry = 7)
Semistandard skew tableaux of size 3 and maximum entry 7
```

Specifying a shape:

```
sage: SemistandardSkewTableaux([[2,1],[1]])
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
```

Specifying both a shape and a maximum entry:

```
sage: S = SemistandardSkewTableaux([[2,1],[1]], max_entry = 3); S
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
sage: S.list()
[[[None, 1], [1]],
 [[None, 2], [1]],
 [[None, 1], [2]],
 [[None, 3], [1]],
```

(continues on next page)

(continued from previous page)

```

[[None, 1], [3]],
[[None, 2], [2]],
[[None, 3], [2]],
[[None, 2], [3]],
[[None, 3], [3]]

sage: for n in range(5):
.....:     print("{} {}".format(n, len(SemistandardSkewTableaux([[2,2,1],[1]], max_
→entry = n))))
0 0
1 0
2 1
3 9
4 35

```

Specifying a shape and a weight:

```

sage: SemistandardSkewTableaux([[2,1],[1]],[2,1])
Semistandard skew tableaux of shape [2, 1] / [1] and weight [2, 1]

```

(the maximum entry is redundant in this case and thus is ignored).

Specifying a size and a weight:

```

sage: SemistandardSkewTableaux(3, [2,1])
Semistandard skew tableaux of size 3 and weight [2, 1]

```

Warning: If the shape is not specified, the iterator of this class yields only skew tableaux whose shape is reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column. (Otherwise it would go on indefinitely.)

Warning: This class acts as a factory. The resulting classes are mainly useful for iteration. Do not rely on their containment tests, as they are not correct, e. g.:

```

sage: SkewTableau([[None]]) in SemistandardSkewTableaux(2)
True

```

class `sage.combinat.skew_tableau.SemistandardSkewTableaux_all`(*max_entry*)

Bases: `sage.combinat.skew_tableau.SemistandardSkewTableaux`

Class of all semistandard skew tableaux, possibly with a given maximum entry.

class `sage.combinat.skew_tableau.SemistandardSkewTableaux_shape`(*p*, *max_entry*)

Bases: `sage.combinat.skew_tableau.SemistandardSkewTableaux`

Class of semistandard skew tableaux of a fixed skew shape λ/μ with a given max entry.

A semistandard skew tableau with max entry i is required to have all its entries less or equal to i . It is not required to actually contain an entry i .

INPUT:

- p – A skew partition

- `max_entry` – The max entry; defaults to the size of `p`.

Warning: Input is not checked; please use `SemistandardSkewTableaux` to ensure the options are properly parsed.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux([[2,1],[ ]]).cardinality()
8
sage: SemistandardSkewTableaux([[2,1],[ ]], max_entry=2).cardinality()
2
```

class `sage.combinat.skew_tableau.SemistandardSkewTableaux_shape_weight`(*p, mu*)

Bases: `sage.combinat.skew_tableau.SemistandardSkewTableaux`

Class of semistandard skew tableaux of a fixed skew shape λ/ν and weight μ .

class `sage.combinat.skew_tableau.SemistandardSkewTableaux_size`(*n, max_entry*)

Bases: `sage.combinat.skew_tableau.SemistandardSkewTableaux`

Class of all semistandard skew tableaux of a fixed size *n*, possibly with a given maximum entry.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2).cardinality()
8
```

class `sage.combinat.skew_tableau.SemistandardSkewTableaux_size_weight`(*n, mu*)

Bases: `sage.combinat.skew_tableau.SemistandardSkewTableaux`

Class of semistandard tableaux of a fixed size *n* and weight μ .

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2, [1,1]).cardinality()
4
```

class `sage.combinat.skew_tableau.SkewTableau`(*parent, st*)

Bases: `sage.structure.list_clone.ClonableList`

A skew tableau.

Note that Sage by default uses the English convention for partitions and tableaux. To change this, see `Tableaux.options()`.

EXAMPLES:

```
sage: st = SkewTableau([[None, 1],[2,3]]); st
[[None, 1], [2, 3]]
sage: st.inner_shape()
[1]
sage: st.outer_shape()
[2, 2]
```

The `expr` form of a skew tableau consists of the inner partition followed by a list of the entries in each row from bottom to top:

```
sage: SkewTableau(expr=[[1, 1], [[5], [3, 4], [1, 2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

The `chain` form of a skew tableau consists of a list of partitions $\lambda_1, \lambda_2, \dots$, such that all cells in λ_{i+1} that are not in λ_i have entry i :

```
sage: SkewTableau(chain=[[2], [2, 1], [3, 1], [4, 3, 2, 1]])
[[None, None, 2, 3], [1, 3, 3], [3, 3], [3]]
```

bender_knuth_involution(k , $rows=None$, $check=True$)

Return the image of `self` under the k -th Bender–Knuth involution, assuming `self` is a skew semistandard tableau.

Let T be a tableau, then a *lower free k in T* means a cell of T which is filled with the integer k and whose direct lower neighbor is not filled with the integer $k + 1$ (in particular, this lower neighbor might not exist at all). Let an *upper free $k + 1$ in T* mean a cell of T which is filled with the integer $k + 1$ and whose direct upper neighbor is not filled with the integer k (in particular, this neighbor might not exist at all). It is clear that for any row r of T , the lower free k 's and the upper free $k + 1$'s in r together form a contiguous interval or r .

The k -th Bender–Knuth switch at row i changes the entries of the cells in this interval in such a way that if it used to have a entries of k and b entries of $k + 1$, it will now have b entries of k and a entries of $k + 1$. For fixed k , the k -th Bender–Knuth switches for different i commute. The composition of the k -th Bender–Knuth switches for all rows is called the k -th Bender–Knuth involution. This is used to show that the Schur functions defined by semistandard (skew) tableaux are symmetric functions.

INPUT:

- k – an integer
- $rows$ – (Default `None`) When set to `None`, the method computes the k -th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the k -th Bender–Knuth switches at row i over all i in $rows$. When set to an integer i , the method computes the k -th Bender–Knuth switch at row i . Note the indexing of the rows starts with 1.
- $check$ – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check.

OUTPUT:

The image of `self` under either the k -th Bender–Knuth involution, the k -th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```
sage: t = SkewTableau([[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
.....:                [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]])
sage: t
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(1)
[[None, None, None, 4, 4, 5, 6, 7], [None, 1, 4, 6, 7, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(4)
[[None, None, None, 4, 5, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [5]]
```

(continues on next page)

(continued from previous page)

```

sage: t.bender_knuth_involution(5)
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 5, 7, 7, 7],
 [None, 4, 6, 8, 8, 9], [None, 5, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(6)
[[None, None, None, 4, 4, 5, 6, 6], [None, 2, 4, 6, 6, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]

```

The Bender–Knuth involution is an involution:

```

sage: t = SkewTableau([[None, 3, 4, 4], [None, 6, 10], [7, 7, 11], [18]])
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k)
.....:      == t for k in range(1, 4))
True

```

The same for the single switches:

```

sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j)
.....:      == t for k in range(1, 5) for j in range(1, 5))
True

```

Locality of the Bender–Knuth involutions:

```

sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l)
.....:      == t.bender_knuth_involution(l).bender_knuth_involution(k)
.....:      for k in range(1, 5) for l in range(1, 5) if abs(k - l) > 1)
True

```

AUTHORS:

- Darij Grinberg (2013-05-14)

cells()

Return the cells in `self`.

EXAMPLES:

```

sage: s = SkewTableau([[None, 1, 2], [3], [6]])
sage: s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]

```

cells_by_content(c)

Return the coordinates of the cells in `self` with content `c`.

EXAMPLES:

```

sage: s = SkewTableau([[None, 1, 2], [3, 4, 5], [6]])
sage: s.cells_by_content(0)
[(1, 1)]

```

(continues on next page)

(continued from previous page)

```

sage: s.cells_by_content(1)
[(0, 1), (1, 2)]
sage: s.cells_by_content(2)
[(0, 2)]
sage: s.cells_by_content(-1)
[(1, 0)]
sage: s.cells_by_content(-2)
[(2, 0)]

```

cells_containing(*i*)

Return the list of cells in which the letter *i* appears in the tableau `self`. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates (a, b) , where both rows and columns are counted from 0 (so $a = 0$ means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```

sage: t = SkewTableau([[None, None, 3], [None, 3, 5], [4, 5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(2)
[]

sage: t = SkewTableau([[None, None, None, None], [None, 4, 5], [None, 5, 6], [None, 9],
↪ [None]])
sage: t.cells_containing(2)
[]
sage: t.cells_containing(4)
[(1, 1)]
sage: t.cells_containing(5)
[(2, 1), (1, 2)]

sage: SkewTableau([]).cells_containing(3)
[]

sage: SkewTableau([[None, None], [None]]).cells_containing(3)
[]

```

check()

Check that `self` is a valid skew tableau. This is currently far too liberal, and only checks some trivial things.

EXAMPLES:

```

sage: t = SkewTableau([[None, 1, 1], [2]])
sage: t.check()

sage: t = SkewTableau([[None, None, 1], [2, 4], [], [3, 4, 5]])
Traceback (most recent call last):
...
TypeError: a skew tableau cannot have an empty list for a row

```

(continues on next page)

(continued from previous page)

```
sage: s = SkewTableau([[1, None, None],[2, None],[3]])
Traceback (most recent call last):
...
TypeError: not a valid skew tableau
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 1],[2, 3]]).conjugate()
[[None, 2], [1, 3]]
```

entries_by_content(*c*)

Return the entries in `self` with content `c`.

EXAMPLES:

```
sage: s = SkewTableau([[None, 1, 2],[3, 4, 5],[6]])
sage: s.entries_by_content(0)
[4]
sage: s.entries_by_content(1)
[1, 5]
sage: s.entries_by_content(2)
[2]
sage: s.entries_by_content(-1)
[3]
sage: s.entries_by_content(-2)
[6]
```

evaluation()

Return the weight (aka evaluation) of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau T is the sequence (a_1, a_2, a_3, \dots) , where a_k is the number of entries of T equal to k . This sequence contains only finitely many nonzero entries.

The weight of a skew tableau T is the same as the weight of the reading word of T , for any reading order.

`evaluation()` is a synonym for this method.

EXAMPLES:

```
sage: SkewTableau([[1, 2],[3, 4]]).weight()
[1, 1, 1, 1]

sage: SkewTableau([[None, 2],[None, 4],[None, 5],[None]]).weight()
[0, 1, 0, 1, 1]

sage: SkewTableau([]).weight()
[]

sage: SkewTableau([[None, None, None],[None]]).weight()
[]
```

(continues on next page)

(continued from previous page)

```
sage: SkewTableau([[None, 3, 4], [None, 6, 7], [4, 8], [5, 13], [6], [7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

filling()

Return a list of the non-empty entries in `self`.

EXAMPLES:

```
sage: t = SkewTableau([[None, 1], [2, 3]])
sage: t.filling()
[[1], [2, 3]]
```

inner_shape()

Return the inner shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 1, 2], [None, 3], [4]]).inner_shape()
[1, 1]
sage: SkewTableau([[1, 2], [3, 4], [7]]).inner_shape()
[]
sage: SkewTableau([[None, None, None, 2, 3], [None, 1], [None], [2]]).inner_shape()
[3, 1, 1]
```

inner_size()

Return the size of the inner shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).inner_size()
2
sage: SkewTableau([[None, 2], [1, 3]]).inner_size()
1
```

is_k_tableau(*k*)

Checks whether `self` is a valid skew weak *k*-tableau.

EXAMPLES:

```
sage: t = SkewTableau([[None, 2, 3], [2, 3], [3]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 3], [2, 2], [3]])
sage: t.is_k_tableau(3)
False
```

is_ribbon()

Return True if and only if the shape of `self` is a ribbon, that is, if it has exactly one cell in each of *q* consecutive diagonals for some nonnegative integer *q*.

EXAMPLES:

```
sage: S = SkewTableau([[None, None, 1, 2], [None, None, 3], [1, 3, 4]])
sage: S.pp()
```

(continues on next page)

(continued from previous page)

```

. . 1 2
. . 3
1 3 4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, 1, 1, 2],[None, 2, 3],[1, 3, 4]])
sage: S.pp()
. 1 1 2
. 2 3
1 3 4
sage: S.is_ribbon()
False

sage: S = SkewTableau([[None, None, 1, 2],[None, None, 3],[1]])
sage: S.pp()
. . 1 2
. . 3
1
sage: S.is_ribbon()
False

sage: S = SkewTableau([[None, None, None, None],[None, None, 3],[1, 2, 4]])
sage: S.pp()
. . . .
. . 3
1 2 4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, None, None, None],[None, None, 3],[None, 2, 4]])
sage: S.pp()
. . . .
. . 3
. 2 4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, None],[None]])
sage: S.pp()
. .
.
sage: S.is_ribbon()
True

```

is_semistandard()

Return True if self is a semistandard skew tableau and False otherwise.

EXAMPLES:

```

sage: SkewTableau([[None, 2, 2], [1, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [2, 4])).is_semistandard()

```

(continues on next page)

(continued from previous page)

```

True
sage: SkewTableau([[None, 3], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 3, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [1, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2, 3], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [None, None, 4]]).is_semistandard()
False

```

is_standard()

Return True if self is a standard skew tableau and False otherwise.

EXAMPLES:

```

sage: SkewTableau([[None, 2], [1, 3]]).is_standard()
True
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 3], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False

```

outer_shape()

Return the outer shape of self.

EXAMPLES:

```

sage: SkewTableau([[None, 1, 2], [None, 3], [4]]).outer_shape()
[3, 2, 1]

```

outer_size()

Return the size of the outer shape of self.

EXAMPLES:

```

sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).outer_size()
6
sage: SkewTableau([[None, 2], [1, 3]]).outer_size()
4

```

pp()

Return a pretty print string of the tableau.

EXAMPLES:

```

sage: SkewTableau([[None, 2, 3], [None, 4], [5]]).pp()
. 2 3

```

(continues on next page)

(continued from previous page)

```
. 4
5
```

rectify(*algorithm=None*)

Return a *StandardTableau*, *SemistandardTableau*, or just *Tableau* formed by applying the jeu de taquin process to *self*.

See page 15 of [Ful1997].

INPUT:

- *algorithm* – optional: if set to 'jdt', rectifies by jeu de taquin; if set to 'schensted', rectifies by Schensted insertion of the reading word; otherwise, guesses which will be faster.

EXAMPLES:

```
sage: S = SkewTableau([[None, 1], [2, 3]])
sage: S.rectify()
[[1, 3], [2]]
sage: T = SkewTableau([[None, None, None, 4], [None, None, 1, 6], [None, None, 5], [2,
↔3]])
sage: T.rectify()
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='jdt')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='schensted')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='spaghetti')
Traceback (most recent call last):
...
ValueError: algorithm must be 'jdt', 'schensted', or None
```

restrict(*n*)

Return the restriction of the (semi)standard skew tableau to all the numbers less than or equal to *n*.

Note: If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method *restriction_outer_shape()* is preferred. Similarly if only the skew shape is needed, use *restriction_shape()*.

EXAMPLES:

```
sage: SkewTableau([[None, 1], [2], [3]]).restrict(2)
[[None, 1], [2]]
sage: SkewTableau([[None, 1], [2], [3]]).restrict(1)
[[None, 1]]
sage: SkewTableau([[None, 1], [1], [2]]).restrict(1)
[[None, 1], [1]]
```

restriction_outer_shape(*n*)

Return the outer shape of the restriction of the semistandard skew tableau *self* to *n*.

If *T* is a semistandard skew tableau and *n* is a nonnegative integer, then the restriction of *T* to *n* is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than *n* from *T*.

This method computes merely the outer shape of the restriction. For the restriction itself, use *restrict()*.

EXAMPLES:

```

sage: SkewTableau([[None, None], [2, 3], [3, 4]]).restriction_outer_shape(3)
[2, 2, 1]
sage: SkewTableau([[None, 2], [None], [4], [5]]).restriction_outer_shape(2)
[2, 1]
sage: T = SkewTableau([[None, None, 3, 5], [None, 4, 4], [17]])
sage: T.restriction_outer_shape(0)
[2, 1]
sage: T.restriction_outer_shape(2)
[2, 1]
sage: T.restriction_outer_shape(3)
[3, 1]
sage: T.restriction_outer_shape(4)
[3, 3]
sage: T.restriction_outer_shape(19)
[4, 3, 1]

```

restriction_shape(*n*)

Return the skew shape of the restriction of the semistandard skew tableau *self* to *n*.

If *T* is a semistandard skew tableau and *n* is a nonnegative integer, then the restriction of *T* to *n* is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than *n* from *T*.

This method computes merely the skew shape of the restriction. For the restriction itself, use *restrict()*.

EXAMPLES:

```

sage: SkewTableau([[None, None], [2, 3], [3, 4]]).restriction_shape(3)
[2, 2, 1] / [2]
sage: SkewTableau([[None, 2], [None], [4], [5]]).restriction_shape(2)
[2, 1] / [1, 1]
sage: T = SkewTableau([[None, None, 3, 5], [None, 4, 4], [17]])
sage: T.restriction_shape(0)
[2, 1] / [2, 1]
sage: T.restriction_shape(2)
[2, 1] / [2, 1]
sage: T.restriction_shape(3)
[3, 1] / [2, 1]
sage: T.restriction_shape(4)
[3, 3] / [2, 1]

```

shape()

Return the shape of *self*.

EXAMPLES:

```

sage: SkewTableau([[None, 1, 2], [None, 3], [4]]).shape()
[3, 2, 1] / [1, 1]

```

shuffle(*t2*)

Shuffle the standard tableaux *self* and *t2*.

Let *t1* = *self*. The shape of *t2* must extend the shape of *t1*, that is, *self*.outer_shape() == *t2*.inner_shape(). Then this function computes the pair of tableaux (*t2_new*, *t1_new*) obtained by using jeu de taquin slides to move the boxes of *t2* behind the boxes of *self*.

The entries of `t2_new` are obtained by performing successive inwards jeu de taquin slides on `t2` in the order indicated by the entries of `t1`, from largest to smallest. The entries of `t1` then slide outwards one by one and land in the squares vacated successively by `t2`, forming `t1_new`.

Note: Equivalently, the entries of `t1_new` are obtained by performing outer jeu de taquin slides on `t1` in the order indicated by the entries of `t2`, from smallest to largest. In this case the entries of `t2` slide backwards and fill the squares successively vacated by `t1` and so form `t2_new`. (This is not how the algorithm is implemented.)

INPUT:

- `self, t2` – a pair of standard `SkewTableaux` with `self.outer_shape() == t2.inner_shape()`

OUTPUT:

- `t2_new, t1_new` – a pair of standard `SkewTableaux` with `t2_new.outer_shape() == t1_new.inner_shape()`

EXAMPLES:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: (t2_new, t1_new) = t1.shuffle(t2)
sage: t1_new
[[None, None, None, 2], [None, None, 1], [None, 3, 4]]
sage: t2_new
[[None, 2, 3], [1, 4], [5]]
sage: t1_new.outer_shape() == t2.outer_shape()
True
sage: t2_new.inner_shape() == t1.inner_shape()
True
```

Shuffling is an involution:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: sh = lambda x,y : x.shuffle(y)
sage: (t1, t2) == sh(*sh(t1, t2))
True
```

Both tableaux must be standard:

```
sage: t1 = SkewTableau([[None, 1, 2], [2, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 6]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
```

The shapes (not just the nonempty cells) must be adjacent:

```

sage: t1 = SkewTableau([[None, None, None], [1]])
sage: t2 = SkewTableau([[None], [None], [1]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the shapes must be adjacent

```

size()

Return the number of cells in `self`.

EXAMPLES:

```

sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).size()
4
sage: SkewTableau([[None, 2], [1, 3]]).size()
3

```

slide(*corner=None, return_vacated=False*)

Apply a jeu de taquin slide to `self` on the specified inner corner and return the resulting tableau.

If no corner is given, the topmost inner corner is chosen.

The optional parameter `return_vacated=True` causes the output to be the pair $(t, (i, j))$ where t is the new tableau and (i, j) are the coordinates of the vacated square.

See [Ful1997] p12-13.

EXAMPLES:

```

sage: st = SkewTableau([[None, None, None, None, 2], [None, None, None, None, ↵
↵6], [None, 2, 4, 4], [2, 3, 6], [5, 5]])
sage: st.slide((2, 0))
[[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3, 5, ↵
↵6], [5]]
sage: st2 = SkewTableau([[None, None, 3], [None, 2, 4], [1, 5]])
sage: st2.slide((1, 0), True)
([[None, None, 3], [1, 2, 4], [5]], (2, 1))

```

standardization(*check=True*)

Return the standardization of `self`, assuming `self` is a semistandard skew tableau.

The standardization of a semistandard skew tableau T is the standard skew tableau $st(T)$ of the same shape as T whose reversed reading word is the standardization of the reversed reading word of T .

The standardization of a word w can be formed by replacing all 1's in w by $1, 2, \dots, k_1$ from left to right, all 2's in w by $k_1 + 1, k_1 + 2, \dots, k_2$, and repeating for all letters that appear in w . See also `Word.standard_permutation()`.

INPUT:

- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check.

EXAMPLES:

```

sage: t = SkewTableau([[None, None, 3, 4, 7, 19], [None, 4, 4, 8], [None, 5, 16, 17], [None], ↵
↵[2], [3]])
sage: t.standardization()
[[None, None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1], ↵
↵[2]]

```

Standard skew tableaux are fixed under standardization:

```
sage: p = Partition([4,3,3,2])
sage: q = Partitions(3).random_element()
sage: all((t == t.standardization() for t in StandardSkewTableaux([p, q]))
True
```

The reading word of the standardization is the standardization of the reading word:

```
sage: t = SkewTableau([[None,3,4,4],[None,6,10],[7,7,11],[18]])
sage: t.to_word().standard_permutation() == t.standardization().to_permutation()
True
```

`to_chain(max_entry=None)`

Return the chain of partitions corresponding to the (semi)standard skew tableau `self`.

The optional keyword parameter `max_entry` can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer `n`, then the chain is constructed from the positions of the letters `1, 2, ..., n` in the tableau.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=2)
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=3)
[[1], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=1)
[[1], [2, 1]]
sage: SkewTableau([[None,None,2],[None,3],[None,5]]).to_chain(max_entry=6)
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
sage: SkewTableau([]).to_chain()
[]
sage: SkewTableau([]).to_chain(max_entry=1)
[], []
```

`to_expr()`

The first list in a result corresponds to the inner partition of the skew shape. The second list is a list of the rows in the skew tableau read from the bottom up.

Provided for compatibility with MuPAD-Combinat. In MuPAD-Combinat, if `t` is a skew tableau, then `to_expr` gives the same result as `expr(t)` would give in MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableau([[None,1,1,3],[None,2,2],[1]]).to_expr()
[[1, 1], [[1], [2, 2], [1, 1, 3]]]
sage: SkewTableau([]).to_expr()
[], []
```

`to_list()`

Return a (mutable) list representation of `self`.

EXAMPLES:

```

sage: stlist = [[None, None, 3], [None, 1, 3], [2, 2]]
sage: st = SkewTableau(stlist)
sage: st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]
sage: st.to_list() == stlist
True

```

to_permutation()

Return a permutation with the entries of `self` obtained by reading `self` row by row, from the bottommost to the topmost row, with each row being read from left to right, in English convention. See [to_word_by_row\(\)](#).

EXAMPLES:

```

sage: SkewTableau([[None, 2], [3, 4], [None], [1]]).to_permutation()
[1, 3, 4, 2]
sage: SkewTableau([[None, 2], [None, 4], [1], [3]]).to_permutation()
[3, 1, 4, 2]
sage: SkewTableau([[None]]).to_permutation()
[]

```

to_ribbon(*check_input=True*)

Return `self` as a ribbon-shaped tableau (*RibbonShapedTableau*), provided that the shape of `self` is a ribbon.

INPUT:

- `check_input` – (default: `True`) whether or not to check that `self` indeed has ribbon shape

EXAMPLES:

```

sage: SkewTableau([[None, 1], [2, 3]]).to_ribbon()
[[None, 1], [2, 3]]

```

to_tableau()

Returns a tableau with the same filling. This only works if the inner shape of the skew tableau has size zero.

EXAMPLES:

```

sage: SkewTableau([[1, 2], [3, 4]]).to_tableau()
[[1, 2], [3, 4]]

```

to_word()

Return a word obtained from a row reading of `self`.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

```

sage: s = SkewTableau([[None, 1], [2, 3]])
sage: s.pp()
. 1
2 3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])

```

(continues on next page)

(continued from previous page)

```

sage: s.pp()
.  2  4
.  3
1
sage: s.to_word_by_row()
word: 1324

```

to_word_by_column()

Return the word obtained from a column reading of the skew tableau.

This is the word obtained by concatenating the columns from the rightmost one (in English notation) to the leftmost one.

EXAMPLES:

```

sage: s = SkewTableau([[None, 1], [2, 3]])
sage: s.pp()
.  1
2  3
sage: s.to_word_by_column()
word: 132

```

```

sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
.  2  4
.  3
1
sage: s.to_word_by_column()
word: 4231

```

to_word_by_row()

Return a word obtained from a row reading of self.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

```

sage: s = SkewTableau([[None, 1], [2, 3]])
sage: s.pp()
.  1
2  3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
.  2  4
.  3
1
sage: s.to_word_by_row()
word: 1324

```

weight()

Return the weight (aka evaluation) of the tableau self. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau T is the sequence (a_1, a_2, a_3, \dots) , where a_k is the number of entries of T equal to k . This sequence contains only finitely many nonzero entries.

The weight of a skew tableau T is the same as the weight of the reading word of T , for any reading order.

`evaluation()` is a synonym for this method.

EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]) .weight()
[1, 1, 1, 1]

sage: SkewTableau([[None,2],[None,4],[None,5],[None]]) .weight()
[0, 1, 0, 1, 1]

sage: SkewTableau([]) .weight()
[]

sage: SkewTableau([[None,None,None],[None]]) .weight()
[]

sage: SkewTableau([[None,3,4],[None,6,7],[4,8],[5,13],[6],[7]]) .weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

class `sage.combinat.skew_tableau.SkewTableau_class`(*parent, st*)

Bases: `sage.combinat.skew_tableau.SkewTableau`

This exists solely for unpickling `SkewTableau_class` objects.

class `sage.combinat.skew_tableau.SkewTableaux`(*category=None*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Class of all skew tableaux.

Element

alias of `SkewTableau`

from_chain(*chain*)

Return the tableau corresponding to the chain of partitions.

EXAMPLES:

```
sage: SkewTableaux().from_chain([[1,1],[2,1],[3,1],[3,2],[3,3],[3,3,1]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_expr(*expr*)

Return a `SkewTableau` from a MuPAD-Combinat expr for a skew tableau.

The first list in *expr* is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableaux().from_expr([[1,1],[[5],[3,4],[1,2]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_shape_and_word(*shape*, *word*)

Return the skew tableau corresponding to the skew partition *shape* and the word *word* obtained from the row reading.

EXAMPLES:

```
sage: t = SkewTableau([[None, 1, 3], [None, 2], [4]])
sage: shape = t.shape()
sage: word = t.to_word()
sage: SkewTableaux().from_shape_and_word(shape, word)
[[None, 1, 3], [None, 2], [4]]
```

options(**get_value*, ***set_value*)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- **ascii_art** – (default: repr) Controls the ascii art output for tableaux
 - compact – minimal length ascii art
 - repr – display using the diagram string representation
 - table – display as a table
- **convention** – (default: English) Sets the convention used for displaying tableaux and partitions
 - English – use the English convention
 - French – use the French convention
- **display** – (default: list) Controls the way in which tableaux are printed
 - array – alias for diagram
 - compact – minimal length string representation
 - diagram – display as Young diagram (similar to *pp()*)
 - ferrers_diagram – alias for diagram
 - list – print tableaux as lists
 - young_diagram – alias for diagram
- **latex** – (default: diagram) Controls the way in which tableaux are latexed
 - array – alias for diagram
 - diagram – as a Young diagram
 - ferrers_diagram – alias for diagram
 - list – as a list
 - young_diagram – alias for diagram
- **notation** – alternative name for convention

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```

sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
  1 2 3
  4 5
sage: Tableaux.options.convention="french"
sage: T
  4 5
  1 2 3

```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```

sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
*
sage: T
  1 2 3
  4 5

```

The ASCII art can also be changed:

```

sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1 2 3
  4 5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+---+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
sage: Tableaux.options._reset()

```

See [GlobalOptions](#) for more features of these options.

```
class sage.combinat.skew_tableau.StandardSkewTableaux(category=None)
```

Bases: [sage.combinat.skew_tableau.SkewTableaux](#)

Standard skew tableaux.

EXAMPLES:

```
sage: S = StandardSkewTableaux(); S
Standard skew tableaux
sage: S.cardinality()
+Infinity
```

```
sage: S = StandardSkewTableaux(2); S
Standard skew tableaux of size 2
sage: S.cardinality()
4
```

```
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).list()
[[[None, 2, 3], [None, 4], [1]],
 [[None, 1, 2], [None, 3], [4]],
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 2, 4], [None, 3], [1]]]
```

class `sage.combinat.skew_tableau.StandardSkewTableaux_all`

Bases: `sage.combinat.skew_tableau.StandardSkewTableaux`

Class of all standard skew tableaux.

class `sage.combinat.skew_tableau.StandardSkewTableaux_shape(skp)`

Bases: `sage.combinat.skew_tableau.StandardSkewTableaux`

Standard skew tableaux of a fixed skew shape λ/μ .

cardinality()

Return the number of standard skew tableaux with shape of the skew partition *skp*. This uses a formula due to Aitken (see Cor. 7.16.3 of [Sta-EC2]).

EXAMPLES:

```
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).cardinality()
8
```

class `sage.combinat.skew_tableau.StandardSkewTableaux_size(n)`

Bases: `sage.combinat.skew_tableau.StandardSkewTableaux`

Standard skew tableaux of a fixed size *n*.

cardinality()

EXAMPLES:

```
sage: StandardSkewTableaux(1).cardinality()
1
sage: StandardSkewTableaux(2).cardinality()
4
sage: StandardSkewTableaux(3).cardinality()
24
sage: StandardSkewTableaux(4).cardinality()
194
```

5.1.310 Functions that compute some of the sequences in Sloane's tables

EXAMPLES:

Type `sloane.[tab]` to see a list of the sequences that are defined.

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a(1)
1
sage: a(6)
4
sage: a(100)
9
```

Type `d._eval??` to see how the function that computes an individual term of the sequence is implemented.

The input must be a positive integer:

```
sage: a(0)
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
sage: a(1/3)
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

You can also change how a sequence prints:

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a.rename('(...', tau(n), ...)')
sage: a
(..., tau(n), ...)
sage: a.reset_name()
sage: a
The integer sequence tau(n), which is the number of divisors of n.
```

See also:

- If you want to get more informations relative to a sequence (references, links, examples, programs, ...), you can use the On-Line Encyclopedia of Integer Sequences provided by the [OEIS](#) module.
- If you plan to do a lot of automatic searches for subsequences, you should consider installing [SloaneEncyclopedia](#), a local partial copy of the OEIS.

AUTHOR:

- J. Gaski (2009-05-29)

class `sage.combinat.sloane_functions.A000009`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

Number of partitions of n into odd parts.

INPUT:

- n – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```
sage: a = sloane.A000009;a
Number of partitions of n into odd parts.
sage: a(0)
1
sage: a(1)
1
sage: a(13)
18
sage: a.list(14)
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

AUTHOR:

- Jaap Spies (2007-01-30)

cf()

EXAMPLES:

```
sage: it = sloane.A000009.cf()
sage: [next(it) for i in range(14)]
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

`list(n)`

EXAMPLES:

```
sage: sloane.A000009.list(14)
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

class `sage.combinat.sloane_functions.A000010`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

The integer sequence A000010 is Euler's totient function.

Number of positive integers $i < n$ that are relative prime to n . Number of totatives of n .

Euler totient function $\phi(n)$: count numbers n and prime to n . `euler_phi` is a standard Sage function implemented in PARI

INPUT:

- `n` – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```
sage: a = sloane.A000010; a
Euler's totient function
sage: a(1)
1
sage: a(0)
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
sage: a(11)
10
sage: a.list(12)
[1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, 4]
sage: a(1/3)
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

AUTHORS:

- Jaap Spies (2007-01-12)

class `sage.combinat.sloane_functions.A000012`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

The all 1's sequence.

INPUT:

- `n` – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```

sage: a = sloane.A000012; a
The all 1's sequence.
sage: a(1)
1
sage: a(2007)
1
sage: a.list(12)
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]

```

AUTHORS:

- Jaap Spies (2007-01-12)

class sage.combinat.sloane_functions.A000015

Bases: *sage.combinat.sloane_functions.SloaneSequence*

Smallest prime power $\geq n$ (where 1 is considered a prime power).

INPUT:

- *n* – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```

sage: a = sloane.A000015; a
Smallest prime power >= n.
sage: a(1)
1
sage: a(8)
8
sage: a(307)
307
sage: a(-4)

```

AUTHORS:

- Jaap Spies (2007-01-18)

class sage.combinat.sloane_functions.A000027

Bases: [sage.combinat.sloane_functions.SloaneSequence](#)

The natural numbers. Also called the whole numbers, the counting numbers or the positive integers.

The following examples are tests of SloaneSequence more than A000027.

EXAMPLES:

```
sage: s = sloane.A000027; s
The natural numbers.
sage: s(10)
10
```

Index n is interpreted as `_eval(n)`:

```
sage: s[10]
10
```

Slices are interpreted with absolute offsets, so the following returns the terms of the sequence up to but not including the third term:

```
sage: s[:3]
[1, 2]
sage: s[3:6]
[3, 4, 5]
sage: s.list(5)
[1, 2, 3, 4, 5]
```

class sage.combinat.sloane_functions.A000030

Bases: [sage.combinat.sloane_functions.SloaneSequence](#)

Initial digit of n .

INPUT:

- `n` – non negative integer

OUTPUT:

- `integer` – function value

EXAMPLES:

```
sage: a = sloane.A000030; a
Initial digit of n
sage: a(0)
0
sage: a(1)
1

class sage.combinat.sloane_functions.**A000587**

Bases: *sage.combinat.sloane_functions.ExponentialNumbers*

The sequence of Uppuluri-Carpenter numbers.

The Uppuluri-Carpenter number C_n counts the imbalance in the number of ways to put n distinguishable things into an even number of indistinguishable boxes versus into an odd number of indistinguishable boxes, such that no box is empty.

Let $S(n, k)$ denote the Stirling number of the second kind. Then

$$C_n = \sum_k 0^n (-1)^k S(n, k).$$

INPUT:

- n – non negative integer

OUTPUT:

- integer – C_n

EXAMPLES:

```
sage: a = sloane.A000587; a

class sage.combinat.sloane_functions.A001836

Bases: [sage.combinat.sloane_functions.SloaneSequence](#)

Numbers n such that $\phi(2n - 1) < \phi(2n)$, where ϕ is Euler's totient function.

Euler's totient function is also known as `euler_phi`, `euler_phi` is a standard Sage function.

INPUT:

- n – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```
sage: a = sloane.A001836; a
Numbers n such that phi(2n-1) < phi(2n), where phi is Euler's totient function.
↪A000010.

```

class sage.combinat.sloane_functions.A008277

Bases: [sage.combinat.sloane_functions.SloaneSequence](#)

Triangle of Stirling numbers of 2nd kind, $S_2(n, k)$, $n \geq 1$, $1 \leq k \leq n$.

INPUT:

- `n` – non negative integer

OUTPUT:

- `integer` – function value

EXAMPLES:

```
sage: a = sloane.A008277;a
Triangle of Stirling numbers of 2nd kind, S2(n,k), n >= 1, 1<=k<=n.
sage: a(0)
Traceback (most recent call last):

Bases: [sage.combinat.sloane_functions.RecurrenceSequence2](#)

Second-order linear recurrence sequence with $a(n) = a(n-1) + a(n-2)$.

$a(0) = 62638280004239857$, $a(1) = 49463435743205655$. This is the second-order linear recurrence sequence with $a(0)$ and $a(1)$ co-prime. It was found by Donald Knuth in 1990.

INPUT:

- n – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```
sage: a = sloane.A083105; a
Second-order linear recurrence sequence with  $a(n) = a(n-1) + a(n-2)$ .

AUTHORS:

- Jaap Spies (2007-01-23)

class sage.combinat.sloane_functions.A109814

Bases: *sage.combinat.sloane_functions.SloaneSequence*

The n th term of the sequence $a(n)$ is the largest k such that n can be written as sum of k consecutive integers.

By definition, n is the sum of at most $a(n)$ consecutive positive integers. Suppose n is to be written as sum of k consecutive integers starting with m , then $2n = k(2m + k - 1)$. Only one of the factors is odd. For each odd divisor d of n there is a unique corresponding $k = \min(d, 2n/d)$. $a(n)$ can be alternatively defined as the largest among those k .

See also:

- [Wikipedia article Polite_number](#)

sage: it = sloane.A000153.gen(0,1,2)
sage: [next(it) for i in range(5)]
[0, 1, 2, 7, 32]
```

`list(n)`

EXAMPLES:

```
sage: sloane.A000153.list(8)
[0, 1, 2, 7, 32, 181, 1214, 9403]
```

`class sage.combinat.sloane_functions.ExtremesOfPermanentsSequence2(offset=1)`

Bases: `sage.combinat.sloane_functions.ExtremesOfPermanentsSequence`

`gen(a0, a1, d)`

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
sage: e = ExtremesOfPermanentsSequence2()
sage: it = e.gen(6,43,6)
sage: [next(it) for i in range(5)]
[6, 43, 307, 2542, 23799]
```

`class sage.combinat.sloane_functions.RecurrenceSequence(offset=1)`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

`list(n)`

EXAMPLES:

```
sage: sloane.A001110.list(8)
[0, 1, 36, 1225, 41616, 1413721, 48024900, 1631432881]
```

`class sage.combinat.sloane_functions.RecurrenceSequence2(offset=1)`

Bases: `sage.combinat.sloane_functions.SloaneSequence`

`list(n)`

EXAMPLES:

```
sage: sloane.A001906.list(10)
[0, 1, 3, 8, 21, 55, 144, 377, 987, 2584]
```

`class sage.combinat.sloane_functions.Sloane`

Bases: `sage.structure.sage_object.SageObject`

A collection of Sloane generating functions.

This class inspects `sage.combinat.sloane_functions`, accumulating all the `SloaneSequence` classes starting with 'A'. These are listed for tab completion, but not instantiated until requested.

EXAMPLES:

Ensure we have lots of entries:

```
sage: len(sloane.__dir__()) > 100
True
```

Ensure none are being incorrectly returned:

```
sage: [ None for n in sloane.__dir__() if not n.startswith('A') ]
[]
```

Ensure we can access dynamic constructions and cache correctly:

```
sage: s = sloane.A000587
sage: s is sloane.A000587
True
```

Ensure that we can access other functions in parent classes:

```
sage: sloane.__class__
<class 'sage.combinat.sloane_functions.Sloane'>
```

AUTHORS:

- Nick Alexander

class `sage.combinat.sloane_functions.SloaneSequence`(*offset=1*)

Bases: `sage.structure.sage_object.SageObject`

Base class for a Sloane integer sequence.

list(*n*)

Return *n* terms of the sequence:

```
sequence[offset], sequence[offset+1], ..., sequence[offset+n-1].
```

EXAMPLES:

```
sage: sloane.A000012.list(4)
[1, 1, 1, 1]
```

`sage.combinat.sloane_functions.perm_mh`(*m, h*)

This function calculates $f(g, h)$ from Sloane's sequences A079908-A079928

INPUT:

- *m* – positive integer
- *h* – non negative integer

OUTPUT: permanent of the $m \times (m + h)$ matrix, etc.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import perm_mh
sage: perm_mh(3,3)
36
sage: perm_mh(3,4)
76
```

AUTHORS:

- Jaap Spies (2006)

`sage.combinat.sloane_functions.recur_gen2`(*a0, a1, a2, a3*)

homogeneous general second-order linear recurrence generator with fixed coefficients

$a(0) = a_0, a(1) = a_1, a(n) = a_2 * a(n-1) + a_3 * a(n-2)$

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen2
sage: it = recur_gen2(1,1,1,1)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

`sage.combinat.sloane_functions.recur_gen2b(a0, a1, a2, a3, b)`
Inhomogeneous second-order linear recurrence generator with fixed coefficients and $b = f(n)$
 $a(0) = a0, a(1) = a1, a(n) = a2 * a(n - 1) + a3 * a(n - 2) + f(n)$.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen2b
sage: it = recur_gen2b(1,1,1,1, lambda n: 0)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

`sage.combinat.sloane_functions.recur_gen3(a0, a1, a2, a3, a4, a5)`
homogeneous general third-order linear recurrence generator with fixed coefficients
 $a(0) = a0, a(1) = a1, a(2) = a2, a(n) = a3*a(n-1) + a4*a(n-2) + a5*a(n-3)$

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen3
sage: it = recur_gen3(1,1,1,1,1,1)
sage: [next(it) for i in range(10)]
[1, 1, 1, 3, 5, 9, 17, 31, 57, 105]
```

5.1.311 Combinatorial species

Todo: Short blurb about species

Todo: Proofread / point to the main classes rather than the modules?

Introductory material

- *Enumeration of trees using generating functions*
- *Species, decomposable combinatorial classes*

Lazy Power Series

- *Streams or Infinite Arrays*
- *Series Order*
- *Lazy Power Series*
- *Generating Series*

Basic Species

- *Combinatorial Species*
- *Empty Species*
- *Recursive Species*
- *Characteristic Species*
- *Cycle Species*
- *Partition Species*
- *Permutation species*
- *Linear-order Species*
- *Set Species*
- *Subset Species*
- *Examples of Combinatorial Species*

Operations on Species

- *Sum species*
- *Product species*
- *Composition species*
- *Functorial composition species*

Miscellaneous

- *Species structures*
- *Miscellaneous Functions*

5.1.312 Characteristic Species

```
class sage.combinat.species.characteristic_species.CharacteristicSpecies(n, min=None,
                                                                    max=None,
                                                                    weight=None)
    Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.
            unique_representation.UniqueRepresentation
    Return the characteristic species of order  $n$ .
```

This species has exactly one structure on a set of size n and no structures on sets of any other size.

EXAMPLES:

```
sage: X = species.CharacteristicSpecies(1)
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, p[1], 0, 0]

sage: F = species.CharacteristicSpecies(3)
sage: c = F.generating_series().coefficients(4)
sage: F._check()
True
sage: F == loads(dumps(F))
True
```

```
class sage.combinat.species.characteristic_species.CharacteristicSpeciesStructure(parent,
                                                                                   labels,
                                                                                   list)
```

Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed. For the characteristic species, there is only one structure, so every permutation is in its automorphism group.

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()
Symmetric group of order 3! as a permutation group
```

canonical_label()

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}
```

transport(*perm*)

Returns the transport of this structure along the permutation *perm*.

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
```

(continues on next page)

(continued from previous page)

```
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'a', 'b', 'c'}
```

sage.combinat.species.characteristic_species.**CharacteristicSpecies_class**
alias of [sage.combinat.species.characteristic_species.CharacteristicSpecies](#)

class sage.combinat.species.characteristic_species.**EmptySetSpecies**(*min=None, max=None, weight=None*)

Bases: [sage.combinat.species.characteristic_species.CharacteristicSpecies](#)

Returns the empty set species.

This species has exactly one structure on the empty set. It is the same (and is implemented) as `CharacteristicSpecies(0)`.

EXAMPLES:

```
sage: X = species.EmptySetSpecies()
sage: X.structures([]).list()
[{}]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[1, 0, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[1, 0, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[p[], 0, 0, 0]
```

sage.combinat.species.characteristic_species.**EmptySetSpecies_class**
alias of [sage.combinat.species.characteristic_species.EmptySetSpecies](#)

class sage.combinat.species.characteristic_species.**SingletonSpecies**(*min=None, max=None, weight=None*)

Bases: [sage.combinat.species.characteristic_species.CharacteristicSpecies](#)

Returns the species of singletons.

This species has exactly one structure on a set of size 1. It is the same (and is implemented) as `CharacteristicSpecies(1)`.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[0, 1, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, p[1], 0, 0]
```

`sage.combinat.species.characteristic_species.SingletonSpecies_class`
 alias of `sage.combinat.species.characteristic_species.SingletonSpecies`

5.1.313 Composition species

class `sage.combinat.species.composition_species.CompositionSpecies`(*F, G, min=None, max=None, weight=None*)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the composition of two species.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: C = species.CycleSpecies()
sage: S = E(C)
sage: S.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
sage: E(C) is S
True
```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: L.weight_ring()
Rational Field
```

class `sage.combinat.species.composition_species.CompositionSpeciesStructure`(*parent, labels, pi, f, gs*)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- *labels*, a list of labels.

OUTPUT:

A structure with the *i*-th label of self replaced with the *i*-th label of the list.

EXAMPLES:

```
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a', 'b', 'c']).list()
sage: a = S[2]; a
F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
sage: a.change_labels([1, 2, 3])
F-structure: {{1, 3}, {2}}; G-structures: [(1, 3), (2)]
```

transport(*perm*)

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a','b','c']).list()
sage: a = S[2]; a
F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
sage: a.transport(p)
F-structure: {{'a', 'b'}, {'c'}}; G-structures: (('a', 'c'), ('b'))
```

sage.combinat.species.composition_species.**CompositionSpecies_class**
alias of [sage.combinat.species.composition_species.CompositionSpecies](#)

5.1.314 Cycle Species

class sage.combinat.species.cycle_species.**CycleSpecies**(*min=None, max=None, weight=None*)
Bases: [sage.combinat.species.species.GenericCombinatorialSpecies](#), [sage.structure.unique_representation.UniqueRepresentation](#)

Returns the species of cycles.

EXAMPLES:

```
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.structures([1,2,3,4]).list()
[(1, 2, 3, 4),
 (1, 2, 4, 3),
 (1, 3, 2, 4),
 (1, 3, 4, 2),
 (1, 4, 2, 3),
 (1, 4, 3, 2)]
```

class sage.combinat.species.cycle_species.**CycleSpeciesStructure**(*parent, labels, list*)
Bases: [sage.combinat.species.structure.GenericSpeciesStructure](#)

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: a = P.structures([1, 2, 3, 4])[0]; a
(1, 2, 3, 4)
sage: a.automorphism_group()
Permutation Group with generators [(1,2,3,4)]
```

```
sage: [a.transport(perm) for perm in a.automorphism_group()]
[(1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4)]
```

canonical_label()

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: P.structures(["a", "b", "c"]).random_element().canonical_label()
('a', 'b', 'c')
```

permutation_group_element()

Returns this cycle as a permutation group element.

EXAMPLES:

```
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
('a', 'b', 'c')
sage: a.permutation_group_element()
(1,2,3)
```

transport(*perm*)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
('a', 'b', 'c')
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
('a', 'c', 'b')
```

`sage.combinat.species.cycle_species.CycleSpecies_class`

alias of `sage.combinat.species.cycle_species.CycleSpecies`

5.1.315 Empty Species

class `sage.combinat.species.empty_species.EmptySpecies`(*min=None, max=None, weight=None*)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the empty species. This species has no structure at all. It is the zero of the semi-ring of species.

EXAMPLES:

```
sage: X = species.EmptySpecies(); X
Empty species
sage: X.structures([]).list()
[]
sage: X.structures([1]).list()
[]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series().coefficients(4)
[0, 0, 0, 0]
sage: X.isotype_generating_series().coefficients(4)
[0, 0, 0, 0]
sage: X.cycle_index_series().coefficients(4)
[0, 0, 0, 0]
```

The empty species is the zero of the semi-ring of species. The following tests that it is neutral with respect to addition:

```
sage: Empt = species.EmptySpecies()
sage: S = species.CharacteristicSpecies(2)
sage: X = S + Empt
sage: X == S      # TODO: Not Implemented
True
sage: (X.generating_series().coefficients(4) ==
.....: S.generating_series().coefficients(4))
True
sage: (X.isotype_generating_series().coefficients(4) ==
.....: S.isotype_generating_series().coefficients(4))
True
sage: (X.cycle_index_series().coefficients(4) ==
.....: S.cycle_index_series().coefficients(4))
True
```

The following tests that it is the zero element with respect to multiplication:

```
sage: Y = Empt*S
sage: Y == Empt  # TODO: Not Implemented
True
sage: Y.generating_series().coefficients(4)
[0, 0, 0, 0]
sage: Y.isotype_generating_series().coefficients(4)
[0, 0, 0, 0]
sage: Y.cycle_index_series().coefficients(4)
[0, 0, 0, 0]
```

```
sage.combinat.species.empty_species.EmptySpecies_class
alias of sage.combinat.species.empty_species.EmptySpecies
```

5.1.316 Functorial composition species

```
class sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies(F,
                                                                                       G,
                                                                                       min=None,
                                                                                       max=None,
                                                                                       weight=None)
```

Bases: *sage.combinat.species.species.GenericCombinatorialSpecies*

Returns the functorial composition of two species.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E2 = species.SetSpecies(size=2)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
sage: G.isotype_generating_series().coefficients(5)
[1, 1, 2, 4, 11]
```

(continues on next page)

(continued from previous page)

```

sage: G = species.SimpleGraphSpecies()
sage: c = G.generating_series().coefficients(2)
sage: type(G)
<class 'sage.combinat.species.functorial_composition_species.
↳FunctorialCompositionSpecies'>
sage: G == loads(dumps(G))
True
sage: G._check() #False due to isomorphism types not being implemented
False

```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```

sage: G = species.SimpleGraphSpecies()
sage: G.weight_ring()
Rational Field

```

sage.combinat.species.functorial_composition_species.**FunctorialCompositionSpecies_class**
 alias of *sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies*

class sage.combinat.species.functorial_composition_species.**FunctorialCompositionStructure**(parent, labels, list)

Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

5.1.317 Generating Series

This file makes a number of extensions to lazy power series by endowing them with some semantic content for how they're to be interpreted.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse10.html>. One notable difference is that we use power-sum symmetric functions as the coefficients of our cycle index series.

REFERENCES:

class sage.combinat.species.generating_series.**CycleIndexSeries**(A, stream=None, order=None, aorder=None, aorder_changed=True, is_initialized=False, name=None)

Bases: *sage.combinat.species.series.LazyPowerSeries*

arithmetic_product(g, check_input=True)

Return the arithmetic product of self with g.

For species M and N such that $M[\text{varnothing}] = N[\text{varnothing}] =$

varnothing, their arithmetic product is the species $M \boxtimes N$ of “ M -assemblies of cloned N -structures”. This operation is defined and several examples are given in [MM].

The cycle index series for M

$\boxtimes N$ can be computed in terms of the component series Z_M and Z_N , as implemented in this method.

INPUT:

- **g** – a cycle index series having the same parent as **self**.
- **check_input** – (default: True) a Boolean which, when set to False, will cause input checks to be skipped.

OUTPUT:

The arithmetic product of **self** with **g**. This is a cycle index series defined in terms of **self** and **g** such that if **self** and **g** are the cycle index series of two species M and N , their arithmetic product is the cycle index series of the species $M \boxtimes N$.

$\boxtimes N$.

EXAMPLES:

For C the species of (oriented) cycles and L_+ the species of nonempty linear orders, $C \boxtimes L_+$

corresponds to the species of “regular octopuses”; a $C \boxtimes L_+$ -structure is a cycle of some length, each of whose elements is an ordered list of a length which is consistent for all the lists in the structure.

```
sage: C = species.CycleSpecies().cycle_index_series()
sage: Lplus = species.LinearOrderSpecies(min=1).cycle_index_series()
sage: RegularOctopuses = C.arithmetic_product(Lplus)
sage: RegOctSpeciesSeq = RegularOctopuses.generating_series().counts(8)
sage: RegOctSpeciesSeq
[0, 1, 3, 8, 42, 144, 1440, 5760]
```

It is shown in [MM] that the exponential generating function for regular octopuses satisfies $(C \boxtimes L_+)(x) =$

$$\sum_{n \geq 1} \sigma(n)(n-1)! \frac{x^n}{n!}$$

(where $\sigma(n)$ is the sum of the divisors of n).

```
sage: RegOctDirectSeq = [0] + [sum(divisors(i))*factorial(i-1) for i in range(1, 8)]
sage: RegOctDirectSeq == RegOctSpeciesSeq
True
```

AUTHORS:

- Andrew Gainer-Dewar (2013)

REFERENCES:

coefficient_cycle_type(*t*)

Returns the coefficient of a cycle type **t** in **self**.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
```

(continues on next page)

(continued from previous page)

```

sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]), 3*p([2,1])])
sage: f.coefficient_cycle_type([1])
1
sage: f.coefficient_cycle_type([1,1])
2
sage: f.coefficient_cycle_type([2,1])
3

```

compositional_inverse()

Return the compositional inverse of `self` if possible.

(Specifically, if `self` is of the form $0 + p_1 + \dots$)

The compositional inverse is the inverse with respect to plethystic substitution. This is the operation on cycle index series which corresponds to substitution, a.k.a. partitional composition, on the level of species. See Section 2.2 of [BLL] for a definition of this operation.

EXAMPLES:

```

sage: Eplus = species.SetSpecies(min=1).cycle_index_series()
sage: Eplus(Eplus.compositional_inverse()).coefficients(8)
[0, p[1], 0, 0, 0, 0, 0, 0]

```

ALGORITHM:

Let F be a species satisfying $F = 0 + X + F_2 + F_3 + \dots$ for X the species of singletons. (Equivalently, $|F[\emptyset]| = 0$ and $|F[\{1\}]| = 1$.) Then there exists a (virtual) species G satisfying $F \circ G = G \circ F = X$.

It follows that $(F - X) \circ G = F \circ G - X \circ G = X - G$. Rearranging, we obtain the recursive equation $G = X - (F - X) \circ G$, which can be solved using iterative methods.

Warning: This algorithm is functional but can be very slow. Use with caution!

See also:

The compositional inverse Ω of the species E_+ of nonempty sets can be handled much more efficiently using specialized methods. See [LogarithmCycleIndexSeries\(\)](#)

AUTHORS:

- Andrew Gainer-Dewar

count(t)

Return the number of structures corresponding to a certain cycle type `t`.

EXAMPLES:

```

sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]), 3*p([2,1])])
sage: f.count([1])
1
sage: f.count([1,1])
4

```

(continues on next page)

(continued from previous page)

```
sage: f.count([2,1])
6
```

derivative(*order=1*)

Return the species-theoretic n -th derivative of `self`, where n is `order`.

For a cycle index series $F(p_1, p_2, p_3, \dots)$, its derivative is the cycle index series $F' = D_{p_1} F$ (that is, the formal derivative of F with respect to the variable p_1).

If F is the cycle index series of a species S then F' is the cycle index series of an associated species S' of S -structures with a “hole”.

EXAMPLES:

The species E of sets satisfies the relationship $E' = E$:

```
sage: E = species.SetSpecies().cycle_index_series()
sage: E.coefficients(8) == E.derivative().coefficients(8)
True
```

The species C of cyclic orderings and the species L of linear orderings satisfy the relationship $C' = L$:

```
sage: C = species.CycleSpecies().cycle_index_series()
sage: L = species.LinearOrderSpecies().cycle_index_series()
sage: L.coefficients(8) == C.derivative().coefficients(8)
True
```

expand_as_sf(*n, alphabet='x'*)

Returns the expansion of a cycle index series as a symmetric function in n variables.

Specifically, this returns a *LazyPowerSeries* whose i th term is obtained by calling `expand()` on the i th term of `self`.

This relies on the (standard) interpretation of a cycle index series as a symmetric function in the power sum basis.

INPUT:

- `self` – a cycle index series
- `n` – a positive integer
- `alphabet` – a variable for the expansion (default: x)

EXAMPLES:

```
sage: from sage.combinat.species.set_species import SetSpecies
sage: SetSpecies().cycle_index_series().expand_as_sf(2).coefficients(4)
[1, x0 + x1, x0^2 + x0*x1 + x1^2, x0^3 + x0^2*x1 + x0*x1^2 + x1^3]
```

exponential()

Return the species-theoretic exponential of `self`.

For a cycle index Z_F of a species F , its exponential is the cycle index series $Z_E \circ Z_F$, where Z_E is the *ExponentialCycleIndexSeries*().

The exponential $Z_E \circ Z_F$ is then the cycle index series of the species $E \circ F$ of “sets of F -structures”.

EXAMPLES:

Let BT be the species of binary trees, BF the species of binary forests, and E the species of sets. Then we have $BF = E \circ BT$:

```
sage: BT = species.BinaryTreeSpecies().cycle_index_series()
sage: BF = species.BinaryForestSpecies().cycle_index_series()
sage: BT.exponential().isotype_generating_series().coefficients(8) == BF.
↳ isotype_generating_series().coefficients(8)
True
```

functorial_composition(g)

Returns the functorial composition of `self` and g .

If F and G are species, their functorial composition is the species $F \square G$ obtained by setting $(F \square G)[A] = F[G[A]]$. In other words, an $(F \square G)$ -structure on a set A of labels is an F -structure whose labels are the set of all G -structures on A .

It can be shown (as in section 2.2 of [BLL]) that there is a corresponding operation on cycle indices:

$$Z_{F \square G} = \sum_{n \geq 0} \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} \text{fix } F[(G[\sigma])_1, (G[\sigma])_2, \dots] p_1^{\sigma_1} p_2^{\sigma_2} \dots$$

This method implements that operation on cycle index series.

EXAMPLES:

The species G of simple graphs can be expressed in terms of a functorial composition: $G = p \square p_2$, where p is the *SubsetSpecies*. This is how it is implemented in *SimpleGraphSpecies()*:

```
sage: S = species.SimpleGraphSpecies()
sage: S.cycle_index_series().coefficients(5)
[p[],
 p[1],
 p[1, 1] + p[2],
 4/3*p[1, 1, 1] + 2*p[2, 1] + 2/3*p[3],
 8/3*p[1, 1, 1, 1] + 4*p[2, 1, 1] + 2*p[2, 2] + 4/3*p[3, 1] + p[4]]
```

generating_series()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: cis = P.cycle_index_series()
sage: f = cis.generating_series()
sage: f.coefficients(5)
[1, 1, 1, 5/6, 5/8]
```

integral(*args)

Given a cycle index G , it is not in general possible to recover a single cycle index F such that $F' = G$ (even up to addition of a constant term).

More broadly, it may be the case that there are many non-isomorphic species S such that $S' = T$ for a given species T . For example, the species $3C_3$ of 3-cycles from three distinct classes and the species X^3 of 3-sets are not isomorphic, but $(3C_3)' = (X^3)' = 3X^2$.

EXAMPLES:

```
sage: C3 = species.CycleSpecies(size=3).cycle_index_series()
sage: X = species.SingletonSpecies().cycle_index_series()
```

(continues on next page)

(continued from previous page)

```
sage: (3*C3).derivative().coefficients(8) == (3*X^2).coefficients(8)
True
sage: (X^3).derivative().coefficients(8) == (3*X^2).coefficients(8)
True
```

Warning: This method has no implementation and exists only to prevent you from doing something strange. Calling it raises a `NotImplementedError`!

isotype_generating_series()

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: cis = P.cycle_index_series()
sage: f = cis.isotype_generating_series()
sage: f.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

logarithm()Return the combinatorial logarithm of `self`.

For a cycle index Z_F of a species F , its logarithm is the cycle index series $Z_\Omega \circ Z_F$, where Z_Ω is the [LogarithmCycleIndexSeries\(\)](#).

The logarithm $Z_\Omega \circ Z_F$ is then the cycle index series of the (virtual) species $\Omega \circ F$ of “connected F -structures”. In particular, if $F = E^+ \circ G$ for E^+ the species of nonempty sets and G some other species, then $\Omega \circ F = G$.

EXAMPLES:

Let G be the species of nonempty graphs and CG be the species of nonempty connected graphs. Then $G = E^+ \circ CG$, so $CG = \Omega \circ G$:

```
sage: G = species.SimpleGraphSpecies().cycle_index_series() - 1
sage: from sage.combinat.species.generating_series import ↵
↵LogarithmCycleIndexSeries
sage: CG = LogarithmCycleIndexSeries().compose(G)
sage: CG.isotype_generating_series().coefficients(8)
[0, 1, 1, 2, 6, 21, 112, 853]
```

pointing()Return the species-theoretic pointing of `self`.

For a cycle index F , its pointing is the cycle index series $F^\bullet = p_1 \cdot F'$.

If F is the cycle index series of a species S then F^\bullet is the cycle index series of an associated species S^\bullet of S -structures with a marked “root”.

EXAMPLES:

The species E^\bullet of “pointed sets” satisfies $E^\bullet = X \cdot E$:

```
sage: E = species.SetSpecies().cycle_index_series()
sage: X = species.SingletonSpecies().cycle_index_series()
sage: E.pointing().coefficients(8) == (X*E).coefficients(8)
True
```

stretch(k)

Return the stretch of the cycle index series `self` by a positive integer k .

If

$$f = \sum_{n=0}^{\infty} f_n(p_1, p_2, p_3, \dots),$$

then the stretch g of f by k is

$$g = \sum_{n=0}^{\infty} f_n(p_k, p_{2k}, p_{3k}, \dots).$$

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([p[], p[1]], p[1], p[2], p.zero())
sage: f.stretch(3).coefficients(10)
[p[], 0, 0, p[3], 0, 0, p[6], 0, 0, 0]
```

weighted_composition($y_species$)

Return the composition of this cycle index series with the cycle index series of the weighted species $y_species$.

Note that this is basically the same algorithm as composition except we can not use the optimization that the powering of cycle index series commutes with ‘stretching’.

EXAMPLES:

```
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: E_cis = E.cycle_index_series()
sage: E_cis.weighted_composition(C).coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
sage: E(C).cycle_index_series().coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
```

sage.combinat.species.generating_series.CycleIndexSeriesRing(R)

Return the ring of cycle index series over R .

This is the ring of formal power series $\Lambda[x]$, where Λ is the ring of symmetric functions over R in the p -basis. Its purpose is to house the cycle index series of species (in a somewhat nonstandard notation tailored to Sage): If F is a species, then the *cycle index series* of F is defined to be the formal power series

$$\sum_{n \geq 0} \frac{1}{n!} \left(\sum_{\sigma \in S_n} \text{fix } F[\sigma] \prod_{z \text{ is a cycle of } \sigma} p_{\text{length of } z} \right) x^n \in \Lambda_{\mathbf{Q}}[x],$$

where $\text{fix } F[\sigma]$ denotes the number of fixed points of the permutation $F[\sigma]$ of $F[n]$. We notice that this power series is “equigraded” (meaning that its x^n -coefficient is homogeneous of degree n). A more standard convention in combinatorics would be to use x_i instead of p_i , and drop the x (that is, evaluate the above power series at $x = 1$); but this would be more difficult to implement in Sage, as it would be an element of a power series ring in infinitely many variables.

Note that it is just a *LazyPowerSeriesRing* (whose base ring is Λ) whose elements have some extra methods.

EXAMPLES:

```

sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: R = CycleIndexSeriesRing(QQ); R
Cycle Index Series Ring over Symmetric Functions over Rational Field in the
↳powersum basis
sage: R([1]).coefficients(4) # This is not combinatorially
.....:                       # meaningful.
[1, 1, 1, 1]

```

```

class sage.combinat.species.generating_series.CycleIndexSeriesRing_class(R)
Bases: sage.combinat.species.series.LazyPowerSeriesRing

```

EXAMPLES:

```

sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: R = CycleIndexSeriesRing(QQ); R
Cycle Index Series Ring over Symmetric Functions over Rational Field in the
↳powersum basis
sage: R == loads(dumps(R))
True

```

```

sage.combinat.species.generating_series.ExponentialCycleIndexSeries(R=Rational Field)
Return the cycle index series of the species  $E$  of sets.

```

This cycle index satisfies

$$Z_E = \sum_{n \geq 0} \sum_{\lambda \vdash n} \frac{p_\lambda}{z_\lambda}.$$

EXAMPLES:

```

sage: from sage.combinat.species.generating_series import
↳ExponentialCycleIndexSeries
sage: ExponentialCycleIndexSeries().coefficients(5)
[p[], p[1], 1/2*p[1, 1] + 1/2*p[2], 1/6*p[1, 1, 1] + 1/2*p[2, 1]
+ 1/3*p[3], 1/24*p[1, 1, 1, 1] + 1/4*p[2, 1, 1] + 1/8*p[2, 2]
+ 1/3*p[3, 1] + 1/4*p[4]]

```

```

class sage.combinat.species.generating_series.ExponentialGeneratingSeries(A, stream=None,
order=None,
aorder=None,
aorder_changed=True,
is_initialized=False,
name=None)

```

Bases: *sage.combinat.species.series.LazyPowerSeries*

count(n)

Return the number of structures of size n .

EXAMPLES:

```

sage: from sage.combinat.species.generating_series import
↳ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R([1])
sage: [f.count(i) for i in range(7)]
[1, 1, 2, 6, 24, 120, 720]

```

counts(*n*)

Return the number of structures on a set for size *i* for each *i* in range(*n*).

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(5)
[0, 1, 4, 18, 96]
```

functorial_composition(*y*)

Return the exponential generating series which is the functorial composition of *self* with *y*.

If $f = \sum_{n=0}^{\infty} f_n \frac{x^n}{n!}$ and $g = \sum_{n=0}^{\infty} g_n \frac{x^n}{n!}$, then functorial composition $f \square g$ is defined as

$$f \square g = \sum_{n=0}^{\infty} f_{g_n} \frac{x^n}{n!}$$

REFERENCES:

- Section 2.2 of [BLL].

EXAMPLES:

```
sage: G = species.SimpleGraphSpecies()
sage: g = G.generating_series()
sage: g.coefficients(10)
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]
```

sage.combinat.species.generating_series.ExponentialGeneratingSeriesRing(*R*)

Return the ring of exponential generating series over *R*.

Note that it is just a *LazyPowerSeriesRing* whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ); R
Lazy Power Series Ring over Rational Field
sage: R([1]).coefficients(4)
[1, 1, 1, 1]
sage: R([1]).counts(4)
[1, 1, 2, 6]
```

class sage.combinat.species.generating_series.ExponentialGeneratingSeriesRing_class(*R*)

Bases: *sage.combinat.species.series.LazyPowerSeriesRing*

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import _
      ↪ ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: R == loads(dumps(R))
True
```

`sage.combinat.species.generating_series.LogarithmCycleIndexSeries` ($R=Rational\ Field$)

Return the cycle index series of the virtual species Ω , the compositional inverse of the species E^+ of nonempty sets.

The notion of virtual species is treated thoroughly in [BLL]. The specific algorithm used here to compute the cycle index of Ω is found in [Labelle2008].

EXAMPLES:

The virtual species Ω is ‘properly virtual’, in the sense that its cycle index has negative coefficients:

```
sage: from sage.combinat.species.generating_series import LogarithmCycleIndexSeries
sage: LogarithmCycleIndexSeries().coefficients(4)
[0, p[1], -1/2*p[1, 1] - 1/2*p[2], 1/3*p[1, 1, 1] - 1/3*p[3]]
```

Its defining property is that $\Omega \circ E^+ = E^+ \circ \Omega = X$ (that is, that composition with E^+ in both directions yields the multiplicative identity X):

```
sage: Eplus = sage.combinat.species.set_species.SetSpecies(min=1).cycle_index_
↪series()
sage: LogarithmCycleIndexSeries().compose(Eplus).coefficients(4)
[0, p[1], 0, 0]
```

```
class sage.combinat.species.generating_series.OrdinaryGeneratingSeries(A, stream=None,
                                                                    order=None,
                                                                    aorder=None,
                                                                    aorder_changed=True,
                                                                    is_initialized=False,
                                                                    name=None)
```

Bases: `sage.combinat.species.series.LazyPowerSeries`

count(n)

Return the number of structures on a set of size n .

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import
↪OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.count(10)
10
```

counts(n)

Return the number of structures on a set for size i for each i in $\text{range}(n)$.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import
↪OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

`sage.combinat.species.generating_series.OrdinaryGeneratingSeriesRing` (R)

Return the ring of ordinary generating series over R .

Note that it is just a *LazyPowerSeriesRing* whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import \_
      ↪ OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ); R
Lazy Power Series Ring over Rational Field
sage: R([1]).coefficients(4)
[1, 1, 1, 1]
sage: R([1]).counts(4)
[1, 1, 1, 1]
```

```
class sage.combinat.species.generating_series.OrdinaryGeneratingSeriesRing_class(R)
Bases: sage.combinat.species.series.LazyPowerSeriesRing
```

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import \_
      ↪ OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: R == loads(dumps(R))
True
```

```
sage.combinat.species.generating_series.factorial_gen()
A generator for the factorials starting at 0.
```

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import factorial_gen
sage: g = factorial_gen()
sage: [next(g) for i in range(5)]
[1, 1, 2, 6, 24]
```

5.1.318 Examples of Combinatorial Species

```
sage.combinat.species.library.BinaryForestSpecies()
```

Returns the species of binary forests. Binary forests are defined as sets of binary trees.

EXAMPLES:

```
sage: F = species.BinaryForestSpecies()
sage: F.generating_series().counts(10)
[1, 1, 3, 19, 193, 2721, 49171, 1084483, 28245729, 848456353]
sage: F.isotype_generating_series().counts(10)
[1, 1, 2, 4, 10, 26, 77, 235, 758, 2504]
sage: F.cycle_index_series().coefficients(7)
[p[],
 p[1],
 3/2*p[1, 1] + 1/2*p[2],
 19/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3],
 193/24*p[1, 1, 1, 1] + 3/4*p[2, 1, 1] + 5/8*p[2, 2] + 1/3*p[3, 1] + 1/4*p[4],
 907/40*p[1, 1, 1, 1, 1] + 19/12*p[2, 1, 1, 1] + 5/8*p[2, 2, 1] + 1/2*p[3, 1, 1] + \_
↪ 1/6*p[3, 2] + 1/4*p[4, 1] + 1/5*p[5],
 49171/720*p[1, 1, 1, 1, 1, 1] + 193/48*p[2, 1, 1, 1, 1] + 15/16*p[2, 2, 1, 1] + 61/
↪ 48*p[2, 2, 2] + 19/18*p[3, 1, 1, 1] + 1/6*p[3, 2, 1] + 7/18*p[3, 3] \(continues on next page\)
↪ 1] + 1/8*p[4, 2] + 1/5*p[5, 1] + 1/6*p[6]]
```

(continued from previous page)

```
sage.combinat.species.library.BinaryTreeSpecies()
```

Return the species of binary trees on n leaves.

The species of binary trees B is defined by $B = X + B*B$ where X is the singleton species.

EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.generating_series().counts(10)
[0, 1, 2, 12, 120, 1680, 30240, 665280, 17297280, 518918400]
sage: B.isotype_generating_series().counts(10)
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
sage: B._check()
True
```

```
sage: B = species.BinaryTreeSpecies()
sage: a = B.structures([1,2,3,4,5])[187]; a
2*((5*3)*(4*1))
sage: a.automorphism_group()
Permutation Group with generators [()]
```

```
sage.combinat.species.library.SimpleGraphSpecies()
```

Returns the species of simple graphs.

EXAMPLES:

```
sage: S = species.SimpleGraphSpecies()
sage: S.generating_series().counts(10)
[1, 1, 2, 8, 64, 1024, 32768, 2097152, 268435456, 68719476736]
sage: S.cycle_index_series().coefficients(5)
[p[],
 p[1],
 p[1, 1] + p[2],
 4/3*p[1, 1, 1] + 2*p[2, 1] + 2/3*p[3],
 8/3*p[1, 1, 1, 1] + 4*p[2, 1, 1] + 2*p[2, 2] + 4/3*p[3, 1] + p[4]]
sage: S.isotype_generating_series().coefficients(6)
[1, 1, 2, 4, 11, 34]
```

5.1.319 Linear-order Species

```
class sage.combinat.species.linear_order_species.LinearOrderSpecies(min=None, max=None,
weight=None)
```

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the species of linear orders.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: L.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
```

(continues on next page)

(continued from previous page)

```

sage: L = species.LinearOrderSpecies()
sage: L._check()
True
sage: L == loads(dumps(L))
True

```

class `sage.combinat.species.linear_order_species.LinearOrderSpeciesStructure`(*parent, labels, list*)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed. For the species of linear orders, there is no non-trivial automorphism.

EXAMPLES:

```

sage: F = species.LinearOrderSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
['a', 'b', 'c']
sage: a.automorphism_group()
Symmetric group of order 1! as a permutation group

```

canonical_label()

EXAMPLES:

```

sage: P = species.LinearOrderSpecies()
sage: s = P.structures(["a", "b", "c"]).random_element()
sage: s.canonical_label()
['a', 'b', 'c']

```

transport(*perm*)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```

sage: F = species.LinearOrderSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
['a', 'b', 'c']
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
['b', 'a', 'c']

```

`sage.combinat.species.linear_order_species.LinearOrderSpecies_class`

alias of `sage.combinat.species.linear_order_species.LinearOrderSpecies`

5.1.320 Miscellaneous Functions

`sage.combinat.species.misc.accept_size(f)`

The purpose of this decorator is to change calls like `species.SetSpecies(size=1)` to `species.SetSpecies(min=1, max=2)`. This is to make caching species easier and to restrict the number of parameters that the lower level code needs to know about.

EXAMPLES:

```
sage: from sage.combinat.species.misc import accept_size
sage: def f(*args, **kwds):
.....:     print("{} {}".format(args, sorted(kwds.items())))
sage: f = accept_size(f)
sage: f(min=1)
() [('min', 1)]
sage: f(size=2)
() [('max', 3), ('min', 2)]
```

`sage.combinat.species.misc.change_support(perm, support, change_perm=None)`

Changes the support of a permutation defined on $[1, \dots, n]$ to support.

EXAMPLES:

```
sage: from sage.combinat.species.misc import change_support
sage: p = PermutationGroupElement((1,2,3)); p
(1,2,3)
sage: change_support(p, [3,4,5])
(3,4,5)
```

5.1.321 Partition Species

class `sage.combinat.species.partition_species.PartitionSpecies`(*min=None, max=None, weight=None*)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`

Returns the species of partitions.

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: P.generating_series().coefficients(5)
[1, 1, 1, 5/6, 5/8]
sage: P.isotype_generating_series().coefficients(5)
[1, 1, 2, 3, 5]

sage: P = species.PartitionSpecies()
sage: P._check()
True
sage: P == loads(dumps(P))
True
```

class `sage.combinat.species.partition_species.PartitionSpeciesStructure`(*parent, labels, list*)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

EXAMPLES:

```

sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: P = species.PartitionSpecies()
sage: s = PartitionSpeciesStructure(P, ['a','b','c'], [[1,2],[3]]); s
{{'a', 'b'}, {'c'}}
sage: s == loads(dumps(s))
True

```

automorphism_group()

Returns the group of permutations whose action on this set partition leave it fixed.

EXAMPLES:

```

sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import _
↪PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.automorphism_group()
Permutation Group with generators [(1,2)]

```

canonical_label()

EXAMPLES:

```

sage: P = species.PartitionSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{{'a', 'b', 'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a'}, {'b'}, {'c'}}]

```

change_labels(labels)

Return a relabelled structure.

INPUT:

- labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```

sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import _
↪PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.change_labels([1,2,3])
{{1, 2}, {3}}

```

transport(perm)

Returns the transport of this set partition along the permutation perm. For set partitions, this is the direct product of the automorphism groups for each of the blocks.

EXAMPLES:

```

sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import 
↳ PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.transport(p)
{{2, 4}, {3}}

```

`sage.combinat.species.partition_species.PartitionSpecies_class`
 alias of `sage.combinat.species.partition_species.PartitionSpecies`

5.1.322 Permutation species

`class sage.combinat.species.permutation_species.PermutationSpecies`(*min=None, max=None, weight=None*)

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the species of permutations.

EXAMPLES:

```

sage: P = species.PermutationSpecies()
sage: P.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
sage: P.isotype_generating_series().coefficients(5)
[1, 1, 2, 3, 5]

sage: P = species.PermutationSpecies()
sage: c = P.generating_series().coefficients(3)
sage: P._check()
True
sage: P == loads(dumps(P))
True

```

`class sage.combinat.species.permutation_species.PermutationSpeciesStructure`(*parent, labels, list*)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

`automorphism_group()`

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```

sage: set_random_seed(0)
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (1,4)]

```

```

sage: [a.transport(perm) for perm in a.automorphism_group()]
[['a', 'c', 'b', 'd'],

```

(continues on next page)

(continued from previous page)

```
['a', 'c', 'b', 'd'],
['a', 'c', 'b', 'd'],
['a', 'c', 'b', 'd']]
```

canonical_label()

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[['a', 'b', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'c', 'a'],
 ['b', 'c', 'a'],
 ['b', 'a', 'c']]
```

permutation_group_element()

Returns self as a permutation group element.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.permutation_group_element()
(2,3)
```

transport(*perm*)Returns the transport of this structure along the permutation *perm*.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.transport(p)
['a', 'd', 'c', 'b']
```

sage.combinat.species.permutation_species.**PermutationSpecies_class**alias of `sage.combinat.species.permutation_species.PermutationSpecies`

5.1.323 Product species

```
class sage.combinat.species.product_species.ProductSpecies(F, G, min=None, max=None,
                                                         weight=None)
```

Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: A = X*X
sage: A.generating_series().coefficients(4)
[0, 0, 1, 0]

sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)
sage: F == loads(dumps(F))
True
sage: F._check()
True
```

left_factor()

Returns the left factor of this product.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: X = species.SingletonSpecies()
sage: F = P*X
sage: F.left_factor()
Permutation species
```

right_factor()

Returns the right factor of this product.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: X = species.SingletonSpecies()
sage: F = P*X
sage: F.right_factor()
Singleton species
```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S*S
sage: C.weight_ring()
Rational Field
```

```
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S*S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

```
sage: S = species.SetSpecies()
sage: C = (S*S).weighted(QQ['t'].gen())
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

class sage.combinat.species.product_species.**ProductSpeciesStructure**(parent, labels, subset, left, right)

Bases: *sage.combinat.species.structure.GenericSpeciesStructure*

automorphism_group()

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures([1,2,3,4])[1]; a
{1}*{2, 3, 4}
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (2,3,4)]
```

```
sage: [a.transport(g) for g in a.automorphism_group()]
[{1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4}]
```

```
sage: a = F.structures([1,2,3,4])[8]; a
{2, 3}*{1, 4}
sage: [a.transport(g) for g in a.automorphism_group()]
[{2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}]
```

canonical_label()

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: F = S * S
sage: S = F.structures(['a','b','c']).list(); S
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'b'}*{'a', 'c'},
 {'c'}*{'a', 'b'},
 {'a', 'b'}*{'c'},
 {'a', 'c'}*{'b'},
 {'b', 'c'}*{'a'},
 {'a', 'b', 'c'}*{}]
```

```

sage: F.isotypes(['a','b','c']).cardinality()
4
sage: [s.canonical_label() for s in S]
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b', 'c'}*{}]

```

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- *labels*, a list of labels.

OUTPUT:

A structure with the *i*-th label of self replaced with the *i*-th label of the list.

EXAMPLES:

```

sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a','b','c'])[0]; a
{}*{'a', 'b', 'c'}
sage: a.change_labels([1,2,3])
{}*{1, 2, 3}

```

transport(*perm*)

EXAMPLES:

```

sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a','b','c'])[4]; a
{'a', 'b'}*{'c'}
sage: a.transport(p)
{'a', 'c'}*{'b'}

```

`sage.combinat.species.product_species.ProductSpecies_class`

alias of `sage.combinat.species.product_species.ProductSpecies`

5.1.324 Recursive Species

class sage.combinat.species.recursive_species.**CombinatorialSpecies**

Bases: *sage.combinat.species.species.GenericCombinatorialSpecies*

EXAMPLES:

```
sage: F = CombinatorialSpecies()
sage: loads(dumps(F))
Combinatorial species
```

```
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.generating_series().coefficients(4)
[1, 1, 1, 1]
sage: LL = loads(dumps(L))
sage: LL.generating_series().coefficients(4)
[1, 1, 1, 1]
```

define(*x*)

Define self to be equal to the combinatorial species *x*.

This is used to define combinatorial species recursively. All of the real work is done by calling the `.set()` method for each of the series associated to self.

EXAMPLES: The species of linear orders *L* can be recursively defined by $L = 1 + X * L$ where 1 represents the empty set species and *X* represents the singleton species.

```
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.generating_series().coefficients(4)
[1, 1, 1, 1]
sage: L.structures([1,2,3]).cardinality()
6
sage: L.structures([1,2,3]).list()
[1*(2*(3*{})),
 1*(3*(2*{})),
 2*(1*(3*{})),
 2*(3*(1*{})),
 3*(1*(2*{})),
 3*(2*(1*{}))]
```

```
sage: L = species.LinearOrderSpecies()
sage: L.generating_series().coefficients(4)
[1, 1, 1, 1]
sage: L.structures([1,2,3]).cardinality()
6
sage: L.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

weight_ring()

EXAMPLES:

```
sage: F = species.CombinatorialSpecies()
sage: F.weight_ring()
Rational Field
```

```
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.weight_ring()
Rational Field
```

```
class sage.combinat.species.recursive_species.CombinatorialSpeciesStructure(parent, s,
                                                                              **options)
```

Bases: *sage.combinat.species.structure.SpeciesStructureWrapper*

5.1.325 Lazy Power Series

This file provides an implementation of lazy univariate power series, which uses the stream class for its internal data structure. The lazy power series keep track of their approximate order as much as possible without forcing the computation of any additional coefficients. This is required for recursively defined power series.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse9.html>.

```
class sage.combinat.species.series.LazyPowerSeries(A, stream=None, order=None, aorder=None,
                                                    aorder_changed=True, is_initialized=False,
                                                    name=None)
```

Bases: *sage.structure.element.AlgebraElement*

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L()
sage: loads(dumps(f))
Uninitialized lazy power series
```

add(y)

EXAMPLES: Test Plus 1

```
sage: from sage.combinat.species.series import *
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: gs0 = L([0])
sage: gs1 = L([1])
sage: sum1 = gs0 + gs1
sage: sum2 = gs1 + gs1
sage: sum3 = gs1 + gs0
sage: [gs0.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
sage: [gs1.coefficient(i) for i in range(11)]
```

(continues on next page)

(continued from previous page)

```
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: [sum1.coefficient(i) for i in range(11)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: [sum2.coefficient(i) for i in range(11)]
[2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
sage: [sum3.coefficient(i) for i in range(11)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

Test Plus 2

```
sage: gs1 = L([1,2,4,8,0])
sage: gs2 = L([-1, 0,-1,-9,22,0])
sage: sum = gs1 + gs2
sage: sum2 = gs2 + gs1
sage: [ sum.coefficient(i) for i in range(5) ]
[0, 2, 3, -1, 22]
sage: [ sum.coefficient(i) for i in range(5, 11) ]
[0, 0, 0, 0, 0, 0]
sage: [ sum2.coefficient(i) for i in range(5) ]
[0, 2, 3, -1, 22]
sage: [ sum2.coefficient(i) for i in range(5, 11) ]
[0, 0, 0, 0, 0, 0]
```

coefficient(*n*)Return the coefficient of x^n in self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(ZZ)
sage: [f.coefficient(i) for i in range(5)]
[0, 1, -1, 2, -2]
```

coefficients(*n*)Return the first n coefficients of self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L([1,2,3,0])
sage: f.coefficients(5)
[1, 2, 3, 0, 0]
```

compose(*y*)Return the composition of this power series and the power series y .

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([1])
sage: t = L([0,0,1])
sage: u = s(t)
sage: u.coefficients(11)
[1, 0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

Test Compose 2

```
sage: s = L([1])
sage: t = L([0,0,1,0])
sage: u = s(t)
sage: u.aorder
0
sage: u.order
Unknown series order
sage: u.coefficients(10)
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: u.aorder
0
sage: u.order
0
```

Test Compose 3 $s = 1/(1-x)$, $t = x/(1-x)$ $s(t) = (1-x)/(1-2x)$

```
sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t)
sage: u.coefficients(14)
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096]
```

composition(y)

Return the composition of this power series and the power series y.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([1])
sage: t = L([0,0,1])
sage: u = s(t)
sage: u.coefficients(11)
[1, 0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

Test Compose 2

```
sage: s = L([1])
sage: t = L([0,0,1,0])
sage: u = s(t)
sage: u.aorder
0
sage: u.order
Unknown series order
sage: u.coefficients(10)
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: u.aorder
0
sage: u.order
0
```

Test Compose 3 $s = 1/(1-x)$, $t = x/(1-x)$ $s(t) = (1-x)/(1-2x)$

```

sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t)
sage: u.coefficients(14)
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096]

```

compute_aorder(*args, **kwargs)

The default compute_aorder does nothing.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: a = L(1)
sage: a.compute_aorder() is None
True

```

compute_coefficients(i)

Computes all the coefficients of self up to i.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([1,2,3])
sage: a.compute_coefficients(5)
sage: a
1 + 2*x + 3*x^2 + 3*x^3 + 3*x^4 + 3*x^5 + ...

```

define(x)

EXAMPLES: Test Recursive 0

```

sage: L = LazyPowerSeriesRing(QQ)
sage: one = L(1)
sage: monom = L.gen()
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s)
sage: s.aorder
0
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(6)]
[1, 1, 1, 1, 1, 1]

```

Test Recursive 1

```

sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s)
sage: s.aorder
0
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(6)]
[1, 1, 2, 5, 14, 42]

```

Test Recursive 1b

```

sage: s = L()
sage: s._name = 's'
sage: s.define(monom + s*s)
sage: s.aorder
1
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(7)]
[0, 1, 1, 2, 5, 14, 42]

```

Test Recursive 2

```

sage: s = L()
sage: s._name = 's'
sage: t = L()
sage: t._name = 't'
sage: s.define(one+monom*t*t*t)
sage: t.define(one+monom*s*s)
sage: [s.coefficient(i) for i in range(9)]
[1, 1, 3, 9, 34, 132, 546, 2327, 10191]
sage: [t.coefficient(i) for i in range(9)]
[1, 1, 2, 7, 24, 95, 386, 1641, 7150]

```

Test Recursive 2b

```

sage: s = L()
sage: s._name = 's'
sage: t = L()
sage: t._name = 't'
sage: s.define(monom + t*t*t)
sage: t.define(monom + s*s)
sage: [s.coefficient(i) for i in range(9)]
[0, 1, 0, 1, 3, 3, 7, 30, 63]
sage: [t.coefficient(i) for i in range(9)]
[0, 1, 1, 0, 2, 6, 7, 20, 75]

```

Test Recursive 3

```

sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s*s)
sage: [s.coefficient(i) for i in range(10)]
[1, 1, 3, 12, 55, 273, 1428, 7752, 43263, 246675]

```

derivative()

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: one = L(1)
sage: monom = L.gen()
sage: s = L([1])

```

(continues on next page)

(continued from previous page)

```
sage: u = s.derivative()
sage: u.coefficients(10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

```
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s)
sage: u = s.derivative()
sage: u.coefficients(5) #[1*1, 2*2, 3*5, 4*14, 5*42]
[1, 4, 15, 56, 210]
```

```
sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t).derivative()
sage: v = (s.derivative().compose(t))*t.derivative()
sage: u.coefficients(11)
[1, 4, 12, 32, 80, 192, 448, 1024, 2304, 5120, 11264]
sage: v.coefficients(11)
[1, 4, 12, 32, 80, 192, 448, 1024, 2304, 5120, 11264]
```

```
sage: s = L(); s._name='s'
sage: t = L(); t._name='t'
sage: s.define(monom+t*t*t)
sage: t.define(monom+s*s)
sage: u = (s*t).derivative()
sage: v = s.derivative()*t + s*t.derivative()
sage: u.coefficients(10)
[0, 2, 3, 4, 30, 72, 133, 552, 1791, 4260]
sage: v.coefficients(10)
[0, 2, 3, 4, 30, 72, 133, 552, 1791, 4260]
sage: u.coefficients(10) == v.coefficients(10)
True
```

```
sage: f = L._new_initial(2, Stream([0,0,4,5,6,0]))
sage: d = f.derivative()
sage: d.get_aorder()
1
sage: d.coefficients(5)
[0, 8, 15, 24, 0]
```

div(*other*)

Divide this power series by other.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: x = L.gen()
```

Fibonacci numbers:

```
sage: b = x / (1-x-x^2); b.compute_coefficients(10); b
x + x^2 + 2*x^3 + 3*x^4 + 5*x^5 + 8*x^6
```

(continues on next page)

(continued from previous page)

```
+ 13*x^7 + 21*x^8 + 34*x^9 + 55*x^10 + O(x^11)
```

exponential()**get_aorder()**

Return the approximate order of self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: a.get_aorder()
1
```

get_order()

Return the order of self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: a.get_order()
1
```

get_stream()

Return self's underlying Stream object.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: s = a.get_stream()
sage: [s[i] for i in range(5)]
[0, 1, 0, 0, 0]
```

initialize_coefficient_stream(*compute_coefficients*)

Initializes the coefficient stream.

INPUT: *compute_coefficients***integral(*integration_constant=0*)**

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: zero = L(0)
sage: s = zero
sage: t = s.integral()
sage: t.is_zero()
True
```

```
sage: s = zero
sage: t = s.integral(1)
sage: t.coefficients(6)
[1, 0, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```
sage: s = L.term(1, 0)
sage: t = s.integral()
sage: t.coefficients(6)
[0, 1, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```
sage: s = L.term(1,0)
sage: t = s.integral(1)
sage: t.coefficients(6)
[1, 1, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```
sage: s = L.term(1, 4)
sage: t = s.integral()
sage: t.coefficients(10)
[0, 0, 0, 0, 0, 1/5, 0, 0, 0, 0]
```

```
sage: s = L.term(1,4)
sage: t = s.integral(1)
sage: t.coefficients(10)
[1, 0, 0, 0, 0, 1/5, 0, 0, 0, 0]
```

invert()

Return 1 over this power series, i.e. invert this power series.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: x = L.gen()
```

Geometric series:

```
sage: a = ~(1-x); a.compute_coefficients(10); a
1 + x + x^2 + x^3 + x^4 + x^5 + x^6 + x^7 + x^8 + x^9 + x^10 + O(x^11)
```

(Shifted) Fibonacci numbers:

```
sage: b = ~(1-x-x^2); b.compute_coefficients(10); b
1 + x + 2*x^2 + 3*x^3 + 5*x^4 + 8*x^5
+ 13*x^6 + 21*x^7 + 34*x^8 + 55*x^9 + 89*x^10 + O(x^11)
```

Series whose constant coefficient is 0 cannot be inverted:

```
sage: ~x
Traceback (most recent call last):
....
ZeroDivisionError: cannot invert x because constant coefficient is 0
```

is_finite(n=None)

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([0,0,1,0,0]); a
0(1)
sage: a.is_finite()
False
sage: c = a[4]
sage: a.is_finite()
False
sage: a.is_finite(4)
False
sage: c = a[5]
sage: a.is_finite()
True
sage: a.is_finite(4)
True

```

is_zero()

Return True if and only if self is zero.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([0,2,3,0])
sage: s.is_zero()
False

```

```

sage: s = L(0)
sage: s.is_zero()
True

```

```

sage: s = L([0])
sage: s.is_zero()
False
sage: s.coefficient(0)
0
sage: s.coefficient(1)
0
sage: s.is_zero()
True

```

iterator(*n=0, initial=None*)

Return an iterator for the coefficients of self starting at n.

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(range(10))
sage: g = f.iterator(2)
sage: [next(g) for i in range(5)]
[2, 3, 4, 5, 6]
sage: g = f.iterator(2, initial=[0,0])
sage: [next(g) for i in range(5)]
[0, 0, 2, 3, 4]

```

refine_aorder()

Refines the approximate order of self as much as possible without computing any coefficients.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([0,0,0,0,1])
sage: a.aorder
0
sage: a.coefficient(2)
0
sage: a.aorder
0
sage: a.refine_aorder()
sage: a.aorder
3
```

```
sage: a = L([0,0])
sage: a.aorder
0
sage: a.coefficient(5)
0
sage: a.refine_aorder()
sage: a.aorder
Infinite series order
```

```
sage: a = L([0,0,1,0,0,0])
sage: a[4]
0
sage: a.refine_aorder()
sage: a.aorder
2
```

restricted(*min=None, max=None*)

Return the power series restricted to the coefficients starting at *min* and going up to, but not including *max*.

If *min* is not specified, then it is assumed to be zero. If *max* is not specified, then it is assumed to be infinity.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([1])
sage: a.restricted().coefficients(10)
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: a.restricted(min=2).coefficients(10)
[0, 0, 1, 1, 1, 1, 1, 1, 1, 1]
sage: a.restricted(max=5).coefficients(10)
[1, 1, 1, 1, 1, 0, 0, 0, 0, 0]
sage: a.restricted(min=2, max=6).coefficients(10)
[0, 0, 1, 1, 1, 1, 0, 0, 0, 0]
```

set_approximate_order(*new_order*)

Sets the approximate order of self and returns True if the approximate order has changed otherwise it will return False.

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: f = L([0,0,0,3,2,1,0])
sage: f.get_aorder()
0
sage: f.set_approximate_order(3)
True
sage: f.set_approximate_order(3)
False

```

tail()

Return the power series whose coefficients obtained by subtracting the constant term from this series and then dividing by x.

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(range(20))
sage: g = f.tail()
sage: g.coefficients(10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

```

times(y)

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: gs0 = L(0)
sage: gs1 = L([1])

```

```

sage: prod0 = gs0 * gs1
sage: [prod0.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

```

```

sage: prod1 = gs1 * gs0
sage: [prod1.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

```

```

sage: prod2 = gs1 * gs1
sage: [prod2.coefficient(i) for i in range(11)]
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]

```

```

sage: gs1 = L([1,2,4,8,0])
sage: gs2 = L([-1, 0,-1,-9,22,0])

```

```

sage: prod1 = gs1 * gs2
sage: [prod1.coefficient(i) for i in range(11)]
[-1, -2, -5, -19, 0, 0, 16, 176, 0, 0, 0]

```

```

sage: prod2 = gs2 * gs1
sage: [prod2.coefficient(i) for i in range(11)]
[-1, -2, -5, -19, 0, 0, 16, 176, 0, 0, 0]

```

```
class sage.combinat.species.series.LazyPowerSeriesRing(R, names=None, element_class=None)
    Bases: sage.rings.ring.Algebra
```

```
gen(i=0)
```

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.gen().coefficients(5)
[0, 1, 0, 0, 0]
```

```
identity_element()
```

Return the one power series.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.identity_element()
1
```

```
ngens()
```

EXAMPLES:

```
sage: LazyPowerSeriesRing(QQ).ngens()
1
```

```
product_generator(g)
```

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s1 = L([1,1,0])
sage: s2 = L([1,0,1,0])
sage: s3 = L([1,0,0,1,0])
sage: s4 = L([1,0,0,0,1,0])
sage: s5 = L([1,0,0,0,0,1,0])
sage: s6 = L([1,0,0,0,0,0,1,0])
sage: s = [s1, s2, s3, s4, s5, s6]
sage: def g():
....:     for a in s:
....:         yield a
sage: p = L.product_generator(g())
sage: p.coefficients(26)
[1, 1, 1, 2, 2, 3, 4, 4, 4, 5, 5, 5, 5, 4, 4, 4, 3, 2, 2, 1, 1, 1, 0, 0, 0, 0]
```

```
sage: def m(n):
....:     yield 1
....:     while True:
....:         for i in range(n-1):
....:             yield 0
....:             yield 1
sage: def s(n):
....:     q = 1/n
....:     yield 0
....:     while True:
....:         for i in range(n-1):
```

(continues on next page)

(continued from previous page)

```

.....:         yield 0
.....:         yield q

```

```

sage: def lhs_gen():
.....:     n = 1
.....:     while True:
.....:         yield L(m(n))
.....:         n += 1

```

```

sage: def rhs_gen():
.....:     n = 1
.....:     while True:
.....:         yield L(s(n))
.....:         n += 1
sage: lhs = L.product_generator(lhs_gen())
sage: rhs = L.sum_generator(rhs_gen()).exponential()
sage: lhs.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
sage: rhs.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]

```

sum(*a*)

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: l = [L(ZZ)]*3
sage: L.sum(l).coefficients(10)
[0, 3, -3, 6, -6, 9, -9, 12, -12, 15]

```

sum_generator(*g*)

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: g = [L([1])] * 6 + [L(0)]
sage: t = L.sum_generator(g)
sage: t.coefficients(10)
[1, 2, 3, 4, 5, 6, 6, 6, 6, 6]

```

```

sage: s = L([1])
sage: def g():
.....:     while True:
.....:         yield s
sage: t = L.sum_generator(g())
sage: t.coefficients(9)
[1, 2, 3, 4, 5, 6, 7, 8, 9]

```

term(*r*, *n*)

EXAMPLES:

```

sage: L = LazyPowerSeriesRing(QQ)
sage: L.term(0,0)
0

```

(continues on next page)

(continued from previous page)

```
sage: L.term(3,2).coefficients(5)
[0, 0, 3, 0, 0]
```

zero()

Return the zero power series.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.zero()
0
```

sage.combinat.species.series.uninitialized()

EXAMPLES:

```
sage: from sage.combinat.species.series import uninitialized
sage: uninitialized()
Traceback (most recent call last):
...
RuntimeError: we should never be here
```

5.1.326 Series Order

This file provides some utility classes which are useful when working with unknown, known, and infinite series orders for univariate power series.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatsu30.html>.

```
class sage.combinat.species.series_order.InfiniteSeriesOrder
```

```
    Bases: sage.combinat.species.series_order.SeriesOrderElement
```

```
class sage.combinat.species.series_order.SeriesOrderElement
```

```
    Bases: object
```

```
class sage.combinat.species.series_order.UnknownSeriesOrder
```

```
    Bases: sage.combinat.species.series_order.SeriesOrderElement
```

```
sage.combinat.species.series_order.bounded_decrement(x)
```

EXAMPLES:

```
sage: from sage.combinat.species.series_order import *
sage: u = UnknownSeriesOrder()
sage: bounded_decrement(u)
Unknown series order
sage: bounded_decrement(4)
3
sage: bounded_decrement(0)
0
```

```
sage.combinat.species.series_order.increment(x)
```

EXAMPLES:

```

sage: from sage.combinat.species.series_order import *
sage: u = UnknownSeriesOrder()
sage: increment(u)
Unknown series order
sage: increment(2)
3

```

5.1.327 Set Species

class `sage.combinat.species.set_species.SetSpecies`(*min=None, max=None, weight=None*)
 Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Returns the species of sets.

EXAMPLES:

```

sage: E = species.SetSpecies()
sage: E.structures([1,2,3]).list()
[1, 2, 3]
sage: E.isotype_generating_series().coefficients(4)
[1, 1, 1, 1]

sage: S = species.SetSpecies()
sage: c = S.generating_series().coefficients(3)
sage: S._check()
True
sage: S == loads(dumps(S))
True

```

class `sage.combinat.species.set_species.SetSpeciesStructure`(*parent, labels, list*)

Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

automorphism_group()

Returns the group of permutations whose action on this set leave it fixed. For the species of sets, there is only one isomorphism class, so every permutation is in its automorphism group.

EXAMPLES:

```

sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()
Symmetric group of order 3! as a permutation group

```

canonical_label()

EXAMPLES:

```

sage: S = species.SetSpecies()
sage: a = S.structures(["a","b","c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}

```

transport(*perm*)

Returns the transport of this set along the permutation perm.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'a', 'b', 'c'}
```

sage.combinat.species.set_species.**SetSpecies_class**
alias of *sage.combinat.species.set_species.SetSpecies*

5.1.328 Combinatorial Species

This file defines the main classes for working with combinatorial species, operations on them, as well as some implementations of basic species required for other constructions.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse8.html>.

Weighted Species:

As a first application of weighted species, we count unlabeled ordered trees by total number of nodes and number of internal nodes. To achieve this, we assign a weight of 1 to the leaves and of q to internal nodes:

```
sage: q = QQ['q'].gen()
sage: leaf = species.SingletonSpecies()
sage: internal_node = species.SingletonSpecies(weight=q)
sage: L = species.LinearOrderSpecies(min=1)
sage: T = species.CombinatorialSpecies()
sage: T.define(leaf + internal_node*L(T))
sage: T.isotype_generating_series().coefficients(6)
[0, 1, q, q^2 + q, q^3 + 3*q^2 + q, q^4 + 6*q^3 + 6*q^2 + q]
```

Consider the following:

```
sage: T.isotype_generating_series().coefficient(4)
q^3 + 3*q^2 + q
```

This means that, among the trees on 4 nodes, one has a single internal node, three have two internal nodes, and one has three internal nodes.

class sage.combinat.species.species.**GenericCombinatorialSpecies**(*min=None, max=None, weight=None*)

Bases: *sage.structure.sage_object.SageObject*

algebraic_equation_system()

Return a system of algebraic equations satisfied by this species.

The nodes are numbered in the order that they appear as vertices of the associated digraph.

EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.algebraic_equation_system()
[-node3^2 + node1, -node1 + node3 + (-z)]
```

```
sage: sorted(B.digraph().vertex_iterator(), key=str)
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
 Singleton species,
 Sum of (Singleton species) and (Product of (Combinatorial species) and
 ↪(Combinatorial species))]
```

```
sage: B.algebraic_equation_system()[0].parent()
Multivariate Polynomial Ring in node0, node1, node2, node3 over Fraction Field
↪of Univariate Polynomial Ring in z over Rational Field
```

composition(*g*)

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: S(S)
Composition of (Set species) and (Set species)
```

cycle_index_series(*base_ring=None*)

Return the cycle index series for this species.

The cycle index series is a sequence of symmetric functions.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.cycle_index_series()
sage: g.coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
```

digraph()

Return a directed graph where the vertices are the individual species that make up this one.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: B = species.CombinatorialSpecies()
sage: B.define(X+B*B)
sage: g = B.digraph(); g
Multi-digraph on 4 vertices

sage: sorted(g, key=str)
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
 Singleton species,
 Sum of (Singleton species) and
 (Product of (Combinatorial species) and (Combinatorial species))]
```

```
sage: d = {sp: i for i, sp in enumerate(g)}
sage: g.relabel(d)
```

(continues on next page)

(continued from previous page)

```
sage: g.canonical_label().edges(sort=True)
[(0, 3, None), (2, 0, None), (2, 0, None), (3, 1, None), (3, 2, None)]
```

functorial_composition(*g*)Return the functorial composition of *self* with *g*.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E2 = E.restricted(min=2, max=3)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
sage: G.isotype_generating_series().coefficients(5)
[1, 1, 2, 4, 11]
```

generating_series(*base_ring=None*)

Return the generating series for this species.

This is an exponential generating series so the *n*-th coefficient of the series corresponds to the number of labeled structures with *n* labels divided by *n!*.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.generating_series()
sage: g.coefficients(4)
[1, 1, 1, 1]
sage: g.counts(4)
[1, 1, 2, 6]
sage: P.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: len(_)
6
```

is_weighted()

Return True if this species has a nontrivial weighting associated with it.

EXAMPLES:

```
sage: C = species.CycleSpecies()
sage: C.is_weighted()
False
```

isotype_generating_series(*base_ring=None*)

Return the isotype generating series for this species.

The *n*-th coefficient of this series corresponds to the number of isomorphism types for the structures on *n* labels.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.isotype_generating_series()
sage: g.coefficients(4)
[1, 1, 2, 3]
```

(continues on next page)

(continued from previous page)

```

sage: g.counts(4)
[1, 1, 2, 3]
sage: P.isotypes([1,2,3]).list()
[[2, 3, 1], [2, 1, 3], [1, 2, 3]]
sage: len(_)
3

```

isotypes(*labels, structure_class=None*)

EXAMPLES:

```

sage: F = CombinatorialSpecies()
sage: F.isotypes([1,2,3]).list()
Traceback (most recent call last):
...
NotImplementedError

```

product(*g*)Return the product of *self* and *g*.

EXAMPLES:

```

sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)

```

restricted(**args, **kws*)

Return the restriction of the species.

INPUT:

- *min* – optional integer
- *max* – optional integer

EXAMPLES:

```

sage: S = species.SetSpecies().restricted(min=3); S
Set species with min=3
sage: S.structures([1,2]).list()
[]
sage: S.generating_series().coefficients(5)
[0, 0, 0, 1/6, 1/24]

```

structures(*labels, structure_class=None*)

EXAMPLES:

```

sage: F = CombinatorialSpecies()
sage: F.structures([1,2,3]).list()
Traceback (most recent call last):
...
NotImplementedError

```

sum(*g*)Return the sum of *self* and *g*.

EXAMPLES:

```

sage: P = species.PermutationSpecies()
sage: F = P + P; F
Sum of (Permutation species) and (Permutation species)
sage: F.structures([1,2]).list()
[[1, 2], [2, 1], [1, 2], [2, 1]]

```

weight_ring()

Return the ring in which the weights of this species occur.

By default, this is just the field of rational numbers.

EXAMPLES:

```

sage: species.SetSpecies().weight_ring()
Rational Field

```

weighted(*weight*)

Return a version of this species with the specified weight.

EXAMPLES:

```

sage: t = ZZ['t'].gen()
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.weighted(t)
Cyclic permutation species with weight=t

```

5.1.329 Streams or Infinite Arrays

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html>. In particular, the relevant section for this file can be found at <http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse12.html>.

`sage.combinat.species.stream.Stream(x=None, const=None)`

Returns a stream.

EXAMPLES: We can create a constant stream by just passing a

```

sage: from sage.combinat.species.stream import Stream
sage: s = Stream(const=0)
sage: [s[i] for i in range(10)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

```

`class sage.combinat.species.stream.Stream_class(gen=None, const=None, func=None)`

Bases: `sage.structure.sage_object.SageObject`

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: from builtins import zip
sage: s = Stream(const=0)
sage: len(s)
1
sage: [x for (x,i) in zip(s, range(4))]
[0, 0, 0, 0]

```

(continues on next page)

(continued from previous page)

```
sage: len(s)
1
```

```
sage: s = Stream(const=4)
sage: g = iter(s)
sage: l1 = [x for (x,i) in zip(g, range(10))]
sage: l = [4 for k in range(10)]
sage: l == l1
True
```

```
sage: h = lambda l: l if len(l) < 2 else l[-1] + l[-2]
sage: fib = Stream(h)
sage: [x for (x,i) in zip(fib, range(11))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
```

```
sage: r = [4, 3, 5, 2, 6, 1, 1, 1, 1, 1]
sage: l = [4, 3, 5, 2, 6, 1]
sage: s = Stream(l)
sage: s[3] = -1
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, 1, 1, 1, 1, 1]
sage: s[5] = -2
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, 1, 1, 1, 1]
sage: s[6] = -3
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, -3, 1, 1, 1]
sage: s[8] = -4
sage: [x for (x,i) in zip(s, r)]
[4, 3, 5, -1, 6, -2, -3, 1, -4, 1]
sage: a = Stream(const=0)
sage: a[2] = 3
sage: [x for (x,i) in zip(a, range(4))]
[0, 0, 3, 0]
```

data()

Returns a list of all the coefficients computed so far.

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream, _integers_from
sage: s = Stream(_integers_from(3))
sage: s.data()
[]
sage: s[5]
8
sage: s.data()
[3, 4, 5, 6, 7, 8]
```

is_constant()

Returns True if and only if

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: s = Stream([1,2,3])
sage: s.is_constant()
False
sage: s[3]
3
sage: s.data()
[1, 2, 3]
sage: s.is_constant()
True

```

map(*f*)

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: s = Stream(ZZ)
sage: square = lambda x: x^2
sage: ss = s.map(square)
sage: [ss[i] for i in range(10)]
[0, 1, 1, 4, 4, 9, 9, 16, 16, 25]

```

number_computed()

Returns the number of coefficients computed so far.

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: l = [4,3,5,7,4,1,9,7]
sage: s = Stream(l)
sage: s[3]
7
sage: len(s)
4
sage: s[3]
7
sage: len(s)
4
sage: s[1]
3
sage: len(s)
4
sage: s[4]
4
sage: len(s)
5

```

set_gen(*gen*)

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: from builtins import zip
sage: fib = Stream()
sage: def g():
....:     yield 1

```

(continues on next page)

(continued from previous page)

```

.....:     yield 1
.....:     n = 0
.....:     while True:
.....:         yield fib[n] + fib[n+1]
.....:         n += 1

```

```

sage: fib.set_gen(g())
sage: [x for (x,i) in zip(fib, range(11))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]

```

```

sage: l = [4,3,5,2,6,1]
sage: s = Stream(l)
sage: s[3]
2
sage: len(s)
4
sage: g = iter(l)
sage: s.set_gen(g)
sage: s[5]
3
sage: len(s)
6

```

stretch(*k*)

EXAMPLES:

```

sage: from sage.combinat.species.stream import Stream
sage: s = Stream(range(1, 10))
sage: s2 = s.stretch(2)
sage: [s2[i] for i in range(10)]
[1, 0, 2, 0, 3, 0, 4, 0, 5, 0]

```

5.1.330 Species structures

We will illustrate the use of the structure classes using the “balls and bars” model for integer compositions. An integer composition of 6 such as [2, 1, 3] can be represented in this model as ‘ooooo’ where the 6 o’s correspond to the balls and the 2 ‘s correspond to the bars. If BB is our species for this model, then it satisfies the following recursive definition:

$$BB = o + o*BB + o*|*BB$$

Here we define this species using the default structures:

```

sage: ball = species.SingletonSpecies(); o = var('o')
sage: bar = species.EmptySetSpecies()
sage: BB = CombinatorialSpecies()
sage: BB.define(ball + ball*BB + ball*bar*BB)
sage: BB.isotypes([o]*3).list()
[o*(o*o), o*((o*{ })*o), (o*{ })*(o*o), (o*{ })*((o*{ })*o)]

```

If we ignore the parentheses, we can read off that the integer compositions are [3], [2, 1], [1, 2], and [1, 1, 1].

```

class sage.combinat.species.structure.GenericSpeciesStructure(parent, labels, list)
    Bases: sage.combinat.combinat.CombinatorialObject

```

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- *labels*, a list of labels.

OUTPUT:

A structure with the *i*-th label of self replaced with the *i*-th label of the list.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.change_labels([1,2,3]) for s in S]
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

is_isomorphic(*x*)

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: a = S.structures([1,2,3]).random_element(); a
{1, 2, 3}
sage: b = S.structures(['a','b','c']).random_element(); b
{'a', 'b', 'c'}
sage: a.is_isomorphic(b)
True
```

labels()

Returns the labels used for this structure.

Note: This includes labels which may not “appear” in this particular structure.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: s = P.structures(["a", "b", "c"]).random_element()
sage: s.labels()
['a', 'b', 'c']
```

parent()

Returns the species that this structure is associated with.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: a,b = L.structures([1,2])
sage: a.parent()
Linear order species
```

class `sage.combinat.species.structure.IsotypesWrapper`(*species, labels, structure_class*)
 Bases: `sage.combinat.species.structure.SpeciesWrapper`

A base class for the set of isotypes of a species with given set of labels. An object of this type is returned when you call the `isotypes()` method of a species.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.isotypes([1,2,3])
sage: S == loads(dumps(S))
True
```

class `sage.combinat.species.structure.SimpleIsotypesWrapper`(*species, labels, structure_class*)
 Bases: `sage.combinat.species.structure.SpeciesWrapper`

Warning: This is deprecated and currently not used for anything.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

class `sage.combinat.species.structure.SimpleStructuresWrapper`(*species, labels, structure_class*)
 Bases: `sage.combinat.species.structure.SpeciesWrapper`

Warning: This is deprecated and currently not used for anything.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

`sage.combinat.species.structure.SpeciesStructure`
 alias of `sage.combinat.species.structure.GenericSpeciesStructure`

class `sage.combinat.species.structure.SpeciesStructureWrapper`(*parent, s, **options*)
 Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

This is a class for the structures of species such as the sum species that do not provide “additional” structure. For example, if you have the sum C of species A and B , then a structure of C will either be either something from A or B . Instead of just returning one of these directly, a “wrapper” is put around them so that they have their parent is C rather than A or B :

```

sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.parent()
Sum of (Singleton species) and (Singleton species)
sage: from sage.combinat.species.structure import SpeciesStructureWrapper
sage: issubclass(type(s), SpeciesStructureWrapper)
True

```

EXAMPLES:

```

sage: E = species.SetSpecies(); B = E+E
sage: s = B.structures([1,2,3]).random_element()
sage: s.parent()
Sum of (Set species) and (Set species)
sage: s == loads(dumps(s))
True

```

canonical_label()

EXAMPLES:

```

sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3])[1]; s
{{1, 3}, {2}}
sage: s.canonical_label()
{{1, 2}, {3}}

```

change_labels(labels)

Return a relabelled structure.

INPUT:

- labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```

sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.change_labels(['a'])
'a'

```

transport(perm)

EXAMPLES:

```

sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3])[1]; s
{{1, 3}, {2}}
sage: s.transport(PermutationGroupElement((2,3)))
{{1, 2}, {3}}

```

class `sage.combinat.species.structure.SpeciesWrapper`(*species, labels, iterator, generating_series, name, structure_class*)

Bases: `sage.combinat.combinat.CombinatorialClass`

This is an abstract base class for the set of structures of a species as well as the set of isotypes of the species.

Note: One typically does not use `SpeciesWrapper` directly, but instead instantiates one of its subclasses: `StructuresWrapper` or `IsotypesWrapper`.

EXAMPLES:

```
sage: from sage.combinat.species.structure import SpeciesWrapper
sage: F = species.SetSpecies()
sage: S = SpeciesWrapper(F, [1,2,3], "_structures", "generating_series", 'Structures
→', None)
sage: S
Structures for Set species with labels [1, 2, 3]
sage: S.list()
[1, 2, 3]
sage: S.cardinality()
1
```

cardinality()

Returns the number of structures in this set.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).cardinality()
1
```

labels()

Returns the labels used on these structures. If X is the species, then `labels()` returns the preimage of these structures under the functor X .

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).labels()
[1, 2, 3]
```

class `sage.combinat.species.structure.StructuresWrapper`(*species, labels, structure_class*)

Bases: `sage.combinat.species.structure.SpeciesWrapper`

A base class for the set of structures of a species with given set of labels. An object of this type is returned when you call the `structures()` method of a species.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

5.1.331 Subset Species

class `sage.combinat.species.subset_species.SubsetSpecies`(*min=None, max=None, weight=None*)
 Bases: `sage.combinat.species.species.GenericCombinatorialSpecies`, `sage.structure.unique_representation.UniqueRepresentation`

Return the species of subsets.

EXAMPLES:

```
sage: S = species.SubsetSpecies()
sage: S.generating_series().coefficients(5)
[1, 2, 2, 4/3, 2/3]
sage: S.isotype_generating_series().coefficients(5)
[1, 2, 3, 4, 5]

sage: S = species.SubsetSpecies()
sage: c = S.generating_series().coefficients(3)
sage: S._check()
True
sage: S == loads(dumps(S))
True
```

class `sage.combinat.species.subset_species.SubsetSpeciesStructure`(*parent, labels, list*)
 Bases: `sage.combinat.species.structure.GenericSpeciesStructure`

automorphism_group()

Return the group of permutations whose action on this subset leave it fixed.

EXAMPLES:

```
sage: F = species.SubsetSpecies()
sage: a = F.structures([1,2,3,4])[6]; a
{1, 3}
sage: a.automorphism_group()
Permutation Group with generators [(2,4), (1,3)]
```

```
sage: [a.transport(g) for g in a.automorphism_group()]
[{1, 3}, {1, 3}, {1, 3}, {1, 3}]
```

canonical_label()

Return the canonical label of self.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{}, {'a'}, {'a'}, {'a'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b', 'c'}]
```

complement()

Return the complement of self.

EXAMPLES:

```

sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: a.complement()
{'b'}

```

label_subset()

Return a subset of the labels that “appear” in this structure.

EXAMPLES:

```

sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.label_subset() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]

```

transport(*perm*)

Return the transport of this subset along the permutation *perm*.

EXAMPLES:

```

sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'b', 'c'}
sage: p = PermutationGroupElement((1,3))
sage: a.transport(p)
{'a', 'c'}

```

`sage.combinat.species.subset_species.SubsetSpecies_class`
 alias of `sage.combinat.species.subset_species.SubsetSpecies`

5.1.332 Sum species

class `sage.combinat.species.sum_species.SumSpecies(F, G, min=None, max=None, weight=None)
 Bases: sage.combinat.species.species.GenericCombinatorialSpecies, sage.structure.unique_representation.UniqueRepresentation`

Returns the sum of two species.

EXAMPLES:

```

sage: S = species.PermutationSpecies()
sage: A = S+S
sage: A.generating_series().coefficients(5)
[2, 2, 2, 2, 2]

sage: P = species.PermutationSpecies()
sage: F = P + P
sage: F._check()
True
sage: F == loads(dumps(F))
True

```

left_summand()

Returns the left summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.left_summand()
Permutation species
```

right_summand()

Returns the right summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.right_summand()
Product of (Permutation species) and (Permutation species)
```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you add elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S+S
sage: C.weight_ring()
Rational Field
```

```
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S + S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

class `sage.combinat.species.sum_species.SumSpeciesStructure`(*parent, s, **options*)
 Bases: `sage.combinat.species.structure.SpeciesStructureWrapper`

`sage.combinat.species.sum_species.SumSpecies_class`
 alias of `sage.combinat.species.sum_species.SumSpecies`

5.1.333 Subsets

The set of subsets of a finite set. The set can be given as a list or a Set or else as an integer n which encodes the set $\{1, 2, \dots, n\}$. See [Subsets](#) for more information and examples.

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods

class `sage.combinat.subset.SubMultiset_s`(*s*)
 Bases: `sage.structure.parent.Parent`

The combinatorial class of the sub multisets of s .

EXAMPLES:

```

sage: S = Subsets([1,2,2,3], submultiset=True)
sage: S.cardinality()
12
sage: S.list()
[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 2],
 [2, 3],
 [1, 2, 2],
 [1, 2, 3],
 [2, 2, 3],
 [1, 2, 2, 3]]
sage: S.first()
[]
sage: S.last()
[1, 2, 2, 3]

```

cardinality()

Return the cardinality of self.

EXAMPLES:

```

sage: S = Subsets([1,1,2,3],submultiset=True)
sage: S.cardinality()
12
sage: len(S.list())
12

sage: S = Subsets([1,1,2,2,3],submultiset=True)
sage: S.cardinality()
18
sage: len(S.list())
18

sage: S = Subsets([1,1,1,2,2,3],submultiset=True)
sage: S.cardinality()
24
sage: len(S.list())
24

```

element_class

alias of builtins.list

generating_serie(*variable='x'*)

Return the polynomial associated to the counting of the elements of self weighted by the number of element they contain.

EXAMPLES:

```

sage: Subsets([1,1],submultiset=True).generating_serie()
x^2 + x + 1

```

(continues on next page)

(continued from previous page)

```

sage: Subsets([1,1,2,3],submultiset=True).generating_serie()
x^4 + 3*x^3 + 4*x^2 + 3*x + 1
sage: Subsets([1,1,1,2,2,3,3,4],submultiset=True).generating_serie()
x^8 + 4*x^7 + 9*x^6 + 14*x^5 + 16*x^4 + 14*x^3 + 9*x^2 + 4*x + 1
sage: S = Subsets([1,1,1,2,2,3,3,4],submultiset=True)
sage: S.cardinality()
72
sage: sum(S.generating_serie())
72

```

random_element()

Return a random element of `self` with uniform law.

EXAMPLES:

```

sage: S = Subsets([1,1,2,3], submultiset=True)
sage: s = S.random_element()
sage: s in S
True

```

class sage.combinat.subset.SubMultiset_sk(s, k)

Bases: [sage.combinat.subset.SubMultiset_s](#)

The combinatorial class of the subsets of size `k` of a multiset `s`. Note that each subset is represented by a list of the elements rather than a set since we can have multiplicities (no multiset data structure yet in sage).

EXAMPLES:

```

sage: S = Subsets([1,2,3,3],2,submultiset=True)
sage: S._k
2
sage: S.cardinality()
4
sage: S.first()
[1, 2]
sage: S.last()
[3, 3]
sage: [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]

```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```

sage: S = Subsets([1,2,2,3,3,3],4,submultiset=True)
sage: S.cardinality()
5
sage: len(list(S))
5
sage: S = Subsets([1,2,2,3,3,3],3,submultiset=True)
sage: S.cardinality()
6

```

(continues on next page)

(continued from previous page)

```
sage: len(list(S))
6
```

generating_serie(*variable='x'*)

Return the polynomial associated to the counting of the elements of `self` weighted by the number of elements they contains

EXAMPLES:

```
sage: x = ZZ['x'].gen()
sage: l = [1,1,1,1,2,2,3]
sage: for k in range(len(l)):
.....:     S = Subsets(l,k,submultiset=True)
.....:     print(S.generating_serie('x') == S.cardinality()*x**k)
True
True
True
True
True
True
True
```

random_element()

Return a random submultiset of given length

EXAMPLES:

```
sage: s = Subsets(7,3).random_element()
sage: s in Subsets(7,3)
True

sage: s = Subsets(7,5).random_element()
sage: s in Subsets(7,5)
True
```

`sage.combinat.subset.Subsets`(*s*, *k=None*, *submultiset=False*)

Return the combinatorial class of the subsets of the finite set `s`. The set can be given as a list, Set or any iterable convertible to a set. Alternatively, a non-negative integer `n` can be provided in place of `s`; in this case, the result is the combinatorial class of the subsets of the set $\{1, 2, \dots, n\}$ (i.e. of the Sage `range(1, n+1)`).

A second optional parameter `k` can be given. In this case, `Subsets` returns the combinatorial class of subsets of `s` of size `k`.

Warning: The subsets are returned as Sets. Do not assume that these Sets are ordered; they often are not! (E.g., `Subsets(10).list()[619]` returns `{10, 4, 5, 6, 7}` on my system.) See [SubsetsSorted](#) for a similar class which returns the subsets as sorted tuples.

Finally the option `submultiset` allows one to deal with sets with repeated elements, usually called multisets. The method then returns the class of all multisets in which every element is contained at most as often as it is contained in `s`. These multisets are encoded as lists.

EXAMPLES:

```

sage: S = Subsets([1, 2, 3]); S
Subsets of {1, 2, 3}
sage: S.cardinality()
8
sage: S.first()
{}
sage: S.last()
{1, 2, 3}
sage: S.random_element() in S
True
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]

```

Here is the same example where the set is given as an integer:

```

sage: S = Subsets(3)
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]

```

We demonstrate various the effect of the various options:

```

sage: S = Subsets(3, 2); S
Subsets of {1, 2, 3} of size 2
sage: S.list()
[{1, 2}, {1, 3}, {2, 3}]

sage: S = Subsets([1, 2, 2], submultiset=True); S
SubMultiset of [1, 2, 2]
sage: S.list()
[[], [1], [2], [1, 2], [2, 2], [1, 2, 2]]

sage: S = Subsets([1, 2, 2, 3], 3, submultiset=True); S
SubMultiset of [1, 2, 2, 3] of size 3
sage: S.list()
[[1, 2, 2], [1, 2, 3], [2, 2, 3]]

sage: S = Subsets(['a', 'b', 'a', 'b'], 2, submultiset=True); S.list()
[['a', 'a'], ['a', 'b'], ['b', 'b']]

```

And it is possible to play with subsets of subsets:

```

sage: S = Subsets(3)
sage: S2 = Subsets(S); S2
Subsets of Subsets of {1, 2, 3}
sage: S2.cardinality()
256
sage: it = iter(S2)
sage: [next(it) for _ in range(8)]
[{}, {{}}, {{1}}, {{2}}, {{3}}, {{1, 2}}, {{1, 3}}, {{2, 3}}]
sage: S2.random_element() # random
{{2}, {1, 2, 3}, {}}
sage: [S2.unrank(k) for k in range(256)] == S2.list()
True

```

(continues on next page)

(continued from previous page)

```

sage: S3 = Subsets(S2)
sage: S3.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: S3.unrank(14123091480) # random
{{{2}, {1, 2, 3}, {1, 2}, {3}, {}},
 {{1, 2, 3}, {2}, {1}, {1, 3}},
 {}, {2}, {2, 3}, {1, 2}},
 {}, {2}, {1, 2, 3}, {1, 2}},
 {},
 {{}, {1}, {1, 2, 3}}}

sage: T = Subsets(S2, 10)
sage: T.cardinality()
278826214642518400
sage: T.unrank(1441231049) # random
{{{1, 2, 3}, {2}, {2, 3}}, {{3}, {1, 3}, ..., {3}, {1}, {}, {1, 3}}}

```

class `sage.combinat.subset.SubsetsSorted(s)`

Bases: `sage.combinat.subset.Subsets_s`

Lightweight class of all subsets of some set S , with each subset being encoded as a sorted tuple.

Used to model indices of algebras given by subsets (so we don't have to explicitly build all 2^n subsets in memory). For example, [CliffordAlgebra](#).

element_class

alias of `builtins.tuple`

first()

Return the first element of `self`.

EXAMPLES:

```

sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.first()
()

```

last()

Return the last element of `self`.

EXAMPLES:

```

sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.last()
(0, 1, 2)

```

random_element()

Return a random element of `self`.

EXAMPLES:

```

sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))

```

(continues on next page)

(continued from previous page)

```
sage: isinstance(S.random_element(), tuple)
True
```

unrank(*r*)Return the subset which has rank *r*.

EXAMPLES:

```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.unrank(4)
(0, 1)
```

class sage.combinat.subset.Subsets_s(*s*)Bases: `sage.structure.parent.Parent`

Subsets of a given set.

EXAMPLES:

```
sage: S = Subsets(4); S
Subsets of {1, 2, 3, 4}
sage: S.cardinality()
16
sage: Subsets(4).list()
[[], {1}, {2}, {3}, {4},
 {1, 2}, {1, 3}, {1, 4}, {2, 3}, {2, 4}, {3, 4},
 {1, 2, 3}, {1, 2, 4}, {1, 3, 4}, {2, 3, 4},
 {1, 2, 3, 4}]

sage: S = Subsets(Subsets(Subsets(GF(3)))); S
Subsets of Subsets of Subsets of Finite Field of size 3
sage: S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: S.unrank(3149254230) # random
{{{1}, {0, 2}}, {{0, 1, 2}, {0, 1}, {1}, {1, 2}},
 {{2}, {1, 2}, {0, 1, 2}, {0, 2}, {1}, {}},
 {{1, 2}, {0}},
 {{0, 1, 2}, {0, 1}, {0, 2}, {1, 2}}}
```

cardinality()Return the number of subsets of the set *s*.This is given by $2^{|s|}$.

EXAMPLES:

```
sage: Subsets(Set([1,2,3])).cardinality()
8
sage: Subsets([1,2,3,3]).cardinality()
8
sage: Subsets(3).cardinality()
8
```

element_classalias of `sage.sets.set.Set_object_enumerated`

first()

Returns the first subset of s . Since we aren't restricted to subsets of a certain size, this is always the empty set.

EXAMPLES:

```
sage: Subsets([1,2,3]).first()
{}
sage: Subsets(3).first()
{}

```

last()

Return the last subset of s . Since we aren't restricted to subsets of a certain size, this is always the set s itself.

EXAMPLES:

```
sage: Subsets([1,2,3]).last()
{1, 2, 3}
sage: Subsets(3).last()
{1, 2, 3}

```

lattice()

Return the lattice of subsets ordered by containment.

EXAMPLES:

```
sage: X = Subsets([7,8,9])
sage: X.lattice()
Finite lattice containing 8 elements
sage: Y = Subsets(0)
sage: Y.lattice()
Finite lattice containing 1 elements

```

random_element()

Return a random element of the class of subsets of s (in other words, a random subset of s).

EXAMPLES:

```
sage: Subsets(3).random_element()      # random
{2}
sage: Subsets([4,5,6]).random_element() # random
{5}

sage: S = Subsets(Subsets(Subsets([0,1,2])))
sage: S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: s = S.random_element()
sage: s      # random
{{{1, 2}, {2}, {0}, {1}}, {{1, 2}, {0, 1, 2}, {0, 2}, {0}, {0, 1}}, ..., {{1, 2}
↔, {2}, {1}}, {{2}, {0, 2}, {}, {1}}}
sage: s in S
True

```

rank(sub)

Return the rank of sub as a subset of s .

EXAMPLES:

```

sage: Subsets(3).rank([])
0
sage: Subsets(3).rank([1,2])
4
sage: Subsets(3).rank([1,2,3])
7
sage: Subsets(3).rank([2,3,4])
Traceback (most recent call last):
...
ValueError: {2, 3, 4} is not a subset of {1, 2, 3}

```

underlying_set()

Return the set of elements.

EXAMPLES:

```

sage: Subsets(GF(13)).underlying_set()
{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}

```

unrank(*r*)Return the subset of *s* that has rank *k*.

EXAMPLES:

```

sage: Subsets(3).unrank(0)
{}
sage: Subsets([2,4,5]).unrank(1)
{2}
sage: Subsets([1,2,3]).unrank(257)
Traceback (most recent call last):
...
IndexError: index out of range

```

class `sage.combinat.subset.Subsets_sk(s, k)`Bases: `sage.combinat.subset.Subsets_s`

Subsets of fixed size of a set.

EXAMPLES:

```

sage: S = Subsets([0,1,2,5,7], 3); S
Subsets of {0, 1, 2, 5, 7} of size 3
sage: S.cardinality()
10
sage: S.first(), S.last()
({0, 1, 2}, {2, 5, 7})
sage: S.random_element() # random
{0, 5, 7}
sage: S([0,2,7])
{0, 2, 7}
sage: S([0,3,5])
Traceback (most recent call last):
...
ValueError: {0, 3, 5} not in Subsets of {0, 1, 2, 5, 7} of size 3

```

(continues on next page)

(continued from previous page)

```

sage: S([0])
Traceback (most recent call last):
...
ValueError: {0} not in Subsets of {0, 1, 2, 5, 7} of size 3

```

an_element()

Returns an example of subset.

EXAMPLES:

```

sage: Subsets(0,0).an_element()
{}
sage: Subsets(3,2).an_element()
{1, 3}
sage: Subsets([2,4,5],2).an_element()
{2, 5}

```

cardinality()

EXAMPLES:

```

sage: Subsets(Set([1,2,3]), 2).cardinality()
3
sage: Subsets([1,2,3,3], 2).cardinality()
3
sage: Subsets([1,2,3], 1).cardinality()
3
sage: Subsets([1,2,3], 3).cardinality()
1
sage: Subsets([1,2,3], 0).cardinality()
1
sage: Subsets([1,2,3], 4).cardinality()
0
sage: Subsets(3,2).cardinality()
3
sage: Subsets(3,4).cardinality()
0

```

first()

Return the first subset of s of size k.

EXAMPLES:

```

sage: Subsets(Set([1,2,3]), 2).first()
{1, 2}
sage: Subsets([1,2,3,3], 2).first()
{1, 2}
sage: Subsets(3,2).first()
{1, 2}
sage: Subsets(3,4).first()
Traceback (most recent call last):
...
EmptySetError

```

last()

Return the last subset of s of size k .

EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).last()
{2, 3}
sage: Subsets([1,2,3,3], 2).last()
{2, 3}
sage: Subsets(3,2).last()
{2, 3}
sage: Subsets(3,4).last()
Traceback (most recent call last):
...
EmptySetError
```

random_element()

Return a random element of the class of subsets of s of size k (in other words, a random subset of s of size k).

EXAMPLES:

```
sage: s = Subsets(3, 2).random_element()
sage: s in Subsets(3, 2)
True

sage: Subsets(3,4).random_element()
Traceback (most recent call last):
...
EmptySetError
```

rank(*sub*)

Return the rank of sub as a subset of s of size k .

EXAMPLES:

```
sage: Subsets(3,2).rank([1,2])
0
sage: Subsets([2,3,4],2).rank([3,4])
2
sage: Subsets([2,3,4],2).rank([2])
Traceback (most recent call last):
...
ValueError: {2} is not a subset of length 2 of {2, 3, 4}
sage: Subsets([2,3,4],4).rank([2,3,4,5])
Traceback (most recent call last):
...
ValueError: {2, 3, 4, 5} is not a subset of length 4 of {2, 3, 4}
```

unrank(*r*)

Return the subset of s of size k that has rank r .

EXAMPLES:

```
sage: Subsets(3,2).unrank(0)
{1, 2}
```

(continues on next page)

(continued from previous page)

```
sage: Subsets([2,4,5],2).unrank(0)
{2, 4}
sage: Subsets([1,2,8],3).unrank(42)
Traceback (most recent call last):
...
IndexError: index out of range
```

`sage.combinat.subset.dict_to_list(d)`

Return a list whose elements are the elements of i of d repeated with multiplicity $d[i]$.

EXAMPLES:

```
sage: from sage.combinat.subset import dict_to_list
sage: dict_to_list({'a':1, 'b':3})
['a', 'b', 'b', 'b']
```

`sage.combinat.subset.list_to_dict(l)`

Return a dictionary of multiplicities and the list of its keys.

INPUT:

a list l with possibly repeated elements

The keys are the elements of l (in the same order in which they appear) and values are the multiplicities of each element in l .

EXAMPLES:

```
sage: from sage.combinat.subset import list_to_dict
sage: list_to_dict(['a', 'b', 'b', 'b'])
({'a': 1, 'b': 3}, ['a', 'b'])
```

5.1.334 Subsets satisfying a hereditary property

`sage.combinat.subsets_hereditary.subsets_with_hereditary_property(f, X,`

`max_obstruction_size=None,`
`ncpus=1)`

Return all subsets S of X such that $f(S)$ is true.

The boolean function f must be decreasing, i.e. $f(S) \Rightarrow f(S')$ if $S' \subseteq S$.

This function is implemented to call f as few times as possible. More precisely, f will be called on all sets S such that $f(S)$ is true, as well as on all inclusionwise minimal sets S such that $f(S)$ is false.

The problem that this function answers is also known as the learning problem on monotone boolean functions, or as computing the set of winning coalitions in a simple game.

INPUT:

- f – a boolean function which takes as input a list of elements from X .
- X – a list/iterable.
- `max_obstruction_size` (integer) – if you know that there is a k such that $f(S)$ is true if and only if $f(S')$ is true for all $S' \subseteq S$ with $|S'| \leq k$, set `max_obstruction_size=k`. It may dramatically decrease the number of calls to f . Set to `None` by default, meaning $k = |X|$.

- `ncpus` – number of cpus to use for this computation. Note that changing the value from 1 (default) to anything different *enables* parallel computations which can have a cost by itself, so it is not necessarily a good move. In some cases, however, it is a *great* move. Set to `None` to automatically detect and use the maximum number of cpus available.

Note: Parallel computations are performed through the `parallel()` decorator. See its documentation for more information, in particular with respect to the memory context.

EXAMPLES:

Sets whose elements all have the same remainder mod 2:

```
sage: from sage.combinat.subsets_hereditary import subsets_with_hereditary_property
sage: f = lambda x: (not x) or all(xx%2 == x[0]%2 for xx in x)
sage: list(subsets_with_hereditary_property(f, range(4)))
[[], [0], [1], [2], [3], [0, 2], [1, 3]]
```

Same, on two threads:

```
sage: sorted(subsets_with_hereditary_property(f, range(4), ncpus=2))
[[], [0], [0, 2], [1], [1, 3], [2], [3]]
```

One can use this function to compute the independent sets of a graph. We know, however, that in this case the maximum obstructions are the edges, and have size 2. We can thus set `max_obstruction_size=2`, which reduces the number of calls to f from 91 to 56:

```
sage: num_calls=0
sage: g = graphs.PetersenGraph()
sage: def is_independent_set(S):
.....:     global num_calls
.....:     num_calls+=1
.....:     return g.subgraph(S).size()==0
sage: l1=list(subsets_with_hereditary_property(is_independent_set, g.
↳vertices(sort=False)))
sage: num_calls
91
sage: num_calls=0
sage: l2=list(subsets_with_hereditary_property(is_independent_set, g.
↳vertices(sort=False), max_obstruction_size=2))
sage: num_calls
56
sage: l1==l2
True
```

5.1.335 Subsets whose elements satisfy a predicate pairwise

```
class sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets(ambient, predicate,
                                                                maximal=False,
                                                                element_class=<class
                                                                'sage.sets.set.Set_object_enumerated'>)
```

Bases: `sage.sets.recursively_enumerated_set.RecursivelyEnumeratedSet_forest`

The set of all subsets of `ambient` whose elements satisfy `predicate` pairwise

INPUT:

- `ambient` – a set (or iterable)
- `predicate` – a binary predicate

Assumptions: `predicate` is symmetric (`predicate(x,y) == predicate(y,x)`) and reflexive (`predicate(x,x) == True`).

Note: in fact, `predicate(x,x)` is never called.

Warning: The current name is suboptimal and is subject to change. Suggestions for a good name, and a good user entry point are welcome. Maybe `Subsets(..., independent = predicate)`.

EXAMPLES:

We construct the set of all subsets of $\{4, 5, 6, 8, 9\}$ whose elements are pairwise relatively prime:

```
sage: from sage.combinat.subsets_pairwise import PairwiseCompatibleSubsets
sage: def predicate(x,y): return gcd(x,y) == 1
sage: P = PairwiseCompatibleSubsets( [4,5,6,8,9], predicate); P
An enumerated set with a forest structure
sage: P.list()
[{}, {4}, {4, 5}, {9, 4, 5}, {9, 4}, {5}, {5, 6}, {8, 5}, {8, 9, 5}, {9, 5}, {6},
↪{8}, {8, 9}, {9}]
sage: P.cardinality()
14
sage: P.category()
Category of finite enumerated sets
```

Here we consider only those subsets which are maximal for inclusion (not yet implemented):

```
sage: P = PairwiseCompatibleSubsets( [4,5,6,8,9], predicate, maximal = True); P
An enumerated set with a forest structure
sage: P.list() # todo: not implemented
[{}9, 4, 5}, {5, 6}, {8, 9, 5}]
sage: P.cardinality() # todo: not implemented
14
sage: P.category()
Category of finite enumerated sets
```

Algorithm

In the following, we order the elements of the ambient set by order of apparition. The elements of `self` are generated by organizing them in a search tree. Each node of this tree is of the form `(subset, rest)`, where:

- `subset` represents an element of `self`, represented by an increasing tuple
- `rest` is the set of all y 's such that y appears after x in the ambient set and `predicate(x, y)` holds, represented by a decreasing tuple

The root of this tree is `((), ambient)`. All the other elements are generated by recursive depth first search, which gives lexicographic order.

children(*subset_rest*)

Returns the children of a node in the tree.

post_process(*subset_rest*)

5.1.336 Subwords

A subword of a word w is a word obtained by deleting the letters at some (non necessarily adjacent) positions in w . It is not to be confused with the notion of factor where one keeps adjacent positions in w . Sometimes it is useful to allow repeated uses of the same letter of w in a “generalized” subword. We call this a subword with repetitions.

For example:

- “bnjr” is a subword of the word “bonjour” but not a factor;
- “njo” is both a factor and a subword of the word “bonjour”;
- “nr” is a subword of “bonjour”;
- “rn” is not a subword of “bonjour”;
- “nnu” is not a subword of “bonjour”;
- “nnu” is a subword with repetitions of “bonjour”;

A word can be given either as a string, as a list or as a tuple.

As repetition can occur in the initial word, in general subwords of a given word form an enumerated multiset rather than a set!

Todo:

- implement subwords with repetitions
 - implement the category of `EnumeratedMultiset` and inheritate from it when needed (i.e. the initial word has repeated letters)
-

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods + bug fixes

`sage.combinat.subword.Subwords`($w, k=None, element_constructor=None$)

Return the set of subwords of w .

INPUT:

- w – a word (can be a list, a string, a tuple or a word)

- `k` – an optional integer to specify the length of subwords
- `element_constructor` – an optional function that will be used to build the subwords

EXAMPLES:

```
sage: S = Subwords(['a','b','c']); S
Subwords of ['a', 'b', 'c']
sage: S.first()
[]
sage: S.last()
['a', 'b', 'c']
sage: S.list()
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

The same example using string, tuple or a word:

```
sage: S = Subwords('abc'); S
Subwords of 'abc'
sage: S.list()
['', 'a', 'b', 'c', 'ab', 'ac', 'bc', 'abc']

sage: S = Subwords((1,2,3)); S
Subwords of (1, 2, 3)
sage: S.list()
[(), (1,), (2,), (3,), (1, 2), (1, 3), (2, 3), (1, 2, 3)]

sage: w = Word([1,2,3])
sage: S = Subwords(w); S
Subwords of word: 123
sage: S.list()
[word: , word: 1, word: 2, word: 3, word: 12, word: 13, word: 23, word: 123]
```

Using word with specified length:

```
sage: S = Subwords(['a','b','c'], 2); S
Subwords of ['a', 'b', 'c'] of length 2
sage: S.list()
[['a', 'b'], ['a', 'c'], ['b', 'c']]
```

An example that uses the `element_constructor` argument:

```
sage: p = Permutation([3,2,1])
sage: Subwords(p, element_constructor=tuple).list()
[(), (3,), (2,), (1,), (3, 2), (3, 1), (2, 1), (3, 2, 1)]
sage: Subwords(p, 2, element_constructor=tuple).list()
[(3, 2), (3, 1), (2, 1)]
```

```
class sage.combinat.subword.Subwords_w(w, element_constructor)
```

Bases: `sage.structure.parent.Parent`

Subwords of a given word.

`cardinality()`

EXAMPLES:

```
sage: Subwords([1,2,3]).cardinality()
8
```

first()

EXAMPLES:

```
sage: Subwords([1,2,3]).first()
[]
sage: Subwords((1,2,3)).first()
()
sage: Subwords('123').first()
''
```

last()

EXAMPLES:

```
sage: Subwords([1,2,3]).last()
[1, 2, 3]
sage: Subwords((1,2,3)).last()
(1, 2, 3)
sage: Subwords('123').last()
'123'
```

random_element()

Return a random subword with uniform law.

EXAMPLES:

```
sage: S1 = Subwords([1,2,3,2,1,3])
sage: S2 = Subwords([4,6,6,6,7,4,5,5])
sage: for i in range(100):
.....:     w = S1.random_element()
.....:     if w in S2:
.....:         assert(not w)
sage: for i in range(100):
.....:     w = S2.random_element()
.....:     if w in S1:
.....:         assert(not w)
```

class `sage.combinat.subword.Subwords_wk(w, k, element_constructor)`

Bases: `sage.combinat.subword.Subwords_w`

Subwords with fixed length of a given word.

cardinality()

Return the number of subwords of w of length k.

EXAMPLES:

```
sage: Subwords([1,2,3], 2).cardinality()
3
```

first()

EXAMPLES:

```

sage: Subwords([1,2,3],2).first()
[1, 2]
sage: Subwords([1,2,3],0).first()
[]
sage: Subwords((1,2,3),2).first()
(1, 2)
sage: Subwords((1,2,3),0).first()
()
sage: Subwords('123',2).first()
'12'
sage: Subwords('123',0).first()
''

```

last()

EXAMPLES:

```

sage: Subwords([1,2,3],2).last()
[2, 3]
sage: Subwords([1,2,3],0).last()
[]
sage: Subwords((1,2,3),2).last()
(2, 3)
sage: Subwords((1,2,3),0).last()
()
sage: Subwords('123',2).last()
'23'
sage: Subwords('123',0).last()
''

```

random_element()

Return a random subword of given length with uniform law.

EXAMPLES:

```

sage: S1 = Subwords([1,2,3,2,1],3)
sage: S2 = Subwords([4,4,5,5,4,5,4,4],3)
sage: for i in range(100):
.....:     w = S1.random_element()
.....:     if w in S2:
.....:         assert(not w)
sage: for i in range(100):
.....:     w = S2.random_element()
.....:     if w in S1:
.....:         assert(not w)

```

`sage.combinat.subword.smallest_positions(word, subword, pos=0)`

Return the smallest positions for which subword appears as a subword of word.

If pos is specified, then it returns the positions of the first appearance of subword starting at pos.

If subword is not found in word, then return False.

EXAMPLES:

```

sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4])
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],2)
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],3)
[3, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,3])
[1, 2]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [5,5])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,4,5], [3,5])
[1, 4]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3])
[1, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3],2)
[2, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,3,4,4], [2,3,3,1])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3],3)
False

```

5.1.337 Subword complex

Fix a Coxeter system (W, S) . The subword complex $\mathcal{SC}(Q, w)$ associated to a word $Q \in S^*$ and an element $w \in W$ is the simplicial complex whose ground set is the set of positions in Q and whose facets are complements of sets of positions defining a reduced expression for w .

A subword complex is a shellable sphere if and only if the Demazure product of Q equals w , otherwise it is a shellable ball.

The code is optimized to be used with ReflectionGroup, it works as well with CoxeterGroup, but many methods fail for WeylGroup.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',3]); I = list(W.index_set())           # optional - gap3
sage: Q = I + W.w0.coxeter_sorting_word(I); Q                       # optional - gap3
[1, 2, 3, 1, 2, 3, 1, 2, 1]

sage: S = SubwordComplex(Q,W.w0)                                    # optional - gap3
sage: for F in S: print("{} {}".format(F, F.root_configuration()))  #_
↳ optional - gap3
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]

```

(continues on next page)

(continued from previous page)

```
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]
```

Testing that the implementation also works with CoxeterGroup:

```
sage: W = CoxeterGroup(['A',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I); Q
[1, 2, 3, 1, 2, 3, 1, 2, 1]
sage: S = SubwordComplex(Q,W.w0); S
Subword complex of type ['A', 3] for Q = (1, 2, 3, 1, 2, 3, 1, 2, 1) and pi = [1, 2, 3, 1, 2, 1]
sage: P = S.increasing_flip_poset(); P; len(P.cover_relations())
Finite poset containing 14 elements
21
```

The root configuration works:

```
sage: for F in S: print("{} {}".format(F, F.root_configuration()))
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]
```

And the weight configuration also works:

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2])
sage: F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

One finally can compute the brick polytope, using all functionality on weight configurations, though it does not realize to live in real space:

```

sage: W = CoxeterGroup(['A',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I)
sage: S = SubwordComplex(Q,W.w0)
sage: S.brick_polytope()
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 14 vertices

sage: W = CoxeterGroup(['H',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I)
sage: S = SubwordComplex(Q,W.w0)
sage: S.brick_polytope()
doctest:...: RuntimeWarning: the polytope is build with rational vertices
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices

```

REFERENCES:

class `sage.combinat.subword_complex.SubwordComplex`($Q, w, algorithm='inductive'$)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.topology.simplicial_complex.SimplicialComplex`

Fix a Coxeter system (W, S) . The subword complex $SC(Q, w)$ associated to a word $Q \in S^*$ and an element $w \in W$ is the simplicial complex whose ground set is the set of positions in Q and whose facets are complements of sets of positions defining a reduced expression for w .

A subword complex is a shellable sphere if and only if the Demazure product of Q equals w , otherwise it is a shellable ball.

Warning: This implementation only works for groups build using `CoxeterGroup`, and does not work with groups build using `WeylGroup`.

EXAMPLES:

As an example, dual associahedra are subword complexes in type A_{n-1} given by the word $[1, \dots, n, 1, \dots, n, 1, \dots, n-1, \dots, 1, 2, 1]$ and the permutation w_0 .

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w); SC # optional - gap3
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets() # optional - gap3
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

```

REFERENCES: [KnuMil], [PilStu]

Element

alias of *SubwordComplexFacet*

barycenter()

Return the barycenter of the brick polytope of *self*.

See also:

brick_polytope()

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: SC.barycenter() # optional - gap3
(2/3, 4/3)

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.barycenter()
(4/3, 8/3)

```

brick_fan()

Return the brick fan of *self*.

It is the normal fan of the brick polytope of *self*. It is formed by the cones generated by the weight configurations of the facets of *self*.

See also:

weight_cone

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.brick_fan() # optional - gap3
Rational polyhedral fan in 2-d lattice N

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.brick_fan()
Rational polyhedral fan in 2-d lattice N

```

brick_polytope(*coefficients=None*)

Return the brick polytope of *self*.

This polytope is the convex hull of the brick vectors of *self*.

INPUT:

- *coefficients* – (optional) a list of coefficients used to scale the fundamental weights

See also:

brick_vectors()

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: X = SC.brick_polytope(); X # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: Y = SC.brick_polytope(coefficients=[1,2]); Y # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: X == Y # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: X = SC.brick_polytope(); X
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: W = ReflectionGroup(['H',3]) # optional - gap3
sage: c = W.index_set(); Q = c + tuple(W.w0.coxeter_sorting_word(c)) #
↳ optional - gap3
sage: SC = SubwordComplex(Q,W.w0) # optional - gap3
sage: SC.brick_polytope() # optional - gap3
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices

```

brick_vectors(*coefficients=None*)

Return the list of all brick vectors of facets of *self*.

INPUT:

- *coefficients* – (optional) a list of coefficients used to scale the fundamental weights

See also:

[brick_vector](#)

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: SC.brick_vectors() # optional - gap3
[(5/3, 7/3), (5/3, 1/3), (2/3, 7/3), (-1/3, 4/3), (-1/3, 1/3)]
sage: SC.brick_vectors(coefficients=(1,2)) # optional - gap3
[(7/3, 11/3), (7/3, 2/3), (4/3, 11/3), (-2/3, 5/3), (-2/3, 2/3)]

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.brick_vectors()
[(10/3, 14/3), (10/3, 2/3), (4/3, 14/3), (-2/3, 8/3), (-2/3, 2/3)]
sage: SC.brick_vectors(coefficients=(1,2))
[(14/3, 22/3), (14/3, 4/3), (8/3, 22/3), (-4/3, 10/3), (-4/3, 4/3)]

```

cartan_type()

Return the Cartan type of *self*.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.cartan_type() # optional - gap3
['A', 2]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.cartan_type()
['A', 2]

```

cover_relations(*label=False*)

Return the set of cover relations in the associated poset.

INPUT:

- *label* – boolean (default `False`) whether or not to label the cover relations by the position of flip

OUTPUT:

a list of pairs of facets

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: sorted(SC.cover_relations()) # optional - gap3
[(0, 1), (0, 4),
 (0, 1), (1, 2)],
[(0, 4), (3, 4)],
[(1, 2), (2, 3)],
[(2, 3), (3, 4)]]

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: sorted(SC.cover_relations())
[(0, 1), (0, 4),
 (0, 1), (1, 2)],
[(0, 4), (3, 4)],
[(1, 2), (2, 3)],
[(2, 3), (3, 4)]]

```

dimension()

Return the dimension of self.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: SC.dimension() # optional - gap3
1

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)

```

(continues on next page)

(continued from previous page)

```
sage: SC.dimension()
1
```

facets()

Return all facets of self.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.facets() # optional - gap3
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

greedy_facet(side='positive')

Return the negative (or positive) greedy facet of self.

This is the lexicographically last (or first) facet of self.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.greedy_facet(side="positive") # optional - gap3
(0, 1)
sage: SC.greedy_facet(side="negative") # optional - gap3
(3, 4)
```

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.greedy_facet(side="positive")
(0, 1)
sage: SC.greedy_facet(side="negative")
(3, 4)
```

group()

Return the group associated to self.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.group() # optional - gap3
Irreducible real reflection group of rank 2 and type A2
```

```
sage: W = CoxeterGroup(['A',2])
```

(continues on next page)

(continued from previous page)

```

sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3]
[3 1]

```

increasing_flip_graph(*label=True*)

Return the increasing flip graph of the subword complex.

OUTPUT:

a directed graph

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: SC.increasing_flip_graph() # optional - gap3
Digraph on 5 vertices

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.increasing_flip_graph()
Digraph on 5 vertices

```

increasing_flip_poset()

Return the increasing flip poset of the subword complex.

OUTPUT:

a poset

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: SC.increasing_flip_poset() # optional - gap3
Finite poset containing 5 elements

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.increasing_flip_poset()
Finite poset containing 5 elements

```

interval(*I, J*)

Return the interval [I,J] in the increasing flip graph subword complex.

INPUT:

- I, J – two facets

OUTPUT:

a set of facets

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: F = SC([1, 2]) # optional - gap3
sage: SC.interval(F, F) # optional - gap3
{(1, 2)}

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: F = SC([1, 2])
sage: SC.interval(F, F)
{(1, 2)}

```

is_ball()

Return True if the subword complex `self` is a ball.

This is the case if and only if it is not a sphere.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3]) # optional - gap3
sage: w = W.from_reduced_word([2, 3, 2]) # optional - gap3
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w) # optional - gap3
sage: SC.is_ball() # optional - gap3
False

sage: SC = SubwordComplex([3, 2, 1, 3, 2, 3], w) # optional - gap3
sage: SC.is_ball() # optional - gap3
True

sage: W = CoxeterGroup(['A', 3])
sage: w = W.from_reduced_word([2, 3, 2])
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w)
sage: SC.is_ball()
False

```

is_double_root_free()

Return True if `self` is double-root-free.

This means that the root configurations of all facets do not contain a root twice.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: SC.is_double_root_free() # optional - gap3
True

sage: SC = SubwordComplex([1, 1, 2, 2, 1, 1], w) # optional - gap3
sage: SC.is_double_root_free() # optional - gap3
True

sage: SC = SubwordComplex([1, 2, 1, 2, 1, 2], w) # optional - gap3
sage: SC.is_double_root_free() # optional - gap3
False

```

(continues on next page)

(continued from previous page)

```

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: SC.is_double_root_free()
True

```

is_pure()

Return True since all subword complexes are pure.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3]) # optional - gap3
sage: w = W.from_reduced_word([2, 3, 2]) # optional - gap3
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w) # optional - gap3
sage: SC.is_pure() # optional - gap3
True

sage: W = CoxeterGroup(['A', 3])
sage: w = W.from_reduced_word([2, 3, 2])
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w)
sage: SC.is_pure()
True

```

is_root_independent()

Return True if self is root-independent.

This means that the root configuration of any (or equivalently all) facets is linearly independent.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0) # optional - gap3
sage: SC.is_root_independent() # optional - gap3
True

sage: SC = SubwordComplex([1, 2, 1, 2, 1, 2], W.w0) # optional - gap3
sage: SC.is_root_independent() # optional - gap3
False

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: SC.is_root_independent()
True

```

is_sphere()

Return True if the subword complex self is a sphere.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 3]) # optional - gap3
sage: w = W.from_reduced_word([2, 3, 2]) # optional - gap3
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w) # optional - gap3
sage: SC.is_sphere() # optional - gap3
True

```

(continues on next page)

(continued from previous page)

```

sage: SC = SubwordComplex([3,2,1,3,2,3], w)           # optional - gap3
sage: SC.is_sphere()                                 # optional - gap3
False

sage: W = CoxeterGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_sphere()
True

```

kappa_preimages()

Return a dictionary containing facets of `self` as keys, and list of elements of `self.group()` as values.

See also:

[*kappa_preimage*](#)

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2])                   # optional - gap3
sage: w = W.from_reduced_word([1,2,1])              # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w)          # optional - gap3
sage: kappa = SC.kappa_preimages()                 # optional - gap3
sage: for F in SC: print("{} {}".format(F, [w.reduced_word() for w in
↳kappa[F]]))   # optional - gap3
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: kappa = SC.kappa_preimages()
sage: for F in SC: print("{} {}".format(F, [w.reduced_word() for w in
↳kappa[F]]))
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

```

minkowski_summand(*i*)

Return the *i* th Minkowski summand of `self`.

INPUT:

i – an integer defining a position in the word *Q*

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2])                   # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)        # optional - gap3

```

(continues on next page)

(continued from previous page)

```

sage: SC.minkowski_summand(1) # optional - gap3
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.minkowski_summand(1)
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex

```

pi()

Return the element in the Coxeter group associated to `self`.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.pi().reduced_word() # optional - gap3
[1, 2, 1]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.pi().reduced_word()
[1, 2, 1]

```

word()

Return the word in the simple generators associated to `self`.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3
sage: SC.word() # optional - gap3
(1, 2, 1, 2, 1)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.word()
(1, 2, 1, 2, 1)

```

class `sage.combinat.subword_complex.SubwordComplexFacet`(*parent, positions, facet_test=True*)

Bases: `sage.topology.simplicial_complex.Simplex`, `sage.structure.element.Element`

A facet of a subword complex.

Facets of the subword complex $\mathcal{SC}(Q, w)$ are complements of sets of positions in Q defining a reduced expression for w .

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], w) # optional - gap3

```

(continues on next page)

(continued from previous page)

```

sage: F = SC[0]; F                                     # optional - gap3
(0, 1)

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC[0]; F
(0, 1)

```

brick_vector(*coefficients=None*)

Return the brick vector of self.

This is the sum of the weight vectors in the extended weight configuration.

INPUT:

- *coefficients* – (optional) a list of coefficients used to scale the fundamental weights

See also:[*extended_weight_configuration\(\)*](#)

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2])                   # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1])             # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)        # optional - gap3
sage: F = SC([1, 2]); F                              # optional - gap3
(1, 2)
sage: F.extended_weight_configuration()               # optional - gap3
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
sage: F.brick_vector()                              # optional - gap3
(2/3, 7/3)
sage: F.brick_vector(coefficients=[1, 2])           # optional - gap3
(4/3, 11/3)

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2])
sage: F.brick_vector()
(4/3, 14/3)
sage: F.brick_vector(coefficients=[1, 2])
(8/3, 22/3)

```

extended_root_configuration()

Return the extended root configuration of self.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The extended root configuration of a facet I of $SC(Q, w)$ is the sequence $r(I, 1), \dots, r(I, m)$ of roots defined by $r(I, k) = \prod_{Q_{[k-1] \setminus I}} (\alpha_{q_k})$, where $\prod_{Q_{[k-1] \setminus I}}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

The extended root configuration is used to perform flips efficiently.

See also:[*flip\(\)*](#)

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w) # optional - gap3
sage: F = SC([1,2]); F # optional - gap3
(1, 2)
sage: F.extended_root_configuration() # optional - gap3
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]

```

extended_weight_configuration(*coefficients=None*)Return the extended weight configuration of *self*.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The extended weight configuration of a facet I of $\mathcal{SC}(Q, w)$ is the sequence $w(I, 1), \dots, w(I, m)$ of weights defined by $w(I, k) = \Pi Q_{[k-1] \setminus I}(\omega_{q_k})$, where $\Pi Q_{[k-1] \setminus I}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

The extended weight configuration is used to compute the brick vector.

INPUT:

- *coefficients* – (optional) a list of coefficients used to scale the fundamental weights

See also:[*brick_vector*](#)()

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w) # optional - gap3
sage: F = SC([1,2]) # optional - gap3
sage: F.extended_weight_configuration() # optional - gap3
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
sage: F.extended_weight_configuration(coefficients=(1,2)) # optional - gap3
[(2/3, 1/3), (2/3, 4/3), (-1/3, 1/3), (2/3, 4/3), (-1/3, 1/3)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2])
sage: F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]

```

flip(*i, return_position=False*)Return the facet obtained after flipping position *i* in *self*.

INPUT:

- i – position in the word Q (integer).
- `return_position` – boolean (default: `False`) tells whether the new position should be returned as well.

OUTPUT:

- The new subword complex facet.
- The new position if `return_position` is `True`.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w) # optional - gap3
sage: F = SC([1,2]); F # optional - gap3
(1, 2)
sage: F.flip(1) # optional - gap3
(2, 3)
sage: F.flip(1, return_position=True) # optional - gap3
((2, 3), 3)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.flip(1)
(2, 3)
sage: F.flip(1, return_position=True)
((2, 3), 3)
```

is_vertex()

Return `True` if `self` is a vertex of the brick polytope of `self.parent`.

A facet is a vertex of the brick polytope if its root cone is pointed. Note that this property is always satisfied for root-independent subword complexes.

See also:

[`root_cone\(\)`](#)

EXAMPLES:

```
sage: W = ReflectionGroup(['A',1]) # optional - gap3
sage: w = W.from_reduced_word([1]) # optional - gap3
sage: SC = SubwordComplex([1,1,1],w) # optional - gap3
sage: F = SC([0,1]); F.is_vertex() # optional - gap3
True
sage: F = SC([0,2]); F.is_vertex() # optional - gap3
False

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1,2,1],w) # optional - gap3
sage: F = SC([0,1,2,3]); F.is_vertex() # optional - gap3
```

(continues on next page)

(continued from previous page)

```

True
sage: F = SC([0,1,2,6]); F.is_vertex()           # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1,2,1],w)
sage: F = SC([0,1,2,3]); F.is_vertex()
True
sage: F = SC([0,1,2,6]); F.is_vertex()
False

```

kappa_preimage()

Return the fiber of `self` under the κ map.

The κ map sends an element $w \in W$ to the unique facet of $I \in \mathcal{SC}(Q, w)$ such that the root configuration of I is contained in $w(\Phi^+)$. In other words, w is in the preimage of `self` under κ if and only if w^{-1} sends every root in the root configuration to a positive root.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2])               # optional - gap3
sage: w = W.from_reduced_word([1,2,1])         # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)      # optional - gap3

sage: F = SC([1,2]); F                         # optional - gap3
(1, 2)
sage: F.kappa_preimage()                       # optional - gap3
[(1,4)(2,3)(5,6)]

sage: F = SC([0,4]); F                         # optional - gap3
(0, 4)
sage: F.kappa_preimage()                       # optional - gap3
[(1,3)(2,5)(4,6), (1,2,6)(3,4,5)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)

sage: F = SC([1,2]); F
(1, 2)
sage: F.kappa_preimage()
[
[-1  1]
[ 0  1]
]

sage: F = SC([0,4]); F
(0, 4)
sage: F.kappa_preimage()
[
[ 1  0] [-1  1]
[ 1 -1], [-1  0]
]

```

(continues on next page)

(continued from previous page)

]

plot(*list_colors=None, labels=[], thickness=3, fontsize=14, shift=(0, 0), compact=False, roots=True, **args*)

In type *A* or *B*, plot a pseudoline arrangement representing the facet *self*.

Pseudoline arrangements are graphical representations of facets of types *A* or *B* subword complexes.

INPUT:

- *list_colors* – list (default: []) to change the colors of the pseudolines.
- *labels* – list (default: []) to change the labels of the pseudolines.
- *thickness* – integer (default: 3) for the thickness of the pseudolines.
- *fontsize* – integer (default: 14) for the size of the font used for labels.
- *shift* – couple of coordinates (default: (0, 0)) to change the origin.
- *compact* – boolean (default: False) to require a more compact representation.
- *roots* – boolean (default: True) to print the extended root configuration.

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 2]) # optional - gap3
sage: w = W.from_reduced_word([1, 2, 1]) # optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w) # optional - gap3
sage: F = SC([1, 2]); F.plot() # optional - gap3
Graphics object consisting of 26 graphics primitives

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: F = SC([1, 2]); F.plot()
Graphics object consisting of 26 graphics primitives

sage: W = ReflectionGroup(['B', 3]) # optional - gap3
sage: c = W.from_reduced_word([1, 2, 3]) # optional - gap3
sage: Q = c.reduced_word()*2 + W.w0.coxeter_sorting_word(c) # optional - gap3
sage: SC = SubwordComplex(Q, W.w0) # optional - gap3
sage: F = SC[15]; F.plot() # optional - gap3
Graphics object consisting of 52 graphics primitives

```

REFERENCES: [PilStu]

root_cone()

Return the polyhedral cone generated by the root configuration of *self*.

See also:

[*root_configuration\(\)*](#)

EXAMPLES:

```

sage: W = ReflectionGroup(['A', 1]) # optional - gap3
sage: w = W.from_reduced_word([1]) # optional - gap3
sage: SC = SubwordComplex([1, 1, 1], w) # optional - gap3

```

(continues on next page)

(continued from previous page)

```

sage: F = SC([0,2]); F.root_cone()           # optional - gap3
1-d cone in 1-d lattice N

sage: W = CoxeterGroup(['A',1])
sage: w = W.from_reduced_word([1])
sage: SC = SubwordComplex([1,1,1],w)
sage: F = SC([0,2]); F.root_cone()
1-d cone in 1-d lattice N

```

root_configuration()

Return the root configuration of `self`.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The root configuration of a facet $I = [i_1, \dots, i_n]$ of $\mathcal{SC}(Q, w)$ is the sequence $r(I, i_1), \dots, r(I, i_n)$ of roots defined by $r(I, k) = \prod_{Q_{[k-1] \setminus I}} (\alpha_{q_k})$, where $\prod_{Q_{[k-1] \setminus I}}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2])           # optional - gap3
sage: w = W.from_reduced_word([1,2,1])      # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)    # optional - gap3
sage: F = SC([1,2]); F                      # optional - gap3
(1, 2)
sage: F.root_configuration()                # optional - gap3
[(1, 1), (-1, 0)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.root_configuration()                # optional - gap3
[(1, 1), (-1, 0)]

```

show(*kws, **args)

Show the facet `self`.

See also:

`plot()`

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2])           # optional - gap3
sage: w = W.from_reduced_word([1,2,1])      # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)    # optional - gap3
sage: F = SC([1,2]); F.show()               # optional - gap3

```

upper_root_configuration()

Return the positive roots of the root configuration of `self`.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2])           # optional - gap3
sage: w = W.from_reduced_word([1,2,1])      # optional - gap3

```

(continues on next page)

(continued from previous page)

sage: F = SC([1,2]); F
(1, 2)
sage: WC = F.weight_cone(); WC
2-d cone in 2-d lattice N

```

weight_configuration()

Return the weight configuration of `self`.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The weight configuration of a facet $I = [i_1, \dots, i_n]$ of $\mathcal{SC}(Q, w)$ is the sequence $w(I, i_1), \dots, w(I, i_n)$ of weights defined by $w(I, k) = \prod_{Q_{[k-1] \setminus I}(\omega_{q_k})}$, where $\prod_{Q_{[k-1] \setminus I}}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

EXAMPLES:

```

sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: w = W.from_reduced_word([1,2,1]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w) # optional - gap3
sage: F = SC([1,2]); F # optional - gap3
(1, 2)
sage: F.weight_configuration() # optional - gap3
[(1/3, 2/3), (-1/3, 1/3)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.weight_configuration()
[(2/3, 4/3), (-2/3, 2/3)]

```

5.1.338 Super Tableaux

AUTHORS:

- Matthew Lancellotti (2007): initial version
- Chaman Agrawal (2019-07-23): Modify standard and semistandard tableaux for super tableaux.

```

class sage.combinat.super_tableau.SemistandardSuperTableau(parent, t, check=True,
preprocessed=False)

```

Bases: *sage.combinat.tableau.Tableau*

A semistandard super tableau.

A semistandard super tableau is a tableau with primed positive integer entries. As defined in [Muth2019], a semistandard super tableau weakly increases along the rows and down the columns. Also, the letters of even parity (unprimed) strictly increases down the columns, and letters of odd parity (primed) strictly increases along the rows. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

INPUT:

- *t* – a tableau, a list of iterables, or an empty list

EXAMPLES:

```

sage: t = SemistandardSuperTableau(['1p',2,"3'"],[2,3]); t
[[1', 2, 3'], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1' 2 3'
2 3
sage: t = Tableau(["1p",2],[2])
sage: s = SemistandardSuperTableau(t); s
[[1', 2], [2]]
sage: SemistandardSuperTableau([]) # The empty tableau
[]

```

check()

Check that `self` is a valid semistandard super tableau.

class `sage.combinat.super_tableau.SemistandardSuperTableaux(**kws)`

Bases: `sage.combinat.tableau.SemistandardTableaux`

The set of semistandard super tableaux.

A semistandard super tableau is a tableau with primed positive integer entries. As defined in [Muth2019], a semistandard super tableau weakly increases along the rows and down the columns. Also, the letters of even parity (unprimed) strictly increases down the columns, and letters of odd parity (primed) strictly increases along the rows. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

EXAMPLES:

```
sage: SST = SemistandardSuperTableaux(); SST
Semistandard super tableaux
```

Element

alias of `SemistandardSuperTableau`

class `sage.combinat.super_tableau.SemistandardSuperTableaux_all`

Bases: `sage.combinat.super_tableau.SemistandardSuperTableaux`

All semistandard super tableaux.

class `sage.combinat.super_tableau.StandardSuperTableau(parent, t, check=True, preprocessed=False)`

Bases: `sage.combinat.super_tableau.SemistandardSuperTableau`

A standard super tableau.

A standard super tableau is a semistandard super tableau whose entries are in bijection with positive primed integers $1', 1, 2' \dots n$.

For more information refer [Muth2019].

INPUT:

- `t` – a Tableau, a list of iterables, or an empty list

EXAMPLES:

```
sage: t = StandardSuperTableau([[["1'", 1, "2'", 2, "3'"], [3, "4'"]]); t
[[1', 1, 2', 2, 3'], [3, 4']]
sage: t.shape()
[5, 2]
sage: t.pp() # pretty printing
1' 1 2' 2 3'
3 4'
sage: t.is_standard()
True
sage: StandardSuperTableau([]) # The empty tableau
[]
```

check()

Check that `self` is a standard tableau.

is_standard()

Return True since `self` is a standard super tableau.

EXAMPLES:

```
sage: StandardSuperTableau([[1'p', 1], [1'2p', 2]]).is_standard()
True
```

class `sage.combinat.super_tableau.StandardSuperTableaux`(***kws*)

Bases: `sage.combinat.super_tableau.SemistandardSuperTableaux`, `sage.structure.parent.Parent`

The set of standard super tableaux.

A standard super tableau is a tableau whose entries are primed positive integers, which are strictly increasing in rows and down columns and contains each letters from $1', 1, 2', \dots, n$ exactly once.

For more information refer [Muth2019].

INPUT:

- *n* – a non-negative integer or a partition.

EXAMPLES:

```
sage: SST = StandardSuperTableaux()
sage: SST
Standard super tableaux
sage: SST([[1'"1", 1, "2'"2, "3'"3"], [3, "4'"4]])
[[1', 1, 2', 2, 3'], [3, 4']]
sage: SST = StandardSuperTableaux(3)
sage: SST
Standard super tableaux of size 3
sage: SST.first()
[[1', 1, 2']]
sage: SST.last()
[[1'], [1], [2']]
sage: SST.cardinality()
4
sage: SST.list()
[[[1', 1, 2']], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]
sage: SST = StandardSuperTableaux([3, 2])
sage: SST
Standard super tableaux of shape [3, 2]
```

Element

alias of `StandardSuperTableau`

class `sage.combinat.super_tableau.StandardSuperTableaux_all`

Bases: `sage.combinat.super_tableau.StandardSuperTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

All standard super tableaux.

class `sage.combinat.super_tableau.StandardSuperTableaux_shape`(*p*)

Bases: `sage.combinat.super_tableau.StandardSuperTableaux`

Standard super tableaux of a fixed shape *p*.

cardinality()

Return the number of standard super tableaux of given shape.

The standard super tableaux of a fixed shape *p* are in bijection with the corresponding standard tableaux (under the alphabet relabeling). Refer `sage.combinat.tableau.StandardTableaux_shape` for more details.

EXAMPLES:

```

sage: StandardSuperTableaux([3,2,1]).cardinality()
16
sage: StandardSuperTableaux([2,2]).cardinality()
2
sage: StandardSuperTableaux([5]).cardinality()
1
sage: StandardSuperTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardSuperTableaux([]).cardinality()
1

```

class `sage.combinat.super_tableau.StandardSuperTableaux_size(n)`

Bases: `sage.combinat.super_tableau.StandardSuperTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

Standard super tableaux of fixed size *n*.

EXAMPLES:

```

sage: [ t for t in StandardSuperTableaux(1) ]
[[[1']]
sage: [ t for t in StandardSuperTableaux(2) ]
[[[1', 1]], [[1'], [1]]]
sage: [ t for t in StandardSuperTableaux(3) ]
[[[1', 1, 2']], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]
sage: StandardSuperTableaux(4)[: ]
[[[1', 1, 2', 2]],
 [[1', 2', 2], [1]],
 [[1', 1, 2], [2']],
 [[1', 1, 2'], [2]],
 [[1', 2'], [1, 2]],
 [[1', 1], [2', 2]],
 [[1', 2], [1], [2']],
 [[1', 2'], [1], [2]],
 [[1', 1], [2'], [2]],
 [[1'], [1], [2'], [2]]]

```

cardinality()

Return the number of all standard super tableaux of size *n*.

The standard super tableaux of size *n* are in bijection with the corresponding standard tableaux (under the alphabet relabeling). Refer `sage.combinat.tableau.StandardTableaux_size` for more details.

EXAMPLES:

```

sage: StandardSuperTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardSuperTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
sage: StandardSuperTableaux(50).cardinality() # long time
27886995605342342839104615869259776

```

5.1.339 Super Partitions

AUTHORS:

- Mike Zabrocki

A super partition of size n and fermionic sector m is a pair consisting of a strict partition of some integer r of length m (that may end in a 0) and an integer partition of $n - r$.

This module provides tools for manipulating super partitions.

Super partitions are the indexing set for symmetric functions in super space.

Super partitions may be input in two different formats: one as a pair consisting of fermionic (strict partition) and a bosonic (partition) part and the other as a list of integer values where the negative entries come first and are listed in strict order followed by the positive values in weak order.

A super partition is displayed as two partitions separated by a semicolon as a default. Super partitions may also be displayed as a weakly increasing sequence of integers that are strict if the numbers are not positive.

These combinatorial objects index the space of symmetric polynomials in two sets of variables, one commuting and one anti-commuting, and they are known as symmetric functions in super space (hence the origin of the name super partitions).

EXAMPLES:

```
sage: SuperPartitions()
Super Partitions
sage: SuperPartitions(2)
Super Partitions of 2
sage: SuperPartitions(2).cardinality()
8
sage: SuperPartitions(4,2)
Super Partitions of 4 and of fermionic sector 2
sage: [[2,0],[1,1]] in SuperPartitions(4,2)
True
sage: [[1,0],[1,1]] in SuperPartitions(4,2)
False
sage: [[1,0],[2,1]] in SuperPartitions(4)
True
sage: [[1,0],[2,2,1]] in SuperPartitions(4)
False
sage: [[1,0],[2,1]] in SuperPartitions()
True
sage: [[1,1],[2,1]] in SuperPartitions()
False
sage: [-2, 0, 1, 1] in SuperPartitions(4,2)
True
sage: [-1, 0, 1, 1] in SuperPartitions(4,2)
False
sage: [-2, -2, 2, 1] in SuperPartitions(7,2)
False
```

REFERENCES:

- [JL2016]

class sage.combinat.superpartition.**SuperPartition**(parent, lst, check=True, immutable=True)
 Bases: sage.structure.list_clone.ClonableArray

A super partition.

A *super partition* of size n and fermionic sector m is a pair consisting of a strict partition of some integer r of length m (that may end in a 0) and an integer partition of $n - r$.

EXAMPLES:

```
sage: sp = SuperPartition([[1,0],[2,2,1]]); sp
[1, 0; 2, 2, 1]
sage: sp[0]
(1, 0)
sage: sp[1]
(2, 2, 1)
sage: sp.fermionic_degree()
2
sage: sp.bosonic_degree()
6
sage: sp.length()
5
sage: sp.conjugate()
[4, 2; ]
```

a_part()

The antisymmetric part as a list of strictly decreasing integers.

OUTPUT:

- a list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).antisymmetric_part()
[3, 1]
sage: SuperPartition([[2,1,0],[3,3]]).antisymmetric_part()
[2, 1, 0]
```

add_horizontal_border_strip_star(h)

Return a list of super partitions that differ from `self` by a horizontal strip.

The notion of horizontal strip comes from the Pieri rule for the Schur-star basis of symmetric functions in super space (see Theorem 7 from [JL2016]).

INPUT:

- h – number of cells in the horizontal strip

OUTPUT:

- a list of super partitions

EXAMPLES:

```
sage: SuperPartition([[4,1],[3]]).add_horizontal_border_strip_star(3)
[[3, 1; 7],
 [4, 1; 6],
 [3, 0; 6, 2],
 [3, 1; 6, 1],
 [4, 0; 5, 2],
 [4, 1; 5, 1],
```

(continues on next page)

(continued from previous page)

```

[3, 0; 5, 3],
[3, 1; 5, 2],
[4, 0; 4, 3],
[4, 1; 4, 2],
[4, 1; 3, 3]]
sage: SuperPartition([[2,1],[3]]).add_horizontal_border_strip_star(2)
[[2, 1; 5], [2, 0; 4, 2], [2, 1; 4, 1], [2, 0; 3, 3], [2, 1; 3, 2]]

```

add_horizontal_border_strip_star_bar(*h*)

List super partitions that differ from `self` by a horizontal strip.

The notion of horizontal strip comes from the Pieri rule for the Schur-star-bar basis of symmetric functions in super space (see Theorem 10 from [JL2016]).

INPUT:

- `h` – number of cells in the horizontal strip

OUTPUT:

- a list of super partitions

EXAMPLES:

```

sage: SuperPartition([[4,1],[5,4]]).add_horizontal_border_strip_star_bar(3)
[[4, 1; 8, 4],
 [4, 1; 7, 5],
 [4, 2; 7, 4],
 [4, 1; 7, 4, 1],
 [4, 2; 6, 5],
 [4, 1; 6, 5, 1],
 [4, 3; 6, 4],
 [4, 2; 6, 4, 1],
 [4, 1; 6, 4, 2],
 [4, 3; 5, 5],
 [4, 2; 5, 5, 1],
 [4, 1; 5, 5, 2],
 [4, 3; 5, 4, 1],
 [4, 1; 5, 4, 3]]
sage: SuperPartition([[3,1],[5]]).add_horizontal_border_strip_star_bar(2)
[[3, 1; 7],
 [4, 1; 6],
 [3, 2; 6],
 [3, 1; 6, 1],
 [4, 2; 5],
 [4, 1; 5, 1],
 [3, 2; 5, 1],
 [3, 1; 5, 2]]

```

antisymmetric_part()

The antisymmetric part as a list of strictly decreasing integers.

OUTPUT:

- a list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).antisymmetric_part()
[3, 1]
sage: SuperPartition([[2,1,0],[3,3]]).antisymmetric_part()
[2, 1, 0]
```

bi_degree()

Return the bidegree of `self`, which is a pair consisting of the bosonic and fermionic degree.

OUTPUT:

- a tuple of two integers

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).bi_degree()
(9, 2)
sage: SuperPartition([[2,1,0],[3,3]]).bi_degree()
(9, 3)
```

bosonic_degree()

Return the bosonic degree of `self`.

The *bosonic degree* is the sum of the sizes of the antisymmetric and symmetric parts.

OUTPUT:

- an integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).bosonic_degree()
9
sage: SuperPartition([[2,1,0],[3,3]]).bosonic_degree()
9
```

bosonic_length()

Return the length of the partition of the symmetric part.

OUTPUT:

- an integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).bosonic_length()
3
sage: SuperPartition([[2,1,0],[3,3]]).bosonic_length()
2
```

check()

Check that `self` is a valid super partition.

EXAMPLES:

```
sage: SP = SuperPartition([[1],[1]])
sage: SP.check()
```

conjugate()

Conjugate of a super partition.

The *conjugate* of a super partition is defined by conjugating the circled diagram.

OUTPUT:

- a *SuperPartition*

EXAMPLES:

```
sage: SuperPartition([[3, 1, 0], [4, 3, 2, 1]]).conjugate()
[6, 4, 1; 3]
sage: all(sp == sp.conjugate().conjugate() for sp in SuperPartitions(4))
True
sage: all(sp.conjugate() in SuperPartitions(3,2) for sp in SuperPartitions(3,2))
True
```

degree()

Return the bosonic degree of *self*.

The *bosonic degree* is the sum of the sizes of the antisymmetric and symmetric parts.

OUTPUT:

- an integer

EXAMPLES:

```
sage: SuperPartition([[3, 1], [2, 2, 1]]).bosonic_degree()
9
sage: SuperPartition([[2, 1, 0], [3, 3]]).bosonic_degree()
9
```

dominates(*other*)

Return True if and only if *self* dominates *other*.

If the symmetric and anti-symmetric parts of *self* and *other* are not the same size then the result is False.

EXAMPLES:

```
sage: LA = SuperPartition([[2, 1], [2, 1, 1]])
sage: LA.dominates([[2, 1], [3, 1]])
False
sage: LA.dominates([[2, 1], [1, 1, 1, 1]])
True
sage: LA.dominates([[3], [2, 1, 1]])
False
sage: LA.dominates([[1], [1]*6])
False
```

fermionic_degree()

Return the fermionic degree of *self*.

The *fermionic degree* is the length of the antisymmetric part.

OUTPUT:

- an integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).fermionic_degree()
2
sage: SuperPartition([[2,1,0],[3,3]]).fermionic_degree()
3
```

fermionic_sector()

Return the fermionic degree of `self`.

The *fermionic degree* is the length of the antisymmetric part.

OUTPUT:

- an integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).fermionic_degree()
2
sage: SuperPartition([[2,1,0],[3,3]]).fermionic_degree()
3
```

static from_circled_diagram(shape, corners)

Construct a super partition from a circled diagram.

A circled diagram consists of a partition of the concatenation of the antisymmetric and symmetric parts and a list of addable cells of the partition which indicate the location of the circled cells.

INPUT:

- `shape` – a partition or list of integers
- `corners` – a list of removable cells of `shape`

OUTPUT:

- a *SuperPartition*

EXAMPLES:

```
sage: SuperPartition.from_circled_diagram([3, 2, 2, 1, 1], [(0, 3), (3, 1)])
[3, 1; 2, 2, 1]
sage: SuperPartition.from_circled_diagram([3, 3, 2, 1], [(2, 2), (3, 1), (4, 0)])
[2, 1, 0; 3, 3]
sage: from_cd = SuperPartition.from_circled_diagram
sage: all(sp == from_cd(*sp.to_circled_diagram()) for sp in SuperPartitions(4))
True
```

length()

Return the length of `self`, which is the sum of the lengths of the antisymmetric and symmetric part.

OUTPUT:

- an integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).length()
5
sage: SuperPartition([[2,1,0],[3,3]]).length()
5
```

s_part()

The symmetric part as a list of weakly decreasing integers.

OUTPUT:

- a list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).symmetric_part()
[2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).symmetric_part()
[3, 3]
```

shape_circled_diagram()

A concatenated partition with an extra cell for each antisymmetric part

OUTPUT:

- a partition

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).shape_circled_diagram()
[4, 2, 2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).shape_circled_diagram()
[3, 3, 3, 2, 1]
```

sign()

Return the sign of a permutation of cycle type the symmetric part of self.

OUTPUT:

- either 1 or -1

EXAMPLES:

```
sage: SuperPartition([[1,0],[3,1,1]]).sign()
-1
sage: SuperPartition([[1,0],[3,2,1]]).sign()
1
sage: sum(sp.sign()/sp.zee() for sp in SuperPartitions(6,0))
0
```

symmetric_part()

The symmetric part as a list of weakly decreasing integers.

OUTPUT:

- a list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).symmetric_part()
[2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).symmetric_part()
[3, 3]
```

to_circled_diagram()

The shape of the circled diagram and a list of addable cells

A circled diagram consists of a partition for the outer shape and a list of removable cells of the partition indicating the location of the circled cells

OUTPUT:

- a list consisting of a partition and a list of pairs of integers

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1])).to_circled_diagram()
[[3, 2, 2, 1, 1], [(0, 3), (3, 1)]]
sage: SuperPartition([[2,1,0],[3,3]]).to_circled_diagram()
[[3, 3, 2, 1], [(2, 2), (3, 1), (4, 0)]]
sage: from_cd = SuperPartition.from_circled_diagram
sage: all(sp == from_cd(*sp.to_circled_diagram()) for sp in SuperPartitions(4))
True
```

to_composition()

Concatenate the antisymmetric and symmetric parts to a composition.

OUTPUT:

- a (possibly weak) composition

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1])).to_composition()
[3, 1, 2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_composition()
[2, 1, 0, 3, 3]
sage: SuperPartition([[2,1,0],[3,3]]).to_composition().parent()
Compositions of non-negative integers
```

to_list()

The list of two lists with the antisymmetric and symmetric parts.

EXAMPLES:

```
sage: SuperPartition([[1],[1]]).to_list()
[[1], [1]]
sage: SuperPartition([], [1]).to_list()
[[], [1]]
```

to_partition()

Concatenate and sort the antisymmetric and symmetric parts to a partition.

OUTPUT:

- a partition

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1])).to_partition()
[3, 2, 2, 1, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_partition()
[3, 3, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_partition().parent()
Partitions
```

zee()

Return the centralizer size of a permutation of cycle type symmetric part of `self`.

OUTPUT:

- a positive integer

EXAMPLES:

```
sage: SuperPartition([[1,0],[3,1,1]]).zee()
6
sage: SuperPartition([[1],[2,2,1]]).zee()
8
sage: sum(1/sp.zee() for sp in SuperPartitions(6,0))
1
```

class `sage.combinat.superpartition.SuperPartitions`(*is_infinite=False*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Super partitions.

A super partition of size n and fermionic sector m is a pair consisting of a strict partition of some integer r of length m (that may end in a 0) and an integer partition of $n - r$.

INPUT:

- n – an integer (optional: default None)
- m – if n is specified, an integer (optional: default None)

Super partitions are the indexing set for symmetric functions in super space.

EXAMPLES:

```
sage: SuperPartitions()
Super Partitions
sage: SuperPartitions(2)
Super Partitions of 2
sage: SuperPartitions(2).cardinality()
8
sage: SuperPartitions(4,2)
Super Partitions of 4 and of fermionic sector 2
sage: [[2,0],[1,1]] in SuperPartitions(4,2)
True
sage: [[1,0],[1,1]] in SuperPartitions(4,2)
False
sage: [[1,0],[2,1]] in SuperPartitions(4)
True
sage: [[1,0],[2,2,1]] in SuperPartitions(4)
False
sage: [[1,0],[2,1]] in SuperPartitions()
True
sage: [[1,1],[2,1]] in SuperPartitions()
False
```

Element

alias of *SuperPartition*

`options(*get_value, **set_value)`

OPTIONS:

- `display` – (default: `default`) Specifies how the super partitions should be printed
 - `default` – the super partition is displayed in a form [fermionic part; bosonic part]
 - `list` – the super partitions are displayed in a list of two lists
 - `pair` – the super partition is displayed as a list of integers

See [GlobalOptions](#) for more features of these options.

`class sage.combinat.superpartition.SuperPartitions_all`

Bases: `sage.combinat.superpartition.SuperPartitions`

Initialize self.

`class sage.combinat.superpartition.SuperPartitions_n(n)`

Bases: `sage.combinat.superpartition.SuperPartitions`

Initialize self.

`class sage.combinat.superpartition.SuperPartitions_n_m(n, m)`

Bases: `sage.combinat.superpartition.SuperPartitions`

Initialize self.

5.1.340 Symmetric Group Algebra

`sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroupT(R, n, q=None)`

Return the Hecke algebra of the symmetric group S_n on the T-basis with quantum parameter q over the ring R .

If R is a commutative ring and q is an invertible element of R , and if n is a nonnegative integer, then the Hecke algebra of the symmetric group S_n over R with quantum parameter q is defined as the algebra generated by the generators T_1, T_2, \dots, T_{n-1} with relations

$$T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$$

for all $i < n - 1$ (“braid relations”),

$$T_i T_j = T_j T_i$$

for all i and j such that $|i - j| > 1$ (“locality relations”), and

$$T_i^2 = q + (q - 1)T_i$$

for all i (the “quadratic relations”, also known in the form $(T_i + 1)(T_i - q) = 0$). (This is only one of several existing definitions in literature, not all of which are fully equivalent. We are following the conventions of [Go1993].) For any permutation $w \in S_n$, we can define an element T_w of this Hecke algebra by setting $T_w = T_{i_1} T_{i_2} \cdots T_{i_k}$, where $w = s_{i_1} s_{i_2} \cdots s_{i_k}$ is a reduced word for w (with s_i meaning the transposition $(i, i + 1)$, and the product of permutations being evaluated by first applying s_{i_k} , then $s_{i_{k-1}}$, etc.). This element is independent of the choice of the reduced decomposition, and can be computed in Sage by calling `H[w]` where `H` is the Hecke algebra and `w` is the permutation.

The Hecke algebra of the symmetric group S_n with quantum parameter q over R can be seen as a deformation of the group algebra RS_n ; indeed, it becomes RS_n when $q = 1$.

Warning: The multiplication on the Hecke algebra of the symmetric group does *not* follow the global option `mult` of the `Permutations` class (see `options()`). It is always as defined above. It does not match the default option (`mult=12r`) of the symmetric group algebra!

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3)
Hecke algebra of the symmetric group of order 3 on the T basis over Univariate_
↪Polynomial Ring in q over Rational Field
```

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2)
Hecke algebra of the symmetric group of order 3 with q=2 on the T basis over_
↪Rational Field
```

The multiplication on the Hecke algebra follows a different convention than the one on the symmetric group algebra does by default:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3([1,3,2]) * H3([2,1,3])
T[3, 1, 2]
sage: S3 = SymmetricGroupAlgebra(QQ, 3)
sage: S3([1,3,2]) * S3([2,1,3])
[2, 3, 1]

sage: TestSuite(H3).run()
```

```
class sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroup_generic(R, n,
                                                                              q=None)
```

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

one_basis()

Return the identity permutation.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).one() # indirect doctest
T[1, 2, 3]
```

q()

Return the variable or parameter q .

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).q()
q
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2).q()
2
```

```
class sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroup_t(R, n, q=None)
Bases: sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroup_generic
```

algebra_generators()

Return the generators of the algebra.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).algebra_generators()
[T[2, 1, 3], T[1, 3, 2]]
```

jucys_murphy(*k*)

Return the Jucys-Murphy element J_k of the Hecke algebra.

These Jucys-Murphy elements are defined by

$$J_k = (T_{k-1}T_{k-2} \cdots T_1)(T_1T_2 \cdots T_{k-1}).$$

More explicitly,

$$J_k = q^{k-1} + \sum_{l=1}^{k-1} (q^l - q^{l-1})T_{(l,k)}.$$

For generic q , the J_k generate a maximal commutative sub-algebra of the Hecke algebra.

Warning: The specialization $q = 1$ does *not* map these elements J_k to the Young-Jucys-Murphy elements of the group algebra RS_n . (Instead, it maps the “reduced” Jucys-Murphy elements $(J_k - q^{k-1})/(q - 1)$ to the Young-Jucys-Murphy elements of RS_n .)

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: j2 = H3.jucys_murphy(2); j2
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: j3 = H3.jucys_murphy(3); j3
q^2*T[1, 2, 3] + (q^2-q)*T[1, 3, 2] + (q-1)*T[3, 2, 1]
sage: j2*j3 == j3*j2
True
sage: j0 = H3.jucys_murphy(1); j0 == H3.one()
True
sage: H3.jucys_murphy(0)
Traceback (most recent call last):
...
ValueError: k (= 0) must be between 1 and n (= 3)
```

product_on_basis(*perm1*, *perm2*)

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: a = H3([2, 1, 3]) + 2*H3([1, 2, 3]) - H3([3, 2, 1])
sage: a^2 #indirect doctest
6*T[1, 2, 3] + 4*T[2, 1, 3] - T[2, 3, 1] - T[3, 1, 2] - 4*T[3, 2, 1]
```

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3([2, 1, 3]) + 2*QS3([1, 2, 3]) - QS3([3, 2, 1])
sage: a^2
6*[1, 2, 3] + 4*[2, 1, 3] - [2, 3, 1] - [3, 1, 2] - 4*[3, 2, 1]
```

t(*i*)

Return the element T_i of the Hecke algebra self.

EXAMPLES:

```

sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t(1)
T[2, 1, 3]
sage: H3.t(2)
T[1, 3, 2]
sage: H3.t(0)
Traceback (most recent call last):
...
ValueError: i (= 0) must be between 1 and n-1 (= 2)

```

t_action(*a*, *i*)

Return the product $T_i \cdot a$.

EXAMPLES:

```

sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: a = H3([2, 1, 3]) + 2*H3([1, 2, 3])
sage: H3.t_action(a, 1)
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
sage: H3.t(1)*a
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]

```

t_action_on_basis(*perm*, *i*)

Return the product $T_i \cdot T_{perm}$, where *perm* is a permutation in the symmetric group S_n .

EXAMPLES:

```

sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t_action_on_basis(Permutation([2, 1, 3]), 1)
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: H3.t_action_on_basis(Permutation([1, 2, 3]), 1)
T[2, 1, 3]
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: H3.t_action_on_basis(Permutation([2, 1, 3]), 1)
T[1, 2, 3]
sage: H3.t_action_on_basis(Permutation([1, 3, 2]), 2)
T[1, 2, 3]

```

`sage.combinat.symmetric_group_algebra.SymmetricGroupAlgebra`(*R*, *W*, *category=None*)

Return the symmetric group algebra of order *W* over the ring *R*.

INPUT:

- *W* – a symmetric group; alternatively an integer *n* can be provided, as shorthand for `Permutations(n)`.
- *R* – a base ring
- *category* – a category (default: the category of *W*)

This supports several implementations of the symmetric group. At this point this has been tested with `W=Permutations(n)` and `W=SymmetricGroup(n)`.

Warning: Some features are failing in the latter case, in particular if the domain of the symmetric group is not $1, \dots, n$.

Note: The brave can also try setting $W=WeylGroup(['A', n-1])$, but little support for this currently exists.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3); QS3
Symmetric group algebra of order 3 over Rational Field
sage: QS3(1)
[1, 2, 3]
sage: QS3(2)
2*[1, 2, 3]
sage: basis = [QS3(p) for p in Permutations(3)]
sage: a = sum(basis); a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: a^2
6*[1, 2, 3] + 6*[1, 3, 2] + 6*[2, 1, 3] + 6*[2, 3, 1] + 6*[3, 1, 2] + 6*[3, 2, 1]
sage: a^2 == 6*a
True
sage: b = QS3([3, 1, 2])
sage: b
[3, 1, 2]
sage: b*a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: b*a == a
True
```

We now construct the symmetric group algebra by providing explicitly the underlying group:

```
sage: SGA = SymmetricGroupAlgebra(QQ, Permutations(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Standard permutations of 4
sage: SGA.an_element()
[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 3*[1, 3, 2, 4] + [4, 1, 2, 3]

sage: SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Symmetric group of order 4! as a permutation group
sage: SGA.an_element()
() + (2,3,4) + 2*(1,3)(2,4) + 3*(1,4)(2,3)

sage: SGA = SymmetricGroupAlgebra(QQ, WeylGroup(['A', 3], prefix='s')); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)
sage: SGA.an_element()
s1*s2*s3 + 3*s3*s2 + 2*s3 + 1
```

The preferred way to construct the symmetric group algebra is to go through the usual algebra method:

```
sage: SGA = Permutations(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field
```

(continues on next page)

(continued from previous page)

```
sage: SGA.group()
Standard permutations of 3

sage: SGA = SymmetricGroup(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field

sage: SGA.group()
Symmetric group of order 3! as a permutation group
```

The canonical embedding from the symmetric group algebra of order n to the symmetric group algebra of order $p > n$ is available as a coercion:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.coerce_map_from(QS3)
Generic morphism:
  From: Symmetric group algebra of order 3 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: x3 = QS3([3,1,2]) + 2 * QS3([2,3,1]); x3
2*[2, 3, 1] + [3, 1, 2]
sage: QS4(x3)
2*[2, 3, 1, 4] + [3, 1, 2, 4]
```

This allows for mixed expressions:

```
sage: x4 = 3*QS4([3, 1, 4, 2])
sage: x3 + x4
2*[2, 3, 1, 4] + [3, 1, 2, 4] + 3*[3, 1, 4, 2]

sage: QS0 = SymmetricGroupAlgebra(QQ, 0)
sage: QS1 = SymmetricGroupAlgebra(QQ, 1)
sage: x0 = QS0([])
sage: x1 = QS1([1])
sage: x0 * x1
[1]
sage: x3 - (2*x0 + x1) - x4
-3*[1, 2, 3, 4] + 2*[2, 3, 1, 4] + [3, 1, 2, 4] - 3*[3, 1, 4, 2]
```

Caveat: to achieve this, constructing `SymmetricGroupAlgebra(QQ, 10)` currently triggers the construction of all symmetric group algebras of smaller order. Is this a feature we really want to have?

Warning: The semantics of multiplication in symmetric group algebras with index set `Permutations(n)` is determined by the order in which permutations are multiplied, which currently defaults to “in such a way that multiplication is associative with permutations acting on integers from the right”, but can be changed to the opposite order at runtime by setting the global variable `Permutations.options['mult']` (see [sage.combinat.permutation.Permutations.options\(\)](#)). On the other hand, the semantics of multiplication in symmetric group algebras with index set `SymmetricGroup(n)` does not depend on this global variable. (This has the awkward consequence that the coercions between these two sorts of symmetric group algebras do not respect multiplication when this global variable is set to 'r2l'.) In view of this, it is recommended that code not rely on the usual multiplication function, but rather use the methods `left_action_product()` and `right_action_product()` for multiplying permutations (these methods don't depend on the setting). See [trac ticket #14885](#) for more information.

We conclude by constructing the algebra of the symmetric group as a monoid algebra:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3, category=Monoids())
sage: QS3.category()
Category of finite dimensional cellular monoid algebras over Rational Field
sage: TestSuite(QS3).run(skip=['_test_construction'])
```

class sage.combinat.symmetric_group_algebra.SymmetricGroupAlgebra_n(*R*, *W*, *category*)
 Bases: sage.algebras.group_algebra.GroupAlgebra_class

algebra_generators()

Return generators of this group algebra (as algebra) as a list of permutations.

The generators used for the group algebra of S_n are the transposition $(2, 1)$ and the n -cycle $(1, 2, \dots, n)$, unless $n \leq 1$ (in which case no generators are needed).

EXAMPLES:

```
sage: SymmetricGroupAlgebra(ZZ, 5).algebra_generators()
Family ([2, 1, 3, 4, 5], [2, 3, 4, 5, 1])

sage: SymmetricGroupAlgebra(QQ, 0).algebra_generators()
Family ()

sage: SymmetricGroupAlgebra(QQ, 1).algebra_generators()
Family ()
```

antipode(*x*)

Return the image of the element *x* of *self* under the antipode of the Hopf algebra *self* (where the comultiplication is the usual one on a group algebra).

Explicitly, this is obtained by replacing each permutation σ by σ^{-1} in *x* while keeping all coefficients as they are.

EXAMPLES:

```
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.antipode(2 * QS4([1, 3, 4, 2]) - 1/2 * QS4([1, 4, 2, 3]))
-1/2*[1, 3, 4, 2] + 2*[1, 4, 2, 3]
sage: all( QS4.antipode(QS4(p)) == QS4(p.inverse())
.....:      for p in Permutations(4) )
True

sage: ZS3 = SymmetricGroupAlgebra(ZZ, 3)
sage: ZS3.antipode(ZS3.zero())
0
sage: ZS3.antipode(-ZS3(Permutation([2, 3, 1])))
-[3, 1, 2]
```

binary_unshuffle_sum(*k*)

Return the k -th binary unshuffle sum in the group algebra *self*.

The k -th binary unshuffle sum in the symmetric group algebra RS_n over a ring R is defined as the sum of all permutations $\sigma \in S_n$ satisfying $\sigma(1) < \sigma(2) < \dots < \sigma(k)$ and $\sigma(k+1) < \sigma(k+2) < \dots < \sigma(n)$.

This element has the property that, if it is denoted by t_k , and if the k -th semi-RSW element (see [semi_rsw_element\(\)](#)) is denoted by s_k , then $s_k S(t_k)$ and $t_k S(s_k)$ both equal the k -th Reiner-Saliola-Welker shuffling element of RS_n (see [rsw_shuffling_element\(\)](#)).

The k -th binary unshuffle sum is the image of the complete non-commutative symmetric function $S^{(k, n-k)}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

EXAMPLES:

The binary unshuffle sums on QS_3 :

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.binary_unshuffle_sum(0)
[1, 2, 3]
sage: QS3.binary_unshuffle_sum(1)
[1, 2, 3] + [2, 1, 3] + [3, 1, 2]
sage: QS3.binary_unshuffle_sum(2)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.binary_unshuffle_sum(3)
[1, 2, 3]
sage: QS3.binary_unshuffle_sum(4)
0
```

Let us check the relation with the k -th Reiner-Saliola-Welker shuffling element stated in the docstring:

```
sage: def test_rsw(n):
.....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
.....:     for k in range(1, n):
.....:         a = ZSn.semi_rsw_element(k)
.....:         b = ZSn.binary_unshuffle_sum(k)
.....:         c = ZSn.left_action_product(a, ZSn.antipode(b))
.....:         d = ZSn.left_action_product(b, ZSn.antipode(a))
.....:         e = ZSn.rsw_shuffling_element(k)
.....:         if c != e or d != e:
.....:             return False
.....:     return True
sage: test_rsw(3)
True
sage: test_rsw(4) # long time
True
sage: test_rsw(5) # long time
True
```

Let us also check the statement about the complete non-commutative symmetric function:

```
sage: def test_rsw_ncsf(n):
.....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
.....:     NSym = NonCommutativeSymmetricFunctions(ZZ)
.....:     S = NSym.S()
.....:     for k in range(1, n):
.....:         a = S(Composition([k, n-k])).to_symmetric_group_algebra()
.....:         if a != ZSn.binary_unshuffle_sum(k):
.....:             return False
.....:     return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
```

(continues on next page)

(continued from previous page)

```
sage: test_rsw_ncsf(5) # long time
True
```

canonical_embedding(*other*)

Return the canonical coercion of `self` into a symmetric group algebra `other`.

INPUT:

- `other` – a symmetric group algebra with order p satisfying $p \geq n$, where n is the order of `self`, over a ground ring into which the ground ring of `self` coerces.

EXAMPLES:

```
sage: QS2 = SymmetricGroupAlgebra(QQ, 2)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: phi = QS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: x = QS2([2,1]) + 2 * QS2([1,2])
sage: phi(x)
2*[1, 2, 3, 4] + [2, 1, 3, 4]

sage: loads(dumps(phi))
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: ZS2 = SymmetricGroupAlgebra(ZZ, 2)
sage: phi = ZS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:   Symmetric group algebra of order 4 over Rational Field

sage: phi = ZS2.canonical_embedding(QS2); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:   Symmetric group algebra of order 2 over Rational Field

sage: QS4.canonical_embedding(QS2)
Traceback (most recent call last):
...
ValueError: There is no canonical embedding from Symmetric group
algebra of order 2 over Rational Field to Symmetric group
algebra of order 4 over Rational Field

sage: QS4g = SymmetricGroup(4).algebra(QQ)
sage: QS4.canonical_embedding(QS4g)(QS4([1,3,2,4]))
(2,3)
sage: QS4g.canonical_embedding(QS4)(QS4g((2,3)))
[1, 3, 2, 4]
sage: ZS2.canonical_embedding(QS4g)(ZS2([2,1]))
(1,2)
```

(continues on next page)

(continued from previous page)

```
sage: ZS2g = SymmetricGroup(2).algebra(ZZ)
sage: ZS2g.canonical_embedding(QS4)(ZS2g((1,2)))
[2, 1, 3, 4]
```

cell_module(*la*, ***kws*)Return the cell module indexed by *la*.

EXAMPLES:

```
sage: S = SymmetricGroupAlgebra(QQ, 3)
sage: M = S.cell_module(Partition([2,1])); M
Cell module indexed by [2, 1] of Cellular basis of
Symmetric group algebra of order 3 over Rational Field
```

We check that the input *la* is standardized:

```
sage: N = S.cell_module([2,1])
sage: M is N
True
```

cell_module_indices(*la*)Return the indices of the cell module of *self* indexed by *la*.This is the finite set $M(\lambda)$.

EXAMPLES:

```
sage: S = SymmetricGroupAlgebra(QQ, 4)
sage: S.cell_module_indices([3,1])
Standard tableaux of shape [3, 1]
```

cell_poset()Return the cell poset of *self*.

EXAMPLES:

```
sage: S = SymmetricGroupAlgebra(QQ, 4)
sage: S.cell_poset()
Finite poset containing 5 elements
```

central_orthogonal_idempotent(*la*, *block=True*)Return the central idempotent for the symmetric group of order n corresponding to the indecomposable block to which the partition *la* is associated.If *self*.*base_ring*() contains \mathbf{Q} , this corresponds to the classical central idempotent corresponding to the irreducible representation indexed by *la*.Alternatively, if *self*.*base_ring*() has characteristic $p > 0$, then Theorem 2.8 in [Mur1983] provides that *la* is associated to an idempotent f_μ , where μ is the p -core of *la*. This f_μ is a sum of classical idempotents,

$$f_\mu = \sum_{c(\lambda)=\mu} e_\lambda,$$

where the sum ranges over the partitions λ of n with p -core equal to μ .

INPUT:

- `la` – a partition of `self.n` or a `self.base_ring().characteristic()`-core of such a partition
- `block` – boolean (default: `True`); when `False`, this returns the classical idempotent associated to `la` (defined over \mathbf{Q})

OUTPUT:

If `block=False` and the corresponding coefficients are not defined over `self.base_ring()`, then return `None`. Otherwise return an element of `self`.

EXAMPLES:

Asking for block idempotents in any characteristic, by passing a partition of `self.n`:

```
sage: S0 = SymmetricGroup(4).algebra(QQ)
sage: S2 = SymmetricGroup(4).algebra(GF(2))
sage: S3 = SymmetricGroup(4).algebra(GF(3))
sage: S0.central_orthogonal_idempotent([2,1,1])
3/8*() - 1/8*(3,4) - 1/8*(2,3) - 1/8*(2,4) - 1/8*(1,2)
- 1/8*(1,2)(3,4) + 1/8*(1,2,3,4) + 1/8*(1,2,4,3)
+ 1/8*(1,3,4,2) - 1/8*(1,3) - 1/8*(1,3)(2,4)
+ 1/8*(1,3,2,4) + 1/8*(1,4,3,2) - 1/8*(1,4)
+ 1/8*(1,4,2,3) - 1/8*(1,4)(2,3)
sage: S2.central_orthogonal_idempotent([2,1,1])
()
sage: idem = S3.central_orthogonal_idempotent([4]); idem
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
sage: idem == S3.central_orthogonal_idempotent([1,1,1,1])
True
sage: S3.central_orthogonal_idempotent([2,2])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for block idempotents in any characteristic, by passing p -cores:

```
sage: S0.central_orthogonal_idempotent([1,1])
Traceback (most recent call last):
...
ValueError: [1, 1] is not a partition of integer 4
sage: S2.central_orthogonal_idempotent([])
()
sage: S2.central_orthogonal_idempotent([1])
Traceback (most recent call last):
...
ValueError: the 2-core of [1] is not a 2-core of a partition of 4
sage: S3.central_orthogonal_idempotent([1])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
sage: S3.central_orthogonal_idempotent([7])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for classical idempotents:

```
sage: S3.central_orthogonal_idempotent([2,2], block=False) is None
True
sage: S3.central_orthogonal_idempotent([2,1,1], block=False)
(3,4) + (2,3) + (2,4) + (1,2) + (1,2)(3,4) + 2*(1,2,3,4)
+ 2*(1,2,4,3) + 2*(1,3,4,2) + (1,3) + (1,3)(2,4)
```

(continues on next page)

(continued from previous page)

```
+ 2*(1, 3, 2, 4) + 2*(1, 4, 3, 2) + (1, 4) + 2*(1, 4, 2, 3)
+ (1, 4)(2, 3)
```

See also:

- [sage.combinat.partition.Partition.core\(\)](#)

central_orthogonal_idempotents()

Return a maximal list of central orthogonal idempotents for `self`.

This method does not require that `self` be semisimple, relying on Nakayama's Conjecture whenever `self.base_ring()` has positive characteristic.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3.central_orthogonal_idempotents()
sage: a[0] # [3]
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1]
+ 1/6*[3, 1, 2] + 1/6*[3, 2, 1]
sage: a[1] # [2, 1]
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]
```

See also:

- [central_orthogonal_idempotent\(\)](#)

dft(*form='seminormal', mult='l2r'*)

Return the discrete Fourier transform for `self`.

INPUT:

- `mult` – string (default: `l2r`). If set to `r2l`, this causes the method to use the antipodes ([antipode\(\)](#)) of the seminormal basis instead of the seminormal basis.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.dft()
[ 1  1  1  1  1  1]
[ 1  1/2 -1 -1/2 -1/2 1/2]
[ 0  3/4  0  3/4 -3/4 -3/4]
[ 0  1  0 -1  1 -1]
[ 1 -1/2  1 -1/2 -1/2 -1/2]
[ 1 -1 -1  1  1 -1]
```

epsilon_ik(*itab, ktab, star=0, mult='l2r'*)

Return the seminormal basis element of `self` corresponding to the pair of tableaux `itab` and `ktab` (or restrictions of these tableaux, if the optional variable `star` is set).

INPUT:

- `itab, ktab` – two standard tableaux of size n .
- `star` – integer (default: 0).
- `mult` – string (default: `l2r`). If set to `r2l`, this causes the method to return the antipode ([antipode\(\)](#)) of $\epsilon(I, K)$ instead of $\epsilon(I, K)$ itself.

OUTPUT:

The element $\epsilon(I, K)$, where I and K are the tableaux obtained by removing all entries higher than $n - \text{star}$ from `itab` and `ktab`, respectively. Here, we are using the notations from `seminormal_basis()`.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3.epsilon_ik([[1,2,3]], [[1,2,3]]); a
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] +
↪ 1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(1, 0, 0, 0, 0, 0)
sage: a = QS3.epsilon_ik([[1,2],[3]], [[1,2],[3]]); a
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] -
↪ 1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(0, 0, 0, 0, 1, 0)
```

Let us take some properties of the seminormal basis listed in the docstring of `seminormal_basis()`, and verify them on the situation of S_3 .

First, check the formula

$$\epsilon(T) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\overline{T}) e(T) \epsilon(\overline{T}).$$

In fact:

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: def test_sn1(n):
.....:     QSn = SymmetricGroupAlgebra(QQ, n)
.....:     QSn1 = SymmetricGroupAlgebra(QQ, n - 1)
.....:     for T in StandardTableaux(n):
.....:         TT = T.restrict(n-1)
.....:         eTT = QSn1.epsilon_ik(TT, TT)
.....:         eT = QSn.epsilon_ik(T, T)
.....:         kT = prod(T.shape().hooks())
.....:         if kT * eT != eTT * e(T) * eTT:
.....:             return False
.....:     return True
sage: test_sn1(3)
True
sage: test_sn1(4) # long time
True
```

Next, we check the identity

$$\epsilon(T, S) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\overline{S}) \pi_{T,S} e(T) \epsilon(\overline{T})$$

which we used to define $\epsilon(T, S)$. In fact:

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: def test_sn2(n):
.....:     QSn = SymmetricGroupAlgebra(QQ, n)
.....:     mul = QSn.left_action_product
```

(continues on next page)

(continued from previous page)

```

.....:   QSn1 = SymmetricGroupAlgebra(QQ, n - 1)
.....:   for lam in Partitions(n):
.....:       k = prod(lam.hooks())
.....:       for T in StandardTableaux(lam):
.....:           for S in StandardTableaux(lam):
.....:               TT = T.restrict(n-1)
.....:               SS = S.restrict(n-1)
.....:               eTT = QSn1.epsilon_ik(TT, TT)
.....:               eSS = QSn1.epsilon_ik(SS, SS)
.....:               eTS = QSn.epsilon_ik(T, S)
.....:               piTS = [0] * n
.....:               for (i, j) in T.cells():
.....:                   piTS[T[i][j] - 1] = S[i][j]
.....:               piTS = QSn(Permutation(piTS))
.....:               if k * eTS != mul(mul(eSS, piTS), mul(e(T), eTT)):
.....:                   return False
.....:       return True
sage: test_sn2(3)
True
sage: test_sn2(4) # long time
True

```

Let us finally check the identity

$$\epsilon(T, S)\epsilon(U, V) = \delta_{T,V}\epsilon(U, S)$$

In fact:

```

sage: def test_sn3(lam):
.....:     n = lam.size()
.....:     QSn = SymmetricGroupAlgebra(QQ, n)
.....:     mul = QSn.left_action_product
.....:     for T in StandardTableaux(lam):
.....:         for S in StandardTableaux(lam):
.....:             for U in StandardTableaux(lam):
.....:                 for V in StandardTableaux(lam):
.....:                     lhs = mul(QSn.epsilon_ik(T, S), QSn.epsilon_ik(U, V))
.....:                     if T == V:
.....:                         rhs = QSn.epsilon_ik(U, S)
.....:                     else:
.....:                         rhs = QSn.zero()
.....:                     if rhs != lhs:
.....:                         return False
.....:     return True
sage: all( test_sn3(lam) for lam in Partitions(3) )
True
sage: all( test_sn3(lam) for lam in Partitions(4) ) # long time
True

```

jucys_murphy(*k*)

Return the Jucys-Murphy element J_k (also known as a Young-Jucys-Murphy element) for the symmetric group algebra self.

The Jucys-Murphy element J_k in the symmetric group algebra RS_n is defined for every $k \in \{1, 2, \dots, n\}$

by

$$J_k = (1, k) + (2, k) + \cdots + (k-1, k) \in RS_n,$$

where the addends are transpositions in S_n (regarded as elements of RS_n). We note that there is not a dependence on n , so it is often suppressed in the notation.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.jucys_murphy(1)
0
sage: QS3.jucys_murphy(2)
[2, 1, 3]
sage: QS3.jucys_murphy(3)
[1, 3, 2] + [3, 2, 1]

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: j3 = QS4.jucys_murphy(3); j3
[1, 3, 2, 4] + [3, 2, 1, 4]
sage: j4 = QS4.jucys_murphy(4); j4
[1, 2, 4, 3] + [1, 4, 3, 2] + [4, 2, 3, 1]
sage: j3*j4 == j4*j3
True

sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.jucys_murphy(4)
[1, 2, 4, 3, 5] + [1, 4, 3, 2, 5] + [4, 2, 3, 1, 5]
```

left_action_product(*left*, *right*)

Return the product of two elements *left* and *right* of *self*, where multiplication is defined in such a way that for two permutations p and q , the product pq is the permutation obtained by first applying q and then applying p . This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the left.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.left_action_product(QS3(p1), QS3(p2))
[3, 2, 1]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])
sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.left_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] - [2, 1, 3] + 1/2*[3, 1, 2]
sage: QS3.left_action_product(0, x)
0
```

The method coerces its input into the algebra *self*:

```
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.left_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.left_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]
```

Warning: Note that coercion presently works from permutations of n into the n -th symmetric group algebra, and also from all smaller symmetric group algebras into the n -th symmetric group algebra, but not from permutations of integers smaller than n into the n -th symmetric group algebra.

monomial_from_smaller_permutation(*permutation*)

Convert *permutation* into a permutation, possibly extending it to the appropriate size, and return the corresponding basis element of self.

EXAMPLES:

```
sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.monomial_from_smaller_permutation([])
[1, 2, 3, 4, 5]
sage: QS5.monomial_from_smaller_permutation(Permutation([3,1,2]))
[3, 1, 2, 4, 5]
sage: QS5.monomial_from_smaller_permutation([5,3,4,1,2])
[5, 3, 4, 1, 2]
sage: QS5.monomial_from_smaller_permutation(SymmetricGroup(2)((1,2)))
[2, 1, 3, 4, 5]

sage: QS5g = SymmetricGroup(5).algebra(QQ)
sage: QS5g.monomial_from_smaller_permutation([2,1])
(1,2)
```

retract_direct_product(*f, m*)

Return the direct-product retract of the element $f \in RS_n$ to RS_m , where $m \leq n$ (and where RS_n is self).

If m is a nonnegative integer less or equal to n , then the direct-product retract from S_n to S_m is defined as an R -linear map $S_n \rightarrow S_m$ which sends every permutation $p \in S_n$ to

$$\begin{cases} \text{dret}(p) & \text{if } \text{dret}(p) \text{ is defined;} \\ 0 & \text{otherwise} \end{cases}$$

Here $\text{dret}(p)$ denotes the direct-product retract of the permutation p to S_m , which is defined in [retract_direct_product\(\)](#).

EXAMPLES:

```
sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_direct_product(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) + 7*SGA3([1,
↪3,2]), 2)
2*[1, 2] - 4*[2, 1]
sage: SGA3.retract_direct_product(2*SGA3([1,3,2]) - 5*SGA3([2,3,1]), 2)
0

sage: SGA5 = SymmetricGroupAlgebra(QQ, 5)
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + ↪
↪11*SGA5([3,2,1,4,5]), 4)
11*[3, 2, 1, 4]
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + ↪
↪11*SGA5([3,2,1,4,5]), 3)
-6*[1, 3, 2] + 11*[3, 2, 1]
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + ↪
↪11*SGA5([3,2,1,4,5]), 2)
```

(continues on next page)

(continued from previous page)

```

0
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +

2*[]

```

See also:*retract_plain(), retract_okounkov_vershik()***retract_okounkov_vershik(*f*, *m*)**

Return the Okounkov-Vershik retract of the element $f \in RS_n$ to RS_m , where $m \leq n$ (and where RS_n is self).

If m is a nonnegative integer less or equal to n , then the Okounkov-Vershik retract from S_n to S_m is defined as an R -linear map $S_n \rightarrow S_m$ which sends every permutation $p \in S_n$ to the Okounkov-Vershik retract of the permutation p to S_m , which is defined in *retract_okounkov_vershik()*.

EXAMPLES:

```

sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_okounkov_vershik(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) +
↳ 7*SGA3([1,3,2]), 2)

```

See also:[`retract_direct_product\(\)`](#), [`retract_okounkov_vershik\(\)`](#)**right_action_product**(*left*, *right*)Return the product of two elements *left* and *right* of self, where multiplication is defined in such a way that for two permutations p and q , the product pq is the permutation obtained by first applying p and then applying q . This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the right.

EXAMPLES:

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.right_action_product(QS3(p1), QS3(p2))
[1, 3, 2]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])
sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.right_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] + 1/2*[3, 1, 2] - [3, 2, 1]
sage: QS3.right_action_product(0, x)
0

```

The method coerces its input into the algebra self:

```

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.right_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.right_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]

```

Warning: Note that coercion presently works from permutations of n into the n -th symmetric group algebra, and also from all smaller symmetric group algebras into the n -th symmetric group algebra, but not from permutations of integers smaller than n into the n -th symmetric group algebra.

`rsw_shuffling_element(k)`

Return the k -th Reiner-Saliola-Welker shuffling element in the group algebra self.

The k -th Reiner-Saliola-Welker shuffling element in the symmetric group algebra RS_n over a ring R is defined as the sum $\sum_{\sigma \in S_n} \text{noninv}_k(\sigma) \cdot \sigma$, where for every permutation σ , the number $\text{noninv}_k(\sigma)$ is the number of all k -noninversions of σ (that is, the number of all k -element subsets of $\{1, 2, \dots, n\}$ on which σ restricts to a strictly increasing map). See `sage.combinat.permutation.number_of_noninversions()` for the `noninv` map.

This element is more or less the operator $\nu_{k,1^{n-k}}$ introduced in [RSW2011]; more precisely, $\nu_{k,1^{n-k}}$ is the left multiplication by this element.

It is a nontrivial theorem (Theorem 1.1 in [RSW2011]) that the operators $\nu_{k,1^{n-k}}$ (for fixed n and varying k) pairwise commute. It is a conjecture (Conjecture 1.2 in [RSW2011]) that all their eigenvalues are integers (which, in light of their commutativity and easily established symmetry, yields that they can be simultaneously diagonalized over \mathbb{Q} with only integer eigenvalues).

EXAMPLES:

The Reiner-Saliola-Welker shuffling elements on QS_3 :

```

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.rsw_shuffling_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.rsw_shuffling_element(1)
3*[1, 2, 3] + 3*[1, 3, 2] + 3*[2, 1, 3] + 3*[2, 3, 1] + 3*[3, 1, 2] + 3*[3, 2, 1]
sage: QS3.rsw_shuffling_element(2)
3*[1, 2, 3] + 2*[1, 3, 2] + 2*[2, 1, 3] + [2, 3, 1] + [3, 1, 2]
sage: QS3.rsw_shuffling_element(3)

```

(continues on next page)

(continued from previous page)

```
[1, 2, 3]
sage: QS3.rsw_shuffling_element(4)
0
```

Checking the commutativity of Reiner-Saliola-Welker shuffling elements (we leave out the ones for which it is trivial):

```
sage: def test_rsw_comm(n):
.....:     QSn = SymmetricGroupAlgebra(QQ, n)
.....:     rsws = [QSn.rsw_shuffling_element(k) for k in range(2, n)]
.....:     return all( all( rsws[i] * rsws[j] == rsws[j] * rsws[i]
.....:                     for j in range(i) )
.....:                 for i in range(len(rsws)) )
sage: test_rsw_comm(3)
True
sage: test_rsw_comm(4)
True
sage: test_rsw_comm(5) # long time
True
```

Note: For large k (relative to n), it might be faster to call `QSn.left_action_product(QSn.semi_rsw_element(k), QSn.antipode(binary_unshuffle_sum(k)))` than `QSn.rsw_shuffling_element(n)`.

See also:

[`semi_rsw_element\(\)`](#), [`binary_unshuffle_sum\(\)`](#)

`semi_rsw_element(k)`

Return the k -th semi-RSW element in the group algebra `self`.

The k -th semi-RSW element in the symmetric group algebra RS_n over a ring R is defined as the sum of all permutations $\sigma \in S_n$ satisfying $\sigma(1) < \sigma(2) < \dots < \sigma(k)$.

This element has the property that, if it is denoted by s_k , then $s_k S(s_k)$ is $(n - k)!$ times the k -th Reiner-Saliola-Welker shuffling element of RS_n (see [`rsw_shuffling_element\(\)`](#)). Here, S denotes the antipode of the group algebra RS_n .

The k -th semi-RSW element is the image of the complete non-commutative symmetric function $S^{(k, 1^{n-k})}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

EXAMPLES:

The semi-RSW elements on QS_3 :

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.semi_rsw_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.semi_rsw_element(1)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.semi_rsw_element(2)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.semi_rsw_element(3)
```

(continues on next page)

(continued from previous page)

```
[1, 2, 3]
sage: Qs3.semi_rsw_element(4)
0
```

Let us check the relation with the k -th Reiner-Saliola-Welker shuffling element stated in the docstring:

```
sage: def test_rsw(n):
.....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
.....:     for k in range(1, n):
.....:         a = ZSn.semi_rsw_element(k)
.....:         b = ZSn.left_action_product(a, ZSn.antipode(a))
.....:         if factorial(n-k) * ZSn.rsw_shuffling_element(k) != b:
.....:             return False
.....:     return True
sage: test_rsw(3)
True
sage: test_rsw(4)
True
sage: test_rsw(5) # long time
True
```

Let us also check the statement about the complete non-commutative symmetric function:

```
sage: def test_rsw_ncsf(n):
.....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
.....:     NSym = NonCommutativeSymmetricFunctions(ZZ)
.....:     S = NSym.S()
.....:     for k in range(1, n):
.....:         a = S(Composition([k] + [1]*(n-k))).to_symmetric_group_algebra()
.....:         if a != ZSn.semi_rsw_element(k):
.....:             return False
.....:     return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
sage: test_rsw_ncsf(5) # long time
True
```

`seminormal_basis` (*mult='l2r'*)

Return a list of the seminormal basis elements of `self`.

The seminormal basis of a symmetric group algebra is defined as follows:

Let n be a nonnegative integer. Let R be a \mathbf{Q} -algebra. In the following, we will use the “left action” convention for multiplying permutations. This means that for all permutations p and q in S_n , the product pq is defined in such a way that $(pq)(i) = p(q(i))$ for each $i \in \{1, 2, \dots, n\}$ (this is the same convention as in `left_action_product()`, but not the default semantics of the `*` operator on permutations in Sage). Thus, for instance, s_2s_1 is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3 (where $s_i = (i, i + 1)$).

For every partition λ of n , let

$$\kappa_\lambda = \frac{n!}{f^\lambda}$$

where f^λ is the number of standard Young tableaux of shape λ . Note that κ_λ is an integer, namely the product of all hook lengths of λ (by the hook length formula). In Sage, this integer can be computed by using `sage.combinat.symmetric_group_algebra.kappa()`.

Let T be a standard tableau of size n .

Let $a(T)$ denote the formal sum (in RS_n) of all permutations in S_n which stabilize the rows of T (as sets), i. e., which map each entry i of T to an entry in the same row as i . (See `sage.combinat.symmetric_group_algebra.a()` for an implementation of this.)

Let $b(T)$ denote the signed formal sum (in RS_n) of all permutations in S_n which stabilize the columns of T (as sets). Here, “signed” means that each permutation is multiplied with its sign. (This is implemented in `sage.combinat.symmetric_group_algebra.b()`.)

Define an element $e(T)$ of RS_n to be $a(T)b(T)$. (This is implemented in `sage.combinat.symmetric_group_algebra.e()` for $R = \mathbf{Q}$.)

Let $\text{sh}(T)$ denote the shape of T . (See `shape()`.)

Let \bar{T} denote the standard tableau of size $n - 1$ obtained by removing the letter n (along with its cell) from T (if $n \geq 1$).

Now, we define an element $\epsilon(T)$ of RS_n . We define it by induction on the size n of T , so we set $\epsilon(\emptyset) = 1$ and only need to define $\epsilon(T)$ for $n \geq 1$, assuming that $\epsilon(\bar{T})$ is already defined. We do this by setting

$$\epsilon(T) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\bar{T}) e(T) \epsilon(\bar{T}).$$

This element $\epsilon(T)$ is implemented as `sage.combinat.symmetric_group_algebra.epsilon()` for $R = \mathbf{Q}$, but it is also a particular case of the elements $\epsilon(T, S)$ defined below.

Now let S be a further tableau of the same shape as T (possibly equal to T). Let $\pi_{T,S}$ denote the permutation in S_n such that applying this permutation to the entries of T yields the tableau S . Define an element $\epsilon(T, S)$ of RS_n by

$$\epsilon(T, S) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\bar{S}) \pi_{T,S} e(T) \epsilon(\bar{T}) = \frac{1}{\kappa_{\text{sh}(T)}} \epsilon(\bar{S}) a(S) \pi_{T,S} b(T) \epsilon(\bar{T}).$$

This element $\epsilon(T, S)$ is called *Young’s seminormal unit corresponding to the bitableau (T, S)* , and is the return value of `epsilon_ik()` applied to T and S . Note that $\epsilon(T, T) = \epsilon(T)$.

If we let λ run through all partitions of n , and (T, S) run through all pairs of tableaux of shape λ , then the elements $\epsilon(T, S)$ form a basis of RS_n . This basis is called *Young’s seminormal basis* and has the properties that

$$\epsilon(T, S) \epsilon(U, V) = \delta_{T,V} \epsilon(U, S)$$

(where δ stands for the Kronecker delta).

Warning: Because of our convention, we are multiplying our elements in reverse of those given in some papers, for example [Ram1997]. Using the other convention of multiplying permutations, we would instead have $\epsilon(U, V) \epsilon(T, S) = \delta_{T,V} \epsilon(U, S)$.

In other words, Young’s seminormal basis consists of the matrix units in a (particular) Artin-Wedderburn decomposition of RS_n into a direct product of matrix algebras over \mathbf{Q} .

The output of `seminormal_basis()` is a list of all elements of the seminormal basis of `self`.

INPUT:

- `mult` – string (default: 'l2r'). If set to 'r2l', this causes the method to return the list of the antipodes (`antipode()`) of all $\epsilon(T, S)$ instead of the $\epsilon(T, S)$ themselves.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.seminormal_basis()
[1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] ↵
↵ + 1/6*[3, 2, 1],
1/3*[1, 2, 3] + 1/3*[1, 3, 2] - 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] ↵
↵ 1/6*[3, 2, 1],
1/3*[1, 3, 2] + 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1],

↵ 1/6*[3, 2, 1]]
```

`sage.combinat.symmetric_group_algebra.a(tableau, star=0, base_ring=Rational Field)`

The row projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the sum (in the group algebra of the relevant symmetric group over \mathbf{Q}) of all the permutations which preserve the rows of `tableau`. It is called a_{tableau} in [EGHLSVY], Section 4.2.

INPUT:

- `tableau` – Young tableau which contains every integer from 1 to its size precisely once.
- `star` – nonnegative integer (default: 0). When this optional variable is set, the method computes not the row projection operator of `tableau`, but the row projection operator of the restriction of `tableau` to the entries 1, 2, ..., `tableau.size() - star` instead.
- `base_ring` – commutative ring (default: \mathbf{QQ}). When this optional variable is set, the row projection operator is computed over a user-determined base ring instead of \mathbf{Q} . (Note that symmetric group algebras currently don't preserve coercion, so e. g. a symmetric group algebra over \mathbf{Z} does not coerce into the corresponding one over \mathbf{Q} ; so convert manually or choose your base rings wisely!)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import a
sage: a([[1,2]])
[1, 2] + [2, 1]
sage: a([[1],[2]])
[1, 2]
sage: a([])
[]
sage: a([[1, 5], [2, 3], [4]])
[1, 2, 3, 4, 5] + [1, 3, 2, 4, 5] + [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: a([[1,4], [2,3]], base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]
```

`sage.combinat.symmetric_group_algebra.b(tableau, star=0, base_ring=Rational Field)`

The column projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the signed sum (in the group algebra of the relevant symmetric group over \mathbf{Q}) of all the permutations which preserve the column of `tableau` (where the signs are the usual signs of the permutations). It is called

b_{tableau} in [EGHLSVY], Section 4.2.

INPUT:

- `tableau` – Young tableau which contains every integer from 1 to its size precisely once.
- `star` – nonnegative integer (default: 0). When this optional variable is set, the method computes not the column projection operator of `tableau`, but the column projection operator of the restriction of `tableau` to the entries 1, 2, ..., `tableau.size()` - `star` instead.
- `base_ring` – commutative ring (default: QQ). When this optional variable is set, the column projection operator is computed over a user-determined base ring instead of \mathbf{Q} . (Note that symmetric group algebras currently don't preserve coercion, so e. g. a symmetric group algebra over \mathbf{Z} does not coerce into the corresponding one over \mathbf{Q} ; so convert manually or choose your base rings wisely!)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import b
sage: b([[1,2]])
[1, 2]
sage: b([[1],[2]])
[1, 2] - [2, 1]
sage: b([])
[]
sage: b([[1, 2, 4], [5, 3]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: b([[1, 4], [2, 3]], base_ring=ZZ)
[1, 2, 3, 4] - [1, 2, 4, 3] - [2, 1, 3, 4] + [2, 1, 4, 3]
sage: b([[1, 4], [2, 3]], base_ring=Integers(5))
[1, 2, 3, 4] + 4*[1, 2, 4, 3] + 4*[2, 1, 3, 4] + [2, 1, 4, 3]
```

With the `l2r` setting for multiplication, the unnormalized Young symmetrizer $e(\text{tableau})$ should be the product $b(\text{tableau}) * a(\text{tableau})$ for every `tableau`. Let us check this on the standard tableaux of size 5:

```
sage: from sage.combinat.symmetric_group_algebra import a, b, e
sage: all( e(t) == b(t) * a(t) for t in StandardTableaux(5) )
True
```

`sage.combinat.symmetric_group_algebra.e(tableau, star=0)`

The unnormalized Young projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

If n is a nonnegative integer, and T is a Young tableau containing every integer from 1 to n exactly once, then the unnormalized Young projection operator $e(T)$ is defined by

$$e(T) = a(T)b(T) \in \mathbf{Q}S_n,$$

where $a(T) \in \mathbf{Q}S_n$ is the sum of all permutations in S_n which fix the rows of T (as sets), and $b(T) \in \mathbf{Q}S_n$ is the signed sum of all permutations in S_n which fix the columns of T (as sets). Here, “signed” means that each permutation is multiplied with its sign; and the product on the group S_n is defined in such a way that $(pq)(i) = p(q(i))$ for any permutations p and q and any $1 \leq i \leq n$.

Note that the definition of $e(T)$ is not uniform across literature. Others define it as $b(T)a(T)$ instead, or include certain scalar factors (we do not, whence “unnormalized”).

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: e([[1,2]])
[1, 2] + [2, 1]
sage: e([[1],[2]])
[1, 2] - [2, 1]
sage: e([])
[]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e([[1,2],[3]])
[1, 2, 3] + [2, 1, 3] - [3, 1, 2] - [3, 2, 1]
```

To obtain the product $b(T)a(T)$, one has to take the antipode of this:

```
sage: QS3 = parent(e([[1,2],[3]]))
sage: QS3.antipode(e([[1,2],[3]]))
[1, 2, 3] + [2, 1, 3] - [2, 3, 1] - [3, 2, 1]
```

See also:

[`e_hat\(\)`](#)

`sage.combinat.symmetric_group_algebra.e_hat(tab, star=0)`

The Young projection operator corresponding to the Young tableau `tab` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard). This is an idempotent in the rational group algebra.

If n is a nonnegative integer, and T is a Young tableau containing every integer from 1 to n exactly once, then the Young projection operator $\widehat{e}(T)$ is defined by

$$\widehat{e}(T) = \frac{1}{\kappa_\lambda} a(T)b(T) \in \mathbf{Q}S_n,$$

where λ is the shape of T , where κ_λ is $n!$ divided by the number of standard tableaux of shape λ , where $a(T) \in \mathbf{Q}S_n$ is the sum of all permutations in S_n which fix the rows of T (as sets), and where $b(T) \in \mathbf{Q}S_n$ is the signed sum of all permutations in S_n which fix the columns of T (as sets). Here, “signed” means that each permutation is multiplied with its sign; and the product on the group S_n is defined in such a way that $(pq)(i) = p(q(i))$ for any permutations p and q and any $1 \leq i \leq n$.

Note that the definition of $\widehat{e}(T)$ is not uniform across literature. Others define it as $\frac{1}{\kappa_\lambda} b(T)a(T)$ instead.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_hat
sage: e_hat([[1,2,3]])
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/
↪6*[3, 2, 1]
sage: e_hat([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e_hat([[1,2],[3]])
1/3*[1, 2, 3] + 1/3*[2, 1, 3] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]
```

See also:

`e()`

`sage.combinat.symmetric_group_algebra.e_ik(itab, ktab, star=0)`

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_ik
sage: e_ik([[1,2,3]], [[1,2,3]])
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: e_ik([[1,2,3]], [[1,2,3]], star=1)
[1, 2] + [2, 1]
```

`sage.combinat.symmetric_group_algebra.epsilon(tab, star=0)`

The (T, T) -th element of the seminormal basis of the group algebra $\mathbf{Q}[S_n]$, where T is the tableau `tab` (with its `star` highest entries removed if the optional variable `star` is set).

See the docstring of `seminormal_basis()` for the notation used herein.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon
sage: epsilon([[1,2]])
1/2*[1, 2] + 1/2*[2, 1]
sage: epsilon([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

`sage.combinat.symmetric_group_algebra.epsilon_ik(itab, ktab, star=0)`

Return the seminormal basis element of the symmetric group algebra $\mathbf{Q}S_n$ corresponding to the pair of tableaux `itab` and `ktab` (or restrictions of these tableaux, if the optional variable `star` is set).

INPUT:

- `itab, ktab` – two standard tableaux of same size.
- `star` – integer (default: 0).

OUTPUT:

The element $\epsilon(I, K) \in \mathbf{Q}S_n$, where I and K are the tableaux obtained by removing all entries higher than $n - \text{star}$ from `itab` and `ktab`, respectively (where n is the size of `itab` and `ktab`). Here, we are using the notations from `seminormal_basis()`.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon_ik
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]])
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1]
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]], star=1)
Traceback (most recent call last):
...
ValueError: the two tableaux must be of the same shape
```

`sage.combinat.symmetric_group_algebra.kappa(alpha)`

Return κ_α , which is $n!$ divided by the number of standard tableaux of shape α (where α is a partition of n).

INPUT:

- `alpha` – integer partition (can be encoded as a list).

OUTPUT:

The factorial of the size of `alpha`, divided by the number of standard tableaux of shape `alpha`. Equivalently, the product of all hook lengths of `alpha`.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import kappa
sage: kappa(Partition([2,1]))
3
sage: kappa([2,1])
3
```

`sage.combinat.symmetric_group_algebra.pi_ik(itab, ktab)`

Return the permutation p which sends every entry of the tableau `itab` to the respective entry of the tableau `ktab`, as an element of the corresponding symmetric group algebra.

This assumes that `itab` and `ktab` are tableaux (possibly given just as lists of lists) of the same shape.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import pi_ik
sage: pi_ik([[1,3],[2]], [[1,2],[3]])
[1, 3, 2]
```

`sage.combinat.symmetric_group_algebra.seminormal_test(n)`

Run a variety of tests to verify that the construction of the seminormal basis works as desired. The numbers appearing are results in James and Kerber's 'Representation Theory of the Symmetric Group' [JK1981].

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import seminormal_test
sage: seminormal_test(3)
True
```

5.1.341 Representations of the Symmetric Group

Todo:

- construct the product of two irreducible representations.
 - implement Induction/Restriction of representations.
-

Warning: This code uses a different convention than in Sagan's book "The Symmetric Group"

`class sage.combinat.symmetric_group_representations.SpechtRepresentation(parent, partition)`

Bases: `sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class`

`representation_matrix(permutation)`

Return the matrix representing the permutation in this irreducible representation.

Note: This method caches the results.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.representation_matrix(Permutation([2,1,3,4]))
[ 0 -1  0]
[-1  0  0]
[ 0  0  1]
sage: spc.representation_matrix(Permutation([3,2,1,4]))
[0 0 1]
[0 1 0]
[1 0 0]
```

scalar_product(*u*, *v*)

Return 0 if $u+v$ is not a permutation, and the signature of the permutation otherwise.

This is the scalar product of a vertex u of the underlying Yang-Baxter graph with the vertex v in the ‘dual’ Yang-Baxter graph.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,2], 'specht')
sage: spc.scalar_product((1,0,2,1,0), (0,3,0,3,0))
-1
sage: spc.scalar_product((1,0,2,1,0), (3,0,0,3,0))
0
```

scalar_product_matrix(*permutation=None*)

Return the scalar product matrix corresponding to *permutation*.

The entries are given by the scalar products of u and $\text{permutation.action}(v)$, where u is a vertex in the underlying Yang-Baxter graph and v is a vertex in the dual graph.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.scalar_product_matrix()
[ 1  0  0]
[ 0 -1  0]
[ 0  0  1]
```

```
class sage.combinat.symmetric_group_representations.SpechtRepresentations(n, ring=None,
                                                                           cache_matrices=True)
    Bases: sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class
```

Element

alias of *SpechtRepresentation*

```
sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation(partition,
                                                                              implementa-
                                                                              tion='specht',
                                                                              ring=None,
                                                                              cache_matrices=True)
```

The irreducible representation of the symmetric group corresponding to *partition*.

INPUT:

- *partition* – a partition of a positive integer

- `implementation` – string (default: "specht"), one of:
 - "seminormal" - for Young's seminormal representation
 - "orthogonal" - for Young's orthogonal representation
 - "specht" - for Specht's representation
- `ring` – the ring over which the representation is defined
- `cache_matrices` – boolean (default: True) if True, then any representation matrices that are computed are cached

EXAMPLES:

Young's orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [2, 1]
sage: all(a*a.transpose() == a.parent().identity_matrix() for a in orth)
True
```

```
sage: orth = SymmetricGroupRepresentation([3,2], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [3, 2]
sage: orth([2,1,3,4,5])
[ 1  0  0  0  0]
[ 0  1  0  0  0]
[ 0  0 -1  0  0]
[ 0  0  0  1  0]
[ 0  0  0  0 -1]
sage: orth([1,3,2,4,5])
[      1      0      0      0      0]
[      0     -1/2  1/2*sqrt(3)  0      0]
[      0  1/2*sqrt(3)      1/2      0      0]
[      0      0      0      -1/2  1/2*sqrt(3)]
[      0      0      0  1/2*sqrt(3)      1/2]
sage: orth([1,2,4,3,5])
[      -1/3  2/3*sqrt(2)      0      0      0]
[ 2/3*sqrt(2)      1/3      0      0      0]
[      0      0      1      0      0]
[      0      0      0      1      0]
[      0      0      0      0     -1]
```

The Specht representation:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc.scalar_product_matrix(Permutation([1,2,3,4,5]))
[ 1  0  0  0  0]
[ 0 -1  0  0  0]
[ 0  0  1  0  0]
[ 0  0  0  1  0]
[-1  0  0  0 -1]
sage: spc.scalar_product_matrix(Permutation([5,4,3,2,1]))
[ 1 -1  0  1  0]
[ 0  0  1  0 -1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
```

(continues on next page)

(continued from previous page)

```

[-1  0  0  0 -1]
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: spc.verify_representation()
True

```

By default, any representation matrices that are computed are cached:

```

sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: spc._cache__representation_matrix
{((([5, 4, 3, 2, 1]),), ()): [ 1 -1  0  1  0]
 [ 0  0 -1  0  1]
 [ 0  0  0 -1  1]
 [ 0  1 -1 -1  1]
 [ 0  1  0 -1  1]}

```

This can be turned off with the keyword `cache_matrices`:

```

sage: spc = SymmetricGroupRepresentation([3,2], "specht", cache_matrices=False)
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: hasattr(spc, '_cache__representation_matrix')
False

```

Note: The implementation is based on the paper [Las].

REFERENCES:

AUTHORS:

- Franco Saliola (2009-04-23)

class sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class(*parent*,
partition)

Bases: sage.structure.element.Element

Generic methods for a representation of the symmetric group.

to_character()

Return the character of the representation.

EXAMPLES:

The trivial character:

```
sage: rho = SymmetricGroupRepresentation([3])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, 1, 1]
sage: all(chi(g) == 1 for g in SymmetricGroup(3))
True
```

The sign character:

```
sage: rho = SymmetricGroupRepresentation([1,1,1])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, -1, 1]
sage: all(chi(g) == g.sign() for g in SymmetricGroup(3))
True
```

The defining representation:

```
sage: triv = SymmetricGroupRepresentation([4])
sage: hook = SymmetricGroupRepresentation([3,1])
sage: def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
sage: list(map(def_rep, Permutations(4)))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
sage: [p.to_matrix().trace() for p in Permutations(4)]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
```

verify_representation()

Verify the representation.

This tests that the images of the simple transpositions are involutions and tests that the braid relations hold.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([1,1,1])
sage: spc.verify_representation()
True
sage: spc = SymmetricGroupRepresentation([4,2,1])
sage: spc.verify_representation()
True
```

```
sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations(n, implementation='specht',
                                                                                   ring=None,
                                                                                   cache_matrices=True)
```

Irreducible representations of the symmetric group.

INPUT:

- *n* – positive integer

- `implementation` – string (default: "specht"), one of:
 - "seminormal" - for Young's seminormal representation
 - "orthogonal" - for Young's orthogonal representation
 - "specht" - for Specht's representation
- `ring` – the ring over which the representation is defined
- `cache_matrices` – boolean (default: True) if True, then any representation matrices that are computed are cached

EXAMPLES:

Young's orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentations(3, "orthogonal"); orth
Orthogonal representations of the symmetric group of order 3! over Symbolic Ring
sage: orth.list()
[Orthogonal representation of the symmetric group corresponding to [3],
 Orthogonal representation of the symmetric group corresponding to [2, 1],
 Orthogonal representation of the symmetric group corresponding to [1, 1, 1]]
sage: orth([2,1])([1,2,3])
[1 0]
[0 1]
```

Young's seminormal representation.

```
sage: snorm = SymmetricGroupRepresentations(3, "seminormal"); snorm
Seminormal representations of the symmetric group of order 3! over Rational Field
sage: sgn = snorm([1,1,1]); sgn
Seminormal representation of the symmetric group corresponding to [1, 1, 1]
sage: list(map(sgn, Permutations(3)))
[[1], [-1], [-1], [1], [1], [-1]]
```

The Specht Representation.

```
sage: spc = SymmetricGroupRepresentations(5, "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring
sage: spc([3,2])([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
```

Note: The implementation is based on the paper [Las].

AUTHORS:

- Franco Saliola (2009-04-23)

```
class sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class(n,
                                                                                               ring=None,
                                                                                               cache_matrices=True)
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent
```

Generic methods for the CombinatorialClass of irreducible representations of the symmetric group.

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: sp = SymmetricGroupRepresentations(4, "specht")
sage: sp.cardinality()
5
```

```
class sage.combinat.symmetric_group_representations.YoungRepresentation_Orthogonal(parent,
                                                                                   parti-
                                                                                   tion)
```

Bases: *sage.combinat.symmetric_group_representations.YoungRepresentation_generic*

```
class sage.combinat.symmetric_group_representations.YoungRepresentation_Seminormal(parent,
                                                                                   parti-
                                                                                   tion)
```

Bases: *sage.combinat.symmetric_group_representations.YoungRepresentation_generic*

```
class sage.combinat.symmetric_group_representations.YoungRepresentation_generic(parent,
                                                                                   partition)
```

Bases: *sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class*

Generic methods for Young's representations of the symmetric group.

representation_matrix(*permutation*)

Return the matrix representing permutation.

EXAMPLES:

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")
sage: orth.representation_matrix(Permutation([2,1,3]))
[ 1  0]
[ 0 -1]
sage: orth.representation_matrix(Permutation([1,3,2]))
[      -1/2  1/2*sqrt(3)]
[1/2*sqrt(3)      1/2]
```

```
sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: p = PermutationGroupElement([2,1,3])
sage: norm.representation_matrix(p)
[ 1  0]
[ 0 -1]
sage: p = PermutationGroupElement([1,3,2])
sage: norm.representation_matrix(p)
[-1/2  3/2]
[ 1/2  1/2]
```

representation_matrix_for_simple_transposition(*i*)

Return the matrix representing the transposition that swaps *i* and *i*+1.

EXAMPLES:

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")
sage: orth.representation_matrix_for_simple_transposition(1)
```

(continues on next page)

(continued from previous page)

```

[ 1  0]
[ 0 -1]
sage: orth.representation_matrix_for_simple_transposition(2)
[      -1/2  1/2*sqrt(3)]
[1/2*sqrt(3)      1/2]

sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: norm.representation_matrix_for_simple_transposition(1)
[ 1  0]
[ 0 -1]
sage: norm.representation_matrix_for_simple_transposition(2)
[-1/2  3/2]
[ 1/2  1/2]

```

```

class sage.combinat.symmetric_group_representations.YoungRepresentations_Orthogonal(n,
                                                                                      ring=None,
                                                                                      cache_matrices=True)
    Bases: sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class

```

Elementalias of *YoungRepresentation_Orthogonal*

```

class sage.combinat.symmetric_group_representations.YoungRepresentations_Seminormal(n,
                                                                                      ring=None,
                                                                                      cache_matrices=True)
    Bases: sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class

```

Elementalias of *YoungRepresentation_Seminormal*

```

sage.combinat.symmetric_group_representations.partition_to_vector_of_contents(partition, reverse=False)

```

Return the “vector of contents” associated to partition.

EXAMPLES:

```

sage: from sage.combinat.symmetric_group_representations import partition_to_vector_
      ↪ of_contents
sage: partition_to_vector_of_contents([3,2])
(0, 1, 2, -1, 0)

```

5.1.342 Tableaux

AUTHORS:

- Mike Hansen (2007): initial version
- Jason Bandlow (2011): updated to use Parent/Element model, and many minor fixes
- Andrew Mathas (2012-13): completed the transition to the parent/element model begun by Jason Bandlow
- Travis Scrimshaw (11-22-2012): Added tuple options, changed *katabolism* to *catabolism*. Cleaned up documentation.
- Andrew Mathas (2016-08-11): Row standard tableaux added

- Oliver Pechenik (2018): Added increasing tableaux.

This file consists of the following major classes:

Element classes:

- *Tableau*
- *SemistandardTableau*
- *StandardTableau*
- *RowStandardTableau*
- *IncreasingTableau*

Factory classes:

- *Tableaux*
- *SemistandardTableaux*
- *StandardTableaux*
- *RowStandardTableaux*
- *IncreasingTableaux*

Parent classes:

- *Tableaux_all*
- *Tableaux_size*
- *SemistandardTableaux_all* (facade class)
- *SemistandardTableaux_size*
- *SemistandardTableaux_size_inf*
- *SemistandardTableaux_size_weight*
- *SemistandardTableaux_shape*
- *SemistandardTableaux_shape_inf*
- *SemistandardTableaux_shape_weight*
- *StandardTableaux_all* (facade class)
- *StandardTableaux_size*
- *StandardTableaux_shape*
- *IncreasingTableaux_all* (facade class)
- *IncreasingTableaux_size*
- *IncreasingTableaux_size_inf*
- *IncreasingTableaux_size_weight*
- *IncreasingTableaux_shape*
- *IncreasingTableaux_shape_inf*
- *IncreasingTableaux_shape_weight*
- *RowStandardTableaux_all* (facade class)
- *RowStandardTableaux_size*

- [RowStandardTableaux_shape](#)

For display options, see [Tableaux.options\(\)](#).

Todo:

- Move methods that only apply to semistandard tableaux from `tableau` to `semistandard tableau`
 - Copy/move functionality to skew tableaux
 - Add a class for tableaux of a given shape (eg `Tableaux_shape`)
-

class `sage.combinat.tableau.IncreasingTableau`(*parent, t, check=True*)

Bases: [sage.combinat.tableau.Tableau](#)

A class to model an increasing tableau.

INPUT:

- `t` – a tableau, a list of iterables, or an empty list

An *increasing tableau* is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns.

EXAMPLES:

```
sage: t = IncreasingTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = IncreasingTableau(t); s
[[1, 2], [2]]
sage: IncreasingTableau([]) # The empty tableau
[]
```

You can also construct an [IncreasingTableau](#) from the appropriate [Parent](#) object:

```
sage: IT = IncreasingTableaux()
sage: IT([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- [Tableaux](#)
- [Tableau](#)
- [SemistandardTableaux](#)
- [SemistandardTableau](#)
- [StandardTableaux](#)
- [StandardTableau](#)
- [IncreasingTableaux](#)

K_bender_knuth(*i*)

Return the *i*-th K-Bender-Knuth operator (as defined in [DPS2017]) applied to `self`.

The *i*-th K-Bender-Knuth operator swaps the letters *i* and *i* + 1 everywhere where doing so would not break increasingness.

EXAMPLES:

```
sage: T = IncreasingTableau([[1, 3, 4], [2, 4, 5]])
sage: T.K_bender_knuth(2)
[[1, 2, 4], [3, 4, 5]]
sage: T.K_bender_knuth(3)
[[1, 3, 4], [2, 4, 5]]
```

K_evacuation(*ceiling=None*)

Return the K-evacuation involution from [TY2009] to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1, 3, 4], [2, 4, 5]])
sage: T.K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1, 3, 4], [3, 4, 5], [5]])
sage: U.K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

K_promotion(*ceiling=None*)

Return the K-promotion operator from [Pec2014] applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1, 3, 4], [2, 4, 5]])
sage: T.K_promotion()
[[1, 2, 3], [3, 4, 5]]
sage: T.K_promotion(6)
[[1, 2, 3], [3, 4, 6]]
sage: U = IncreasingTableau([[1, 3, 4], [3, 4, 5], [5]])
sage: U.K_promotion()
[[2, 3, 4], [3, 4, 5], [4]]
```

K_promotion_inverse(*ceiling=None*)

Return the inverse of K-promotion operator applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1, 3, 4], [2, 4, 5]])
sage: T.K_promotion_inverse()
[[1, 2, 4], [3, 4, 5]]
sage: T.K_promotion_inverse(6)
[[2, 4, 5], [3, 5, 6]]
sage: U = IncreasingTableau([[1, 3, 4], [3, 4, 5], [5]])
sage: U.K_promotion_inverse()
[[1, 2, 4], [2, 4, 5], [4]]
```

check()

Check that `self` is a valid increasing tableau.

descent_set()

Compute the descents of the increasing tableau `self` as defined in [DPS2017].

The number i is a *descent* of an increasing tableau if some instance of $i + 1$ appears in a lower row than some instance of i .

Note: This notion is close to the notion of descent for a standard tableau but is unrelated to the notion for semistandard tableaux.

EXAMPLES:

```
sage: T = IncreasingTableau([[1, 2, 4], [3, 5, 6]])
sage: T.descent_set()
[2, 4]
sage: U = IncreasingTableau([[1, 3, 4], [2, 4, 5]])
sage: U.descent_set()
[1, 3, 4]
sage: V = IncreasingTableau([[1, 3, 4], [3, 4, 5], [4, 5]])
sage: V.descent_set()
[3, 4]
```

dual_K_evacuation(ceiling=None)

Return the dual K-evacuation involution applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1, 3, 4], [2, 4, 5]])
sage: T.dual_K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.dual_K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1, 3, 4], [3, 4, 5], [5]])
sage: U.dual_K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

class sage.combinat.tableau.IncreasingTableaux(kws)**

Bases: `sage.combinat.tableau.Tableaux`

A factory class for the various classes of increasing tableaux.

An *increasing tableau* is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

INPUT:

Keyword arguments:

- `size` – the size of the tableaux
- `shape` – the shape of the tableaux
- `eval` – the weight (also called binary content) of the tableaux, where values can be either 0 or 1 with position i being 1 if and only if i can appear in the tableaux

- `max_entry` – positive integer or infinity (`oo`); the maximum entry for the tableaux; if `size` or `shape` are specified, `max_entry` defaults to be `size` or the size of `shape`

Positional arguments:

- the first argument is interpreted as either `size` or `shape` according to whether it is an integer or a partition
- the second keyword argument will always be interpreted as `eval`

Warning: The `eval` is not the usual notion of `eval` or `weight`, where the i -th entry counts how many i 's appear in the tableau.

EXAMPLES:

```
sage: IT = IncreasingTableaux([2,1]); IT
Increasing tableaux of shape [2, 1] and maximum entry 3
sage: IT.list()
[[[1, 3], [2]], [[1, 2], [3]], [[1, 2], [2]], [[1, 3], [3]], [[2, 3], [3]]]

sage: IT = IncreasingTableaux(3); IT
Increasing tableaux of size 3 and maximum entry 3
sage: IT.list()
[[[1, 2, 3]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1, 2], [2]],
 [[1, 3], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]

sage: IT = IncreasingTableaux(3, max_entry=2); IT
Increasing tableaux of size 3 and maximum entry 2
sage: IT.list()
[[[1, 2], [2]]]

sage: IT = IncreasingTableaux(3, max_entry=4); IT
Increasing tableaux of size 3 and maximum entry 4
sage: IT.list()
[[[1, 2, 3]],
 [[1, 2, 4]],
 [[1, 3, 4]],
 [[2, 3, 4]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1, 4], [2]],
 [[1, 2], [4]],
 [[1, 2], [2]],
 [[1, 4], [3]],
 [[1, 3], [4]],
 [[1, 3], [3]],
 [[1, 4], [4]],
 [[2, 4], [3]],
 [[2, 3], [4]],
```

(continues on next page)

(continued from previous page)

```

[[2, 3], [3]],
[[2, 4], [4]],
[[3, 4], [4]],
[[1], [2], [3]],
[[1], [2], [4]],
[[1], [3], [4]],
[[2], [3], [4]]

sage: IT = IncreasingTableaux(3, max_entry=oo); IT
Increasing tableaux of size 3
sage: IT[123]
[[5, 7], [6]]

sage: IT = IncreasingTableaux(max_entry=2)
sage: list(IT)
[[], [[1]], [[2]], [[1, 2]], [[1], [2]]]
sage: IT[4]
[[1], [2]]

sage: IncreasingTableaux()[0]
[]

```

Elementalias of *IncreasingTableau***class** `sage.combinat.tableau.IncreasingTableaux_all`(*max_entry=None*)

Bases: `sage.combinat.tableau.IncreasingTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

All increasing tableaux.

EXAMPLES:

```

sage: T = IncreasingTableaux()
sage: T.cardinality()
+Infinity

sage: T = IncreasingTableaux(max_entry=3)
sage: list(T)
[[],
 [[1]],

```

(continues on next page)

[[1, 2], [2]],
[[1, 3], [3]],
[[2, 3], [3]],
[[1], [2], [3]]

```

class `sage.combinat.tableau.IncreasingTableaux_shape`(*p*, *max_entry=None*)

Bases: `sage.combinat.tableau.IncreasingTableaux`

Increasing tableaux of fixed shape *p* with a given max entry.

An increasing tableau with max entry *i* is required to have all its entries less or equal to *i*. It is not required to actually contain an entry *i*.

INPUT:

- *p* – a partition
- *max_entry* – the max entry; defaults to the size of *p*

class `sage.combinat.tableau.IncreasingTableaux_shape_inf`(*p*)

Bases: `sage.combinat.tableau.IncreasingTableaux`

Increasing tableaux of fixed shape *p* and no maximum entry.

class `sage.combinat.tableau.IncreasingTableaux_shape_weight`(*p*, *wt*)

Bases: `sage.combinat.tableau.IncreasingTableaux_shape`

Increasing tableaux of fixed shape *p* and binary weight *wt*.

class `sage.combinat.tableau.IncreasingTableaux_size`(*n*, *max_entry=None*)

Bases: `sage.combinat.tableau.IncreasingTableaux`

Increasing tableaux of fixed size *n*.

class `sage.combinat.tableau.IncreasingTableaux_size_inf`(*n*)

Bases: `sage.combinat.tableau.IncreasingTableaux`

Increasing tableaux of fixed size *n* with no maximum entry.

class `sage.combinat.tableau.IncreasingTableaux_size_weight`(*n*, *wt*)

Bases: `sage.combinat.tableau.IncreasingTableaux`

Increasing tableaux of fixed size *n* and weight *wt*.

class `sage.combinat.tableau.RowStandardTableau`(*parent*, *t*, *check=True*)

Bases: `sage.combinat.tableau.Tableau`

A class to model a row standard tableau.

A row standard tableau is a tableau whose entries are positive integers from 1 to *m* that increase along rows.

INPUT:

- `t` – a `Tableau`, a list of iterables, or an empty list

EXAMPLES:

```
sage: t = RowStandardTableau([[3,4,5],[1,2]]); t
[[3, 4, 5], [1, 2]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
3 4 5
1 2
sage: t.is_standard()
False
sage: RowStandardTableau([]) # The empty tableau
[]
sage: RowStandardTableau([[3,4,5],[1,2]]) in StandardTableaux()
False
sage: RowStandardTableau([[1,2,5],[3,4]]) in StandardTableaux()
True
```

When using code that will generate a lot of tableaux, it is more efficient to construct a `RowStandardTableau` from the appropriate `Parent` object:

```
sage: ST = RowStandardTableaux()
sage: ST([[3, 4, 5], [1, 2]])
[[3, 4, 5], [1, 2]]
```

See also:

- [Tableau](#)
- [StandardTableau](#)
- [SemistandardTableau](#)
- [Tableaux](#)
- [StandardTableaux](#)
- [RowStandardTableaux](#)
- [SemistandardTableaux](#)

check()

Check that `self` is a valid row standard tableau.

class `sage.combinat.tableau.RowStandardTableaux`

Bases: `sage.combinat.tableau.Tableaux`

A factory for the various classes of row standard tableaux.

INPUT:

- either a non-negative integer (possibly specified with the keyword `n`) or a partition

OUTPUT:

- with no argument, the class of all standard tableaux
- with a non-negative integer argument, `n`, the class of all standard tableaux of size `n`

- with a partition argument, the class of all standard tableaux of that shape

A row standard tableau is a tableau that contains each of the entries from 1 to n exactly once and is increasing along rows.

All classes of row standard tableaux are iterable.

EXAMPLES:

```
sage: ST = RowStandardTableaux(3); ST
Row standard tableaux of size 3
sage: ST.first()
[[1, 2, 3]]
sage: ST.last()
[[3], [1], [2]]
sage: ST.cardinality()
10
sage: ST.list()
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```

See also:

- [Tableaux](#)
- [Tableau](#)
- [SemistandardTableaux](#)
- [SemistandardTableau](#)
- [RowStandardTableau](#)
- [StandardSkewTableaux](#)

Element

alias of [RowStandardTableau](#)

class `sage.combinat.tableau.RowStandardTableaux_all`

Bases: [sage.combinat.tableau.RowStandardTableaux](#), [sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets](#)

All row standard tableaux.

class `sage.combinat.tableau.RowStandardTableaux_shape(p)`

Bases: [sage.combinat.tableau.RowStandardTableaux](#)

Row Standard tableaux of a fixed shape p .

cardinality()

Return the number of row standard tableaux of this shape.

This is just the index of the corresponding Young subgroup in the full symmetric group.

EXAMPLES:

```
sage: RowStandardTableaux([3,2,1]).cardinality()
60
sage: RowStandardTableaux([2,2]).cardinality()
6
sage: RowStandardTableaux([5]).cardinality()
1
sage: RowStandardTableaux([6,5,5,3]).cardinality()
1955457504
sage: RowStandardTableaux([]).cardinality()
1
```

class `sage.combinat.tableau.RowStandardTableaux_size(n)`

Bases: `sage.combinat.tableau.RowStandardTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

Row standard tableaux of fixed size n .

EXAMPLES:

```
sage: [ t for t in RowStandardTableaux(1) ]
[[[1]]]
sage: [ t for t in RowStandardTableaux(2) ]
[[[1, 2]], [[2], [1]], [[1], [2]]]
sage: list(RowStandardTableaux(3))
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: RowStandardTableaux(4).an_element()
[[1, 2, 3, 4]]
```

class `sage.combinat.tableau.SemistandardTableau(parent, t, check=True)`

Bases: `sage.combinat.tableau.Tableau`

A class to model a semistandard tableau.

INPUT:

- t – a tableau, a list of iterables, or an empty list

OUTPUT:

- A `SemistandardTableau` object constructed from t .

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns.

EXAMPLES:

```
sage: t = SemistandardTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = SemistandardTableau(t); s
[[1, 2], [2]]
sage: SemistandardTableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a Semistandard-Tableau from the appropriate `Parent` object:

```
sage: SST = SemistandardTableaux()
sage: SST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- [Tableaux](#)
- [Tableau](#)
- [SemistandardTableaux](#)
- [StandardTableaux](#)
- [StandardTableau](#)

check()

Check that `self` is a valid semistandard tableau.

class `sage.combinat.tableau.SemistandardTableaux`(***kws*)

Bases: `sage.combinat.tableau.Tableaux`

A factory class for the various classes of semistandard tableaux.

INPUT:

Keyword arguments:

- `size` – The size of the tableaux
- `shape` – The shape of the tableaux
- `eval` – The weight (also called content or evaluation) of the tableaux
- `max_entry` – A maximum entry for the tableaux. This can be a positive integer or infinity (`oo`). If `size` or `shape` are specified, `max_entry` defaults to be `size` or the size of `shape`.

Positional arguments:

- The first argument is interpreted as either `size` or `shape` according to whether it is an integer or a partition

- The second keyword argument will always be interpreted as `eval`

OUTPUT:

- The appropriate class, after checking basic consistency tests. (For example, specifying `eval` implies a value for `max_entry`).

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

Classes of semistandard tableaux can be iterated over if and only if there is some restriction.

EXAMPLES:

```
sage: SST = SemistandardTableaux([2,1]); SST
Semistandard tableaux of shape [2, 1] and maximum entry 3
sage: SST.list()
[[[1, 1], [2]],
 [[1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]]]

sage: SST = SemistandardTableaux(3); SST
Semistandard tableaux of size 3 and maximum entry 3
sage: SST.list()
[[[1, 1, 1]],
 [[1, 1, 2]],
 [[1, 1, 3]],
 [[1, 2, 2]],
 [[1, 2, 3]],
 [[1, 3, 3]],
 [[2, 2, 2]],
 [[2, 2, 3]],
 [[2, 3, 3]],
 [[3, 3, 3]],
 [[1, 1], [2]],
 [[1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]

sage: SST = SemistandardTableaux(3, max_entry=2); SST
Semistandard tableaux of size 3 and maximum entry 2
sage: SST.list()
[[[1, 1, 1]],
 [[1, 1, 2]],
 [[1, 2, 2]],
```

(continues on next page)

(continued from previous page)

```

[[2, 2, 2]],
[[1, 1], [2]],
[[1, 2], [2]]

sage: SST = SemistandardTableaux(3, max_entry=oo); SST
Semistandard tableaux of size 3
sage: SST[123]
[[3, 4], [6]]

sage: SemistandardTableaux(max_entry=2)[11]
[[1, 1], [2]]

sage: SemistandardTableaux()[0]
[]

```

- [StandardTableau](#)

Elementalias of [SemistandardTableau](#)

class `sage.combinat.tableau.SemistandardTableaux_all`(*max_entry=None*)
 Bases: `sage.combinat.tableau.SemistandardTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

All semistandard tableaux.

list()

class `sage.combinat.tableau.SemistandardTableaux_shape`(*p, max_entry=None*)
 Bases: `sage.combinat.tableau.SemistandardTableaux`

Semistandard tableaux of fixed shape *p* with a given max entry.A semistandard tableau with max entry *i* is required to have all its entries less or equal to *i*. It is not required to actually contain an entry *i*.

INPUT:

- *p* – a partition
- *max_entry* – the max entry; defaults to the size of *p*

cardinality(*algorithm='hook'*)Return the cardinality of `self`.

INPUT:

- *algorithm* – (default: 'hook') any one of the following:
 - 'hook' – use Stanley's hook length formula

- 'sum' – sum over the compositions of `max_entry` the number of semistandard tableau with shape and given weight vector

This is computed using *Stanley's hook length formula*:

$$f_{\lambda} = \prod_{u \in \lambda} \frac{n + c(u)}{h(u)}.$$

where n is the `max_entry`, $c(u)$ is the content of u , and $h(u)$ is the hook length of u . See [Sta-EC2] Corollary 7.21.4.

EXAMPLES:

```
sage: SemistandardTableaux([2,1]).cardinality()
8
sage: SemistandardTableaux([2,2,1]).cardinality()
75
sage: SymmetricFunctions(QQ).schur()([2,2,1]).expand(5)(1,1,1,1,1) # cross check
75
sage: SemistandardTableaux([5]).cardinality()
126
sage: SemistandardTableaux([3,2,1]).cardinality()
896
sage: SemistandardTableaux([3,2,1], max_entry=7).cardinality()
2352
sage: SemistandardTableaux([6,5,4,3,2,1], max_entry=30).cardinality()
208361017592001331200
sage: ssts = [SemistandardTableaux(p, max_entry=6) for p in Partitions(5)]
sage: all(sst.cardinality() == sst.cardinality(algorithm='sum')
....:      for sst in ssts)
True
```

random_element()

Return a uniformly distributed random tableau of the given shape and `max_entry`.

Uses the algorithm from [Kra1999] based on the Novelli-Pak-Stoyanovskii bijection <http://www.sciencedirect.com/science/article/pii/S0012365X9290368P>

[//www.sciencedirect.com/science/article/pii/S0012365X9290368P](http://www.sciencedirect.com/science/article/pii/S0012365X9290368P)

EXAMPLES:

```
sage: S = SemistandardTableaux([2, 2, 1, 1])
sage: S.random_element() in S
True
sage: S = SemistandardTableaux([2, 2, 1, 1], max_entry=7)
sage: S.random_element() in S
True
```

class `sage.combinat.tableau.SemistandardTableaux_shape_inf(p)`

Bases: `sage.combinat.tableau.SemistandardTableaux`

Semistandard tableaux of fixed shape p and no maximum entry.

class `sage.combinat.tableau.SemistandardTableaux_shape_weight(p, mu)`

Bases: `sage.combinat.tableau.SemistandardTableaux_shape`

Semistandard tableaux of fixed shape p and weight μ .

cardinality()

Return the number of semistandard tableaux of the given shape and weight, as computed by `kostka_number` function of `symmetrica`.

EXAMPLES:

```
sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).cardinality()
1
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).cardinality()
2
```

list()

Return a list of all semistandard tableaux in `self` generated by `symmetrica`.

EXAMPLES:

```
sage: SemistandardTableaux([2,2], [2, 1, 1]).list()
[[[1, 1], [2, 3]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).list()
[[[1, 1], [2, 2], [3, 4]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).list()
[[[1, 1], [2, 2], [3, 3]]]
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]
```

class `sage.combinat.tableau.SemistandardTableaux_size`(*n*, *max_entry=None*)

Bases: `sage.combinat.tableau.SemistandardTableaux`

Semistandard tableaux of fixed size *n*.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: SemistandardTableaux(3).cardinality()
19
sage: SemistandardTableaux(4).cardinality()
116
sage: SemistandardTableaux(4, max_entry=2).cardinality()
9
sage: SemistandardTableaux(4, max_entry=10).cardinality()
4225
sage: ns = list(range(1, 6))
sage: ssts = [ SemistandardTableaux(n) for n in ns ]
sage: all(sst.cardinality() == len(sst.list()) for sst in ssts)
True
```

random_element()

Generate a random *SemistandardTableau* with uniform probability.

The RSK algorithm gives a bijection between symmetric $k \times k$ matrices of nonnegative integers that sum to n and semistandard tableaux with size n and maximum entry k .

The number of $k \times k$ symmetric matrices of nonnegative integers having sum of elements on the diagonal i and sum of elements above the diagonal j is $\binom{k+i-1}{k-1} \binom{\binom{k}{2}+j-1}{\binom{k}{2}-1}$. We first choose the sum of the elements on the diagonal randomly weighted by the number of matrices having that trace. We then create random integer vectors of length k having that sum and use them to generate a $k \times k$ diagonal matrix. Then we take a random integer vector of length $\binom{k}{2}$ summing to half the remainder and distribute it symmetrically to the remainder of the matrix.

Applying RSK to the random symmetric matrix gives us a pair of identical *SemistandardTableau* of which we choose the first.

EXAMPLES:

```
sage: SemistandardTableaux(6).random_element() # random
[[1, 1, 2], [3, 5, 5]]
sage: SemistandardTableaux(6, max_entry=7).random_element() # random
[[2, 4, 4, 6, 6, 6]]
```

class sage.combinat.tableau.SemistandardTableaux_size_inf(n)

Bases: *sage.combinat.tableau.SemistandardTableaux*

Semistandard tableaux of fixed size n with no maximum entry.

list()

class sage.combinat.tableau.SemistandardTableaux_size_weight(n, μ)

Bases: *sage.combinat.tableau.SemistandardTableaux*

Semistandard tableaux of fixed size n and weight μ .

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: SemistandardTableaux(3, [2,1]).cardinality()
2
sage: SemistandardTableaux(4, [2,2]).cardinality()
3
```

class sage.combinat.tableau.StandardTableau($parent, t, check=True$)

Bases: *sage.combinat.tableau.SemistandardTableau*

A class to model a standard tableau.

INPUT:

- t – a Tableau, a list of iterables, or an empty list

A standard tableau is a semistandard tableau whose entries are exactly the positive integers from 1 to n , where n is the size of the tableau.

EXAMPLES:

```
sage: t = StandardTableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
4 5
```

(continues on next page)

(continued from previous page)

```

sage: t.is_standard()
True
sage: StandardTableau([]) # The empty tableau
[]
sage: StandardTableau([[1,2,3],[4,5]]) in RowStandardTableaux()
True

```

When using code that will generate a lot of tableaux, it is more efficient to construct a `StandardTableau` from the appropriate `Parent` object:

```

sage: ST = StandardTableaux()
sage: ST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]

```

See also:

- [Tableaux](#)
- [Tableau](#)
- [SemistandardTableaux](#)
- [SemistandardTableau](#)
- [StandardTableaux](#)

check()

Check that `self` is a standard tableau.

dominates(*t*)

Return `True` if `self` dominates the tableau `t`.

That is, if the shape of the tableau restricted to k dominates the shape of `t` restricted to k , for $k = 1, 2, \dots, n$.

When the two tableaux have the same shape, then this ordering coincides with the Bruhat ordering for the corresponding permutations.

INPUT:

- `t` – a tableau

EXAMPLES:

```

sage: s = StandardTableau([[1,2,3],[4,5]])
sage: t = StandardTableau([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False
sage: all(StandardTableau(s).dominates(t) for t in StandardTableaux([3,2]))
True
sage: s.dominates([[1,2,3,4,5]])
False

```

down()

An iterator for all the standard tableaux that can be obtained from `self` by removing a cell. Note that this iterates just over a single tableau (or nothing if `self` is empty).

EXAMPLES:

```

sage: t = StandardTableau([[1,2],[3]])
sage: [x for x in t.down()]
[[1, 2]]
sage: t = StandardTableau([])
sage: [x for x in t.down()]
[]

```

down_list()

Return a list of all the standard tableaux that can be obtained from `self` by removing a cell. Note that this is just a singleton list if `self` is nonempty, and an empty list otherwise.

EXAMPLES:

```

sage: t = StandardTableau([[1,2],[3]])
sage: t.down_list()
[[1, 2]]
sage: t = StandardTableau([])
sage: t.down_list()
[]

```

is_standard()

Return True since `self` is a standard tableau.

EXAMPLES:

```

sage: StandardTableau([[1, 3], [2, 4]]).is_standard()
True

```

promotion(*n=None*)

Return the image of `self` under the promotion operator.

The promotion operator, applied to a standard tableau t , does the following:

Remove the letter n from t , thus leaving a hole where it used to be. Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of t . Fill 0 into the hole once jeu de taquin has completed. Finally, add 1 to each letter in the tableau. The resulting standard tableau is the image of t under the promotion operator.

This definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called “promotion” in [Sag2011] (p. 23) and in [Stan2009].

See the `promotion()` method for a more general operator.

EXAMPLES:

```

sage: ST = StandardTableaux(7)
sage: all( st.promotion().promotion_inverse() == st for st in ST ) # long time
True
sage: all( st.promotion_inverse().promotion() == st for st in ST ) # long time
True
sage: st = StandardTableau([[1,2,5],[3,4]])
sage: parent(st.promotion())
Standard tableaux

```

promotion_inverse(*n=None*)

Return the image of `self` under the inverse promotion operator. The optional variable m should be set to the size of `self` minus 1 for a minimal speedup; otherwise, it defaults to this number.

The inverse promotion operator, applied to a standard tableau t , does the following:

Remove the letter 1 from t , thus leaving a hole where it used to be. Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of t . Fill $n + 1$ into this hole, where n is the size of t . Finally, subtract 1 from each letter in the tableau. This yields a new standard tableau.

This definition of inverse promotion is the map called “promotion” in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called “promotion” in [Hai1992] (p. 90).

See the `promotion_inverse()` method for a more general operator.

EXAMPLES:

```
sage: t = StandardTableau([[1,3],[2,4]])
sage: t.promotion_inverse()
[[1, 2], [3, 4]]
```

We check the equivalence of two definitions of inverse promotion on standard tableaux:

```
sage: ST = StandardTableaux(7)
sage: def bk_promotion_inverse7(st):
....:     st2 = st
....:     for i in range(1, 7):
....:         st2 = st2.bender_knuth_involution(i, check=False)
....:     return st2
sage: all( bk_promotion_inverse7(st) == st.promotion_inverse() for st in ST ) #_
↪long time
True
```

`standard_descents()`

Return a list of the integers i such that i appears strictly further north than $i + 1$ in `self` (this is not to say that i and $i + 1$ must be in the same column). The list is sorted in increasing order.

EXAMPLES:

```
sage: StandardTableau( [[1,3,4],[2,5]] ).standard_descents()
[1, 4]
sage: StandardTableau( [[1,2],[3,4]] ).standard_descents()
[2]
sage: StandardTableau( [[1,2,5],[3,4],[6,7],[8],[9]] ).standard_descents()
[2, 5, 7, 8]
sage: StandardTableau( [] ).standard_descents()
[]
```

`standard_major_index()`

Return the major index of the standard tableau `self` in the standard meaning of the word. The major index is defined to be the sum of the descents of `self` (see `standard_descents()` for their definition).

EXAMPLES:

```
sage: StandardTableau( [[1,4,5],[2,6],[3]] ).standard_major_index()
8
sage: StandardTableau( [[1,2],[3,4]] ).standard_major_index()
2
sage: StandardTableau( [[1,2,3],[4,5]] ).standard_major_index()
3
```

standard_number_of_descents()

Return the number of all integers i such that i appears strictly further north than $i + 1$ in `self` (this is not to say that i and $i + 1$ must be in the same column). A list of these integers can be obtained using the `standard_descents()` method.

EXAMPLES:

```
sage: StandardTableau( [[1,2],[3,4],[5]] ).standard_number_of_descents()
2
sage: StandardTableau( [] ).standard_number_of_descents()
0
sage: tabs = StandardTableaux(5)
sage: all( t.standard_number_of_descents() == t.schuetzenberger_involution().
↪standard_number_of_descents() for t in tabs )
True
```

up()

An iterator for all the standard tableaux that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: [x for x in t.up()]
[[[1, 2, 3]], [[1, 2], [3]]]
```

up_list()

Return a list of all the standard tableaux that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: t.up_list()
[[[1, 2, 3]], [[1, 2], [3]]]
```

class `sage.combinat.tableau.StandardTableaux(**kws)`

Bases: `sage.combinat.tableau.SemistandardTableaux`

A factory for the various classes of standard tableaux.

INPUT:

- Either a non-negative integer (possibly specified with the keyword `n`) or a partition.

OUTPUT:

- With no argument, the class of all standard tableaux
- With a non-negative integer argument, `n`, the class of all standard tableaux of size `n`
- With a partition argument, the class of all standard tableaux of that shape.

A standard tableau is a semistandard tableaux which contains each of the entries from 1 to `n` exactly once.

All classes of standard tableaux are iterable.

EXAMPLES:

```
sage: ST = StandardTableaux(3); ST
Standard tableaux of size 3
sage: ST.first()
```

(continues on next page)

(continued from previous page)

```

[[1, 2, 3]]
sage: ST.last()
[[1], [2], [3]]
sage: ST.cardinality()
4
sage: ST.list()
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]

```

- [SemistandardTableau](#)
- [StandardTableau](#)
- [StandardSkewTableaux](#)

Elementalias of [StandardTableau](#)**class** `sage.combinat.tableau.StandardTableaux_all`Bases: `sage.combinat.tableau.StandardTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

All standard tableaux.

class `sage.combinat.tableau.StandardTableaux_shape(p)`Bases: `sage.combinat.tableau.StandardTableaux`Semistandard tableaux of a fixed shape p .**cardinality()**

Return the number of standard Young tableaux of this shape.

This method uses the so-called *hook length formula*, a formula for the number of Young tableaux associated with a given partition. The formula says the following: Let λ be a partition. For each cell c of the Young diagram of λ , let the *hook length* of c be defined as 1 plus the number of cells horizontally to the right of c plus the number of cells vertically below c . The number of standard Young tableaux of shape λ is then $n!$ divided by the product of the hook lengths of the shape of λ , where $n = |\lambda|$.

For example, consider the partition $[3, 2, 1]$ of 6 with Ferrers diagram:

```

# # #
# #
#

```

When we fill in the cells with their respective hook lengths, we obtain:

```

5 3 1
3 1
1

```

The hook length formula returns

$$\frac{6!}{5 \cdot 3 \cdot 1 \cdot 3 \cdot 1 \cdot 1} = 16.$$

EXAMPLES:

```
sage: StandardTableaux([3,2,1]).cardinality()
16
sage: StandardTableaux([2,2]).cardinality()
2
sage: StandardTableaux([5]).cardinality()
1
sage: StandardTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardTableaux([]).cardinality()
1
```

REFERENCES:

- <http://mathworld.wolfram.com/HookLengthFormula.html>

list()

Return a list of the standard Young tableaux of the specified shape.

EXAMPLES:

```
sage: StandardTableaux([2,2]).list()
[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]
sage: StandardTableaux([5]).list()
[[[1, 2, 3, 4, 5]]]
sage: StandardTableaux([3,2,1]).list()
[[[1, 4, 6], [2, 5], [3]],
 [[1, 3, 6], [2, 5], [4]],
 [[1, 2, 6], [3, 5], [4]],
 [[1, 3, 6], [2, 4], [5]],
 [[1, 2, 6], [3, 4], [5]],
 [[1, 4, 5], [2, 6], [3]],
 [[1, 3, 5], [2, 6], [4]],
 [[1, 2, 5], [3, 6], [4]],
 [[1, 3, 4], [2, 6], [5]],
 [[1, 2, 4], [3, 6], [5]],
 [[1, 2, 3], [4, 6], [5]],
 [[1, 3, 5], [2, 4], [6]],
 [[1, 2, 5], [3, 4], [6]],
 [[1, 3, 4], [2, 5], [6]],
 [[1, 2, 4], [3, 5], [6]],
 [[1, 2, 3], [4, 5], [6]]]
```

random_element()

Return a random standard tableau of the given shape using the Greene-Nijenhuis-Wilf Algorithm.

EXAMPLES:

```
sage: t = StandardTableaux([2,2]).random_element()
sage: t.shape()
[2, 2]
```

(continues on next page)

(continued from previous page)

```
sage: StandardTableaux([]).random_element()
[]
```

class sage.combinat.tableau.StandardTableaux_size(*n*)

Bases: `sage.combinat.tableau.StandardTableaux`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

Standard tableaux of fixed size *n*.

EXAMPLES:

```
sage: [ t for t in StandardTableaux(1) ]
[[[1]]]
sage: [ t for t in StandardTableaux(2) ]
[[[1, 2]], [[1], [2]]]
sage: [ t for t in StandardTableaux(3) ]
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
sage: StandardTableaux(4)[: ]
[[[1, 2, 3, 4]],
 [[1, 3, 4], [2]],
 [[1, 2, 4], [3]],
 [[1, 2, 3], [4]],
 [[1, 3], [2, 4]],
 [[1, 2], [3, 4]],
 [[1, 4], [2], [3]],
 [[1, 3], [2], [4]],
 [[1, 2], [3], [4]],
 [[1], [2], [3], [4]]]
```

cardinality()

Return the number of all standard tableaux of size *n*.

The number of standard tableaux of size *n* is equal to the number of involutions in the symmetric group S_n . This is a consequence of the symmetry of the RSK correspondence, that if $\sigma \mapsto (P, Q)$, then $\sigma^{-1} \mapsto (Q, P)$. For more information, see [Wikipedia article Robinson-Schensted-Knuth_correspondence#Symmetry](#).

ALGORITHM:

The algorithm uses the fact that standard tableaux of size *n* are in bijection with the involutions of size *n*, (see page 41 in section 4.1 of [Ful1997]). For each number of fixed points, you count the number of ways to choose those fixed points multiplied by the number of perfect matchings on the remaining values.

EXAMPLES:

```
sage: StandardTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
```

The cardinality can be computed without constructing all elements in this set, so this computation is fast (see also [trac ticket #28273](#)):

```
sage: StandardTableaux(500).cardinality()
423107565308608549951551753690...221285999236657443927937253376
```

random_element()

Return a random `StandardTableau` with uniform probability.

This algorithm uses the fact that the Robinson-Schensted correspondence returns a pair of identical standard Young tableaux (SYTs) if and only if the permutation was an involution. Thus, generating a random SYT is equivalent to generating a random involution.

To generate an involution, we first need to choose its number of fixed points k (if the size of the involution is even, the number of fixed points will be even, and if the size is odd, the number of fixed points will be odd). To do this, we choose a random integer r between 0 and the number N of all involutions of size n . We then decompose the interval $\{1, 2, \dots, N\}$ into subintervals whose lengths are the numbers of involutions of size n with respectively $0, 1, \dots, \lfloor N/2 \rfloor$ fixed points. The interval in which our random integer r lies then decides how many fixed points our random involution will have. We then place those fixed points randomly and then compute a perfect matching (an involution without fixed points) on the remaining values.

EXAMPLES:

```
sage: StandardTableaux(10).random_element() # random
[[1, 3, 6], [2, 5, 7], [4, 8], [9], [10]]
sage: StandardTableaux(0).random_element()
[]
sage: StandardTableaux(1).random_element()
[[1]]
```

class `sage.combinat.tableau.Tableau`(*parent, t, check=True*)

Bases: `sage.structure.list_clone.ClonableList`

A class to model a tableau.

INPUT:

- t – a `Tableau`, a list of iterables, or an empty list

OUTPUT:

- A `Tableau` object constructed from t .

A tableau is abstractly a mapping from the cells in a partition to arbitrary objects (called entries). It is often represented as a finite list of nonempty lists (or, more generally an iterator of iterables) of weakly decreasing lengths. This list, in particular, can be empty, representing the empty tableau.

Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
4 5
sage: t.is_standard()
True
```

(continues on next page)

(continued from previous page)

```
sage: Tableau([[ 'a', 'c', 'b' ], [[ ], (2, 1) ]])
[[ 'a', 'c', 'b' ], [[ ], (2, 1) ]]
```

```
sage: Tableau([ ]) # The empty tableau
[ ]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a Tableau from the appropriate Parent object:

```
sage: T = Tableaux()
sage: T([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- [Tableaux](#)
- [SemistandardTableaux](#)
- [SemistandardTableau](#)
- [StandardTableaux](#)
- [StandardTableau](#)

add_entry(*cell*, *m*)

Return the result of setting the entry in cell *cell* equal to *m* in the tableau *self*.

This tableau has larger size than *self* if *cell* does not belong to the shape of *self*; otherwise, the tableau has the same shape as *self* and has the appropriate entry replaced.

INPUT:

- *cell* – a pair of nonnegative integers

OUTPUT:

The tableau *self* with the entry in cell *cell* set to *m*. This entry overwrites an existing entry if *cell* already belongs to *self*, or is added to the tableau if *cell* is a cocorner of the shape *self*. (Either way, the input is not modified.)

Note: Both coordinates of *cell* are interpreted as starting at 0. So, *cell* == (0, 0) corresponds to the northwesternmost cell.

EXAMPLES:

```
sage: s = StandardTableau([[1,2,5],[3,4]]); s.pp()
 1 2 5
 3 4
sage: t = s.add_entry( (1,2), 6); t.pp()
 1 2 5
 3 4 6
sage: t.category()
Category of elements of Standard tableaux
sage: s.add_entry( (2,0), 6).pp()
 1 2 5
 3 4
```

(continues on next page)

(continued from previous page)

```

6
sage: u = s.add_entry( (1,2), 3); u.pp()
 1 2 5
 3 4 3
sage: u.category()
Category of elements of Tableaux
sage: s.add_entry( (2,2),3)
Traceback (most recent call last):
...
IndexError: (2, 2) is not an addable cell of the tableau

```

anti_restrict(*n*)

Return the skew tableau formed by removing all of the cells from `self` that are filled with a number at most *n*.

EXAMPLES:

```

sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.anti_restrict(1)
[[None, 2, 3], [4, 5]]
sage: t.anti_restrict(2)
[[None, None, 3], [4, 5]]
sage: t.anti_restrict(3)
[[None, None, None], [4, 5]]
sage: t.anti_restrict(4)
[[None, None, None], [None, 5]]
sage: t.anti_restrict(5)
[[None, None, None], [None, None]]

```

atom()

EXAMPLES:

```

sage: Tableau([[1,2],[3,4]]) .atom()
[2, 2]
sage: Tableau([[1,2,3],[4,5],[6]]) .atom()
[3, 2, 1]

```

bender_knuth_involution(*k*, rows=None, check=True)

Return the image of `self` under the *k*-th Bender–Knuth involution, assuming `self` is a semistandard tableau.

Let *T* be a tableau, then a *lower free* *k* in *T* means a cell of *T* which is filled with the integer *k* and whose direct lower neighbor is not filled with the integer *k* + 1 (in particular, this lower neighbor might not exist at all). Let an *upper free* *k* + 1 in *T* mean a cell of *T* which is filled with the integer *k* + 1 and whose direct upper neighbor is not filled with the integer *k* (in particular, this neighbor might not exist at all). It is clear that for any row *r* of *T*, the lower free *k*'s and the upper free *k* + 1's in *r* together form a contiguous interval or *r*.

The *k*-th Bender–Knuth switch at row *i* changes the entries of the cells in this interval in such a way that if it used to have *a* entries of *k* and *b* entries of *k* + 1, it will now have *b* entries of *k* and *a* entries of *k* + 1. For fixed *k*, the *k*-th Bender–Knuth switches for different *i* commute. The composition of the *k*-th Bender–Knuth switches for all rows is called the *k*-th Bender–Knuth involution. This is used to show that the Schur functions defined by semistandard tableaux are symmetric functions.

INPUT:

- `k` – an integer
- `rows` – (Default `None`) When set to `None`, the method computes the k -th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the k -th Bender–Knuth switches at row i over all i in `rows`. When set to an integer i , the method computes the k -th Bender–Knuth switch at row i . Note the indexing of the rows starts with 1.
- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check.

OUTPUT:

The image of `self` under either the k -th Bender–Knuth involution, the k -th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```
sage: t = Tableau([[1,1,3,4,4,5,6,7],[2,2,4,6,7,7,7],[3,4,5,8,8,9],[6,6,7,10],
↪[7,8,8,11],[8]])
sage: t.bender_knuth_involution(1) == t
True
sage: t.bender_knuth_involution(2)
[[1, 1, 2, 4, 4, 5, 6, 7], [2, 3, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6, 7, ↪
↪10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(3)
[[1, 1, 3, 3, 3, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6, 7, ↪
↪10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(4)
[[1, 1, 3, 4, 5, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6, 7, ↪
↪10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(5)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 5, 7, 7, 7], [3, 4, 6, 8, 8, 9], [5, 5, 7, ↪
↪10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6, 7, ↪
↪10], [7, 8, 8, 11], [8]]
```

The `rows` keyword can be an iterator:

```
sage: t.bender_knuth_involution(6, iter([1,2])) == t
False
sage: t.bender_knuth_involution(6, iter([3,4])) == t
True
```

The Bender–Knuth involution is an involution:

```
sage: T = SemistandardTableaux(shape=[3,1,1], max_entry=4)
sage: all(all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t for ↪
↪k in range(1,5)) for t in T)
True
```

The same holds for the single switches:

```
sage: all(all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t
↳ t for k in range(1,5) for j in range(1, 5)) for t in T)
True
```

Locality of the Bender–Knuth involutions:

```
sage: all(all(t.bender_knuth_involution(k).bender_knuth_involution(l) == t.
↳ bender_knuth_involution(l).bender_knuth_involution(k) for k in range(1,5) for
↳ l in range(1,5) if abs(k - l) > 1) for t in T)
True
```

Berenstein and Kirillov [KB1995] have shown that $(s_1 s_2)^6 = id$ (for tableaux of straight shape):

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k +
↳ 1)
sage: all(p(p(p(p(p(p(t,1),1),1),1),1),1) == t for t in T)
True
```

However, $(s_2 s_3)^6 = id$ is false:

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k +
↳ 1)
sage: t = Tableau([[1,2,2],[3,4]])
sage: x = t
sage: for i in range(6): x = p(x, 2)
sage: x
[[1, 2, 3], [2, 4]]
sage: x == t
False
```

bump(*x*)

Insert *x* into self using Schensted’s row-bumping (or row-insertion) algorithm.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.bump(1)
[[1, 1], [2], [3]]
sage: t
[[1, 2], [3]]
sage: t.bump(2)
[[1, 2, 2], [3]]
sage: t.bump(3)
[[1, 2, 3], [3]]
sage: t
[[1, 2], [3]]
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t.bump(2)
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
sage: t.bump(1)
[[1, 1, 2, 3], [2, 2, 5, 5], [3, 4, 6], [4, 6], [5]]
```

bump_multiply(*other*)

Multiply two tableaux using Schensted’s bump.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid. See pp. 11-12 of [Ful1997].

The same product operation is implemented in a different way in `slide_multiply()`.

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.bump_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

`catabolism()`

Remove the top row of `self` and insert it back in using column Schensted insertion (starting with the largest letter).

EXAMPLES:

```
sage: Tableau([]).catabolism()
[]
sage: Tableau([[1,2,3,4,5]].catabolism()
[[1, 2, 3, 4, 5]]
sage: Tableau([[1,1,3,3],[2,3],[3]]).catabolism()
[[1, 1, 2, 3, 3, 3], [3]]
sage: Tableau([[1, 1, 2, 3, 3, 3], [3]]).catabolism()
[[1, 1, 2, 3, 3, 3, 3]]
```

`catabolism_projector(parts)`

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.catabolism_projector([[4,2,1]])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.catabolism_projector([[1]])
[]
sage: t.catabolism_projector([[2,1],[1]])
[]
sage: t.catabolism_projector([[1,1],[4,1]])
[[1, 1, 3, 3], [2, 3], [3]]
```

`catabolism_sequence()`

Perform `catabolism()` on `self` until it returns a tableau consisting of a single row.

EXAMPLES:

```
sage: t = Tableau([[1,2,3,4,5,6,8],[7,9]])
sage: t.catabolism_sequence()
[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
 [[1, 2, 3, 4, 5, 6, 7, 9], [8]],
 [[1, 2, 3, 4, 5, 6, 7, 8], [9]],
 [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
sage: Tableau([]).catabolism_sequence()
[[]]
```

`cells()`

Return a list of the coordinates of the cells of `self`.

Coordinates start at 0, so the northwesternmost cell (in English notation) has coordinates (0, 0).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

cells_containing(*i*)

Return the list of cells in which the letter *i* appears in the tableau `self`. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates (*a*, *b*), where both rows and columns are counted from 0 (so *a* = 0 means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```
sage: t = Tableau([[1,1,3],[2,3,5],[4,5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(6)
[]

sage: t = Tableau([[1,1,2,4],[2,4,4],[4]])
sage: t.cells_containing(4)
[(2, 0), (1, 1), (1, 2), (0, 3)]

sage: t = Tableau([[1,1,2,8,9],[2,5,6,11],[3,7,7,13],[4,8,9],[5],[13],[14]])
sage: t.cells_containing(8)
[(3, 1), (0, 3)]

sage: Tableau([]).cells_containing(3)
[]
```

charge()

Return the charge of the reading word of `self`. See [charge\(\)](#) for more information.

EXAMPLES:

```
sage: Tableau([[1,1],[2,2],[3]]) .charge()
0
sage: Tableau([[1,1,3],[2,2]]) .charge()
1
sage: Tableau([[1,1,2],[2],[3]]) .charge()
1
sage: Tableau([[1,1,2],[2,3]]) .charge()
2
sage: Tableau([[1,1,2,3],[2]]) .charge()
2
sage: Tableau([[1,1,2,2],[3]]) .charge()
3
sage: Tableau([[1,1,2,2,3]]) .charge()
4
```

check()

Check that `self` is a valid straight-shape tableau.

EXAMPLES:

```
sage: t = Tableau([[1,1],[2]])
sage: t.check()

sage: t = Tableau([[None, None, 1], [2, 4], [3, 4, 5]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: a tableau must be a list of iterables of weakly decreasing length
```

cocharge()

Return the cocharge of the reading word of `self`. See [cocharge\(\)](#) for more information.

EXAMPLES:

```
sage: Tableau([[1,1],[2,2],[3]]) .cocharge()
4
sage: Tableau([[1,1,3],[2,2]]) .cocharge()
3
sage: Tableau([[1,1,2],[2],[3]]) .cocharge()
3
sage: Tableau([[1,1,2],[2,3]]) .cocharge()
2
sage: Tableau([[1,1,2,3],[2]]) .cocharge()
2
sage: Tableau([[1,1,2,2],[3]]) .cocharge()
1
sage: Tableau([[1,1,2,2,3]]) .cocharge()
0
```

codegree(*e*, multicharge=(0,))

Return the Brundan-Kleshchev-Wang [BKW2011] codegree of the standard tableau `self`.

The *codegree* of a tableau is an integer that is defined recursively by successively stripping off the number k , for $k = n, n - 1, \dots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and are above k in the diagram.

The codegree of the tableau T gives the degree of “dual” homogeneous basis element of the Graded Specht module that is indexed by T .

INPUT:

- *e* – the *quantum characteristic*
- `multicharge` – (default: `[0]`) the multicharge

OUTPUT:

The codegree of the tableau `self`, which is an integer.

EXAMPLES:

```
sage: StandardTableau([[1,3,5],[2,4]]) .codegree(3)
0
sage: StandardTableau([[1,2,5],[3,4]]) .codegree(3)
1
sage: StandardTableau([[1,2,5],[3,4]]) .codegree(4)
0
```

column_stabilizer()

Return the PermutationGroup corresponding to the column stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```
sage: cs = Tableau([[1,2,3],[4,5]]).column_stabilizer()
sage: cs.order() == factorial(2)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

components()

This function returns a list containing itself. It exists mainly for compatibility with *TableauTuple* as it allows constructions like the example below.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: for s in t.components(): print(s.to_list())
[[1, 2, 3], [4, 5]]
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).conjugate()
[[1, 3], [2, 4]]
sage: c = StandardTableau([[1,2],[3,4]]).conjugate()
sage: c.parent()
Standard tableaux
```

content(*k*, multicharge=[0])

Return the content of k in the standard tableau `self`.

The content of k is $c - r$ if k appears in row r and column c of the tableau.

The multicharge is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with *sage.combinat.tableau_tuple.TableauTuple*.

EXAMPLES:

```
sage: StandardTableau([[1,2],[3,4]]).content(3)
-1

sage: StandardTableau([[1,2],[3,4]]).content(6)
Traceback (most recent call last):
...
ValueError: 6 does not appear in tableau
```

corners()

Return the corners of the tableau `self`.

EXAMPLES:

```
sage: Tableau([[1, 4, 6], [2, 5], [3]]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Tableau([[1, 3], [2, 4]]).corners()
[(1, 1)]
```

degree(*e*, *multicharge*=(0,))

Return the Brundan-Kleshchev-Wang [BKW2011] degree of `self`.

The *degree* is an integer that is defined recursively by successively stripping off the number k , for $k = n, n - 1, \dots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and which are below k in the diagram.

The degrees of the tableau T gives the degree of the homogeneous basis element of the graded Specht module that is indexed by T .

INPUT:

- *e* – the *quantum characteristic*
- *multicharge* – (default: [0]) the multicharge

OUTPUT:

The degree of the tableau `self`, which is an integer.

EXAMPLES:

```
sage: StandardTableau([[1,2,5],[3,4]]).degree(3)
0
sage: StandardTableau([[1,2,5],[3,4]]).degree(4)
1
```

descents()

Return a list of the cells (i, j) such that `self[i][j] > self[i-1][j]`.

Warning: This is not to be confused with the descents of a standard tableau.

EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).descents()
[(1, 0)]
sage: Tableau( [[1,2],[3,4]] ).descents()
[(1, 0), (1, 1)]
sage: Tableau( [[1,2,3],[4,5]] ).descents()
[(1, 0), (1, 1)]
```

entries()

Return the tuple of all entries of `self`, in the order obtained by reading across the rows from top to bottom (in English notation).

EXAMPLES:

```
sage: t = Tableau([[1,3], [2]])
sage: t.entries()
(1, 3, 2)
```

entry(*cell*)

Return the entry of cell *cell* in the tableau *self*. Here, *cell* should be given as a tuple (i, j) of zero-based coordinates (so the northwesternmost cell in English notation is $(0, 0)$).

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,4]])
sage: t.entry( (0,0) )
1
sage: t.entry( (1,1) )
4
```

evacuation(*n=None, check=True*)

Return the evacuation of the tableau *self*.

This is an alias for [schuetzenberger_involution\(\)](#).

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If *n* is specified, the underlying alphabet is assumed to be $[1, 2, \dots, n]$. If no alphabet is specified, *n* is the maximal letter appearing in *self*.

INPUT:

- *n* – an integer specifying the maximal letter in the alphabet (optional)
- *check* – (Default: True) Check to make sure *self* is semistandard. Set to False to avoid this check. (optional)

OUTPUT:

- a tableau, the evacuation of *self*

EXAMPLES:

```
sage: t = Tableau([[1,1,1],[2,2]])
sage: t.evacuation(3)
[[2, 2, 3], [3, 3]]

sage: t = Tableau([[1,2,3],[4,5]])
sage: t.evacuation()
[[1, 2, 5], [3, 4]]

sage: t = Tableau([[1,3,5,7],[2,4,6],[8,9]])
sage: t.evacuation()
[[1, 2, 6, 8], [3, 4, 9], [5, 7]]

sage: t = Tableau([])
sage: t.evacuation()
[]

sage: t = StandardTableau([[1,2,3],[4,5]])
sage: s = t.evacuation()
sage: s.parent()
Standard tableaux
```

evaluation()

Return the weight of the tableau *self*. Trailing zeroes are omitted when returning the weight.

The weight of a tableau T is the sequence (a_1, a_2, a_3, \dots) , where a_k is the number of entries of T equal to k . This sequence contains only finitely many nonzero entries.

The weight of a tableau T is the same as the weight of the reading word of T , for any reading order.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]) .weight()
[1, 1, 1, 1]

sage: Tableau([]) .weight()
[]

sage: Tableau([[1,3,3,7],[4,2],[2,3]]) .weight()
[1, 2, 3, 1, 0, 0, 1]
```

first_column_descent()

Return the first cell where `self` is not column standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell (r, c) with r and c minimal such that the entry in position (r, c) is bigger than the entry in position $(r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is column strict.

OUTPUT:

The first cell which there is a descent or `None` if no such cell exists.

EXAMPLES:

```
sage: Tableau([[1,4,5],[2,3]]) .first_column_descent()
(0, 1)
sage: Tableau([[1,2,3],[4]]) .first_column_descent() is None
True
```

first_row_descent()

Return the first cell where the tableau `self` is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell (r, c) with r and c minimal such that the entry in position (r, c) is bigger than the entry in position $(r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is row strict.

OUTPUT:

The first cell which there is a descent or `None` if no such cell exists.

EXAMPLES:

```
sage: t = Tableau([[1,3,2],[4]]); t.first_row_descent()
(0, 1)
sage: Tableau([[1,2,3],[4]]) .first_row_descent() is None
True
```

flush()

Return the number of flush segments in `self`, as in [Sal2014].

Let $1 \leq i < k \leq r + 1$ and suppose ℓ is the smallest integer greater than k such that there exists an ℓ -segment in the $(i + 1)$ -st row of T . A k -segment in the i -th row of T is called *flush* if the leftmost box in the k -segment and the leftmost box of the ℓ -segment are in the same column of T . If, however, no such ℓ exists, then this k -segment is said to be *flush* if the number of boxes in the k -segment is equal to θ_i , where

$\theta_i = \lambda_i - \lambda_{i+1}$ and the shape of T is $\lambda = (\lambda_1 > \lambda_2 > \dots > \lambda_r)$. Denote the number of flush k -segments in T by $\text{flush}(T)$.

EXAMPLES:

```
sage: t = Tableau([[1,1,2,3,5],[2,3,5,5],[3,4]])
sage: t.flush()
3

sage: B = crystals.Tableaux("A4", shape=[4,3,2,1])
sage: t = B[32].to_tableau()
sage: t.flush()
4
```

height()

Return the height of self.

EXAMPLES:

```
sage: Tableau([[1,2,3],[4,5]]).height()
2
sage: Tableau([[1,2,3]]).height()
1
sage: Tableau([]).height()
0
```

hillman_grassl()

Return the image of the λ -array self under the Hillman-Grassl correspondence (as a *WeakReversePlanePartition*).

This relies on interpreting self as a λ -array in the sense of *hillman_grassl*.

Fix a partition λ (see *Partition()*). We draw all partitions and tableaux in English notation.

A λ -array will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape* λ (short: λ -rpp) will mean a λ -array whose entries weakly increase along each row and weakly increase along each column.

The Hillman-Grassl correspondence H is the map that sends a λ -array M to a λ -rpp $H(M)$ defined recursively as follows:

- If all entries of M are 0, then $H(M) = M$.
- Otherwise, let s be the index of the leftmost column of M containing a nonzero entry. Let r be the index of the bottommost nonzero entry in the s -th column of M . Let M' be the λ -array obtained from M by subtracting 1 from the (r, s) -th entry of M . Let $Q = (q_{i,j})$ be the image $H(M')$ (which is already defined by recursion).
- Define a sequence $((i_1, j_1), (i_2, j_2), \dots, (i_n, j_n))$ of boxes in the diagram of λ (actually a lattice path made of southward and westward steps) as follows: Set $(i_1, j_1) = (r, \lambda_r)$ (the rightmost box in the r -th row of λ). If (i_k, j_k) is defined for some $k \geq 1$, then (i_{k+1}, j_{k+1}) is constructed as follows: If q_{i_k+1, j_k} is well-defined and equals q_{i_k, j_k} , then we set $(i_{k+1}, j_{k+1}) = (i_k + 1, j_k)$. Otherwise, if $j_k = s$, then the sequence ends here. Otherwise, we set $(i_{k+1}, j_{k+1}) = (i_k, j_k - 1)$.
- Let $H(M)$ be the array obtained from Q by adding 1 to the (i_k, j_k) -th entry of Q for each $k \in \{1, 2, \dots, n\}$.

See [Gans1981] (Section 3) for this construction.

See also:

`hillman_grassl()` for the Hillman-Grassl correspondence as a standalone function.

`hillman_grassl_inverse()` for the inverse map.

EXAMPLES:

```
sage: a = Tableau([[2, 1, 1], [0, 2, 0], [1, 1]])
sage: A = a.hillman_grassl(); A
[[2, 2, 4], [2, 3, 4], [3, 5]]
sage: A.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

`insert_word(w, left=False)`

Insert the word `w` into the tableau `self` letter by letter using Schensted insertion. By default, the word `w` is being processed from left to right, and the insertion used is row insertion. If the optional keyword `left` is set to `True`, the word `w` is being processed from right to left, and column insertion is used instead.

EXAMPLES:

```
sage: t0 = Tableau([])
sage: w = [1,1,2,3,3,3,3]
sage: t0.insert_word(w)
[[1, 1, 2, 3, 3, 3, 3]]
sage: t0.insert_word(w, left=True)
[[1, 1, 2, 3, 3, 3, 3]]
sage: w.reverse()
sage: t0.insert_word(w)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t0.insert_word(w, left=True)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t1 = Tableau([[1,3],[2]])
sage: t1.insert_word([4,5])
[[1, 3, 4, 5], [2]]
sage: t1.insert_word([4,5], left=True)
[[1, 3], [2, 5], [4]]
```

`inversion_number()`

Return the inversion number of `self`.

The inversion number is defined to be the number of inversions of `self` minus the sum of the arm lengths of the descents of `self` (see the `inversions()` and `descents()` methods for the relevant definitions).

Warning: This has none of the meanings in which the word “inversion” is used in the theory of standard tableaux.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversion_number()
0
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.inversion_number()
0
```

inversions()

Return a list of the inversions of `self`.

Let T be a tableau. An inversion is an attacking pair (c, d) of the shape of T (see [attacking_pairs\(\)](#) for a definition of this) such that the entry of c in T is greater than the entry of d .

Warning: Do not mistake this for the inversions of a standard tableau.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversions()
[((1, 1), (0, 0))]
sage: t = Tableau([[1,4,3],[5,2],[2,6],[3]])
sage: t.inversions()
[((0, 1), (0, 2)), ((1, 0), (1, 1)), ((1, 1), (0, 0)), ((2, 1), (1, 0))]
```

is_column_increasing(*weak=False*)

Return True if the entries in each column are in increasing order, and False otherwise.

By default, this checks for strictly increasing columns. Set `weak` to True to test for weakly increasing columns.

EXAMPLES:

```
sage: T = Tableau([[1, 1, 3], [1, 2]])
sage: T.is_column_increasing(weak=True)
True
sage: T.is_column_increasing()
False
sage: Tableau([[2], [1]]).is_column_increasing(weak=True)
False
```

is_column_strict()

Return True if `self` is a column strict tableau and False otherwise.

A tableau is column strict if the entries in each column are in (strictly) increasing order.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_column_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_column_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([[5, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([]).is_column_strict()
True
sage: Tableau([[1, 4, 2]]).is_column_strict()
True
sage: Tableau([[1, 4, 2], [2, 5]]).is_column_strict()
True
```

(continues on next page)

(continued from previous page)

```
sage: Tableau([[1, 4, 2], [2, 3]]).is_column_strict()
False
```

is_increasing()

Return True if `self` is an increasing tableau and False otherwise.

A tableau is increasing if it is both row strict and column strict.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_increasing()
True
sage: Tableau([[1, 2], [2, 4]]).is_increasing()
True
sage: Tableau([[2, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[5, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[1, 2, 3], [2, 3], [3]]).is_increasing()
True
```

is_k_tableau(*k*)

Checks whether `self` is a valid weak k -tableau.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = Tableau([[1,1,3],[2,2],[3]])
sage: t.is_k_tableau(3)
False
```

is_key_tableau()

Return True if `self` is a key tableau or False otherwise.

A tableau is a *key tableau* if the set of entries in the j -th column is a subset of the set of entries in the $(j - 1)$ -st column.

REFERENCES:

- [LS1990]
- [Wil2010]

EXAMPLES:

```
sage: t = Tableau([[1,1,1],[2,3],[3]])
sage: t.is_key_tableau()
True

sage: t = Tableau([[1,1,2],[2,3],[3]])
sage: t.is_key_tableau()
False
```

is_rectangular()

Return True if the tableau `self` is rectangular and False otherwise.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).is_rectangular()
True
sage: Tableau([[1,2,3],[4,5],[6]]).is_rectangular()
False
sage: Tableau([]).is_rectangular()
True
```

is_row_increasing(*weak=False*)

Return True if the entries in each row are in increasing order, and False otherwise.

By default, this checks for strictly increasing rows. Set *weak* to True to test for weakly increasing rows.

EXAMPLES:

```
sage: T = Tableau([[1, 1, 3], [1, 2]])
sage: T.is_row_increasing(weak=True)
True
sage: T.is_row_increasing()
False
sage: Tableau([[2, 1]]).is_row_increasing(weak=True)
False
```

is_row_strict()

Return True if *self* is a row strict tableau and False otherwise.

A tableau is row strict if the entries in each row are in (strictly) increasing order.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_row_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_row_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_row_strict()
True
sage: Tableau([[5, 3], [2, 4]]).is_row_strict()
False
```

is_semistandard()

Return True if *self* is a semistandard tableau, and False otherwise.

A tableau is semistandard if its rows weakly increase and its columns strictly increase.

EXAMPLES:

```
sage: Tableau([[1,1],[1,2]]).is_semistandard()
False
sage: Tableau([[1,2],[1,2]]).is_semistandard()
False
sage: Tableau([[1,1],[2,2]]).is_semistandard()
True
sage: Tableau([[1,2],[2,3]]).is_semistandard()
True
sage: Tableau([[4,1],[3,2]]).is_semistandard()
False
```

is_standard()

Return True if `self` is a standard tableau and False otherwise.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_standard()
True
sage: Tableau([[1, 2], [2, 4]]).is_standard()
False
sage: Tableau([[2, 3], [2, 4]]).is_standard()
False
sage: Tableau([[5, 3], [2, 4]]).is_standard()
False
```

k_weight(k)

Return the k -weight of `self`.

A tableau has k -weight $\alpha = (\alpha_1, \dots, \alpha_n)$ if there are exactly α_i distinct residues for the cells occupied by the letter i for each i . The residue of a cell in position (a, b) is $a - b$ modulo $k + 1$.

This definition is the one used in [Ive2012] (p. 12).

EXAMPLES:

```
sage: Tableau([[1,2],[2,3]]).k_weight(1)
[1, 1, 1]
sage: Tableau([[1,2],[2,3]]).k_weight(2)
[1, 2, 1]
sage: t = Tableau([[1,1,1,2,5],[2,3,6],[3],[4]])
sage: t.k_weight(1)
[2, 1, 1, 1, 1, 1]
sage: t.k_weight(2)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(3)
[3, 1, 2, 1, 1, 1]
sage: t.k_weight(4)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(5)
[3, 2, 2, 1, 1, 1]
```

lambda_catabolism(part)

Return the `part`-catabolism of `self`, where `part` is a partition (which can be just given as an array).

For a partition λ and a tableau T , the λ -catabolism of T is defined by performing the following steps.

1. Truncate the parts of λ so that λ is contained in the shape of T . Let m be the length of this partition.
2. Let T_a be the first m rows of T , and T_b be the remaining rows.
3. Let S_a be the skew tableau T_a/λ .
4. Concatenate the reading words of S_a and T_b , and insert into a tableau.

EXAMPLES:

```
sage: Tableau([[1,1,3],[2,4,5]]).lambda_catabolism([2,1])
[[3, 5], [4]]
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.lambda_catabolism([])
```

(continues on next page)

(continued from previous page)

```

[[1, 1, 3, 3], [2, 3], [3]]
sage: t.lambda_catabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.lambda_catabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.lambda_catabolism([2,1])
[[3, 3, 3, 3]]
sage: t.lambda_catabolism([4,2,1])
[]
sage: t.lambda_catabolism([5,1])
[[3, 3]]
sage: t.lambda_catabolism([4,1])
[[3, 3]]

```

last_letter_lequal(*tab2*)

Return True if self is less than or equal to *tab2* in the last letter ordering.

EXAMPLES:

```

sage: st = StandardTableaux([3,2])
sage: f = lambda b: 1 if b else 0
sage: matrix( [ [ f(t1.last_letter_lequal(t2)) for t2 in st] for t1 in st] )
[1 1 1 1 1]
[0 1 1 1 1]
[0 0 1 1 1]
[0 0 0 1 1]
[0 0 0 0 1]

```

left_key_tableau()

Return the left key tableau of self.

The left key tableau of a tableau T is the key tableau whose entries are weakly lesser than the corresponding entries in T , and whose column reading word is subject to certain conditions. See [LS1990] for the full definition.

ALGORITHM:

The following algorithm follows [Wil2010]. Note that if T is a key tableau then the output of the algorithm is T .

To compute the left key tableau L of a tableau T we iterate over the columns of T . Let T_j be the j -th column of T and iterate over the entries in T_j from bottom to top. Initialize the corresponding entry k in L as the largest entry in T_j . Scan the columns to the left of T_j and with each column update k to be the lowest entry in that column which is weakly less than k . Update T_j and all columns to the left by removing all scanned entries.

See also:

- [is_key_tableau\(\)](#)

EXAMPLES:

```

sage: t = Tableau([[1,2],[2,3]])
sage: t.left_key_tableau()
[[1, 1], [2, 2]]

```

(continues on next page)

(continued from previous page)

```
sage: t = Tableau([[1,1,2,4],[2,3,3],[4],[5]])
sage: t.left_key_tableau()
[[1, 1, 1, 2], [2, 2, 2], [4], [5]]
```

leq(*secondtab*)

Check whether each entry of *self* is less-or-equal to the corresponding entry of a further tableau *secondtab*.

INPUT:

- *secondtab* – a tableau of the same shape as *self*

EXAMPLES:

```
sage: T = Tableau([[1, 2], [3]])
sage: S = Tableau([[1, 3], [3]])
sage: G = Tableau([[2, 1], [4]])
sage: H = Tableau([[1, 2], [4]])
sage: T.leq(S)
True
sage: T.leq(T)
True
sage: T.leq(G)
False
sage: T.leq(H)
True
sage: S.leq(T)
False
sage: S.leq(G)
False
sage: S.leq(H)
False
sage: G.leq(H)
False
sage: H.leq(G)
False
```

level()

Return the level of *self*, which is always 1.

This function exists mainly for compatibility with *TableauTuple*.

EXAMPLES:

```
sage: Tableau([[1,2,3],[4,5]]).level()
1
```

major_index()

Return the major index of *self*.

The major index of a tableau *T* is defined to be the sum of the number of descents of *T* (defined in *descents*() with the sum of their legs' lengths.

Warning: This is not to be confused with the major index of a standard tableau.

EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).major_index()
1
sage: Tableau( [[1,2],[3,4]] ).major_index()
2
```

If the major index would be defined in the sense of standard tableaux theory, then the following would give 3 for a result:

```
sage: Tableau( [[1,2,3],[4,5]] ).major_index()
2
```

plot(*descents=False*)

Return a plot self.

INPUT:

- *descents* – boolean (default: `False`); if `True`, then the descents are marked in the tableau; only valid if *self* is a standard tableau

EXAMPLES:

```
sage: t = Tableau([[1,2,4],[3]])
sage: t.plot()
Graphics object consisting of 11 graphics primitives
sage: t.plot(descents=True)
Graphics object consisting of 12 graphics primitives

sage: t = Tableau([[2,2,4],[3]])
sage: t.plot()
Graphics object consisting of 11 graphics primitives
sage: t.plot(descents=True)
Traceback (most recent call last):
...
ValueError: the tableau must be standard for 'descents=True'
```

pp()

Pretty print a string of the tableau.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[3,4],[5]])
sage: T.pp()
 1 2 3
 3 4
 5
sage: Tableaux.options.convention="french"
sage: T.pp()
 5
 3 4
 1 2 3
sage: Tableaux.options._reset()
```

promotion(*n*)

Return the image of *self* under the promotion operator.

Warning: You might know this operator as the inverse promotion operator – literature does not agree on the name. You might also be looking for the Lapointe-Lascoux-Morse promotion operator (`promotion_operator()`).

The promotion operator, applied to a tableau t , does the following:

Iterate over all letters $n + 1$ in the tableau t , from left to right. For each of these letters, do the following:

- Remove the letter from t , thus leaving a hole where it used to be.
- Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of t .
- Fill 0 into the hole once jeu de taquin has completed.

Once this all is done, add 1 to each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all $\leq n + 1$, this is the usual promotion operator defined on this class.

When `self` is a standard tableau of size $n + 1$, this definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called “promotion” in [Sag2011] (p. 23) and in [Stan2009].

Warning: To my (Darij’s) knowledge, the fact that the above promotion operator really is the inverse of the “inverse promotion operator” `promotion_inverse()` for semistandard tableaux has never been proven in literature. Corrections are welcome.

REFERENCES:

- [Hai1992]
- [Sag2011]

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,1,1],[2,2,3],[3,4,4]])
sage: t.promotion(3)
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]

sage: t = Tableau([[1,2],[2]])
sage: t.promotion(3)
[[2, 3], [3]]

sage: t = Tableau([[1,1,3],[2,2]])
sage: t.promotion(2)
[[1, 2, 2], [3, 3]]

sage: t = Tableau([[1,1,3],[2,3]])
sage: t.promotion(2)
[[1, 1, 2], [2, 3]]

sage: t = Tableau([])
```

(continues on next page)

(continued from previous page)

```
sage: t.promotion(2)
[]
```

promotion_inverse(*n*)

Return the image of `self` under the inverse promotion operator.

Warning: You might know this operator as the promotion operator (without “inverse”) – literature does not agree on the name.

The inverse promotion operator, applied to a tableau t , does the following:

Iterate over all letters 1 in the tableau t , from right to left. For each of these letters, do the following:

- Remove the letter from t , thus leaving a hole where it used to be.
- Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of t .
- Fill $n + 2$ into the hole once jeu de taquin has completed.

Once this all is done, subtract 1 from each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all $\leq n + 1$, this is the usual inverse promotion operator defined on this class.

When `self` is a standard tableau of size $n + 1$, this definition of inverse promotion is the map called “promotion” in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called “promotion” in [Hai1992] (p. 90).

Warning: To my (Darij’s) knowledge, the fact that the above “inverse promotion operator” really is the inverse of the promotion operator `promotion()` for semistandard tableaux has never been proven in literature. Corrections are welcome.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion_inverse(2)
[[1, 2], [2, 3]]

sage: t = Tableau([[1,2],[2,3]])
sage: t.promotion_inverse(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,2,5],[3,3,6],[4,7]])
sage: t.promotion_inverse(8)
[[1, 2, 4], [2, 5, 9], [3, 6]]

sage: t = Tableau([])
sage: t.promotion_inverse(2)
[]
```

promotion_operator(*i*)

Return a list of semistandard tableaux obtained by the i -th Lapointe-Lascoux-Morse promotion operator from the semistandard tableau `self`.

Warning: This is not Schuetzenberger's jeu de taquin promotion! For the latter, see `promotion()` and `promotion_inverse()`.

This operator is defined by taking the maximum entry m of T , then adding a horizontal i -strip to T in all possible ways, each time filling this strip with $m + 1$'s, and finally letting the permutation $\sigma_1\sigma_2\cdots\sigma_m = (2, 3, \dots, m + 1, 1)$ act on each of the resulting tableaux via the Lascoux-Schuetzenberger action (`symmetric_group_action_on_values()`). This method returns the list of all resulting tableaux. See [LLM2003] for the purpose of this operator.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.promotion_operator(1)
[[[1, 2, 4], [3]], [[1, 2], [3, 4]], [[1, 2], [3], [4]]]
sage: t.promotion_operator(2)
[[[1, 1, 2, 4], [3]],
 [[1, 1, 4], [2, 3]],
 [[1, 1, 2], [3], [4]],
 [[1, 1], [2, 3], [4]]]
sage: Tableau([[1]]).promotion_operator(2)
[[[1, 1, 2]], [[1, 1], [2]]]
sage: Tableau([[1,1],[2]]).promotion_operator(3)
[[[1, 1, 1, 2, 3], [2]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1], [2, 2], [3]]]
```

The example from [LLM2003] p. 12:

```
sage: Tableau([[1,1],[2,2]]).promotion_operator(3)
[[[1, 1, 1, 3, 3], [2, 2]],
 [[1, 1, 1, 3], [2, 2], [3]],
 [[1, 1, 1], [2, 2], [3, 3]]]
```

`raise_action_from_words(f, *args)`

EXAMPLES:

```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: import functools
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: f = functools.partial(t.raise_action_from_words, symmetric_group_action_
↪ on_values)
sage: f([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: f([3,2,1])
[[1, 1, 1, 1], [2, 3], [3]]
sage: f([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]
```

`reading_word_permutation()`

Return the permutation obtained by reading the entries of the standardization of `self` row by row, starting with the bottommost row (in English notation).

EXAMPLES:

```
sage: StandardTableau([[1,2],[3,4]]).reading_word_permutation()
[3, 4, 1, 2]
```

Check that [trac ticket #14724](#) is fixed:

```
sage: SemistandardTableau([[1,1]]).reading_word_permutation()
[1, 2]
```

reduced_column_word()

Return the lexicographically minimal reduced expression for the permutation that maps the conjugate of the `initial_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the columns of the tableau in order from top to bottom.

EXAMPLES:

```
sage: StandardTableau([[1,4,6],[2,5],[3]]).reduced_column_word()
[]
sage: StandardTableau([[1,4,5],[2,6],[3]]).reduced_column_word()
[5]
sage: StandardTableau([[1,3,6],[2,5],[4]]).reduced_column_word()
[3]
sage: StandardTableau([[1,3,5],[2,6],[4]]).reduced_column_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_column_word()
[3, 2, 5]
```

reduced_lambda_catabolism(*part*)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.reduced_lambda_catabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.reduced_lambda_catabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([2,1])
[[3, 3, 3, 3]]
sage: t.reduced_lambda_catabolism([4,2,1])
[]
sage: t.reduced_lambda_catabolism([5,1])
0
sage: t.reduced_lambda_catabolism([4,1])
0
```

reduced_row_word()

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau in order from top to bottom.

EXAMPLES:

```
sage: StandardTableau([[1,2,3],[4,5],[6]]).reduced_row_word()
[]
sage: StandardTableau([[1,2,3],[4,6],[5]]).reduced_row_word()
[5]
sage: StandardTableau([[1,2,4],[3,6],[5]]).reduced_row_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_row_word()
[3, 5, 4]
sage: StandardTableau([[1,2,6],[3,5],[4]]).reduced_row_word()
[3, 4, 5, 4]
```

residue(*k*, *e*, *multicharge*=(0,))

Return the residue of the integer *k* in the tableau *self*.

The *residue* of *k* in a standard tableau is $c - r + m$ in $\mathbf{Z}/e\mathbf{Z}$, where *k* appears in row *r* and column *c* of the tableau with multicharge *m*.

INPUT:

- *k* – an integer in $\{1, 2, \dots, n\}$
- *e* – an integer in $\{0, 2, 3, 4, 5, \dots\}$
- *multicharge* – (default: [0]) a list of length 1

Here *n* is its size of *self*.

The *multicharge* is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `residue()`.

OUTPUT:

The residue in $\mathbf{Z}/e\mathbf{Z}$.

EXAMPLES:

```
sage: StandardTableau([[1,2,5],[3,4]]).residue(1,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(2,3)
1
sage: StandardTableau([[1,2,5],[3,4]]).residue(3,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(4,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(5,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(6,3)
Traceback (most recent call last):
...
ValueError: 6 does not appear in the tableau
```

residue_sequence(*e*, *multicharge*=(0,))

Return the `sage.combinat.tableau_residues.ResidueSequence` of the tableau *self*.

INPUT:

- *e* – an integer in $\{0, 2, 3, 4, 5, \dots\}$
- *multicharge* – (default: [0]) a sequence of integers of length 1

The *multicharge* is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with `residue()`.

OUTPUT:

The corresponding residue sequence of the tableau; see `ResidueSequence`.

EXAMPLES:

```
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(4)
4-residue sequence (0,1,3,0) with multicharge (0)
```

restrict(*n*)

Return the restriction of the semistandard tableau `self` to `n`. If possible, the restricted tableau will have the same parent as this tableau.

If T is a semistandard tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than n from T .

Note: If only the shape of the restriction, rather than the whole restriction, is needed, then the faster method `restriction_shape()` is preferred.

EXAMPLES:

```
sage: Tableau([[1,2],[3],[4]]).restrict(3)
[[1, 2], [3]]
sage: StandardTableau([[1,2],[3],[4]]).restrict(2)
[[1, 2]]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)
[]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(2)
[[1, 2], [2]]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(3)
[[1, 2, 3], [2], [3]]
sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(5)
[[1, 2, 3], [2, 4, 4], [3]]
```

If possible the restricted tableau will belong to the same category as the original tableau:

```
sage: S = StandardTableau([[1,2,4,7],[3,5],[6]]); S.category()
Category of elements of Standard tableaux
sage: S.restrict(4).category()
Category of elements of Standard tableaux
sage: SS=StandardTableaux([4,2,1])([[1,2,4,7],[3,5],[6]]); SS.category()
Category of elements of Standard tableaux of shape [4, 2, 1]
sage: SS.restrict(4).category()
Category of elements of Standard tableaux

sage: Tableau([[1,2],[3],[4]]).restrict(3)
[[1, 2], [3]]
sage: Tableau([[1,2],[3],[4]]).restrict(2)
```

(continues on next page)

(continued from previous page)

```

[[1, 2]]
sage: SemistandardTableau([[1,1],[2]]).restrict(1)
[[1, 1]]
sage: _.category()
Category of elements of Semistandard tableaux

```

restriction_shape(*n*)

Return the shape of the restriction of the semistandard tableau `self` to `n`.

If T is a semistandard tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than n from T .

This method computes merely the shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```

sage: Tableau([[1,2],[2,3],[3,4]]).restriction_shape(3)
[2, 2, 1]
sage: StandardTableau([[1,2],[3],[4],[5]]).restriction_shape(2)
[2]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(0)
[]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(2)
[1, 1]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(3)
[3, 1]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(5)
[4, 3]

sage: all( T.restriction_shape(i) == T.restrict(i).shape()
.....:      for T in StandardTableaux(5) for i in range(1, 5) )
True

```

reverse_bump(*loc*)

Reverse row bump the entry of `self` at the specified location `loc` (given as a row index or a corner (`r`, `c`) of the tableau).

This is the reverse of Schensted's row-insertion algorithm. See Section 1.1, page 8, of Fulton's [Ful1997].

INPUT:

- `loc` – Can be either of the following:
 - The coordinates (`r`, `c`) of the square to reverse-bump (which must be a corner of the tableau);
 - The row index `r` of this square.

Note that both `r` and `c` are 0-based, i.e., the topmost row and the leftmost column are the 0-th row and the 0-th column.

OUTPUT:

An ordered pair consisting of:

1. The resulting (smaller) tableau;
2. The entry bumped out at the end of the process.

See also:`bump()`**EXAMPLES:**

This is the reverse of Schensted's bump:

```
sage: T = Tableau([[1, 1, 2, 2, 4], [2, 3, 3], [3, 4], [4]])
sage: T.reverse_bump(2)
([[1, 1, 2, 3, 4], [2, 3, 4], [3], [4]], 2)
sage: T == T.reverse_bump(2)[0].bump(2)
True
sage: T.reverse_bump((3, 0))
([[1, 2, 2, 2, 4], [3, 3, 3], [4, 4]], 1)
```

Some errors caused by wrong input:

```
sage: T.reverse_bump((3, 1))
Traceback (most recent call last):
...
ValueError: invalid corner
sage: T.reverse_bump(4)
Traceback (most recent call last):
...
IndexError: list index out of range
sage: Tableau([[2, 2, 1], [3, 3]]).reverse_bump(0)
Traceback (most recent call last):
...
ValueError: reverse bumping is only defined for semistandard tableaux
```

Some edge cases:

```
sage: Tableau([[1]]).reverse_bump(0)
([], 1)
sage: Tableau([[1, 1]]).reverse_bump(0)
([[1]], 1)
sage: Tableau([]).reverse_bump(0)
Traceback (most recent call last):
...
IndexError: list index out of range
```

Note: Reverse row bumping is only implemented for tableaux with weakly increasing and strictly increasing columns (though the tableau does not need to be an instance of class *SemistandardTableau*).

right_key_tableau()

Return the right key tableau of `self`.

The right key tableau of a tableau T is a key tableau whose entries are weakly greater than the corresponding entries in T , and whose column reading word is subject to certain conditions. See [LS1990] for the full definition.

ALGORITHM:

The following algorithm follows [Wil2010]. Note that if T is a key tableau then the output of the algorithm is T .

To compute the right key tableau R of a tableau T we iterate over the columns of T . Let T_j be the j -th column of T and iterate over the entries in T_j from bottom to top. Initialize the corresponding entry k in R to be the largest entry in T_j . Scan the bottom of each column of T to the right of T_j , updating k to be the scanned entry whenever the scanned entry is weakly greater than k . Update T_j and all columns to the right by removing all scanned entries.

See also:

- `is_key_tableau()`

EXAMPLES:

```
sage: t = Tableau([[1,2],[2,3]])
sage: t.right_key_tableau()
[[2, 2], [3, 3]]
sage: t = Tableau([[1,1,2,4],[2,3,3],[4],[5]])
sage: t.right_key_tableau()
[[2, 2, 2, 4], [3, 4, 4], [4], [5]]
```

rotate_180()

Return the tableau obtained by rotating `self` by 180 degrees.

This only works for rectangular tableaux.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).rotate_180()
[[4, 3], [2, 1]]
```

row_stabilizer()

Return the `PermutationGroup` corresponding to the row stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```
sage: rs = Tableau([[1,2,3],[4,5]]).row_stabilizer()
sage: rs.order() == factorial(3)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs = Tableau([[1, 2],[3]]).row_stabilizer()
sage: PermutationGroupElement([(1,2),(3,)]) in rs
True
sage: rs.one().domain()
[1, 2, 3]
sage: rs = Tableau([[1],[2],[3]]).row_stabilizer()
sage: rs.order()
1
sage: rs = Tableau([[2,4,5],[1,3]]).row_stabilizer()
sage: rs.order()
12
sage: rs = Tableau([]).row_stabilizer()
sage: rs.order()
1
```

schensted_insert(*i*, *left=False*)

Insert *i* into *self* using Schensted's row-bumping (or row-insertion) algorithm.

INPUT:

- *i* – a number to insert
- *left* – (default: `False`) boolean; if set to `True`, the insertion will be done from the left. That is, if one thinks of the algorithm as appending a letter to the reading word of *self*, we append the letter to the left instead of the right

EXAMPLES:

```
sage: t = Tableau([[3,5],[7]])
sage: t.schensted_insert(8)
[[3, 5, 8], [7]]
sage: t.schensted_insert(8, left=True)
[[3, 5], [7], [8]]
```

schuetzenberger_involution(*n=None*, *check=True*)

Return the Schuetzenberger involution of the tableau *self*.

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If *n* is specified, the underlying alphabet is assumed to be $[1, 2, \dots, n]$. If no alphabet is specified, *n* is the maximal letter appearing in *self*.

INPUT:

- *n* – an integer specifying the maximal letter in the alphabet (optional)
- *check* – (Default: `True`) Check to make sure *self* is semistandard. Set to `False` to avoid this check. (optional)

OUTPUT:

- a tableau, the Schuetzenberger involution of *self*

EXAMPLES:

```
sage: t = Tableau([[1,1,1],[2,2]])
sage: t.schuetzenberger_involution(3)
[[2, 2, 3], [3, 3]]

sage: t = Tableau([[1,2,3],[4,5]])
sage: t.schuetzenberger_involution()
[[1, 2, 5], [3, 4]]

sage: t = Tableau([[1,3,5,7],[2,4,6],[8,9]])
sage: t.schuetzenberger_involution()
[[1, 2, 6, 8], [3, 4, 9], [5, 7]]

sage: t = Tableau([])
sage: t.schuetzenberger_involution()
[]

sage: t = StandardTableau([[1,2,3],[4,5]])
sage: s = t.schuetzenberger_involution()
sage: s.parent()
Standard tableaux
```

seg()

Return the total number of segments in `self`, as in [Sal2014].

Let T be a tableaux. We define a k -segment of T (in the i -th row) to be a maximal consecutive sequence of k -boxes in the i -th row for any $i + 1 \leq k \leq r + 1$. Denote the total number of k -segments in T by $\text{seg}(T)$.

REFERENCES:

- [Sal2014]

EXAMPLES:

```
sage: t = Tableau([[1,1,2,3,5],[2,3,5,5],[3,4]])
sage: t.seg()
6

sage: B = crystals.Tableaux("A4", shape=[4,3,2,1])
sage: t = B[31].to_tableau()
sage: t.seg()
3
```

shape()

Return the shape of a tableau `self`.

EXAMPLES:

```
sage: Tableau([[1,2,3],[4,5],[6]]).shape()
[3, 2, 1]
```

size()

Return the size of the shape of the tableau `self`.

EXAMPLES:

```
sage: Tableau([[1, 4, 6], [2, 5], [3]]).size()
6
sage: Tableau([[1, 3], [2, 4]]).size()
4
```

slide_multiply(*other*)

Multiply two tableaux using jeu de taquin.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid.

See pp. 15 of [Ful1997].

The same product operation is implemented in a different way in `bump_multiply()`.

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.slide_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

socle()

EXAMPLES:

```
sage: Tableau([[1,2],[3,4])).socle()
2
sage: Tableau([[1,2,3,4])).socle()
4
```

standardization(*check=True*)

Return the standardization of `self`, assuming `self` is a semistandard tableau.

The standardization of a semistandard tableau T is the standard tableau $\text{st}(T)$ of the same shape as T whose reversed reading word is the standardization of the reversed reading word of T .

The standardization of a word w can be formed by replacing all 1's in w by $1, 2, \dots, k_1$ from left to right, all 2's in w by $k_1 + 1, k_1 + 2, \dots, k_2$, and repeating for all letters which appear in w . See also `Word.standard_permutation()`.

INPUT:

- `check` – (Default: `True`) Check to make sure `self` is semistandard. Set to `False` to avoid this check.

EXAMPLES:

```
sage: t = Tableau([[1,3,3,4],[2,4,4],[5,16]])
sage: t.standardization()
[[1, 3, 4, 7], [2, 5, 6], [8, 9]]
```

Standard tableaux are fixed under standardization:

```
sage: all((t == t.standardization() for t in StandardTableaux(6)))
True
sage: t = Tableau([])
sage: t.standardization()
[]
```

The reading word of the standardization is the standardization of the reading word:

```
sage: T = SemistandardTableaux(shape=[5,2,2,1], max_entry=4)
sage: all(t.to_word().standard_permutation() == t.standardization().reading_
↪word_permutation() for t in T) # long time
True
```

sulzgruber_correspondence()

Return the image of the λ -array `self` under the Sulzgruber correspondence (as a [WeakReversePlanePartition](#)).

This relies on interpreting `self` as a λ -array in the sense of [hillman_grassl](#). See [hillman_grassl](#) for definitions of the objects involved.

The Sulzgruber correspondence is the map Φ_λ from [Sulzgr2017] Section 7, and is the map ξ_λ^{-1} from [Pak2002] Section 5. It is denoted by \mathcal{RSK} in [Hopkins2017]. It is the inverse of the Pak correspondence (`pak_correspondence()`). The following description of the Sulzgruber correspondence follows [Hopkins2017] (which denotes it by \mathcal{RSK}):

Fix a partition λ (see [Partition\(\)](#)). We draw all partitions and tableaux in English notation.

A λ -array will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape* λ (short: λ -rpp) will mean a λ -array whose entries weakly increase along each row and weakly increase along each column.

We shall also use the following notation: If (u, v) is a cell of λ , and if π is a λ -rpp, then:

- the *lower bound* of π at (u, v) (denoted by $\pi_{<(u,v)}$) is defined to be $\max\{\pi_{u-1,v}, \pi_{u,v-1}\}$ (where $\pi_{0,v}$ and $\pi_{u,0}$ are understood to mean 0).
- the *upper bound* of π at (u, v) (denoted by $\pi_{>(u,v)}$) is defined to be $\min\{\pi_{u+1,v}, \pi_{u,v+1}\}$ (where $\pi_{i,j}$ is understood to mean $+\infty$ if (i, j) is not in λ ; thus, the upper bound at a corner cell is $+\infty$).
- *toggling* π at (u, v) means replacing the entry $\pi_{u,v}$ of π at (u, v) by $\pi_{<(u,v)} + \pi_{>(u,v)} - \pi_{u,v}$ (this is well-defined as long as (u, v) is not a corner of λ).

Note that every λ -rpp π and every cell (u, v) of λ satisfy $\pi_{<(u,v)} \leq \pi_{u,v} \leq \pi_{>(u,v)}$. Note that toggling a λ -rpp (at a cell that is not a corner) always results in a λ -rpp. Also, toggling is an involution).

The Pak correspondence ξ_λ sends a λ -rpp π to a λ -array $\xi_\lambda(\pi)$. It is defined by recursion on λ (that is, we assume that ξ_μ is already defined for every partition μ smaller than λ), and its definition proceeds as follows:

- If $\lambda = \emptyset$, then ξ_λ is the obvious bijection sending the only \emptyset -rpp to the only \emptyset -array.
- Pick any corner $c = (i, j)$ of λ , and let μ be the result of removing this corner c from the partition λ . (The exact choice of c is immaterial.)
- Let π' be what remains of π when the corner cell c is removed.
- For each positive integer k such that $(i - k, j - k)$ is a cell of λ , toggle π' at $(i - k, j - k)$. (All these togglings commute, so the order in which they are made is immaterial.)
- Let $M = \xi_\mu(\pi')$.
- Extend the μ -array M to a λ -array M' by adding the cell c and writing the number $\pi_{i,j} - \pi_{<(i,j)}$ into this cell.
- Set $\xi_\lambda(\pi) = M'$.

See also:

[`sulzgruber_correspondence\(\)`](#) for the Sulzgruber correspondence as a standalone function.

[`pak_correspondence\(\)`](#) for the inverse map.

EXAMPLES:

```
sage: a = Tableau([[2, 1, 1], [0, 2, 0], [1, 1]])
sage: A = a.sulzgruber_correspondence(); A
[[0, 1, 4], [1, 5, 5], [3, 6]]
sage: A.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)

sage: a = Tableau([[1, 3], [0, 1]])
sage: a.sulzgruber_correspondence()
[[0, 4], [1, 5]]
```

`symmetric_group_action_on_entries(w)`

Return the tableau obtained from this tableau by acting by the permutation w .

Let T be a standard tableau of size n , then the action of $w \in S_n$ is defined by permuting the entries of T (recall they are $1, 2, \dots, n$). In particular, suppose the entry at cell (i, j) is a , then the entry becomes $w(a)$. In general, the resulting tableau wT may *not* be standard.

Note: This is different than `symmetric_group_action_on_values()` which is defined on semistandard tableaux and is guaranteed to return a semistandard tableau.

INPUT:

- `w` – a permutation

EXAMPLES:

```
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(
↳Permutation(((4,5))) )
[[1, 2, 5], [3, 4]]
sage: _.category()
Category of elements of Standard tableaux
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(
↳Permutation(((1,2))) )
[[2, 1, 4], [3, 5]]
sage: _.category()
Category of elements of Tableaux
```

`symmetric_group_action_on_values(perm)`

Return the image of the semistandard tableau `self` under the action of the permutation `perm` using the Lascoux-Schuetzenberger action of the symmetric group S_n on the semistandard tableaux with ceiling n .

If n is a nonnegative integer, then the Lascoux-Schuetzenberger action is a group action of the symmetric group S_n on the set of semistandard Young tableaux with ceiling n (that is, with entries taken from the set $\{1, 2, \dots, n\}$). It is defined as follows:

Let $i \in \{1, 2, \dots, n-1\}$, and let T be a semistandard tableau with ceiling n . Let w be the reading word (`to_word()`) of T . Replace all letters i in w by closing parentheses, and all letters $i+1$ in w by opening parentheses. Whenever an opening parenthesis stands left of a closing parenthesis without there being any parentheses in between (it is allowed to have letters in-between as long as they are not parentheses), consider these two parentheses as matched with each other, and replace them back by the letters $i+1$ and i . Repeat this procedure until there are no more opening parentheses standing left of closing parentheses. Then, let a be the number of opening parentheses in the word, and b the number of closing parentheses (notice that all opening parentheses are right of all closing parentheses). Replace the first a parentheses by the letters i , and replace the remaining b parentheses by the letters $i+1$. Let w' be the resulting word. Let T' be the tableau with the same shape as T but with reading word w' . This tableau T' can be shown to be semistandard. We define the image of T under the action of the simple transposition $s_i = (i, i+1) \in S_n$ to be this tableau T' . It can be shown that these actions of the transpositions s_1, s_2, \dots, s_{n-1} satisfy the Moore-Coxeter relations of S_n , and thus this extends to a unique action of the symmetric group S_n on the set of semistandard tableaux with ceiling n . This is the Lascoux-Schuetzenberger action.

This action of the symmetric group S_n on the set of all semistandard tableaux of given shape λ with entries in $\{1, 2, \dots, n\}$ is the one defined in [Loth02] Theorem 5.6.3. In particular, the action of s_i is denoted by σ_i in said source. (Beware of the typo in the definition of σ_i : it should say $\sigma_i(a_i^r a_{i+1}^s) = a_i^s a_{i+1}^r$, not $\sigma_i(a_i^r a_{i+1}^s) = a_i^s a_{i+1}^s$.)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.symmetric_group_action_on_values([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([2,1,3])
[[1, 2, 3, 3], [2, 3], [3]]
```

(continues on next page)

(continued from previous page)

```

sage: t.symmetric_group_action_on_values([3,1,2])
[[1, 2, 2, 2], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([2,3,1])
[[1, 1, 1, 1], [2, 2], [3]]
sage: t.symmetric_group_action_on_values([3,2,1])
[[1, 1, 1, 1], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]

```

to_Gelfand_Tsetlin_pattern()

Return the *Gelfand-Tsetlin pattern* corresponding to *self* when semistandard.

EXAMPLES:

```

sage: T = Tableau([[1,2,3],[2,3],[3]])
sage: G = T.to_Gelfand_Tsetlin_pattern(); G
[[3, 2, 1], [2, 1], [1]]
sage: G.to_tableau() == T
True
sage: T = Tableau([[1,3],[2]])
sage: T.to_Gelfand_Tsetlin_pattern()
[[2, 1, 0], [1, 1], [1]]

```

to_chain(max_entry=None)

Return the chain of partitions corresponding to the (semi)standard tableau *self*.

The optional keyword parameter *max_entry* can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer *n*, then the chain is constructed from the positions of the letters $1, 2, \dots, n$ in the tableau.

EXAMPLES:

```

sage: Tableau([[1,2],[3],[4]]).to_chain()
[[], [1], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2]]).to_chain()
[[], [2], [2, 1]]
sage: Tableau([[1,1],[3]]).to_chain()
[[], [2], [2], [2, 1]]
sage: Tableau([]).to_chain()
[[]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=2)
[[], [2], [2, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=3)
[[], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=4)
[[], [2], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: Tableau([[1,1,2],[2,3],[4,5]]).to_chain(max_entry=6)
[[], [2], [3, 1], [3, 2], [3, 2, 1], [3, 2, 2], [3, 2, 2]]

```

to_list()

Return *self* as a list of lists (not tuples!).

EXAMPLES:

```

sage: t = Tableau([[1,2],[3,4]])
sage: l = t.to_list(); l
[[1, 2], [3, 4]]
sage: l[0][0] = 2
sage: t
[[1, 2], [3, 4]]

```

to_sign_matrix(*max_entry=None*)

Return the sign matrix of *self*.

A sign matrix is an $m \times n$ matrix of 0's, 1's and -1's such that the partial sums of each column is either 0 or 1 and the partial sums of each row is non-negative. [Ava2007]

INPUT:

- *max_entry* – A non-negative integer, the maximum allowable number in the tableau. Defaults to the largest entry in the tableau if not specified.

EXAMPLES:

```

sage: t = SemistandardTableau([[1,1,1,2,4],[3,3,4],[4,5],[6,6]])
sage: t.to_sign_matrix(6)
[ 0  0  0  1  0  0]
[ 0  1  0 -1  0  0]
[ 1 -1  0  1  0  0]
[ 0  0  1 -1  1  1]
[ 0  0  0  1 -1  0]
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.to_sign_matrix(7)
[ 0  0  0  1  0  0  0]
[ 0  1  0 -1  1  0  0]
[ 1 -1  1  0 -1  0  0]
sage: t = Tableau([(4,5,4,3),(2,1,3)])
sage: t.to_sign_matrix(5)
[ 0  0  1  0  0]
[ 0  0  0  1  0]
[ 1  0 -1 -1  1]
[-1  1  0  1 -1]
sage: s = Tableau([(1,0,-2,4),(3,4,5)])
sage: s.to_sign_matrix(6)
Traceback (most recent call last):
...
ValueError: the entries must be non-negative integers

```

to_word()

An alias for *to_word_by_row*().

EXAMPLES:

```

sage: Tableau([[1,2],[3,4]].to_word()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word()
word: 325146

```

to_word_by_column()

Return the word obtained from a column reading of the tableau *self* (starting with the leftmost column,

reading every column from bottom to top).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]].to_word_by_column()
word: 3142
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_column()
word: 321546
```

to_word_by_row()

Return the word obtained from a row reading of the tableau `self` (starting with the lowermost row, reading every row from left to right).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]].to_word_by_row()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_row()
word: 325146
```

vertical_flip()

Return the tableau obtained by vertically flipping the tableau `self`.

This only works for rectangular tableaux.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]].vertical_flip()
[[3, 4], [1, 2]]
```

weight()

Return the weight of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a tableau T is the sequence (a_1, a_2, a_3, \dots) , where a_k is the number of entries of T equal to k . This sequence contains only finitely many nonzero entries.

The weight of a tableau T is the same as the weight of the reading word of T , for any reading order.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]].weight()
[1, 1, 1, 1]

sage: Tableau([]).weight()
[]

sage: Tableau([[1,3,3,7],[4,2],[2,3]]).weight()
[1, 2, 3, 1, 0, 0, 1]
```

class `sage.combinat.tableau.Tableau_class`(*parent, t, check=True*)

Bases: `sage.combinat.tableau.Tableau`

This exists solely for unpickling `Tableau_class` objects.

class `sage.combinat.tableau.Tableaux`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

A factory class for the various classes of tableaux.

INPUT:

- `n` (optional) – a non-negative integer

OUTPUT:

- If `n` is specified, the class of tableaux of size `n`. Otherwise, the class of all tableaux.

A tableau in Sage is a finite list of lists, whose lengths are weakly decreasing, or an empty list, representing the empty tableau. The entries of a tableau can be any Sage objects. Because of this, no enumeration through the set of Tableaux is possible.

EXAMPLES:

```
sage: T = Tableaux(); T
Tableaux
sage: T3 = Tableaux(3); T3
Tableaux of size 3
sage: [['a', 'b']] in T
True
sage: [['a', 'b']] in T3
False
sage: t = T3([[1, 1, 1]]); t
[[1, 1, 1]]
sage: t in T
True
sage: t.parent()
Tableaux of size 3
sage: T([]) # the empty tableau
[]
sage: T.category()
Category of sets
```

- [StandardTableaux](#)
- [StandardTableau](#)

Element

alias of [Tableau](#)

options(*get_value, **set_value)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- `ascii_art` – (default: `repr`) Controls the ascii art output for tableaux
 - `compact` – minimal length ascii art
 - `repr` – display using the diagram string representation
 - `table` – display as a table

- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
 - `English` – use the English convention
 - `French` – use the French convention
- `display` – (default: `list`) Controls the way in which tableaux are printed
 - `array` – alias for `diagram`
 - `compact` – minimal length string representation
 - `diagram` – display as Young diagram (similar to `pp()`)
 - `ferrers_diagram` – alias for `diagram`
 - `list` – print tableaux as lists
 - `young_diagram` – alias for `diagram`
- `latex` – (default: `diagram`) Controls the way in which tableaux are latexed
 - `array` – alias for `diagram`
 - `diagram` – as a Young diagram
 - `ferrers_diagram` – alias for `diagram`
 - `list` – as a list
 - `young_diagram` – alias for `diagram`
- `notation` – alternative name for `convention`

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
 1 2 3
 4 5
sage: Tableaux.options.convention="french"
sage: T
 4 5
 1 2 3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
```

(continues on next page)

(continued from previous page)

```

***
***
*
sage: T
  1 2 3
  4 5

```

The ASCII art can also be changed:

```

sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1 2 3
  4 5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+---+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
sage: Tableaux.options._reset()

```

See [GlobalOptions](#) for more features of these options.

```

class sage.combinat.tableau.Tableaux_all
  Bases: sage.combinat.tableau.Tableaux

```

Initializes the class of all tableaux

```

an_element()

```

Return a particular element of the class.

```

class sage.combinat.tableau.Tableaux_size(n)
  Bases: sage.combinat.tableau.Tableaux

```

Tableaux of a fixed size n .

```

an_element()

```

Return a particular element of the class.

```

sage.combinat.tableau.from_chain(chain)

```

Return a semistandard tableau from a chain of partitions.

EXAMPLES:

```

sage: from sage.combinat.tableau import from_chain
sage: from_chain([], [2], [2, 1], [3, 2, 1])
[[1, 1, 3], [2, 3], [3]]

```

```

sage.combinat.tableau.from_shape_and_word(shape, w, convention='French')

```

Return a tableau from a shape and word.

INPUT:

- `shape` – a partition
- `w` – a word whose length equals that of the partition
- `convention` – a string which can take values "French" or "English"; the default is "French"

OUTPUT:

A tableau, whose shape is `shape` and whose reading word is `w`. If the `convention` is specified as "French", the reading word is to be read starting from the top row in French convention (= the bottom row in English convention). If the `convention` is specified as "English", the reading word is to be read starting with the top row in English convention.

EXAMPLES:

```
sage: from sage.combinat.tableau import from_shape_and_word
sage: t = Tableau([[1, 3], [2], [4]])
sage: shape = t.shape(); shape
[2, 1, 1]
sage: word = t.to_word(); word
word: 4213
sage: from_shape_and_word(shape, word)
[[1, 3], [2], [4]]
sage: word = Word(flatten(t))
sage: from_shape_and_word(shape, word, convention="English")
[[1, 3], [2], [4]]
```

`sage.combinat.tableau.symmetric_group_action_on_values(word, perm)`

Return the image of the word `word` under the Lascoux-Schuetzenberger action of the permutation `perm`.

See `Tableau.symmetric_group_action_on_values()` for the definition of the Lascoux-Schuetzenberger action on semistandard tableaux. The transformation that the reading word of the tableau undergoes in said definition is precisely the Lascoux-Schuetzenberger action on words.

EXAMPLES:

```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: symmetric_group_action_on_values([1, 1, 1], [1, 3, 2])
[1, 1, 1]
sage: symmetric_group_action_on_values([1, 1, 1], [2, 1, 3])
[2, 2, 2]
sage: symmetric_group_action_on_values([1, 2, 1], [2, 1, 3])
[2, 2, 1]
sage: symmetric_group_action_on_values([2, 2, 2], [2, 1, 3])
[1, 1, 1]
sage: symmetric_group_action_on_values([2, 1, 2], [2, 1, 3])
[2, 1, 1]
sage: symmetric_group_action_on_values([2, 2, 3, 1, 1, 2, 2, 3], [1, 3, 2])
[2, 3, 3, 1, 1, 2, 3, 3]
sage: symmetric_group_action_on_values([2, 1, 1], [2, 1])
[2, 1, 2]
sage: symmetric_group_action_on_values([2, 2, 1], [2, 1])
[1, 2, 1]
sage: symmetric_group_action_on_values([1, 2, 1], [2, 1])
[2, 2, 1]
```

`sage.combinat.tableau.unmatched_places(w, open, close)`

Given a word `w` and two letters `open` and `close` to be treated as opening and closing parentheses (respectively),

return a pair (xs, ys) that encodes the positions of the unmatched parentheses after the standard parenthesis matching procedure is applied to w .

More precisely, xs will be the list of all i such that $w[i]$ is an unmatched closing parenthesis, while ys will be the list of all i such that $w[i]$ is an unmatched opening parenthesis. Both lists returned are in increasing order.

EXAMPLES:

```
sage: from sage.combinat.tableau import unmatched_places
sage: unmatched_places([2,2,2,1,1,1],2,1)
([], [])
sage: unmatched_places([1,1,1,2,2,2],2,1)
([0, 1, 2], [3, 4, 5])
sage: unmatched_places([], 2, 1)
([], [])
sage: unmatched_places([1,2,4,6,2,1,5,3],2,1)
([0], [1])
sage: unmatched_places([2,2,1,2,4,6,2,1,5,3], 2, 1)
([], [0, 3])
sage: unmatched_places([3,1,1,1,2,1,2], 2, 1)
([1, 2, 3], [6])
```

5.1.343 Residue sequences of tableaux

A *residue sequence* for a *StandardTableau*, or *StandardTableauTuple*, of size n is an n -tuple (i_1, i_2, \dots, i_n) of elements of $\mathbf{Z}/e\mathbf{Z}$ for some positive integer $e \geq 1$. Such sequences arise in the representation theory of the symmetric group and the closely related cyclotomic Hecke algebras, and cyclotomic quiver Hecke algebras, where the residue sequences play a similar role to weights in the representations of Lie groups and Lie algebras. These Hecke algebras are semisimple when e is “large enough” and in these cases residue sequences are essentially the same as content sequences (see `sage.combinat.partition.Partition.content()`) and it is not difficult to see that residue sequences are in bijection with the set of standard tableaux. In the non-semisimple case, when e is “small”, different standard tableaux can have the same residue sequence. In this case the residue sequences describe how to decompose modules into generalised eigenspaces for the Jucys-Murphy elements for these algebras.

By definition, if t is a *StandardTableau* of size n then the residue sequence of t is the n -tuple (i_1, \dots, i_n) where $i_m = c - r + e\mathbf{Z}$, if m appears in row r and column c of t . If p is prime then such sequence arise in the representation theory of the symmetric group n characteristic p . More generally, e -residue sequences arise in the representation theory of the Iwahori-Hecke algebra (see *IwahoriHeckeAlgebra*) the symmetric group with Hecke parameter at an e -th root of unity.

More generally, the e -residue sequence of a *StandardTableau* of size n and level l is the n -tuple (i_1, \dots, i_n) determined by e and a *multicharge* $\kappa = (\kappa_1, \dots, \kappa_l)$ by setting $i_m = \kappa_k + c - r + e\mathbf{Z}$, if m appears in component k , row r and column c of t . These sequences arise in the representation theory of the cyclotomic Hecke algebras of type A , which are also known as Ariki-Koike algebras.

The residue classes are constructed from standard tableaux:

```
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)

sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue_sequence(3,[0,0])
3-residue sequence (0,1,2,0,0) with multicharge (0,0)
sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue_sequence(3,[0,1])
```

(continues on next page)

(continued from previous page)

```

3-residue sequence (1,2,0,1,0) with multicharge (0,1)
sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue_sequence(3,[0,2])
3-residue sequence (2,0,1,2,0) with multicharge (0,2)

```

One of the most useful functions of a *ResidueSequence* is that it can return the *StandardTableaux_residue* and *StandardTableaux_residue_shape* that contain all of the tableaux with this residue sequence. Again, these are best accessed via the standard tableaux classes:

```

sage: res = StandardTableau([[1,2],[3,4]]).residue_sequence(2)
sage: res.standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
sage: res.standard_tableaux()[:]
[[[1, 2, 4], [3]],
 [[1, 2], [3, 4]],
 [[1, 2], [3], [4]],
 [[1, 3, 4], [2]],
 [[1, 3], [2, 4]],
 [[1, 3], [2], [4]]]
sage: res.standard_tableaux(shape=[4])
Standard (4)-tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
sage: res.standard_tableaux(shape=[4])[:]
[]

sage: res=StandardTableauTuple([[5]],[[1,2],[3,4]]).residue_sequence(3,[0,0])
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,0) and multicharge (0,0)
sage: res.standard_tableaux(shape=[[1],[2,2]])[:]
[[[5]],[[1, 2], [3, 4]], ([[4]],[[1, 2], [3, 5]])]

```

These residue sequences are particularly useful in the graded representation theory of the cyclotomic KLR algebras and the cyclotomic Hecke algebras of type $\sim A$; see [DJM1998] and [BK2009].

This module implements the following classes:

- *ResidueSequence*
- *ResidueSequences*

See also:

- *Partitions*
- *PartitionTuples*
- *StandardTableaux_residue*
- *StandardTableaux_residue_shape*
- *RowStandardTableauTuples_residue*
- *RowStandardTableauTuples_residue_shape*
- *StandardTableaux*
- *StandardTableauTuples*
- *Tableaux*
- *TableauTuples*

Todo: Strictly speaking this module implements residue sequences of type $A_e^{(1)}$. Residue sequences of other types also need to be implemented.

AUTHORS:

- Andrew Mathas (2016-07-01): Initial version

class `sage.combinat.tableau_residues.ResidueSequence`(*parent, residues, check*)

Bases: `sage.structure.list_clone.ClonableArray`

A residue sequence.

The *residue sequence* of a tableau t (of partition or partition tuple shape) is the sequence (i_1, i_2, \dots, i_n) where i_k is the residue of l in t , for $k = 1, 2, \dots, n$, where n is the size of t . Residue sequences are important in the representation theory of the cyclotomic Hecke algebras of type $G(r, 1, n)$, and of the cyclotomic quiver Hecke algebras, because they determine the eigenvalues of the Jucys-Murphy elements upon all modules. More precisely, they index and completely determine the irreducible representations of the (cyclotomic) Gelfand-Tsetlin algebras.

Rather than being called directly, residue sequences are best accessed via the standard tableaux classes `StandardTableau` and `StandardTableauTuple`.

INPUT:

Can be of the form:

- `ResidueSequence(e, res)`,
- `ResidueSequence(e, multicharge, res)`,

where e is a positive integer not equal to 1 and `res` is a sequence of integers (the residues).

EXAMPLES:

```
sage: res = StandardTableauTuple([[[1,3],[6]], [[2,7],[4],[5]]) .residue_sequence(3,
↪(0,5))
sage: res
3-residue sequence (0,2,1,1,0,2,0) with multicharge (0,2)
sage: res.quantum_characteristic()
3
sage: res.level()
2
sage: res.size()
7
sage: res.residues()
[0, 2, 1, 1, 0, 2, 0]
sage: res.restrict(2)
3-residue sequence (0,2) with multicharge (0,2)
sage: res.standard_tableaux([[2,1],[1],[2,1]])
Standard (2,1|1|2,1)-tableaux with 3-residue sequence (0,2,1,1,0,2,0) and
↪multicharge (0,2)
sage: res.standard_tableaux([[2,2],[3]]).list()
[]
sage: res.standard_tableaux([[2,2],[3]])[: ]
[]
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,2,1,1,0,2,0) and multicharge (0,2)
```

(continues on next page)

(continued from previous page)

```
sage: res.standard_tableaux()[:10]
[[[1, 3, 6, 7], [2, 5], [4]], []],
[[[1, 3, 6], [2, 5], [4], [7]], []],
[[[1, 3], [2, 5], [4, 6], [7]], []],
[[[1, 3], [2, 5], [4], [7]], [[6]]],
[[[1, 3], [2, 5], [4]], [[6, 7]]],
[[[1, 3, 6, 7], [2], [4], [5]], []],
[[[1, 3, 6], [2, 7], [4], [5]], []],
[[[1, 3], [2, 7], [4], [5], [6]], []],
[[[1, 3], [2, 7], [4], [5]], [[6]]],
[[[1, 3], [2], [4], [5]], [[6, 7]]]]
```

The TestSuite fails `_test_pickling` because `__getitem__` does not support slices, so we skip this.

base_ring()

Return the base ring for the residue sequence.

If the `quantum_characteristic()` of the residue sequence `self` is e then the base ring for the sequence is $\mathbf{Z}/e\mathbf{Z}$, or \mathbf{Z} if $e = 0$.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).base_ring()
Ring of integers modulo 3
```

block()

Return a dictionary β that determines the block associated to the residue sequence `self`.

Two Specht modules for a cyclotomic Hecke algebra of type A belong to the same block, in this sense, if and only if the residue sequences of their standard tableaux have the same block in this sense. The blocks of these algebras are actually indexed by positive roots in the root lattice of an affine special linear group. Instead of than constructing the root lattice, this method simply returns a dictionary β where the keys are residues i and where the value of the key i is equal to the numbers of nodes in the residue sequence `self` that are equal to i . The dictionary β corresponds to the positive root:

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+,$$

These positive roots also index the blocks of the cyclotomic KLR algebras of type A .

We return a dictionary because when the `quantum_characteristic()` is 0, the Cartan type is A_∞ , in which case the simple roots are indexed by the integers, which is infinite.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,0], [0,1,2,0,1,2,0,1,2]).block()
{0: 3, 1: 3, 2: 3}
```

check()

Raise a `ValueError` if `self` is not a residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).check()
sage: ResidueSequence(3, [0,0,1], [2,0,1,1,2,2,3,3]).check()
```

level()

Return the level of the residue sequence. That is, the level of the corresponding (tuples of) standard tableaux.

The *level* of a residue sequence is the length of its `multicharge()`. This is the same as the level of the `standard_tableaux()` that belong to the residue class of tableaux determined by `self`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).level()
3
```

multicharge()

Return the multicharge for the residue sequence `self`.

The e -residue sequences are associated with a cyclotomic Hecke algebra with Hecke parameter q of `quantum_characteristic()` e and multicharge $(\kappa_1, \dots, \kappa_l)$. This means that the cyclotomic parameters of the Hecke algebra are $q^{\kappa_1}, \dots, q^{\kappa_l}$. Equivalently, the Hecke algebra is determined by the dominant weight

$$\sum_{r \in \mathbf{Z}/e\mathbf{Z}} \kappa_r \Lambda_r \in P^+.$$

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).multicharge()
(0, 0, 1)
```

negative()

Return the negative of the residue sequence `self`.

That is, if `self` is the residue sequence (i_1, \dots, i_n) then return $(-i_1, \dots, -i_n)$. Taking the negative residue sequences is a shadow of tensoring with the sign representation from the cyclotomic Hecke algebras of type A .

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).negative()
3-residue sequence (0,0,2,2,1,1,0,0) with multicharge (0,0,1)
```

quantum_characteristic()

Return the quantum characteristic of the residue sequence `self`.

The e -residue sequences are associated with a cyclotomic Hecke algebra that has a parameter q of `quantum_characteristic()` e . This is the smallest positive integer such that $1 + q + \dots + q^{e-1} = 0$, or $e = 0$ if no such integer exists.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).quantum_characteristic()
3
```

residues()

Return a list of the residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).residues()
[0, 0, 1, 1, 2, 2, 0, 0]
```

restrict(*m*)

Return the subsequence of this sequence of length *m*.

The residue sequence `self` is of the form (r_1, \dots, r_n) . The function returns the residue sequence (r_1, \dots, r_m) , with the same `quantum_characteristic()` and `multicharge()`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).restrict(7)
3-residue sequence (0,0,1,1,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).restrict(6)
3-residue sequence (0,0,1,1,2,2) with multicharge (0,0,1)
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).restrict(4)
3-residue sequence (0,0,1,1) with multicharge (0,0,1)
```

restrict_row(*cell*, *row*)

Return a residue sequence for the tableau obtained by swapping the row in ending in *cell* with the row that is *row* rows above it and which has the same length.

The residue sequence `self` is of the form (r_1, \dots, r_n) . The function returns the residue sequence (r_1, \dots, r_m) , with the same `quantum_characteristic()` and `multicharge()`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,1,2,2,0,1]).restrict_row((1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (0)
sage: ResidueSequence(3, [1,0], [0,1,2,2,0,1]).restrict_row((1,1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (1,0)
```

row_standard_tableaux(*shape=None*)

Return the residue-class of row standard tableaux that have residue sequence `self`.

INPUT:

- *shape* – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the row standard tableaux with this residue sequence. If the *shape* is given then only tableaux of this shape are returned, otherwise all of the full residue-class of row standard tableaux, or row standard tableaux tuples, is returned. The residue sequence `self` specifies the `multicharge()` of the tableaux which, in turn, determines the `level()` of the tableaux in the residue class.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,0), [0,1,2,0,1,2,0,1,2]).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and
multicharge (0,0,0)
```

(continues on next page)

(continued from previous page)

```
sage: ResidueSequence(3, (0,0,0), [0,1,2,0,1,2,0,1,2]).row_standard_tableaux([[3],
↪ [3], [3]])
Row standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and
↪ multicharge (0,0,0)
```

size()

Return the size of the residue sequence.

This is the size, or length, of the residue sequence, which is the same as the size of the `standard_tableaux()` that belong to the residue class of tableaux determined by `self`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).size()
8
```

standard_tableaux(shape=None)

Return the residue-class of standard tableaux that have residue sequence `self`.

INPUT:

- `shape` – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the standard tableaux with this residue sequence. If the `shape` is given then only tableaux of this shape are returned, otherwise all of the full residue-class of standard tableaux, or standard tableaux tuples, is returned. The residue sequence `self` specifies the `multicharge()` of the tableaux which, in turn, determines the `level()` of the tableaux in the residue class.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,0), [0,1,2,0,1,2,0,1,2]).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge
↪ (0,0,0)
sage: ResidueSequence(3, (0,0,0), [0,1,2,0,1,2,0,1,2]).standard_tableaux([[3], [3],
↪ [3]])
Standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and
↪ multicharge (0,0,0)
```

swap_residues(i, j)

Return the *new* residue sequence obtained by swapping the residues for `i` and `j`.

INPUT:

- `i` and `j` – two integers between 1 and the length of the residue sequence

If residue sequence `self` is of the form (r_1, \dots, r_n) , and $i < j$, then the residue sequence $(r_1, \dots, r_j, \dots, r_i, \dots, r_m)$, with the same `quantum_characteristic()` and `multicharge()`, is returned.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: res = ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]); res
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
```

(continues on next page)

(continued from previous page)

```

sage: ser = res.swap_residues(2,6); ser
3-residue sequence (0,2,1,1,2,0,0,0) with multicharge (0,0,1)
sage: res == ser
False

```

class sage.combinat.tableau_residues.**ResidueSequences**(*e*, *multicharge*=(0,))

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A parent class for *ResidueSequence*.

This class exists because *ResidueSequence* needs to have a parent. Apart from being a parent the only useful method that it provides is *cell_residue()*, which is a short-hand for computing the residue of a cell using the *ResidueSequence.quantum_characteristic()* and *ResidueSequence.multicharge()* for the residue class.

EXAMPLES:

```

sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(e=0, multicharge=(0,1,2))
0-residue sequences with multicharge (0, 1, 2)
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=0,
↳ multicharge=(0,1,2))
True
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=3,
↳ multicharge=(0,1,2))
False
sage: ResidueSequences(e=0, multicharge=(0,1,2)).element_class
<class 'sage.combinat.tableau_residues.ResidueSequences_with_category.element_class'
↳ '>

```

Element

alias of *ResidueSequence*

an_element()

Return a particular element of self.

EXAMPLES:

```

sage: TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])

```

cell_residue(*args)

Return the residue a cell with respect to the quantum characteristic and the multicharge of the residue sequence.

INPUT:

- *r* and *c* – the row and column indices in level one
- *k*, *r* and *c* – the component, row and column indices in higher levels

EXAMPLES:

```

sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(3).cell_residue(1,1)
0

```

(continues on next page)

(continued from previous page)

```

sage: ResidueSequences(3).cell_residue(2,1)
2
sage: ResidueSequences(3).cell_residue(3,1)
1
sage: ResidueSequences(3).cell_residue(3,2)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,0,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,0)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,2)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,0,0)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,1,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,0,1)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,0,0)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,1,0)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,0,1)
0

```

check_element(*element*)

Check that *element* is a residue sequence with multicharge `self.multicharge()`.

This is weak criteria in that we only require that *element* is a tuple of elements in the underlying base ring of `self`. Such a sequence is always a valid residue sequence, although there may be no tableaux with this residue sequence.

EXAMPLES:

```

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,4,2,2,5,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,0,0) with multicharge (0,0,1)

```

5.1.344 TableauTuples

A *TableauTuple* is a tuple of tableaux. These objects arise naturally in representation theory of the wreath products of cyclic groups and the symmetric groups where the standard tableau tuples index bases for the ordinary irreducible representations. This generalises the well-known fact the ordinary irreducible representations of the symmetric groups have bases indexed by the standard tableaux of a given shape. More generally, *TableauTuples*, or multitableaux, appear in the representation theory of the degenerate and non-degenerate cyclotomic Hecke algebras and in the crystal theory of the integral highest weight representations of the affine special linear groups.

A *TableauTuple* is an ordered tuple $(t^{(1)}, t^{(2)}, \dots, t^{(l)})$ of tableaux. The length of the tuple is its *level* and the tableaux $t^{(1)}, t^{(2)}, \dots, t^{(l)}$ are the components of the *TableauTuple*.

A tableaux can be thought of as the labelled diagram of a partition. Analogously, a *TableauTuple* is the labelled diagram of a *PartitionTuple*. That is, a *TableauTuple* is a tableau of *PartitionTuple* shape. As much as possible, *TableauTuples* behave in exactly the same way as *Tableaux*. There are obvious differences in that the cells of a partition are ordered pairs (r, c) , where r is a row index and c a column index, whereas the cells of a *PartitionTuple* are ordered triples (k, r, c) , with r and c as before and k indexes the component.

Frequently, we will call a *TableauTuple* a tableau, or a tableau of *PartitionTuple* shape. If the shape of the tableau is known this should not cause any confusion.

Warning: In sage the convention is that the (k, r, c) -th entry of a tableau tuple t is the entry in row r , column c and component k of the tableau. This is because it makes much more sense to let $t[k]$ be component of the tableau. In particular, we want $t(k, r, c) == t[k][r][c]$. In the literature, the cells of a tableau tuple are usually written in the form (r, c, k) , where r is the row index, c is the column index, and k is the component index.

The same convention applies to the cells of *PartitionTuples*.

Note: As with partitions and tableaux, the cells are 0-based. For example, the (lexicographically) first cell in any non-empty tableau tuple is $[0, 0, 0]$.

EXAMPLES:

```
sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
sage: t = TableauTuple([ [[6,7],[8,9]],[[1,2,3],[4,5]] ]); t
([[6, 7], [8, 9]], [[1, 2, 3], [4, 5]])
sage: t.pp()
 6 7   1 2 3
 8 9   4 5
sage: t(0,0,1)
7
sage: t(1,0,1)
2
sage: t.shape()
([2, 2], [3, 2])
sage: t.size()
9
sage: t.level()
2
sage: t.components()
[[[6, 7], [8, 9]], [[1, 2, 3], [4, 5]]]
sage: t.entries()
[6, 7, 8, 9, 1, 2, 3, 4, 5]
sage: t.parent()
Tableau tuples
sage: t.category()
Category of elements of Tableau tuples
```

One reason for implementing *TableauTuples* is to be able to consider *StandardTableauTuples*. These objects arise in many areas of algebraic combinatorics. In particular, they index bases for the Specht modules of the cyclotomic Hecke algebras of type $G(r, 1, n)$. A *StandardTableauTuple* of tableau whose entries are increasing along rows and down columns in each component and which contain the numbers $1, 2, \dots, n$, where the shape of the *StandardTableauTuple* is a *PartitionTuple* of n .

```

sage: s = StandardTableauTuple([ [[1,2],[3]], [[4,5]] ])
sage: s.category()
Category of elements of Standard tableau tuples
sage: t = TableauTuple([ [[1,2],[3]], [[4,5]] ])
sage: t.is_standard(), t.is_column_strict(), t.is_row_strict()
(True, True, True)
sage: t.category()
Category of elements of Tableau tuples
sage: s == t
True
sage: s is t
False
sage: s == StandardTableauTuple(t)
True
sage: StandardTableauTuples([ [2,1],[1] ])[: ]
[[([1, 2], [3]), ([4])],
 ([1, 3], [2]), ([4])],
 ([1, 2], [4]), ([3])],
 ([1, 3], [4]), ([2])],
 ([2, 3], [4]), ([1])],
 ([1, 4], [2]), ([3])],
 ([1, 4], [3]), ([2])],
 ([2, 4], [3]), ([1])]

```

As tableaux (of partition shape) are in natural bijection with 1-tuples of tableaux all of the *TableauTuple* classes return an ordinary *Tableau* when given *TableauTuple* of level 1.

```

sage: TableauTuples( level=1 ) is Tableaux()
True
sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
sage: TableauTuple([ [[1,2,3],[4,5]] ])
[[1, 2, 3], [4, 5]]
sage: TableauTuple([[1,2,3],[4,5]]) == Tableau([[1,2,3],[4,5]])
True

```

There is one situation where a 1-tuple of tableau is not actually a *Tableau*; tableaux generated by the *StandardTableauTuples()* iterators must have the correct parents, so in this one case 1-tuples of tableaux are different from *Tableaux*:

```

sage: StandardTableauTuples()[:10]
[(),
 ([1]),
 ([], []),
 ([1, 2]),
 ([1], [2]),
 ([1]), [],
 ([], [1]),
 ([], [], []),
 ([1, 2, 3]),
 ([1, 3], [2])]

```

Todo: Implement semistandard tableau tuples as defined in [DJM1998].

Much of the combinatorics implemented here is motivated by this and subsequent papers on the representation theory of these algebras.

class `sage.combinat.tableau_tuple.RowStandardTableauTuple`(*parent, t, check=True*)

Bases: `sage.combinat.tableau_tuple.TableauTuple`

A class for row standard tableau tuples of shape a partition tuple.

A row standard tableau tuple of size n is an ordered tuple of row standard tableaux (see [RowStandardTableau](#)), with entries $1, 2, \dots, n$ such that, in each component, the entries are in increasing order along each row. If the tableau in component k has shape $\lambda^{(k)}$ then $\lambda = (\lambda^{(1)}, \dots, \lambda^{(l)})$ is a [PartitionTuple](#).

Note: The tableaux appearing in a [RowStandardTableauTuple](#) are row strict, but individually they are not standard tableaux because the entries in any single component of a [RowStandardTableauTuple](#) will typically not be in bijection with $\{1, 2, \dots, n\}$.

INPUT:

- `t` – a tableau, a list of (standard) tableau or an equivalent list

OUTPUT:

- A [RowStandardTableauTuple](#) object constructed from `t`.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with [PartitionTuple](#), in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0, 0, 0]$. Further, the coordinates $[k, r, c]$ in a [TableauTuple](#) refer to the component, row and column indices, respectively.

EXAMPLES:

```
sage: t = RowStandardTableauTuple([[4, 7], [3]], [[2, 6, 8], [1, 5]], [[9]]); t
([[4, 7], [3]], [[2, 6, 8], [1, 5]], [[9]])
sage: t.pp()
 4 7   2 6 8   9
 3       1 5
sage: t.shape()
([2, 1], [3, 2], [1])
sage: t[0].pp() # pretty printing
 4 7
 3
sage: t.is_row_strict()
True
sage: t[0].is_standard()
False
sage: RowStandardTableauTuple([], [], []) # An empty tableau tuple
([], [], [])
sage: RowStandardTableauTuple([[4, 5], [6]], [[1, 2, 3]]) in StandardTableauTuples()
```

(continues on next page)

(continued from previous page)

```
True
sage: RowStandardTableauTuple([[5,6],[4]],[[1,2,3]]) in StandardTableauTuples()
False
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a *RowStandardTableauTuple* from the appropriate parent object:

```
sage: RST = RowStandardTableauTuples()
sage: RST([[4,5],[7]],[[1,2,3],[6,8]],[[9]])
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
```

See also:

- [RowTableau](#)
- [RowTableaux](#)
- [TableauTuples](#)
- [TableauTuple](#)
- [StandardTableauTuples](#)
- [StandardTableauTuple](#)
- [RowStandardTableauTuples](#)

codegree(*e*, *multicharge*)

Return the Brundan-Kleshchev-Wang [BKW2011] codegree of *self*.

The *codegree* of a tableau is an integer that is defined recursively by successively stripping off the number k , for $k = n, n - 1, \dots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and which are above k in the diagram.

The codegree of the tableau *self* gives the degree of “dual” homogeneous basis element of the graded Specht module which is indexed by *self*.

INPUT:

- *e* – the *quantum characteristic*
- *multicharge* – the *multicharge*

OUTPUT:

The codegree of the tableau *self*, which is an integer.

EXAMPLES:

```
sage: StandardTableauTuple([[1]], [], []).codegree(0,(0,0,0))
0
sage: StandardTableauTuple([], [[1]], []).codegree(0,(0,0,0))
1
sage: StandardTableauTuple([], [], [[1]]).codegree(0,(0,0,0))
2
sage: StandardTableauTuple([[1]], [[2]], []).codegree(0,(0,0,0))
-1
sage: StandardTableauTuple([[1]], [], [[2]]).codegree(0,(0,0,0))
0
```

(continues on next page)

(continued from previous page)

```

sage: StandardTableauTuple([[[]],[[1]],[[2]]) .codegree(0,(0,0,0))
1
sage: StandardTableauTuple([[2]],[[1]],[[]]) .codegree(0,(0,0,0))
1
sage: StandardTableauTuple([[2]],[[]],[[1]]) .codegree(0,(0,0,0))
2
sage: StandardTableauTuple([[[]],[[2]],[[1]]) .codegree(0,(0,0,0))
3

```

degree(*e*, *multicharge*)

Return the Brundan-Kleshchev-Wang [BKW2011] degree of `self`.

The *degree* of a tableau is an integer that is defined recursively by successively stripping off the number k , for $k = n, n - 1, \dots, 1$, and at stage adding the count of the number of addable cell of the same residue minus the number of removable cells of them same residue as k and that are below k in the diagram.

Note that even though this degree function was defined by Brundan-Kleshchev-Wang [BKW2011] the underlying combinatorics is much older, going back at least to Misra and Miwa.

The degrees of the tableau T gives the degree of the homogeneous basis element of the graded Specht module which is indexed by T .

INPUT:

- *e* – the *quantum characteristic* *e*
- *multicharge* – (default: `[0]`) the multicharge

OUTPUT:

The degree of the tableau `self`, which is an integer.

EXAMPLES:

```

sage: StandardTableauTuple([[1]],[[]],[[]]) .degree(0,(0,0,0))
2
sage: StandardTableauTuple([[[]],[1]],[[]]) .degree(0,(0,0,0))
1
sage: StandardTableauTuple([[[]],[[]],[1]]) .degree(0,(0,0,0))
0
sage: StandardTableauTuple([[1]],[2]],[[]]) .degree(0,(0,0,0))
3
sage: StandardTableauTuple([[1]],[[]],[2]]) .degree(0,(0,0,0))
2
sage: StandardTableauTuple([[[]],[1]],[2]]) .degree(0,(0,0,0))
1
sage: StandardTableauTuple([[2]],[1]],[[]]) .degree(0,(0,0,0))
1
sage: StandardTableauTuple([[2]],[[]],[1]]) .degree(0,(0,0,0))
0
sage: StandardTableauTuple([[[]],[2]],[[1]]) .degree(0,(0,0,0))
-1

```

inverse(*k*)

Return the cell containing *k* in the tableau tuple `self`.

EXAMPLES:

```

sage: RowStandardTableauTuple([[3,4],[1,2]],[5,6,7],[8]],[9,10],[11],[12])).
↪inverse(1)
(0, 1, 0)
sage: RowStandardTableauTuple([[3,4],[1,2]],[5,6,7],[8]],[9,10],[11],[12])).
↪inverse(2)
(0, 1, 1)
sage: RowStandardTableauTuple([[3,4],[1,2]],[5,6,7],[8]],[9,10],[11],[12])).
↪inverse(3)
(0, 0, 0)
sage: RowStandardTableauTuple([[3,4],[1,2]],[5,6,7],[8]],[9,10],[11],[12])).
↪inverse(4)
(0, 0, 1)
sage: StandardTableauTuple([[1,2],[3,4]],[5,6,7],[8]],[9,10],[11],[12])).
↪inverse(1)
(0, 0, 0)
sage: StandardTableauTuple([[1,2],[3,4]],[5,6,7],[8]],[9,10],[11],[12])).
↪inverse(2)
(0, 0, 1)
sage: StandardTableauTuple([[1,2],[3,4]],[5,6,7],[8]],[9,10],[11],[12])).
↪inverse(3)
(0, 1, 0)
sage: StandardTableauTuple([[1,2],[3,4]],[5,6,7],[8]],[9,10],[11],[12])).
↪inverse(12)
(2, 2, 0)

```

residue_sequence(*e*, *multicharge*)

Return the `sage.combinat.tableau_residues.ResidueSequence` of `self`.

INPUT:

- *e* – integer in $\{0, 2, 3, 4, 5, \dots\}$
- *multicharge* – a sequence of integers of length equal to the level/length of `self`

OUTPUT:

The *residue sequence* of the tableau.

EXAMPLES:

```

sage: RowStandardTableauTuple([[5]],[3,4],[1,2])).residue_sequence(3,[0,0])
3-residue sequence (2,0,0,1,0) with multicharge (0,0)
sage: StandardTableauTuple([[5]],[1,2],[3,4])).residue_sequence(3,[0,1])
3-residue sequence (1,2,0,1,0) with multicharge (0,1)
sage: StandardTableauTuple([[5]],[1,2],[3,4])).residue_sequence(3,[0,2])
3-residue sequence (2,0,1,2,0) with multicharge (0,2)

```

class `sage.combinat.tableau_tuple.RowStandardTableauTuples`

Bases: `sage.combinat.tableau_tuple.TableauTuples`

A factory class for the various classes of tuples of row standard tableau.

INPUT:

There are three optional arguments:

- *level* – the `level()` of the tuples of tableaux
- *size* – the `size()` of the tuples of tableaux

- `shape` – a list or a partition tuple specifying the `shape()` of the row standard tableau tuples

It is not necessary to use the keywords. If they are not used then the first integer argument specifies the `level()` and the second the `size()` of the tableau tuples.

OUTPUT:

The appropriate subclass of `RowStandardTableauTuples`.

A tuple of row standard tableau is a tableau whose entries are positive integers which increase from left to right along the rows in each component. The entries do NOT need to increase from left to right along the components.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with `PartitionTuple`, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is `[0, 0, 0]`.

EXAMPLES:

```
sage: tabs = RowStandardTableauTuples([[2],[1,1]]); tabs
Row standard tableau tuples of shape ([2], [1, 1])
sage: tabs.cardinality()
12
sage: tabs[:]
[[[3, 4], [2, 1]],
 [[2, 4], [3, 1]],
 [[1, 4], [3, 2]],
 [[1, 2], [4, 3]],
 [[1, 3], [4, 2]],
 [[2, 3], [4, 1]],
 [[1, 4], [2, 3]],
 [[1, 3], [2, 4]],
 [[1, 2], [3, 4]],
 [[2, 3], [1, 4]],
 [[2, 4], [1, 3]],
 [[3, 4], [1, 2]]]

sage: tabs = RowStandardTableauTuples(level=3); tabs
Row standard tableau tuples of level 3
sage: tabs[100]
([], [], [[2, 3], [1]])

sage: RowStandardTableauTuples()[0]
([])
```

- [RowStandardTableauTuples](#)

Element

alias of `RowStandardTableauTuple`

level_one_parent_classalias of `sage.combinat.tableau.RowStandardTableaux_all`**shape()**Return the shape of the set of *RowStandardTableauTuples*, or `None` if it is not defined.

EXAMPLES:

```

sage: tabs=RowStandardTableauTuples(shape=[[5,2],[3,2],[],[1,1,1],[3]]); tabs
Row standard tableau tuples of shape ([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: tabs.shape()
([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: RowStandardTableauTuples().shape() is None
True

```

class sage.combinat.tableau_tuple.RowStandardTableauTuples_allBases: `sage.combinat.tableau_tuple.RowStandardTableauTuples`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`Default class of all *RowStandardTableauTuples* with an arbitrary *level()* and *size()*.**an_element()**

Return a particular element of the class.

EXAMPLES:

```

sage: RowStandardTableauTuples().an_element()
([[4, 5, 6, 7]], [[2, 3]], [[1]])

```

class sage.combinat.tableau_tuple.RowStandardTableauTuples_level(level)Bases: `sage.combinat.tableau_tuple.RowStandardTableauTuples`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`Class of all *RowStandardTableauTuples* with a fixed level and arbitrary size.**an_element()**

Return a particular element of the class.

EXAMPLES:

```

sage: RowStandardTableauTuples(2).an_element()
([[1]], [[2, 3]])
sage: RowStandardTableauTuples(3).an_element()
([[1]], [[2, 3]], [[4, 5, 6, 7]])

```

class sage.combinat.tableau_tuple.RowStandardTableauTuples_level_size(level, size)Bases: `sage.combinat.tableau_tuple.RowStandardTableauTuples`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`Class of all *RowStandardTableauTuples* with a fixed level and a fixed size.**an_element()**

Return a particular element of self.

EXAMPLES:

```

sage: RowStandardTableauTuples(5,size=2).an_element()
([], [], [], [], [[1], [2]])
sage: RowStandardTableauTuples(2,size=4).an_element()
([[1]], [[2, 3], [4]])

```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_residue**(*residue*)

Bases: *sage.combinat.tableau_tuple.RowStandardTableauTuples*

Class of all row standard tableau tuples with a fixed residue sequence.

Implicitly, this also specifies the quantum characteristic, multicharge and hence the level and size of the tableaux.

Note: This class is not intended to be called directly, but rather, it is accessed through the row standard tableaux.

EXAMPLES:

```
sage: RowStandardTableau([[3,4,5],[1,2]]).residue_sequence(2).row_standard_
↳tableaux()
Row standard tableaux with 2-residue sequence (1,0,0,1,0) and multicharge (0)
sage: RowStandardTableau([[3,4,5],[1,2]]).residue_sequence(3).row_standard_
↳tableaux()
Row standard tableaux with 3-residue sequence (2,0,0,1,2) and multicharge (0)
sage: RowStandardTableauTuple([[5,6],[7]],[[1,2,3],[4]]).residue_sequence(2,(0,
↳0)).row_standard_tableaux()
Row standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,0)
sage: RowStandardTableauTuple([[5,6],[7]],[[1,2,3],[4]]).residue_sequence(3,(0,
↳1)).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,1)
```

an_element()

Return a particular element of *self*.

EXAMPLES:

```
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3).row_standard_
↳tableaux().an_element()
[[2, 3], [1]]
sage: StandardTableau([[1,3],[2]]).residue_sequence(3).row_standard_tableaux().
↳an_element()
[[1, 3], [2]]
sage: RowStandardTableauTuple([[4]],[[2,3],[1]]).residue_sequence(3,(0,1)).
↳row_standard_tableaux().an_element()
sage: StandardTableauTuple([[4]],[[1,3],[2]]).residue_sequence(3,(0,1)).row_
↳standard_tableaux().an_element()
([[4], [3], [1], [2]], [])
```

level()

Return the level of *self*.

EXAMPLES:

```
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_
↳tableaux().level()
2
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_
↳tableaux().level()
2
sage: RowStandardTableauTuple([[4]],[[2,3],[1]]).residue_sequence(3,(0,1)).
↳row_standard_tableaux().level()
2
```

(continues on next page)

(continued from previous page)

```
sage: StandardTableauTuple([[4]], [[1, 3], [2]]) .residue_sequence(3, (0, 1)) .row_
↳ standard_tableaux().level()
2
```

multicharge()

Return the multicharge of self.

EXAMPLES:

```
sage: RowStandardTableau([[2, 3], [1]]) .residue_sequence(3, (0, 1)) .row_standard_
↳ tableaux().multicharge()
(0, 1)
sage: StandardTableau([[1, 2], [3]]) .residue_sequence(3, (0, 1)) .row_standard_
↳ tableaux().multicharge()
(0, 1)
sage: RowStandardTableauTuple([[4]], [[2, 3], [1]]) .residue_sequence(3, (0, 1)) .
↳ row_standard_tableaux().multicharge()
(0, 1)
sage: StandardTableauTuple([[4]], [[1, 3], [2]]) .residue_sequence(3, (0, 1)) .row_
↳ standard_tableaux().multicharge()
(0, 1)
```

quantum_characteristic()

Return the quantum characteristic of self.

EXAMPLES:

```
sage: RowStandardTableau([[2, 3], [1]]) .residue_sequence(3, (0, 1)) .row_standard_
↳ tableaux().quantum_characteristic()
3
sage: StandardTableau([[1, 2], [3]]) .residue_sequence(3, (0, 1)) .row_standard_
↳ tableaux().quantum_characteristic()
3
sage: RowStandardTableauTuple([[4]], [[2, 3], [1]]) .residue_sequence(3, (0, 1)) .
↳ row_standard_tableaux().quantum_characteristic()
3
sage: StandardTableauTuple([[4]], [[1, 3], [2]]) .residue_sequence(3, (0, 1)) .row_
↳ standard_tableaux().quantum_characteristic()
3
```

residue_sequence()

Return the residue sequence of self.

EXAMPLES:

```
sage: RowStandardTableau([[2, 3], [1]]) .residue_sequence(3, (0, 1)) .row_standard_
↳ tableaux().residue_sequence()
3-residue sequence (2, 0, 1) with multicharge (0, 1)
sage: StandardTableau([[1, 2], [3]]) .residue_sequence(3, (0, 1)) .row_standard_
↳ tableaux().residue_sequence()
3-residue sequence (0, 1, 2) with multicharge (0, 1)
sage: RowStandardTableauTuple([[4]], [[2, 3], [1]]) .residue_sequence(3, (0, 1)) .
↳ row_standard_tableaux().residue_sequence()
3-residue sequence (0, 1, 2, 0) with multicharge (0, 1)
```

(continues on next page)

(continued from previous page)

```
sage: StandardTableauTuple([[4]], [[1, 3], [2]]) .residue_sequence(3, (0, 1)) .row_
↳ standard_tableaux().residue_sequence()
3-residue sequence (1, 0, 2, 0) with multicharge (0, 1)
```

size()

Return the size of self.

EXAMPLES:

```
sage: RowStandardTableau([[2, 3], [1]]) .residue_sequence(3, (0, 1)) .row_standard_
↳ tableaux().size()
3
sage: StandardTableau([[1, 2], [3]]) .residue_sequence(3, (0, 1)) .row_standard_
↳ tableaux().size()
3
sage: RowStandardTableauTuple([[4]], [[2, 3], [1]]) .residue_sequence(3, (0, 1)) .
↳ row_standard_tableaux().size()
4
sage: StandardTableauTuple([[4]], [[1, 3], [2]]) .residue_sequence(3, (0, 1)) .row_
↳ standard_tableaux().size()
4
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_residue_shape**(*residue, shape*)

Bases: *sage.combinat.tableau_tuple.RowStandardTableauTuples_residue*

All row standard tableau tuples with a fixed residue and shape.

INPUT:

- *shape* – the shape of the partitions or partition tuples
- *residue* – the residue sequence of the label

EXAMPLES:

```
sage: res = RowStandardTableauTuple([[3, 6], [1]], [[5, 7], [4], [2]]) .residue_
↳ sequence(3, (0, 0))
sage: tabs = res.row_standard_tableaux([[2, 1], [2, 1, 1]]); tabs
Row standard (2, 1|2, 1^2)-tableaux with 3-residue sequence (2, 1, 0, 2, 0, 1, 1) and
↳ multicharge (0, 0)
sage: tabs.shape()
([2, 1], [2, 1, 1])
sage: tabs.level()
2
sage: tabs[:6]
([([5, 7], [4]), ([3, 6], [1], [2])],
 ([5, 7], [1]), ([3, 6], [4], [2])],
 ([3, 7], [4]), ([5, 6], [1], [2])],
 ([3, 7], [1]), ([5, 6], [4], [2])],
 ([5, 6], [4]), ([3, 7], [1], [2])],
 ([5, 6], [1]), ([3, 7], [4], [2]))]
```

class sage.combinat.tableau_tuple.**RowStandardTableauTuples_shape**(*shape*)

Bases: *sage.combinat.tableau_tuple.RowStandardTableauTuples*Class of all *RowStandardTableauTuples* of a fixed shape.

an_element()

Return a particular element of `self`.

EXAMPLES:

```
sage: RowStandardTableauTuples([[2],[2,1]]).an_element()
([[4, 5]], [[1, 3], [2]])
sage: RowStandardTableauTuples([[10],[],[ ]]).an_element()
([[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]], [[ ], [ ]])
```

cardinality()

Return the number of row standard tableau tuples of with the same shape as the partition tuple `self`.

This is just the index of the corresponding Young subgroup in the full symmetric group.

EXAMPLES:

```
sage: RowStandardTableauTuples([[3,2,1],[ ]]).cardinality()
60
sage: RowStandardTableauTuples([[1],[1],[1]]).cardinality()
6
sage: RowStandardTableauTuples([[2,1],[1],[1]]).cardinality()
60
```

class sage.combinat.tableau_tuple.RowStandardTableauTuples_size(size)

Bases: `sage.combinat.tableau_tuple.RowStandardTableauTuples`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

Class of all *RowStandardTableauTuples* with an arbitrary level and a fixed size.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: RowStandardTableauTuples(size=2).an_element()
([[1]], [[2]], [[ ], [ ]])
sage: RowStandardTableauTuples(size=4).an_element()
([[1]], [[2, 3, 4]], [[ ], [ ]])
```

class sage.combinat.tableau_tuple.StandardTableauTuple(parent, t, check=True)

Bases: `sage.combinat.tableau_tuple.RowStandardTableauTuple`

A class to model a standard tableau of shape a partition tuple. This is a tuple of standard tableau with entries $1, 2, \dots, n$, where n is the size of the underlying partition tuple, such that the entries increase along rows and down columns in each component of the tuple.

```
sage: s = StandardTableauTuple([[1,2,3],[4,5]]) sage: t = StandardTableauTu-
ple([[1,2],[3,5],[4]]) sage: s.dominates(t) True sage: t.dominates(s) False sage: Stan-
dardTableauTuple([[1,2,3],[4,5]]) in RowStandardTableauTuples() True
```

The tableaux appearing in a *StandardTableauTuple* are both row and column strict, but individually they are not standard tableaux because the entries in any single component of a *StandardTableauTuple* will typically not be in bijection with $\{1, 2, \dots, n\}$.

INPUT:

- `t` – a tableau, a list of (standard) tableau or an equivalent list

OUTPUT:

- A *StandardTableauTuple* object constructed from *t*.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with *PartitionTuple*, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is [0, 0, 0]. Further, the coordinates [k, r, c] in a *TableauTuple* refer to the component, row and column indices, respectively.

EXAMPLES:

```
sage: t = TableauTuple([ [[1,3,4],[7,9]], [[2,8,11],[6]], [[5,10]] ])
sage: t
([[1, 3, 4], [7, 9]], [[2, 8, 11], [6]], [[5, 10]])
sage: t[0][0][0]
1
sage: t[1][1][0]
6
sage: t[2][0][0]
5
sage: t[2][0][1]
10

sage: t = StandardTableauTuple([[[4,5],[7]], [[1,2,3],[6,8]], [[9]]]); t
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
sage: t.pp()
 4 5      1 2 3      9
 7      6 8
sage: t.shape()
([2, 1], [3, 2], [1])
sage: t[0].pp() # pretty printing
 4 5
 7
sage: t.is_standard()
True
sage: t[0].is_standard()
False
sage: StandardTableauTuple([[],[],[]]) # An empty tableau tuple
([], [], [])
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a *StandardTableauTuple* from the appropriate parent object:

```
sage: STT = StandardTableauTuples()
sage: STT([[[4,5],[7]], [[1,2,3],[6,8]], [[9]]])
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
```

See also:

- *Tableau*
- *Tableaux*
- *TableauTuples*
- *TableauTuple*

- *StandardTableauTuples*

dominates(*t*)

Return True if the tableau (tuple) *self* dominates the tableau *t*. The two tableaux do not need to be of the same shape.

EXAMPLES:

```
sage: s = StandardTableauTuple([[1,2,3],[4,5]])
sage: t = StandardTableauTuple([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False
```

restrict(*m=None*)

Return the restriction of the standard tableau *self* to *m*, which defaults to one less than the current *size()*.

EXAMPLES:

```
sage: StandardTableauTuple([[5]],[1,2],[3,4])).restrict(6)
([[5]],[1,2],[3,4]))
sage: StandardTableauTuple([[5]],[1,2],[3,4])).restrict(5)
([[5]],[1,2],[3,4]))
sage: StandardTableauTuple([[5]],[1,2],[3,4])).restrict(4)
([], [1,2],[3,4]))
sage: StandardTableauTuple([[5]],[1,2],[3,4])).restrict(3)
([], [1,2],[3]))
sage: StandardTableauTuple([[5]],[1,2],[3,4])).restrict(2)
([], [1,2]))
sage: StandardTableauTuple([[5]],[1,2],[3,4])).restrict(1)
([], [1]))
sage: StandardTableauTuple([[5]],[1,2],[3,4])).restrict(0)
([], [])
```

Where possible the restricted tableau belongs to the same category as the tableau *self*:

```
sage: TableauTuple([[5]],[1,2],[3,4])).restrict(3).category()
Category of elements of Tableau tuples
sage: StandardTableauTuple([[5]],[1,2],[3,4])).restrict(3).category()
Category of elements of Standard tableau tuples
sage: StandardTableauTuples([1],[2,2])([5]],[1,2],[3,4])).restrict(3).
↪category()
Category of elements of Standard tableau tuples
sage: StandardTableauTuples(level=2)([5]],[1,2],[3,4])).restrict(3).
↪category()
Category of elements of Standard tableau tuples of level 2
```

to_chain()

Return the chain of partitions corresponding to the standard tableau tuple *self*.

EXAMPLES:

```
sage: StandardTableauTuple([[5]],[1,2],[3,4])).to_chain()
([], [])
```

(continues on next page)

(continued from previous page)

```
([], [1]),
([], [2]),
([], [2, 1]),
([], [2, 2]),
([1], [2, 2])]
```

class `sage.combinat.tableau_tuple.StandardTableauTuples`

Bases: `sage.combinat.tableau_tuple.RowStandardTableauTuples`

A factory class for the various classes of tuples of standard tableau.

INPUT:

There are three optional arguments:

- `level` – the `level()` of the tuples of tableaux
- `size` – the `size()` of the tuples of tableaux
- `shape` – a list or a partition tuple specifying the `shape()` of the standard tableau tuples

It is not necessary to use the keywords. If they are not used then the first integer argument specifies the `level()` and the second the `size()` of the tableau tuples.

OUTPUT:

The appropriate subclass of `StandardTableauTuples`.

A tuple of standard tableau is a tableau whose entries are positive integers which increase from left to right along the rows, and from top to bottom down the columns, in each component. The entries do NOT need to increase from left to right along the components.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with `PartitionTuple`, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is `[0, 0, 0]`.

EXAMPLES:

```
sage: tabs=StandardTableauTuples([[3],[2,2]]); tabs
Standard tableau tuples of shape ([3], [2, 2])
sage: tabs.cardinality()
70
sage: tabs[10:16]
([([1, 2, 3]), ([4, 6], [5, 7])],
 ([1, 2, 4]), ([3, 6], [5, 7])),
 ([1, 3, 4]), ([2, 6], [5, 7])),
 ([2, 3, 4]), ([1, 6], [5, 7])),
 ([1, 2, 5]), ([3, 6], [4, 7])),
 ([1, 3, 5]), ([2, 6], [4, 7]))]

sage: tabs=StandardTableauTuples(level=3); tabs
Standard tableau tuples of level 3
sage: tabs[100]
([1, 2], [3]), [], [[4]])
```

(continues on next page)

```
sage: StandardTableauTuples()[0]
()
```

See also:

- [TableauTuples](#)
- [Tableau](#)
- [StandardTableau](#)
- [StandardTableauTuples](#)

Element

alias of [StandardTableauTuple](#)

level_one_parent_class

alias of [sage.combinat.tableau.StandardTableaux_all](#)

shape()

Return the shape of the set of [StandardTableauTuples](#), or None if it is not defined.

EXAMPLES:

```
sage: tabs=StandardTableauTuples(shape=[[5,2],[3,2],[],[1,1,1],[3]]); tabs
Standard tableau tuples of shape ([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: tabs.shape()
([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: StandardTableauTuples().shape() is None
True
```

class [sage.combinat.tableau_tuple.StandardTableauTuples_all](#)

Bases: [sage.combinat.tableau_tuple.StandardTableauTuples](#), [sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets](#)

Default class of all [StandardTableauTuples](#) with an arbitrary [level\(\)](#) and [size\(\)](#).

class [sage.combinat.tableau_tuple.StandardTableauTuples_level\(level\)](#)

Bases: [sage.combinat.tableau_tuple.StandardTableauTuples](#), [sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets](#)

Class of all [StandardTableauTuples](#) with a fixed level and arbitrary size.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(size=2).an_element()
([[1]], [[2]], [], [])
sage: StandardTableauTuples(size=4).an_element()
([[1]], [[2, 3, 4]], [], [])
```

class [sage.combinat.tableau_tuple.StandardTableauTuples_level_size\(level, size\)](#)

Bases: [sage.combinat.tableau_tuple.StandardTableauTuples](#), [sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets](#)

Class of all [StandardTableauTuples](#) with a fixed level and a fixed size.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(5,size=2).an_element()
([], [], [], [], [[1], [2]])
sage: StandardTableauTuples(2,size=4).an_element()
([[1]], [[2, 3], [4]])
```

cardinality()

Return the number of elements in this set of tableaux.

EXAMPLES:

```
sage: StandardTableauTuples(3,2).cardinality()
12
sage: StandardTableauTuples(4,6).cardinality()
31936
```

class sage.combinat.tableau_tuple.**StandardTableauTuples_shape**(*shape*)

Bases: *sage.combinat.tableau_tuple.StandardTableauTuples*

Class of all *StandardTableauTuples* of a fixed shape.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples([[2], [2, 1]]).an_element()
([[2, 4]], [[1, 3], [5]])
sage: StandardTableauTuples([[10], [], []]).an_element()
([[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]], [], [])
```

cardinality()

Return the number of standard Young tableau tuples of with the same shape as the partition tuple *self*.

Let $\mu = (\mu^{(1)}, \dots, \mu^{(l)})$ be the shape of the tableaux in *self* and let $m_k = |\mu^{(k)}|$, for $1 \leq k \leq l$. Multiplying by a (unique) coset representative of the Young subgroup $S_{m_1} \times \dots \times S_{m_l}$ inside the symmetric group S_n , we can assume that *t* is standard and the numbers $1, 2, \dots, n$ are entered in order from to right along the components of the tableau. Therefore, there are

$$\binom{n}{m_1, \dots, m_l} \prod_{k=1}^l |\text{Std}(\mu^{(k)})|$$

standard tableau tuples of this shape, where $|\text{Std}(\mu^{(k)})|$ is the number of standard tableau of shape $\mu^{(k)}$, for $1 \leq k \leq l$. This is given by the hook length formula.

EXAMPLES:

```
sage: StandardTableauTuples([[3, 2, 1], []]).cardinality()
16
sage: StandardTableauTuples([[1], [1], [1]]).cardinality()
6
sage: StandardTableauTuples([[2, 1], [1], [1]]).cardinality()
40
```

(continues on next page)

(continued from previous page)

```
sage: StandardTableauTuples([[3,2,1],[3,2]]).cardinality()
36960
```

last()

Return the last standard tableau tuple in `self`, with respect to the order that they are generated by the iterator.

This is just the standard tableau tuple with the numbers $1, 2, \dots, n$, where n is `size()`, entered in order down the columns from right to left along the components.

EXAMPLES:

```
sage: StandardTableauTuples([[2],[2,2]]).last().pp()
5 6      1 3
      2 4
```

random_element()

Return a random standard tableau in `self`.

We do this by randomly selecting addable nodes to place $1, 2, \dots, n$. Of course we could do this recursively, but it is more efficient to keep track of the (changing) list of addable nodes as we go.

EXAMPLES:

```
sage: StandardTableauTuples([[2],[2,1]]).random_element() # random
([[1, 2]], [[3, 4], [5]])
```

class `sage.combinat.tableau_tuple.StandardTableauTuples_size(size)`

Bases: `sage.combinat.tableau_tuple.StandardTableauTuples`, `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

Class of all *StandardTableauTuples* with an arbitrary level and a fixed size.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: StandardTableauTuples(size=2).an_element()
([[1]], [[2]], [], [])
sage: StandardTableauTuples(size=4).an_element()
([[1]], [[2, 3, 4]], [], [])
```

class `sage.combinat.tableau_tuple.StandardTableaux_residue(residue)`

Bases: `sage.combinat.tableau_tuple.StandardTableauTuples`

Class of all standard tableau tuples with a fixed residue sequence.

Implicitly, this also specifies the quantum characteristic, multicharge and hence the level and size of the tableaux.

Note: This class is not intended to be called directly, but rather, it is accessed through the standard tableaux.

EXAMPLES:

```
sage: StandardTableau([[1,2,3],[4,5]]).residue_sequence(2).standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,0,1,0) and multicharge (0)
```

(continues on next page)

(continued from previous page)

```

sage: StandardTableau([[1,2,3],[4,5]]).residue_sequence(3).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,2,0) and multicharge (0)
sage: StandardTableauTuple([[5,6],[7]],[[1,2,3],[4]]).residue_sequence(2,(0,0)).
↪standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,0)
sage: StandardTableauTuple([[5,6],[7]],[[1,2,3],[4]]).residue_sequence(3,(0,1)).
↪standard_tableaux()
Standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,1)

```

class sage.combinat.tableau_tuple.**StandardTableaux_residue_shape**(*residue, shape*)

Bases: *sage.combinat.tableau_tuple.StandardTableaux_residue*

All standard tableau tuples with a fixed residue and shape.

INPUT:

- *shape* – the shape of the partitions or partition tuples
- *residue* – the residue sequence of the label

EXAMPLES:

```

sage: res = StandardTableauTuple([[1,3],[6]],[[2,7],[4],[5]]).residue_sequence(3,
↪(0,0))
sage: tabs = res.standard_tableaux([[2,1],[2,1,1]]); tabs
Standard (2,1|2,1^2)-tableaux with 3-residue sequence (0,0,1,2,1,2,1) and
↪multicharge (0,0)
sage: tabs.shape()
([2, 1], [2, 1, 1])
sage: tabs.level()
2
sage: tabs[:6]
([([2, 7], [6]), ([1, 3], [4], [5])],
 ([1, 7], [6]), ([2, 3], [4], [5])),
 ([2, 3], [6]), ([1, 7], [4], [5])),
 ([1, 3], [6]), ([2, 7], [4], [5])),
 ([2, 5], [6]), ([1, 3], [4], [7])),
 ([1, 5], [6]), ([2, 3], [4], [7]))

```

an_element()

Return a particular element of self.

EXAMPLES:

```

sage: T = StandardTableau([[1,3],[2]]).residue_sequence(3).standard_tableaux([2,
↪1])
sage: T.an_element()
[[1, 3], [2]]

```

class sage.combinat.tableau_tuple.**TableauTuple**(*parent, t, check=True*)

Bases: *sage.combinat.combinat.CombinatorialElement*

A class to model a tuple of tableaux.

INPUT:

- *t* – a list or tuple of *Tableau*, a list or tuple of lists of lists

OUTPUT:

- The Tableau tuple object constructed from `t`.

A *TableauTuple* is a tuple of tableau of shape *PartitionTuple*. These combinatorial objects are useful in several areas of algebraic combinatorics. In particular, they are important in:

- the representation theory of the complex reflection groups of type $G(l, 1, n)$ and the representation theory of the associated (degenerate and non-degenerate) Hecke algebras. See, for example, [DJM1998]
- the crystal theory of (quantum) affine special linear groups and its integral highest weight modules and their canonical bases. See, for example, [BK2009].

These apparently different and unrelated contexts are, in fact, intimately related as in characteristic zero the cyclotomic Hecke algebras categorify the canonical bases of the integral highest weight modules of the quantum affine special linear groups.

The *level()* of a tableau tuple is the length of the tuples. This corresponds to the level of the corresponding highest weight module.

In sage a *TableauTuple* looks and behaves like a real tuple of (level 1) *Tableaux*. Many of the operations which are defined on *Tableau* extend to *TableauTuples*. Tableau tuples of level 1 are just ordinary *Tableau*.

In sage, the entries of *Tableaux* can be very general, including arbitrarily nested lists, so some lists can be interpreted either as a tuple of tableaux or simply as tableaux. If it is possible to interpret the input to *TableauTuple* as a tuple of tableaux then *TableauTuple* returns the corresponding tuple. Given a 1-tuple of tableaux the tableau itself is returned.

EXAMPLES:

```
sage: t = TableauTuple([ [[6,9,10],[11]], [[1,2,3],[4,5]], [[7],[8]] ]); t
([[6, 9, 10], [11]], [[1, 2, 3], [4, 5]], [[7], [8]])
sage: t.level()
3
sage: t.size()
11
sage: t.shape()
([3, 1], [3, 2], [1, 1])
sage: t.is_standard()
True
sage: t.pp() # pretty printing
 6 9 10    1 2 3    7
11         4 5      8
sage: t.category()
Category of elements of Tableau tuples
sage: t.parent()
Tableau tuples

sage: s = TableauTuple([ [['a','c','b'],['d','e']], [(2,1)]]); s
([['a', 'c', 'b'], ['d', 'e']], [(2, 1)])
sage: s.shape()
([3, 2], [1])
sage: s.size()
6

sage: TableauTuple([], [], []) # The empty 3-tuple of tableaux
([], [], [])
```

(continues on next page)

(continued from previous page)

```

sage: TableauTuple([[1,2,3],[4,5]])
[[1, 2, 3], [4, 5]]
sage: TableauTuple([[1,2,3],[4,5]]) == Tableau([[1,2,3],[4,5]])
True

```

Element

alias of `sage.combinat.tableau.Tableau`

add_entry(*cell, m*)

Set the entry in *cell* equal to *m*. If the cell does not exist then extend the tableau, otherwise just replace the entry.

EXAMPLES:

```

sage: s = StandardTableauTuple([ [[3,4,7],[6,8]], [[9,13],[12]], [[1,5],[2,11],
↪[10]] ]); s.pp()
 3 4 7   9 13   1 5
 6 8     12     2 11
                10
sage: t = s.add_entry( (0,0,3),14); t.pp(); t.category()
 3 4 7 14   9 13   1 5
 6 8     12     2 11
                10
Category of elements of Standard tableau tuples
sage: t = s.add_entry( (0,0,3),15); t.pp(); t.category()
 3 4 7 15   9 13   1 5
 6 8     12     2 11
                10
Category of elements of Tableau tuples
sage: t = s.add_entry( (1,1,1),14); t.pp(); t.category()
 3 4 7   9 13   1 5
 6 8     12 14   2 11
                10
Category of elements of Standard tableau tuples
sage: t = s.add_entry( (2,1,1),14); t.pp(); t.category()
 3 4 7   9 13   1 5
 6 8     12     2 14
                10
Category of elements of Tableau tuples

```

(continues on next page)

(continued from previous page)

```
sage: t = s.add_entry( (2,1,2),14); t.pp(); t.category()
Traceback (most recent call last):
...
IndexError: (2, 1, 2) is not an addable cell of the tableau
```

cells_containing(*m*)

Return the list of cells in which the letter *m* appears in the tableau *self*.

The list is ordered with cells appearing from left to right.

EXAMPLES:

```
sage: t = TableauTuple([[4,5]],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]])
sage: t.cells_containing(4)
[(0, 0, 0),
 (1, 2, 0),
 (1, 1, 1),
 (1, 1, 2),
 (1, 0, 3),
 (2, 1, 1),
 (2, 0, 2)]
sage: t.cells_containing(6)
[]
```

charge()

Return the charge of the reading word of *self*.

See [charge\(\)](#) for more information.

EXAMPLES:

```
sage: TableauTuple([[4,5]],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]]).charge()
4
```

cocharge()

Return the cocharge of the reading word of *self*.

See [cocharge\(\)](#) for more information.

EXAMPLES:

```
sage: TableauTuple([[4,5]],[[1,1,2,4],[2,4,4],[4]],[[1,3,4],[3,4]]).cocharge()
4
```

column_stabilizer()

Return the [PermutationGroup](#) corresponding to *self*. That is, return subgroup of the symmetric group of degree [size\(\)](#) which is the column stabilizer of *self*.

EXAMPLES:

```
sage: cs = TableauTuple([[1,2,3],[4,5]],[[6,7]],[[8],[9]]).column_stabilizer()
sage: cs.order()
8
sage: PermutationGroupElement([(1,3,2),(4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

components()

Return a list of the components of tableau tuple `self`.

The *components* are the individual *Tableau* which are contained in the tuple `self`.

For compatibility with *TableauTuples* of *level()* 1, *components()* should be used to iterate over the components of *TableauTuples*.

EXAMPLES:

```
sage: for t in TableauTuple([[1,2,3],[4,5]]).components(): t.pp()
  1 2 3
  4 5
sage: for t in TableauTuple([ [[1,2,3],[4,5]], [[6,7],[8,9]] ]).components(): t.
↳pp()
  1 2 3
  4 5
  6 7
  8 9
```

conjugate()

Return the conjugate of the tableau tuple `self`.

The conjugate tableau tuple T' is the *TableauTuple* obtained from T by reversing the order of the components and conjugating each component – that is, swapping the rows and columns of the all of *Tableau* in T (see *sage.combinat.tableau.Tableau.conjugate()*).

EXAMPLES:

```
sage: TableauTuple([[[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]])].conjugate()
([[9, 11, 12], [10]], [[5, 8], [6], [7]], [[1, 3], [2, 4]])
```

content(*k*, *multicharge*)

Return the content k in `self`.

The content of k in a standard tableau. That is, if k appears in row r and column c of the tableau, then we return $c - r + a_k$, where the multicharge is (a_1, a_2, \dots, a_l) and l is the level of the tableau.

The multicharge determines the dominant weight

$$\Lambda = \sum_{i=1}^l \Lambda_{a_i}$$

of the affine special linear group. In the combinatorics, the multicharge simply offsets the contents in each component so that the cell (k, r, c) has content $a_k + c - r$.

INPUT:

- k – an integer in $\{1, 2, \dots, n\}$
- *multicharge* – a sequence of integers of length l

Here l is the *level()* and n is the *size()* of `self`.

EXAMPLES:

```
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]])].content(3,[0,0])
-1
sage: StandardTableauTuple([[[5]],[[1,2],[3,4]])].content(3,[0,1])
0
```

(continues on next page)

(continued from previous page)

```

sage: StandardTableauTuple([[5]], [[1,2], [3,4]]).content(3, [0,2])
1
sage: StandardTableauTuple([[5]], [[1,2], [3,4]]).content(6, [0,2])
Traceback (most recent call last):
...
ValueError: 6 must be contained in the tableaux

```

entries()

Return a sorted list of all entries of `self`, in the order obtained by reading across the rows.

EXAMPLES:

```

sage: TableauTuple([[1,2], [3,4]], [[5,6,7], [8]], [[9,10], [11], [12]]).entries()
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
sage: TableauTuple([[1,2], [3,4]], [[9,10], [11], [12]], [[5,6,7], [8]]).entries()
[1, 2, 3, 4, 9, 10, 11, 12, 5, 6, 7, 8]

```

entry(*l, r, c*)

Return the entry of the cell (`l`, `r`, `c`) in `self`.

A cell is a tuple (`l`, `r`, `c`) of coordinates, where `l` is the component index, `r` is the row index, and `c` is the column index.

EXAMPLES:

```

sage: t = TableauTuple([[1,2], [3,4]], [[5,6,7], [8]], [[9,10], [11], [12]])
sage: t.entry(1, 0, 0)
5
sage: t.entry(1, 1, 1)
Traceback (most recent call last):
...
IndexError: tuple index out of range

```

first_column_descent()

Return the first cell of `self` is not column standard.

Cells are ordered left to right along the rows and then top to bottom. That is, return the cell (k, r, c) with (k, r, c) minimal such that the entry in position (k, r, c) is bigger than the entry in position $(k, r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is column strict.

OUTPUT:

The cell corresponding to the first column descent or `None` if the tableau is column strict.

EXAMPLES:

```

sage: TableauTuple([[3,5,6], [2,4,5]], [[1,4,5], [2,3]]) .first_column_descent()
(0, 0, 0)
sage: Tableau([[1,2,3], [4]], [[5,6,7], [8,9]]) .first_column_descent() is None
True

```

first_row_descent()

Return the first cell of `self` that is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell minimal (k, r, c) such that the entry in position (k, r, c) is bigger than the entry in position $(k, r, c + 1)$. If there is no such cell then `None` is returned - in this case the tableau is row strict.

OUTPUT:

The cell corresponding to the first row descent or `None` if the tableau is row strict.

EXAMPLES:

```
sage: TableauTuple([[5,6,7],[1,2]],[[1,3,2],[4]]).first_row_descent()
(1, 0, 1)
sage: TableauTuple([[1,2,3],[4]],[[6,7,8],[1,2,3]],[[1,11]]).first_row_
↪ descent() is None
True
```

`is_column_strict()`

Return True if the tableau `self` is column strict and False otherwise.

A tableau tuple is *column strict* if the entries in each column of each component are in increasing order, when read from top to bottom.

EXAMPLES:

```
sage: TableauTuple([[5,7],[8]],[[1, 3], [2, 4]],[[6]])).is_column_strict()
True
sage: TableauTuple([[1, 2], [2, 4]],[[4,5,6],[7,8]])).is_column_strict()
True
sage: TableauTuple([[1]],[[2, 3], [2, 4]])).is_column_strict()
False
sage: TableauTuple([[1]],[[2, 2], [4,5]])).is_column_strict()
True
sage: TableauTuple([[1,2],[6,7]],[[4,8], [6, 9]],[[]])).is_column_strict()
True
```

`is_row_strict()`

Return True if the tableau `self` is row strict and False otherwise.

A tableau tuple is *row strict* if the entries in each row of each component are in increasing order, when read from left to right.

EXAMPLES:

```
sage: TableauTuple([[5,7],[8]],[[1, 3], [2, 4]],[[6]])).is_row_strict()
True
sage: TableauTuple([[1, 2], [2, 4]],[[4,5,6],[7,8]])).is_row_strict()
True
sage: TableauTuple([[1]],[[2, 3], [2, 4]])).is_row_strict()
True
sage: TableauTuple([[1]],[[2, 2], [4,5]])).is_row_strict()
False
sage: TableauTuple([[1,2],[6,7]],[[4,8], [6, 9]],[[]])).is_row_strict()
True
```

`is_standard()`

Return True if the tableau `self` is a standard tableau and False otherwise.

A tableau tuple is *standard* if it is row standard, column standard and the entries in the tableaux are $1, 2, \dots, n$, where n is the `size()` of the underlying partition tuple of `self`.

EXAMPLES:

```

sage: TableauTuple([[5,7],[8]],[[1,3],[2,4]],[[6]]).is_standard()
True
sage: TableauTuple([[1,2],[2,4]],[[4,5,6],[7,8]]).is_standard()
False
sage: TableauTuple([[1]],[[2,3],[2,4]]).is_standard()
False
sage: TableauTuple([[1]],[[2,2],[4,5]]).is_row_strict()
False
sage: TableauTuple([[1,2],[6,7]],[[4,8],[6,9]],[[]]).is_standard()
False

```

level()

Return the level of the tableau self.

This is just the number of components in the tableau tuple self.

EXAMPLES:

```

sage: TableauTuple([[7,8,9]],[[1,2,3],[4,5],[6]]).level()
3

```

pp()

Pretty printing for the tableau tuple self.

EXAMPLES:

```

sage: TableauTuple([ [[1,2,3],[4,5]], [[1,2,3],[4,5]] ]).pp()
 1 2 3      1 2 3
 4 5        4 5
sage: TableauTuple([ [[1,2],[3],[4]],[[6,7,8],[10,11],[12],[13]] ]).pp()
 1 2      -      6 7 8
 3
 4
          10 11
          12
          13
sage: t = TableauTuple([ [[1,2,3],[4,5],[6],[9]], [[1,2,3],[4,5,8]], [[11,12,
↪13],[14]] ])
sage: t.pp()
 1 2 3      1 2 3      11 12 13
 4 5        4 5 8      14
 6
 9
sage: TableauTuples.options(convention="french")
sage: t.pp()
 9
 6
 4 5        4 5 8      14
 1 2 3      1 2 3      11 12 13
sage: TableauTuples.options._reset()

```

reduced_column_word()

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_column_tableau()` to self.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau from top to bottom in each component, and then left to right along the components.

EXAMPLES:

```

sage: StandardTableauTuple([[7,9],[8]],[[1,4,6],[2,5],[3]]).reduced_column_
↳word()
[]
sage: StandardTableauTuple([[7,9],[8]],[[1,3,6],[2,5],[4]]).reduced_column_
↳word()
[3]
sage: StandardTableauTuple([[6,9],[8]],[[1,3,7],[2,5],[4]]).reduced_column_
↳word()
[3, 6]
sage: StandardTableauTuple([[6,8],[9]],[[1,3,7],[2,5],[4]]).reduced_column_
↳word()
[3, 6, 8]
sage: StandardTableauTuple([[5,8],[9]],[[1,3,7],[2,6],[4]]).reduced_column_
↳word()
[3, 6, 5, 8]

```

reduced_row_word()

Return the lexicographically minimal reduced expression for the permutation that maps the `initial_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau from top to bottom in each component, and then left to right along the components.

EXAMPLES:

```

sage: StandardTableauTuple([[1,2],[3]],[[4,5,6],[7,8],[9]]).reduced_row_word()
[]
sage: StandardTableauTuple([[1,2],[3]],[[4,5,6],[7,9],[8]]).reduced_row_word()
[8]
sage: StandardTableauTuple([[1,2],[3]],[[4,5,7],[6,9],[8]]).reduced_row_word()
[6, 8]
sage: StandardTableauTuple([[1,2],[3]],[[4,5,8],[6,9],[7]]).reduced_row_word()
[6, 8, 7]
sage: StandardTableauTuple([[1,2],[3]],[[4,5,9],[6,8],[7]]).reduced_row_word()
[6, 7, 8, 7]
sage: StandardTableauTuple([[7,9],[8]],[[1,3,5],[2,6],[4]]).reduced_row_word()
[2, 3, 2, 1, 4, 3, 2, 5, 4, 3, 6, 5, 4, 3, 2, 7, 6, 5, 8, 7, 6, 5, 4]

```

residue(*k*, *e*, *multicharge*)

Return the *residue* of the integer *k* in the tableau `self`.

The *residue* of *k* is $c - r + a_k$ in $\mathbf{Z}/e\mathbf{Z}$, where *k* appears in row *r* and column *c* of the tableau and the multicharge is (a_1, a_2, \dots, a_l) .

The multicharge determines the dominant weight

$$\sum_{i=1}^l \Lambda_{a_i}$$

for the affine special linear group. In the combinatorics, it simply offsets the contents in each component so that the cell $(k, 0, 0)$ has content a_k .

INPUT:

- *k* – an integer in $\{1, 2, \dots, n\}$

- `e` – an integer in $\{0, 2, 3, 4, 5, \dots\}$
- `multicharge` – a list of integers of length l

Here l is the `level()` and n is the `size()` of `self`.

OUTPUT:

The residue of `k` in a standard tableau. That is,

EXAMPLES:

```
sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue(1, 3,[0,0])
0
sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue(1, 3,[0,1])
1
sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue(1, 3,[0,2])
2
sage: StandardTableauTuple([[5]],[[1,2],[3,4]]).residue(6, 3,[0,2])
Traceback (most recent call last):
...
ValueError: 6 must be contained in the tableaux
```

restrict(`m=None`)

Return the restriction of the standard tableau `self` to `m`.

The restriction is the subtableau of `self` whose entries are less than or equal to `m`.

By default, `m` is one less than the current size.

EXAMPLES:

```
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict()
([], [[1, 2], [3, 4]])
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(6)
([[5]],[[1, 2], [3, 4]])
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(5)
([[5]],[[1, 2], [3, 4]])
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(4)
([], [[1, 2], [3, 4]])
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(3)
([], [[1, 2], [3]])
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(2)
([], [[1, 2]])
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(1)
([], [[1]])
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(0)
([], [])
```

Where possible the restricted tableau belongs to the same category as the original tableaux:

```
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(3).category()
Category of elements of Tableau tuples
sage: TableauTuple([[5]],[[1,2],[3,4]]).restrict(3).category()
Category of elements of Tableau tuples
sage: TableauTuples(level=2)([[5]],[[1,2],[3,4]]).restrict(3).category()
Category of elements of Tableau tuples of level 2
```

row_stabilizer()

Return the `PermutationGroup` corresponding to `self`. That is, return subgroup of the symmetric group of degree `size()` which is the row stabilizer of `self`.

EXAMPLES:

```
sage: rs = TableauTuple([[1,2,3],[4,5]],[[6,7]],[[8],[9]]).row_stabilizer()
sage: rs.order()
24
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs.one().domain()
[1, 2, 3, 4, 5, 6, 7, 8, 9]
```

shape()

Return the `PartitionTuple` which is the shape of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[7,8,9]],[[1,2,3],[4,5],[6]]).shape()
([3], [], [3, 2, 1])
```

size()

Return the size of the tableau tuple `self`.

This is just the number of boxes, or the size, of the underlying `PartitionTuple`.

EXAMPLES:

```
sage: TableauTuple([[7,8,9]],[[1,2,3],[4,5],[6]]).size()
9
```

symmetric_group_action_on_entries(w)

Return the action of a permutation `w` on `self`.

Consider a standard tableau tuple $T = (t^{(1)}, t^{(2)}, \dots, t^{(l)})$ of size n , then the action of $w \in S_n$ is defined by permuting the entries of T (recall they are $1, 2, \dots, n$). In particular, suppose the entry at cell (k, i, j) is a , then the entry becomes $w(a)$. In general, the resulting tableau tuple wT may *not* be standard.

INPUT:

- `w` – a permutation

EXAMPLES:

```
sage: TableauTuple([[1,2],[4]],[[3,5]]).symmetric_group_action_on_entries(↵
↵Permutation(((4,5))) )
([[1, 2], [5]], [[3, 4]])
sage: TableauTuple([[1,2],[4]],[[3,5]]).symmetric_group_action_on_entries(↵
↵Permutation(((1,2))) )
([[2, 1], [4]], [[3, 5]])
```

to_list()

Return the list representation of the tableaux tuple `self`.

EXAMPLES:

```
sage: TableauTuple([ [[1,2,3],[4,5]], [[6,7],[8,9]] ]).to_list()
[[[1, 2, 3], [4, 5]], [[6, 7], [8, 9]]]
```

to_permutation()

Return a permutation with the entries in the tableau tuple `self`.

The permutation is obtained from `self` by reading the entries of the tableau tuple in order from left to right along the rows, and then top to bottom, in each component and then left to right along the components.

EXAMPLES:

```
sage: TableauTuple([[[[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]]])).to_
↪permutation()
[12, 11, 9, 10, 8, 5, 6, 7, 3, 4, 1, 2]
```

to_word()

Return a word obtained from a row reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[[[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]]])).to_word_by_
↪row()
word: 12,11,9,10,8,5,6,7,3,4,1,2
```

to_word_by_column()

Return the word obtained from a column reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[[[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]]])).to_word_by_
↪column()
word: 12,11,9,10,8,5,6,7,3,1,4,2
```

to_word_by_row()

Return a word obtained from a row reading of the tableau tuple `self`.

EXAMPLES:

```
sage: TableauTuple([[[[1,2],[3,4]], [[5,6,7],[8]], [[9,10],[11],[12]]])).to_word_by_
↪row()
word: 12,11,9,10,8,5,6,7,3,4,1,2
```

up($n=None$)

An iterator for all the *TableauTuple* that can be obtained from `self` by adding a cell with the label `n`. If `n` is not specified then a cell with label `n` will be added to the tableau tuple, where `n-1` is the size of the tableau tuple before any cells are added.

EXAMPLES:

```
sage: list(TableauTuple([[[[1,2]], [[3]]])).up()
[[[1, 2, 4]], [[3]]],
 ([[1, 2], [4]], [[3]]),
 ([[1, 2]], [[3, 4]]),
 ([[1, 2]], [[3], [4]])]
```

class sage.combinat.tableau_tuple.TableauTuples

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

A factory class for the various classes of tableau tuples.

INPUT:

There are three optional arguments:

- `shape` – determines a *PartitionTuple* which gives the shape of the *TableauTuples*
- `level` – the level of the tableau tuples (positive integer)
- `size` – the size of the tableau tuples (non-negative integer)

It is not necessary to use the keywords. If they are not specified then the first integer argument specifies the level and the second the size of the tableaux.

OUTPUT:

- The corresponding class of tableau tuples.

The entries of a tableau can be any sage object. Because of this, no enumeration of the set of *TableauTuples* is possible.

EXAMPLES:

```
sage: T3 = TableauTuples(3); T3
Tableau tuples of level 3
sage: [['a', 'b']] in TableauTuples()
True
sage: [['a', 'b']] in TableauTuples(level=3)
False
sage: t = TableauTuples(level=3)([], [[1, 1, 1]], []); t
([], [[1, 1, 1]], [])
sage: t in T3
True
sage: t in TableauTuples()
True
sage: t in TableauTuples(size=3)
True
sage: t in TableauTuples(size=4)
False
sage: t in StandardTableauTuples()
False
sage: t.parent()
Tableau tuples of level 3
sage: t.category()
Category of elements of Tableau tuples of level 3
```

See also:

- *Tableau*
- *StandardTableau*
- *StandardTableauTuples*

Element

alias of *TableauTuple*

level()

Return the level of a tableau tuple in `self`, or `None` if different tableau tuples in `self` can have different sizes. The level of a tableau tuple is just the level of the underlying *PartitionTuple*.

EXAMPLES:

```
sage: TableauTuples().level() is None
True
sage: TableauTuples(7).level()
7
```

level_one_parent_class

alias of `sage.combinat.tableau.Tableaux_all`

list()

If the set of tableau tuples `self` is finite then this function returns the list of these tableau tuples. If the class is infinite an error is returned.

EXAMPLES:

```
sage: StandardTableauTuples([[2,1],[2]]).list()
[[[1, 2], [3]], [[4, 5]],
 [[1, 3], [2]], [[4, 5]],
 [[1, 2], [4]], [[3, 5]],
 [[1, 3], [4]], [[2, 5]],
 [[2, 3], [4]], [[1, 5]],
 [[1, 4], [2]], [[3, 5]],
 [[1, 4], [3]], [[2, 5]],
 [[2, 4], [3]], [[1, 5]],
 [[1, 2], [5]], [[3, 4]],
 [[1, 3], [5]], [[2, 4]],
 [[2, 3], [5]], [[1, 4]],
 [[1, 4], [5]], [[2, 3]],
 [[2, 4], [5]], [[1, 3]],
 [[3, 4], [5]], [[1, 2]],
 [[1, 5], [2]], [[3, 4]],
 [[1, 5], [3]], [[2, 4]],
 [[2, 5], [3]], [[1, 4]],
 [[1, 5], [4]], [[2, 3]],
 [[2, 5], [4]], [[1, 3]],
 [[3, 5], [4]], [[1, 2]]]
```

options(*get_value, **set_value)

Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- `ascii_art` – (default: `repr`) Controls the ascii art output for tableaux
 - `compact` – minimal length ascii art
 - `repr` – display using the diagram string representation
 - `table` – display as a table
- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
 - `English` – use the English convention
 - `French` – use the French convention
- `display` – (default: `list`) Controls the way in which tableaux are printed

- array – alias for diagram
- compact – minimal length string representation
- diagram – display as Young diagram (similar to `pp()`)
- ferrers_diagram – alias for diagram
- list – print tableaux as lists
- young_diagram – alias for diagram
- latex – (default: diagram) Controls the way in which tableaux are latexed
 - array – alias for diagram
 - diagram – as a Young diagram
 - ferrers_diagram – alias for diagram
 - list – as a list
 - young_diagram – alias for diagram
- notation – alternative name for convention

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.options.display="array"
sage: T
 1  2  3
 4  5
sage: Tableaux.options.convention="french"
sage: T
 4  5
 1  2  3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print(P.ferrers_diagram())
*
***
***
sage: Partitions.options.convention="english"
sage: print(P.ferrers_diagram())
***
***
*
sage: T
 1  2  3
 4  5
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1  2  3
  4  5
sage: Tableaux.options.ascii_art = "table"
sage: ascii_art(t)
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
| 4 | 5 |
+---+---+
sage: Tableaux.options.ascii_art = "compact"
sage: ascii_art(t)
|1|2|3|
|4|5|
sage: Tableaux.options._reset()
```

See [GlobalOptions](#) for more features of these options.

size()

Return the size of a tableau tuple in `self`, or `None` if different tableau tuples in `self` can have different sizes. The size of a tableau tuple is just the size of the underlying *PartitionTuple*.

EXAMPLES:

```
sage: TableauTuples(size=14).size()
14
```

class sage.combinat.tableau_tuple.TableauTuples_all

Bases: [sage.combinat.tableau_tuple.TableauTuples](#)

The parent class of all *TableauTuples*, with arbitrary level and size.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])
```

class sage.combinat.tableau_tuple.TableauTuples_level(level)

Bases: [sage.combinat.tableau_tuple.TableauTuples](#)

Class of all *TableauTuples* with a fixed level and arbitrary size.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(3).an_element()
([], [], [])
sage: TableauTuples(5).an_element()
([], [], [], [], [])
sage: T = TableauTuples(0)
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: the level must be a positive integer
```

class sage.combinat.tableau_tuple.**TableauTuples_level_size**(level, size)

Bases: *sage.combinat.tableau_tuple.TableauTuples*

Class of all *TableauTuples* with a fixed level and a fixed size.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(3,0).an_element()
([], [], [])
sage: TableauTuples(3,1).an_element()
([[1]], [], [])
sage: TableauTuples(3,2).an_element()
([[1, 2]], [], [])
```

class sage.combinat.tableau_tuple.**TableauTuples_size**(size)

Bases: *sage.combinat.tableau_tuple.TableauTuples*

Class of all *TableauTuples* with a arbitrary level and fixed size.

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: TableauTuples(size=3).an_element()
([], [[1, 2, 3]], [])
sage: TableauTuples(size=0).an_element()
([], [], [])
```

5.1.345 Generalized Tamari lattices

These lattices depend on three parameters a , b and m , where a and b are coprime positive integers and m is a nonnegative integer.

The elements are *Dyck paths* in the $(a \times b)$ -rectangle. The order relation depends on m .

To use the provided functionality, you should import Generalized Tamari lattices by typing:

```
sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
```

Then,

```
sage: GeneralizedTamariLattice(3,2)
Finite lattice containing 2 elements
sage: GeneralizedTamariLattice(4,3)
Finite lattice containing 5 elements
```

The classical **Tamari lattices** are special cases of this construction and are also available directly using the catalogue of posets, as follows:

```
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements
```

See also:

For more detailed information see `TamariLattice()`, `GeneralizedTamariLattice()`.

```
sage.combinat.tamari_lattices.DexterSemilattice(n)
```

Return the n -th Dexter meet-semilattice.

INPUT:

- n – a nonnegative integer (the index)

OUTPUT:

a finite meet-semilattice

The elements of the semilattice are *Dyck paths* in the $(n + 1 \times n)$ -rectangle.

EXAMPLES:

```
sage: posets.DexterSemilattice(3)
Finite meet-semilattice containing 5 elements

sage: P = posets.DexterSemilattice(4); P
Finite meet-semilattice containing 14 elements
sage: len(P.maximal_chains())
15
sage: len(P.maximal_elements())
4
sage: P.chain_polynomial()
q^5 + 19*q^4 + 47*q^3 + 42*q^2 + 14*q + 1
```

REFERENCES:

- [Cha18]

```
sage.combinat.tamari_lattices.GeneralizedTamariLattice(a, b, m=1, check=True)
```

Return the (a, b) -Tamari lattice of parameter m .

INPUT:

- a and b – coprime integers with $a \geq b$
- m – a nonnegative integer such that $a \geq bm$

OUTPUT:

- a finite lattice (the lattice property is only conjectural in general)

The elements of the lattice are *Dyck paths* in the $(a \times b)$ -rectangle.

The parameter m (slope) is used only to define the covering relations. When the slope m is 0, two paths are comparable if and only if one is always above the other.

The usual *Tamari lattice* of index b is the special case $a = b + 1$ and $m = 1$.

Other special cases give the m -Tamari lattices studied in [BMFPR].

EXAMPLES:

```

sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
sage: GeneralizedTamariLattice(3,2)
Finite lattice containing 2 elements
sage: GeneralizedTamariLattice(4,3)
Finite lattice containing 5 elements
sage: GeneralizedTamariLattice(4,4)
Traceback (most recent call last):
...
ValueError: the numbers a and b must be coprime with a>=b
sage: GeneralizedTamariLattice(7,5,2)
Traceback (most recent call last):
...
ValueError: the condition a>=b*m does not hold
sage: P = GeneralizedTamariLattice(5,3);P
Finite lattice containing 7 elements

```

REFERENCES:

`sage.combinat.tamari_lattices.TamariLattice($n, m=1$)`

Return the n -th Tamari lattice.

Using the slope parameter m , one can also get the m -Tamari lattices.

INPUT:

- n – a nonnegative integer (the index)
- m – an optional nonnegative integer (the slope, default to 1)

OUTPUT:

a finite lattice

In the usual case, the elements of the lattice are *Dyck paths* in the $(n + 1 \times n)$ -rectangle. For a general slope m , the elements are Dyck paths in the $(mn + 1 \times n)$ -rectangle.

See [Tamari lattice](#) for mathematical background.

EXAMPLES:

```

sage: posets.TamariLattice(3)
Finite lattice containing 5 elements

sage: posets.TamariLattice(3, 2)
Finite lattice containing 12 elements

```

REFERENCES:

- [BMFPR]

`sage.combinat.tamari_lattices.paths_in_triangle(i, j, a, b)`

Return all Dyck paths from $(0, 0)$ to (i, j) in the $(a \times b)$ -rectangle.

This means that at each step of the path, one has $ay \geq bx$.

A path is represented by a sequence of 0 and 1, where 0 is an horizontal step $(1, 0)$ and 1 is a vertical step $(0, 1)$.

INPUT:

- a and b – coprime integers with $a \geq b$
- i and j – nonnegative integers with $1 \geq \frac{j}{b} \geq \frac{bi}{a} \geq 0$

OUTPUT:

- a list of paths

EXAMPLES:

```
sage: from sage.combinat.tamari_lattices import paths_in_triangle
sage: paths_in_triangle(2,2,2,2)
[(1, 0, 1, 0), (1, 1, 0, 0)]
sage: paths_in_triangle(2,3,4,4)
[(1, 0, 1, 0, 1), (1, 1, 0, 0, 1), (1, 0, 1, 1, 0),
(1, 1, 0, 1, 0), (1, 1, 1, 0, 0)]
sage: paths_in_triangle(2,1,4,4)
Traceback (most recent call last):
...
ValueError: the endpoint is not valid
sage: paths_in_triangle(3,2,5,3)
[(1, 0, 1, 0, 0), (1, 1, 0, 0, 0)]
```

`sage.combinat.tamari_lattices.swap`($p, i, m=1$)

Perform a covering move in the (a, b) -Tamari lattice of parameter m .

The letter at position i in p must be a 0, followed by at least one 1.

INPUT:

- p – a Dyck path in the $(a \times b)$ -rectangle
- i – an integer between 0 and $a + b - 1$

OUTPUT:

- a Dyck path in the $(a \times b)$ -rectangle

EXAMPLES:

```
sage: from sage.combinat.tamari_lattices import swap
sage: swap((1,0,1,0,0),1)
(1, 1, 0, 0, 0)
sage: swap((1,1,0,0,1,1,0,0,0),3)
(1, 1, 0, 1, 1, 0, 0, 0, 0)
```

`sage.combinat.tamari_lattices.swap_dexter`(p, i)

Perform covering moves in the (a, b) -Dexter posets.

The letter at position i in p must be a 0, followed by at least one 1.

INPUT:

- p – a Dyck path in the $(a \times b)$ -rectangle
- i – an integer between 0 and $a + b - 1$

OUTPUT:

- a list of Dyck paths in the $(a \times b)$ -rectangle

EXAMPLES:

```
sage: from sage.combinat.tamari_lattices import swap_dexter
sage: swap_dexter((1,0,1,0,0),1)
[(1, 1, 0, 0, 0)]
```

(continues on next page)

(continued from previous page)

```
sage: swap_dexter((1,1,0,0,1,1,0,0,0),3)
[(1, 1, 0, 1, 1, 0, 0, 0, 0), (1, 1, 1, 1, 0, 0, 0, 0, 0)]
sage: swap_dexter((1,1,0,1,0,0,0),2)
[]
```

5.1.346 Tiling Solver

Tiling a n -dimensional polyomino with n -dimensional polyominoes.

This module defines two classes:

- `sage.combinat.tiling.Polyomino` class, to represent polyominoes in arbitrary dimension. The goal of this class is to return all the rotated, reflected and/or translated copies of a polyomino that are contained in a certain box.
- `sage.combinat.tiling.TilingSolver` class, to solve the problem of tiling a n -dimensional polyomino with a set of n -dimensional polyominoes. One can specify if rotations and reflections are allowed or not and if pieces can be reused or not. This class convert the tiling data into rows of a matrix that are passed to the DLX solver. It also allows to compute the number of solutions.

This uses dancing links code which is in Sage. Dancing links were originally introduced by Donald Knuth in 2000 [Knuth1]. Knuth used dancing links to solve tilings of a region by 2d pentaminoes. Here we extend the method to any dimension.

In particular, the `sage.games.quantumino` module is based on the Tiling Solver and allows to solve the 3d Quantumino puzzle.

AUTHOR:

- Sébastien Labbé, June 2011, initial version
- Sébastien Labbé, July 2015, count solutions up to rotations
- Sébastien Labbé, April 2017, tiling a polyomino, not only a rectangular box

EXAMPLES:

2d Easy Example

Here is a 2d example. Let us try to fill the 3×2 rectangle with a 1×2 rectangle and a 2×2 square. Obviously, there are two solutions:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2])
sage: it = T.solve()
sage: next(it)
[Polyomino: [(0, 0), (0, 1), (1, 0), (1, 1)], Color: gray, Polyomino: [(2, 0), (2, 1)],
→Color: gray]
sage: next(it)
[Polyomino: [(1, 0), (1, 1), (2, 0), (2, 1)], Color: gray, Polyomino: [(0, 0), (0, 1)],
→Color: gray]
sage: next(it)
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
StopIteration
sage: T.number_of_solutions()
2
```

Scott's pentamino problem

As mentioned in the introduction of [Knuth1], Scott's pentamino problem consists in tiling a chessboard leaving the center four squares vacant with the 12 distinct pentaminoes.

The 12 pentaminoes:

```
sage: from sage.combinat.tiling import Polyomino
sage: I = Polyomino([(0,0),(1,0),(2,0),(3,0),(4,0)], color='brown')
sage: N = Polyomino([(1,0),(1,1),(1,2),(0,2),(0,3)], color='yellow')
sage: L = Polyomino([(0,0),(1,0),(0,1),(0,2),(0,3)], color='magenta')
sage: U = Polyomino([(0,0),(1,0),(0,1),(0,2),(1,2)], color='violet')
sage: X = Polyomino([(1,0),(0,1),(1,1),(1,2),(2,1)], color='pink')
sage: W = Polyomino([(2,0),(2,1),(1,1),(1,2),(0,2)], color='green')
sage: P = Polyomino([(1,0),(2,0),(0,1),(1,1),(2,1)], color='orange')
sage: F = Polyomino([(1,0),(1,1),(0,1),(2,1),(2,2)], color='gray')
sage: Z = Polyomino([(0,0),(1,0),(1,1),(1,2),(2,2)], color='yellow')
sage: T = Polyomino([(0,0),(0,1),(1,1),(2,1),(0,2)], color='red')
sage: Y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)], color='green')
sage: V = Polyomino([(0,0),(0,1),(0,2),(1,0),(2,0)], color='blue')
```

A 8×8 chessboard leaving the center four squares vacant:

```
sage: import itertools
sage: s = set(itertools.product(range(8), repeat=2))
sage: s.difference_update([(3,3), (3,4), (4,3), (4,4)])
sage: chessboard = Polyomino(s)
sage: len(chessboard)
60
```

This problem is represented by a matrix made of 1568 rows and 72 columns. It has 65 different solutions up to isometries:

```
sage: from sage.combinat.tiling import TilingSolver
sage: T = TilingSolver([I,N,L,U,X,W,P,F,Z,T,Y,V], box=chessboard, reflection=True)
sage: T
Tiling solver of 12 pieces into a box of size 60
Rotation allowed: True
Reflection allowed: True
Reusing pieces allowed: False
sage: len(T.rows()) # long time
1568
sage: T.number_of_solutions() # long time
520
sage: 520 / 8
65
```

Showing one solution:

```

sage: solution = next(T.solve()) # long time
sage: G = sum([piece.show2d() for piece in solution], Graphics()) # long time
sage: G.show(aspect_ratio=1, axes=False) # long time

```

1d Easy Example

Here is an easy one dimensional example where we try to tile a stick of length 6 with three sticks of length 1, 2 and 3. There are six solutions:

```

sage: p = Polyomino([[0]])
sage: q = Polyomino([[0],[1]])
sage: r = Polyomino([[0],[1],[2]])
sage: T = TilingSolver([p,q,r], box=[6])
sage: len(T.rows())
15
sage: it = T.solve()
sage: next(it)
[Polyomino: [(0)], Color: gray, Polyomino: [(1), (2)], Color: gray, Polyomino: [(3), (4),
↪ (5)], Color: gray]
sage: next(it)
[Polyomino: [(0)], Color: gray, Polyomino: [(1), (2), (3)], Color: gray, Polyomino: [(4),
↪ (5)], Color: gray]
sage: T.number_of_solutions()
6

```

2d Puzzle allowing reflections

The following is a puzzle owned by Florent Hivert:

```

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: L = []
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,2),(1,3)], 'yellow'))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,2)], 'black'))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,1),(1,3)], 'gray'))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,3)], 'cyan'))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,0),(1,1)], 'red'))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,1),(1,2)], 'blue'))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(0,3),(1,1),(1,3)], 'green'))
sage: L.append(Polyomino([(0,1),(0,2),(0,3),(1,0),(1,1),(1,3)], 'magenta'))
sage: L.append(Polyomino([(0,1),(0,2),(0,3),(1,0),(1,1),(1,2)], 'orange'))
sage: L.append(Polyomino([(0,0),(0,1),(0,2),(1,0),(1,1),(1,2)], 'pink'))

```

By default, rotations are allowed and reflections are not. In this case, there are no solution for tiling a 8×8 rectangular box:

```

sage: T = TilingSolver(L, box=(8,8))
sage: T.number_of_solutions() # long time (2.5 s)
0

```

If reflections are allowed, there are solutions. Solve the puzzle and show one solution:

```

sage: T = TilingSolver(L, box=(8,8), reflection=True)
sage: solution = next(T.solve()) # long time (7s)
sage: G = sum([piece.show2d() for piece in solution], Graphics()) # long time (<1s)
sage: G.show(aspect_ratio=1, axes=False) # long time (2s)

```

Compute the number of solutions:

```

sage: T.number_of_solutions() # long time (2.6s)
328

```

Create a animation of all the solutions:

```

sage: a = T.animate() # not tested
sage: a # not tested
Animation with 328 frames

```

3d Puzzle

The same thing done in 3d *without* allowing reflections this time:

```

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: L = []
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0),(1,3,
↪0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,3,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,3,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,1,0),(1,2,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(0,3,0),(1,1,0),(1,3,0)]))
sage: L.append(Polyomino([(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,3,0)]))
sage: L.append(Polyomino([(0,1,0),(0,2,0),(0,3,0),(1,0,0),(1,1,0),(1,2,0)]))
sage: L.append(Polyomino([(0,0,0),(0,1,0),(0,2,0),(1,0,0),(1,1,0),(1,2,0)]))

```

Solve the puzzle and show one solution:

```

sage: T = TilingSolver(L, box=(8,8,1))
sage: solution = next(T.solve()) # long time (8s)
sage: G = sum([p.show3d(size=0.85) for p in solution], Graphics()) # long time (<1s)
sage: G.show(aspect_ratio=1, viewer='tachyon') # long time (2s)

```

Let us compute the number of solutions:

```

sage: T.number_of_solutions() # long time (3s)
328

```

Donald Knuth example : the Y pentamino

Donald Knuth [Knuth1] considered the problem of packing 45 Y pentaminoes into a 15×15 square:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)])
sage: T = TilingSolver([y], box=(5,10), reusable=True, reflection=True)
sage: T.number_of_solutions()
10
sage: solution = next(T.solve())
sage: G = sum([p.show2d() for p in solution], Graphics())
sage: G.show(aspect_ratio=1) # long time (2s)
```

```
sage: T = TilingSolver([y], box=(15,15), reusable=True, reflection=True)
sage: T.number_of_solutions() # not tested
1696
```

Up to the symmetries of the square, there are 212 distinct solutions:

```
sage: 1696 // 8
212
```

Animation of Donald Knuth's dancing links

Animation of the solutions:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: Y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)], color='yellow')
sage: T = TilingSolver([Y], box=(15,15), reusable=True, reflection=True)
sage: a = T.animate(stop=40) # long time # optional -- ImageMagick
sage: a # long time # optional -- ImageMagick
Animation with 40 frames
```

Incremental animation of the solutions (one piece is removed/added at a time):

```
sage: a = T.animate('incremental', stop=40) # long time # optional -- ImageMagick
sage: a # long time # optional -- ImageMagick
Animation with 40 frames
sage: a.show(delay=50, iterations=1) # long time # optional -- ImageMagick
```

5d Easy Example

Here is a 5d example. Let us try to fill the $2 \times 2 \times 2 \times 2 \times 2$ rectangle with reusable $1 \times 1 \times 1 \times 1 \times 1$ rectangles. Obviously, there is one solution:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: p = Polyomino([(0,0,0,0,0)])
sage: T = TilingSolver([p], box=(2,2,2,2,2), reusable=True)
sage: rows = T.rows() # long time (3s)
sage: rows # long time (fast)
[[0], [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [14], [15], ↵
↵ [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], ↵
↵ [30], [31]]
```

(continues on next page)

(continued from previous page)

```
sage: T.number_of_solutions() # long time (fast)
1
```

REFERENCES:

class `sage.combinat.tiling.Polyomino`(*coords*, *color*='gray', *dimension*=None)

Bases: `sage.structure.sage_object.SageObject`

A polyomino in \mathbf{Z}^d .

The polyomino is the union of the unit square (or cube, or n-cube) centered at those coordinates. Such an object should be connected, but the code does not make this assumption.

INPUT:

- *coords* – iterable of integer coordinates in \mathbf{Z}^d
- *color* – string (default: 'gray'), color for display
- *dimension* – integer (default: None), dimension of the space, if None, it is guessed from the *coords* if *coords* is non empty

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
Polyomino: [(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)], Color: blue
```

boundary()

Return the boundary of a 2d polyomino.

INPUT:

- *self* - a 2d polyomino

OUTPUT:

- list of edges (an edge is a pair of adjacent 2d coordinates)

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0), (1,0), (0,1), (1,1)])
sage: sorted(p.boundary())
[((-0.5, -0.5), (-0.5, 0.5)), ((-0.5, -0.5), (0.5, -0.5)), ((-0.5, 0.5), (-0.5, 1.5)),
 (-0.5, 1.5), (0.5, 1.5)), ((0.5, -0.5), (1.5, -0.5)), ((0.5, 1.5), (1.5, 1.5)),
 ((1.5, -0.5), (1.5, 0.5)), ((1.5, 0.5), (1.5, 1.5))]
sage: len(_)
8
sage: p = Polyomino([(5,5)])
sage: sorted(p.boundary())
[((4.5, 4.5), (4.5, 5.5)), ((4.5, 4.5), (5.5, 4.5)), ((4.5, 5.5), (5.5, 5.5)),
 ((5.5, 4.5), (5.5, 5.5))]
```

bounding_box()

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink')
```

(continues on next page)

(continued from previous page)

```
sage: p.bounding_box()
[[0, 0, 0], [1, 2, 1]]
```

canonical()

Return the translated copy of `self` having minimal and nonnegative coordinates

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink')
sage: p
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: ↵
↵deeppink
sage: p.canonical()
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color: ↵
↵deeppink
```

canonical_isometric_copies(orientation_preserving=True, mod_box_isometries=False)

Return the list of image of `self` under isometries of the n -cube where the coordinates are all nonnegative and minimal.

INPUT:

- `orientation_preserving` – bool (optional, default: True); if True, the group of isometries of the n -cube is restricted to those that preserve the orientation, i.e. of determinant 1.
- `mod_box_isometries` – bool (default: False), whether to quotient the group of isometries of the n -cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where the a_i are assumed to be distinct.

OUTPUT:

set of Polyomino

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: s = p.canonical_isometric_copies()
sage: len(s)
12
```

With the non orientation-preserving:

```
sage: s = p.canonical_isometric_copies(orientation_preserving=False)
sage: len(s)
24
```

Modulo rotation by angle 180 degrees:

```
sage: s = p.canonical_isometric_copies(mod_box_isometries=True)
sage: len(s)
3
```

center()

Return the center of the polyomino.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(0,0,1)])
sage: p.center()
(0, 0, 1/2)
```

In 3d:

```
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink')
sage: p.center()
(4/5, 4/5, 1/5)
```

In 2d:

```
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)])
sage: p.center()
(3/4, 3/4)
```

color(*color=None*)

Return or change the color of the polyomino.

INPUT:

- *color* – string, RGB tuple or None (default: None), if None, it returns the current color

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.color()
'blue'
```

frozenset()

Return the elements of \mathbf{Z}^d in the polyomino as a frozenset.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='red')
sage: p.frozenset()
frozenset({(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)})
```

intersection(*other*)

Return the intersection of *self* and *other*.

INPUT:

- *other* - a polyomino

OUTPUT:

polyomino

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: a = Polyomino([(0,0)])
sage: b = Polyomino([(0,0), (0,1), (1,1), (2,1)])
sage: a.intersection(b)
```

(continues on next page)

(continued from previous page)

```
Polyomino: [(0, 0)], Color: gray
sage: a.intersection(b+(1,1))
Polyomino: [], Color: gray
```

isometric_copies(*box*, *orientation_preserving*=True, *mod_box_isometries*=False)

Return the translated and isometric images of `self` that lies in the box.

INPUT:

- `box` – Polyomino or tuple of integers (size of a box)
- `orientation_preserving` – bool (optional, default: True); If True, the group of isometries of the n -cube is restricted to those that preserve the orientation, i.e. of determinant 1.
- `mod_box_isometries` – bool (default: False), whether to quotient the group of isometries of the n -cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where the a_i are assumed to be distinct.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink')
sage: L = list(p.isometric_copies(box=(5,8,2)))
sage: len(L)
360
```

```
sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,2,0),(1,2,1)], color='orange')
sage: L = list(p.isometric_copies(box=(5,8,2)))
sage: len(L)
180
sage: L = list(p.isometric_copies((5,8,2), False))
sage: len(L)
360
sage: L = list(p.isometric_copies((5,8,2), mod_box_isometries=True))
sage: len(L)
45
```

```
sage: p = Polyomino([(0,0), (1,0), (0,1)])
sage: b = Polyomino([(0,0), (1,0), (2,0), (0,1), (1,1), (0,2)])
sage: sorted(p.isometric_copies(b), key=lambda p: p.sorted_list())
[Polyomino: [(0, 0), (0, 1), (1, 0)], Color: gray,
Polyomino: [(0, 0), (0, 1), (1, 1)], Color: gray,
Polyomino: [(0, 0), (1, 0), (1, 1)], Color: gray,
Polyomino: [(0, 1), (0, 2), (1, 1)], Color: gray,
Polyomino: [(0, 1), (1, 0), (1, 1)], Color: gray,
Polyomino: [(1, 0), (1, 1), (2, 0)], Color: gray]
```

isometric_copies_intersection(*box*, *orientation_preserving*=True)

Return the set of non empty intersections of isometric images of `self` with a polyomino.

INPUT:

- `box` – Polyomino or tuple of integers (size of a box)
- `orientation_preserving` – bool (optional, default: True); if True, the group of isometries of the n -cube is restricted to those that preserve the orientation, i.e. of determinant 1.

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(1,0)], color='deeppink')
sage: sorted(sorted(a.frozenset()) for a in p.isometric_copies_
↳intersection(box=(2,3)))
[[ (0, 0)],
 [ (0, 0), (0, 1)],
 [ (0, 0), (1, 0)],
 [ (0, 1)],
 [ (0, 1), (0, 2)],
 [ (0, 1), (1, 1)],
 [ (0, 2)],
 [ (0, 2), (1, 2)],
 [ (1, 0)],
 [ (1, 0), (1, 1)],
 [ (1, 1)],
 [ (1, 1), (1, 2)],
 [ (1, 2)]]

```

neighbor_edges()

Return an iterator over the pairs of neighbor coordinates inside of the polyomino.

Two points P and Q in the polyomino are neighbor if $P - Q$ has one coordinate equal to $+1$ or -1 and zero everywhere else.

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0),(0,0,1)])
sage: [sorted(edge) for edge in p.neighbor_edges()]
[[ (0, 0, 0), (0, 0, 1)]]

```

In 3d:

```

sage: p = Polyomino([(0,0,0),(1,0,0),(1,1,0),(1,1,1),(1,2,0)], color='deeppink')
sage: L = sorted(sorted(edge) for edge in p.neighbor_edges())
sage: for a in L: a
[(0, 0, 0), (1, 0, 0)]
[(1, 0, 0), (1, 1, 0)]
[(1, 1, 0), (1, 1, 1)]
[(1, 1, 0), (1, 2, 0)]

```

In 2d:

```

sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)])
sage: L = sorted(sorted(edge) for edge in p.neighbor_edges())
sage: for a in L: a
[(0, 0), (1, 0)]
[(1, 0), (1, 1)]
[(1, 1), (1, 2)]

```

self_surrounding(radius, remove_incomplete_copies=True, ncpus=None)

Return a list of isometric copies of `self` surrounding it with an annulus of given radius.

INPUT:

- `self` - a polyomino of dimension 2
- `radius` - integer
- `remove_incomplete_copies` - bool (default: True), whether to keep only complete copies of `self` in the output
- `ncpus` - integer (default: None), maximal number of subprocesses to use at the same time. If None, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`. If `ncpus=1`, the first solution is searched serially.

OUTPUT:

list of polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: H = Polyomino([(-1, 1), (-1, 4), (-1, 7), (0, 0), (0, 1), (0, 2),
.....: (0, 3), (0, 4), (0, 5), (0, 6), (0, 7), (0, 8), (1, 1), (1, 2),
.....: (1, 3), (1, 4), (1, 5), (1, 6), (1, 7), (1, 8), (2, 0), (2, 2),
.....: (2, 3), (2, 5), (2, 6), (2, 8)])
sage: solution = H.self_surrounding(8)
sage: G = sum([p.show2d() for p in solution], Graphics())
```

```
sage: solution = H.self_surrounding(8, remove_incomplete_copies=False)
sage: G = sum([p.show2d() for p in solution], Graphics())
```

show2d(*size=0.7, color='black', thickness=1*)

Return a 2d Graphic object representing the polyomino.

INPUT:

- `self` - a polyomino of dimension 2
- `size` - number (optional, default: 0.7), the size of each square.
- `color` - color (optional, default: 'black'), color of the boundary line.
- `thickness` - number (optional, default: 1), how thick the boundary line is.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(1,0),(1,1),(1,2)], color='deeppink')
sage: p.show2d() # long time (0.5s)
Graphics object consisting of 17 graphics primitives
```

show3d(*size=1*)

Return a 3d Graphic object representing the polyomino.

INPUT:

- `self` - a polyomino of dimension 3
- `size` - number (optional, default: 1), the size of each 1 \times 1 \times 1 cube. This does a homothety with respect to the center of the polyomino.

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.show3d() # long time (2s)
Graphics3d Object

```

sorted_list()

Return the color of the polyomino.

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (0,1,0), (1,1,0), (1,1,1)], color='blue')
sage: p.sorted_list()
[(0, 0, 0), (0, 1, 0), (1, 1, 0), (1, 1, 1)]

```

translated_copies(box)

Return an iterator over the translated images of self inside a polyomino.

INPUT:

- box – Polyomino or tuple of integers (size of a box)

OUTPUT:

iterator of 3d polyominoes

EXAMPLES:

```

sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0,0), (1,0,0), (1,1,0), (1,1,1), (1,2,0)], color='deeppink')
sage: for t in p.translated_copies(box=(5,8,2)): t
Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color:↵
↵deeppink
Polyomino: [(0, 1, 0), (1, 1, 0), (1, 2, 0), (1, 2, 1), (1, 3, 0)], Color:↵

Polyomino: [(3, 5, 0), (4, 5, 0), (4, 6, 0), (4, 6, 1), (4, 7, 0)], Color:↵
↳deeppink

```

This method is independent of the translation of the polyomino:

```

sage: q = Polyomino([(0,0,0), (1,0,0)])
sage: list(q.translated_copies((2,2,1)))
[Polyomino: [(0, 0, 0), (1, 0, 0)], Color: gray, Polyomino: [(0, 1, 0), (1, 1, ↵
↳0)], Color: gray]
sage: q = Polyomino([(34,7,-9), (35,7,-9)])
sage: list(q.translated_copies((2,2,1)))
[Polyomino: [(0, 0, 0), (1, 0, 0)], Color: gray, Polyomino: [(0, 1, 0), (1, 1, ↵
↳0)], Color: gray]

```

Inside smaller boxes:

```

sage: list(p.translated_copies(box=(2,2,3)))
[]
sage: list(p.translated_copies(box=(2,3,2)))
[Polyomino: [(0, 0, 0), (1, 0, 0), (1, 1, 0), (1, 1, 1), (1, 2, 0)], Color:↵
↳deeppink]
sage: list(p.translated_copies(box=(3,2,2)))
[]
sage: list(p.translated_copies(box=(1,1,1)))
[]

```

Using a Polyomino as input:

```

sage: b = Polyomino([(0,0), (0,1), (0,2), (1,0), (1,1), (1,2)])
sage: p = Polyomino([(0,0)])
sage: list(p.translated_copies(b))
[Polyomino: [(0, 0)], Color: gray,
Polyomino: [(0, 1)], Color: gray,

```

(continues on next page)

(continued from previous page)

```
Polyomino: [(0, 2)], Color: gray,
Polyomino: [(1, 0)], Color: gray,
Polyomino: [(1, 1)], Color: gray,
Polyomino: [(1, 2)], Color: gray]
```

```
sage: p = Polyomino([(0,0), (1,0), (0,1)])
sage: b = Polyomino([(0,0), (1,0), (2,0), (0,1), (1,1), (0,2)])
sage: list(p.translated_copies(b))
[Polyomino: [(0, 0), (0, 1), (1, 0)], Color: gray,
Polyomino: [(0, 1), (0, 2), (1, 1)], Color: gray,
Polyomino: [(1, 0), (1, 1), (2, 0)], Color: gray]
```

translated_copies_intersection(*box*)

Return the set of non empty intersections of translated images of `self` with a polyomino.

INPUT:

- `box` – Polyomino or tuple of integers (size of a box)

OUTPUT:

set of 3d polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino
sage: p = Polyomino([(0,0),(1,0)], color='deeppink')
sage: sorted(sorted(a.frozenset()) for a in p.translated_copies_
↳ intersection(box=(2,3)))
[[ (0, 0)],
 [ (0, 0), (1, 0)],
 [ (0, 1)],
 [ (0, 1), (1, 1)],
 [ (0, 2)],
 [ (0, 2), (1, 2)],
 [ (1, 0)],
 [ (1, 1)],
 [ (1, 2)]]
```

Using a Polyomino as input:

```
sage: b = Polyomino([(0,0), (0,1), (0,2), (1,0), (2,0)])
sage: p = Polyomino([(0,0), (1,0)])
sage: sorted(sorted(a.frozenset()) for a in p.translated_copies_intersection(b))
[[ (0, 0)], [ (0, 0), (1, 0)], [ (0, 1)], [ (0, 2)], [ (1, 0), (2, 0)], [ (2, 0)]]
```

class `sage.combinat.tiling.TilingSolver`(*pieces*, *box*, *rotation=True*, *reflection=False*, *reusable=False*, *outside=False*)

Bases: `sage.structure.sage_object.SageObject`

Tiling solver

Solve the problem of tiling a polyomino with a certain number of polyominoes.

INPUT:

- `pieces` – iterable of Polyominoes

- `box` – Polyomino or tuple of integers (size of a box)
- `rotation` – bool (optional, default: `True`), whether to allow rotations
- `reflection` – bool (optional, default: `False`), whether to allow reflections
- `reusable` – bool (optional, default: `False`), whether to allow the pieces to be reused
- `outside` – bool (optional, default: `False`), whether to allow pieces to partially go outside of the box (all non-empty intersection of the pieces with the box are considered)

EXAMPLES:

By default, rotations are allowed and reflections are not allowed:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T
Tiling solver of 3 pieces into a box of size 6
Rotation allowed: True
Reflection allowed: False
Reusing pieces allowed: False
```

Solutions are given by an iterator:

```
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
```

Another solution:

```
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
```

Tiling of a polyomino by polyominoes:

```
sage: b = Polyomino([(0,0), (1,0), (1,1), (2,1), (1,2), (2,2), (0,3), (1,3)])
sage: p = Polyomino([(0,0), (1,0)])
sage: T = TilingSolver([p], box=b, reusable=True)
sage: T.number_of_solutions()
2
```

animate (*partial=None, stop=None, size=0.75, axes=False*)

Return an animation of evolving solutions.

INPUT:

- `partial` - string (optional, default: `None`), whether to include partial (incomplete) solutions. It can be one of the following:
 - `None` - include only complete solutions
 - `'common_prefix'` - common prefix between two consecutive solutions

- 'incremental' - one piece change at a time
- stop - integer (optional, default:None), number of frames
- size - number (optional, default: 0.75), the size of each 1 \times 1 square. This does a homothety with respect to the center of each polyomino.
- axes - bool (optional, default:False), whether the x and y axes are shown.

EXAMPLES:

```
sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: y = Polyomino([(0,0),(1,0),(2,0),(3,0),(2,1)], color='cyan')
sage: T = TilingSolver([y], box=(5,10), reusable=True, reflection=True)
sage: a = T.animate()
sage: a          # optional -- ImageMagick    # long time
Animation with 10 frames
```

Include partial solutions (common prefix between two consecutive solutions):

```
sage: a = T.animate('common_prefix')
sage: a          # optional -- ImageMagick    # long time
Animation with 19 frames
```

Incremental solutions (one piece removed or added at a time):

```
sage: a = T.animate('incremental')          # long time (2s)
sage: a          # long time (2s) # optional --
↪ImageMagick
Animation with 123 frames
```

```
sage: a.show()          # optional -- ImageMagick    # long time
```

The show function takes arguments to specify the delay between frames (measured in hundredths of a second, default value 20) and the number of iterations (default value 0, which means to iterate forever). To iterate 4 times with half a second between each frame:

```
sage: a.show(delay=50, iterations=4) # optional -- ImageMagick # long time
```

Limit the number of frames:

```
sage: a = T.animate('incremental', stop=13) # not tested
sage: a          # not tested
Animation with 13 frames
```

coord_to_int_dict()

Return a dictionary mapping coordinates to integers.

OUTPUT:

dict

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
```

(continues on next page)

(continued from previous page)

```

sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: A = T.coord_to_int_dict()
sage: sorted(A.items())
[((0, 0, 0), 3), ((0, 0, 1), 4), ((0, 0, 2), 5), ((0, 0, 3), 6), ((0, 0, 4), 7),
↪ ((0, 0, 5), 8)]

```

Reusable pieces:

```

sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2], reusable=True)
sage: B = T.coord_to_int_dict()
sage: sorted(B.items())
[((0, 0), 0), ((0, 1), 1), ((1, 0), 2), ((1, 1), 3), ((2, 0), 4), ((2, 1), 5)]

```

dlx_solver()

Return the sage DLX solver of that tiling problem.

OUTPUT:

DLX Solver

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.dlx_solver()
Dancing links solver for 9 columns and 15 rows

```

int_to_coord_dict()

Return a dictionary mapping integers to coordinates.

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: B = T.int_to_coord_dict()
sage: sorted(B.items())
[(3, (0, 0, 0)), (4, (0, 0, 1)), (5, (0, 0, 2)), (6, (0, 0, 3)), (7, (0, 0, 4)),
↪ (8, (0, 0, 5))]

```

Reusable pieces:

```

sage: from sage.combinat.tiling import Polyomino, TilingSolver
sage: p = Polyomino([(0,0), (0,1)])
sage: q = Polyomino([(0,0), (0,1), (1,0), (1,1)])
sage: T = TilingSolver([p,q], box=[3,2], reusable=True)
sage: B = T.int_to_coord_dict()

```

(continues on next page)

(continued from previous page)

```
sage: sorted(B.items())
[(0, (0, 0)), (1, (0, 1)), (2, (1, 0)), (3, (1, 1)), (4, (2, 0)), (5, (2, 1))]
```

is_suitable()

Return whether the volume of the box is equal to sum of the volume of the polyominoes and the number of rows sent to the DLX solver is larger than zero.

If these conditions are not verified, then the problem is not suitable in the sense that there are no solution.

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.is_suitable()
True
sage: T = TilingSolver([p,q,r], box=(1,1,7))
sage: T.is_suitable()
False
```

nrows_per_piece()

Return the number of rows necessary by each piece.

OUTPUT:

list

EXAMPLES:

```
sage: from sage.games.quantumino import QuantuminoSolver
sage: q = QuantuminoSolver(0)
sage: T = q.tiling_solver()
sage: T.nrows_per_piece() # long time (10s)
[360, 360, 360, 360, 360, 180, 180, 672, 672, 360, 360, 180, 180, 360, 360, 180]
```

number_of_solutions()

Return the number of distinct solutions.

OUTPUT:

integer

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0)])
sage: q = Polyomino([(0,0), (0,1)])
sage: r = Polyomino([(0,0), (0,1), (0,2)])
sage: T = TilingSolver([p,q,r], box=(1,6))
sage: T.number_of_solutions()
6
```

```
sage: T = TilingSolver([p,q,r], box=(1,7))
sage: T.number_of_solutions()
0
```

pieces()

Return the list of pieces.

OUTPUT:

list of 3d polyominoes

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: for p in T._pieces: p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 0), (0, 0, 1), (0, 0, 2)], Color: gray
```

row_to_polyomino(row_number)

Return a polyomino associated to a row.

INPUT:

- row_number – integer, the i-th row

OUTPUT:

polyomino

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: a = Polyomino([(0,0,0), (0,0,1), (1,0,0)], color='blue')
sage: b = Polyomino([(0,0,0), (1,0,0), (0,1,0)], color='red')
sage: T = TilingSolver([a,b], box=(2,1,3))
sage: len(T.rows())
16
```

```
sage: T.row_to_polyomino(7)
Polyomino: [(0, 0, 2), (1, 0, 1), (1, 0, 2)], Color: blue
```

```
sage: T.row_to_polyomino(13)
Polyomino: [(0, 0, 1), (1, 0, 1), (1, 0, 2)], Color: red
```

rows()

Creation of the rows

EXAMPLES:

```
sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: rows = T.rows()
sage: for row in rows: row
[0, 3]
```

(continues on next page)

(continued from previous page)

```

[0, 4]
[0, 5]
[0, 6]
[0, 7]
[0, 8]
[1, 3, 4]
[1, 4, 5]
[1, 5, 6]
[1, 6, 7]
[1, 7, 8]
[2, 3, 4, 5]
[2, 4, 5, 6]
[2, 5, 6, 7]
[2, 6, 7, 8]

```

rows_for_piece(*i*, *mod_box_isometries*=False)

Return the rows for the *i*-th piece.

INPUT:

- *i* – integer, the *i*-th piece
- *mod_box_isometries* – bool (default: False), whether to consider only rows for positions up to the action of the quotient the group of isometries of the *n*-cube by the subgroup of isometries of the $a_1 \times a_2 \cdots \times a_n$ rectangular box where the a_i are assumed to be distinct.

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.rows_for_piece(0)
[[0, 3], [0, 4], [0, 5], [0, 6], [0, 7], [0, 8]]
sage: T.rows_for_piece(1)
[[1, 3, 4], [1, 4, 5], [1, 5, 6], [1, 6, 7], [1, 7, 8]]
sage: T.rows_for_piece(2)
[[2, 3, 4, 5], [2, 4, 5, 6], [2, 5, 6, 7], [2, 6, 7, 8]]

```

Less rows when using *mod_box_isometries*=True:

```

sage: a = Polyomino([(0,0,0), (0,0,1), (1,0,0)])
sage: b = Polyomino([(0,0,0), (1,0,0), (0,1,0)])
sage: T = TilingSolver([a,b], box=(2,1,3))
sage: T.rows_for_piece(0)
[[0, 2, 3, 5],
 [0, 3, 4, 6],
 [0, 2, 3, 6],
 [0, 3, 4, 7],
 [0, 2, 5, 6],
 [0, 3, 6, 7],
 [0, 3, 5, 6],
 [0, 4, 6, 7]]

```

(continues on next page)

(continued from previous page)

```

sage: T.rows_for_piece(0, mod_box_isometries=True)
[[0, 2, 3, 5], [0, 3, 4, 6]]
sage: T.rows_for_piece(1, mod_box_isometries=True)
[[1, 2, 3, 5], [1, 3, 4, 6]]

```

solve(*partial=None*)

Return an iterator of list of polyominoes that are an exact cover of the box.

INPUT:

- *partial* - string (optional, default: None), whether to include partial (incomplete) solutions. It can be one of the following:
 - None - include only complete solution
 - 'common_prefix' - common prefix between two consecutive solutions
 - 'incremental' - one piece change at a time

OUTPUT:

iterator of list of polyominoes

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray
Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 2), (0, 0, 3), (0, 0, 4)], Color: gray
Polyomino: [(0, 0, 5)], Color: gray

```

Including the partial solutions:

```

sage: it = T.solve(partial='common_prefix')
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2)], Color: gray
Polyomino: [(0, 0, 3), (0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: gray
Polyomino: [(0, 0, 1), (0, 0, 2), (0, 0, 3)], Color: gray

```

(continues on next page)

(continued from previous page)

```

Polyomino: [(0, 0, 4), (0, 0, 5)], Color: gray
sage: for p in next(it): p
sage: for p in next(it): p
Polyomino: [(0, 0, 0), (0, 0, 1)], Color: gray
Polyomino: [(0, 0, 2), (0, 0, 3), (0, 0, 4)], Color: gray
Polyomino: [(0, 0, 5)], Color: gray

```

Colors are preserved when the polyomino can be reused:

```

sage: p = Polyomino([(0,0,0)], color='yellow')
sage: q = Polyomino([(0,0,0), (0,0,1)], color='yellow')
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)], color='yellow')
sage: T = TilingSolver([p,q,r], box=(1,1,6), reusable=True)
sage: it = T.solve()
sage: for p in next(it): p
Polyomino: [(0, 0, 0)], Color: yellow
Polyomino: [(0, 0, 1)], Color: yellow
Polyomino: [(0, 0, 2)], Color: yellow
Polyomino: [(0, 0, 3)], Color: yellow
Polyomino: [(0, 0, 4)], Color: yellow
Polyomino: [(0, 0, 5)], Color: yellow

```

space()

Return an iterator over all the non negative integer coordinates contained in the space to tile.

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: list(T.space())
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 0, 3), (0, 0, 4), (0, 0, 5)]

```

starting_rows()

Return the starting rows for each piece.

EXAMPLES:

```

sage: from sage.combinat.tiling import TilingSolver, Polyomino
sage: p = Polyomino([(0,0,0)])
sage: q = Polyomino([(0,0,0), (0,0,1)])
sage: r = Polyomino([(0,0,0), (0,0,1), (0,0,2)])
sage: T = TilingSolver([p,q,r], box=(1,1,6))
sage: T.starting_rows()
[0, 6, 11, 15]

```

`sage.combinat.tiling.ncube_isometry_group(n, orientation_preserving=True)`

Return the isometry group of the *n*-cube as a list of matrices.

INPUT:

- *n* – positive integer, dimension of the space
- *orientation_preserving* – bool (optional, default: True), whether the orientation is preserved

OUTPUT:

list of matrices

EXAMPLES:

```
sage: from sage.combinat.tiling import ncube_isometry_group
sage: ncube_isometry_group(2)
[
[1 0] [ 0 1] [-1 0] [ 0 -1]
[0 1], [-1 0], [ 0 -1], [ 1 0]
]
sage: ncube_isometry_group(2, orientation_preserving=False)
[
[1 0] [ 0 -1] [ 1 0] [ 0 1] [0 1] [-1 0] [ 0 -1] [-1 0]
[0 1], [-1 0], [ 0 -1], [-1 0], [1 0], [ 0 -1], [ 1 0], [ 0 1]
]
]
```

There are 24 orientation preserving isometries of the 3-cube:

```
sage: ncube_isometry_group(3)
[
[1 0 0] [ 1 0 0] [ 1 0 0] [ 0 1 0] [0 1 0] [ 0 0 1]
[0 1 0] [ 0 0 1] [ 0 0 -1] [-1 0 0] [0 0 1] [ 0 -1 0]
[0 0 1], [ 0 -1 0], [ 0 1 0], [ 0 0 1], [1 0 0], [ 1 0 0],

[-1 0 0] [ 0 -1 0] [-1 0 0] [-1 0 0] [ 0 -1 0] [ 0 0 -1]
[ 0 -1 0] [ 0 0 -1] [ 0 0 -1] [ 0 1 0] [ 0 0 1] [ 1 0 0]
[ 0 0 1], [ 1 0 0], [ 0 -1 0], [ 0 0 -1], [-1 0 0], [ 0 -1 0],

[ 0 1 0] [ 0 0 1] [0 0 1] [ 0 -1 0] [ 0 0 -1] [-1 0 0]
[ 1 0 0] [ 0 1 0] [1 0 0] [ 1 0 0] [ 0 1 0] [ 0 0 1]
[ 0 0 -1], [-1 0 0], [0 1 0], [ 0 0 1], [ 1 0 0], [ 0 1 0],

[ 0 -1 0] [ 0 0 -1] [ 0 0 1] [ 1 0 0] [ 0 0 -1] [ 0 1 0]
[-1 0 0] [-1 0 0] [-1 0 0] [ 0 -1 0] [ 0 -1 0] [ 0 0 -1]
[ 0 0 -1], [ 0 1 0], [ 0 -1 0], [ 0 0 -1], [-1 0 0], [-1 0 0]
]
]
```

`sage.combinat.tiling.ncube_isometry_group_cosets(n, orientation_preserving=True)`

Return the quotient of the isometry group of the *n*-cube by the the isometry group of the rectangular parallelepiped.

INPUT:

- *n* – positive integer, dimension of the space
- *orientation_preserving* – bool (optional, default: True), whether the orientation is preserved

OUTPUT:

list of cosets, each coset being a sorted list of matrices

EXAMPLES:

```
sage: from sage.combinat.tiling import ncube_isometry_group_cosets
sage: sorted(ncube_isometry_group_cosets(2))
[[
```

(continues on next page)

(continued from previous page)

```

[-1 0] [1 0]
[ 0 -1], [0 1]
], [
[ 0 -1] [ 0 1]
[ 1 0], [-1 0]
]]
sage: sorted(ncube_isometry_group_cosets(2, False))
[[
[-1 0] [-1 0] [ 1 0] [1 0]
[ 0 -1], [ 0 1], [ 0 -1], [0 1]
], [
[ 0 -1] [ 0 -1] [ 0 1] [0 1]
[-1 0], [ 1 0], [-1 0], [1 0]
]]

```

```

sage: sorted(ncube_isometry_group_cosets(3))
[[
[-1 0 0] [-1 0 0] [ 1 0 0] [1 0 0]
[ 0 -1 0] [ 0 1 0] [ 0 -1 0] [0 1 0]
[ 0 0 1], [ 0 0 -1], [ 0 0 -1], [0 0 1]
], [
[-1 0 0] [-1 0 0] [ 1 0 0] [ 1 0 0]
[ 0 0 -1] [ 0 0 1] [ 0 0 -1] [ 0 0 1]
[ 0 -1 0], [ 0 1 0], [ 0 1 0], [ 0 -1 0]
], [
[ 0 -1 0] [ 0 -1 0] [ 0 1 0] [ 0 1 0]
[-1 0 0] [ 1 0 0] [-1 0 0] [ 1 0 0]
[ 0 0 -1], [ 0 0 1], [ 0 0 1], [ 0 0 -1]
], [
[ 0 -1 0] [ 0 -1 0] [ 0 1 0] [0 1 0]
[ 0 0 -1] [ 0 0 1] [ 0 0 -1] [0 0 1]
[ 1 0 0], [-1 0 0], [-1 0 0], [1 0 0]
], [
[ 0 0 -1] [ 0 0 -1] [ 0 0 1] [0 0 1]
[-1 0 0] [ 1 0 0] [-1 0 0] [1 0 0]
[ 0 1 0], [ 0 -1 0], [ 0 -1 0], [0 1 0]
], [
[ 0 0 -1] [ 0 0 -1] [ 0 0 1] [ 0 0 1]
[ 0 -1 0] [ 0 1 0] [ 0 -1 0] [ 0 1 0]
[-1 0 0], [ 1 0 0], [ 1 0 0], [-1 0 0]
]]

```

5.1.347 Transitive ideal closure tool

`sage.combinat.tools.transitive_ideal(f, x)`

Return a list of all elements reachable from x in the abstract reduction system whose reduction relation is given by the function f .

In more elementary terms:

If S is a set, and f is a function sending every element of S to a list of elements of S , then we can define a digraph on the vertex set S by drawing an edge from s to t for every $s \in S$ and every $t \in f(s)$.

If $x \in S$, then an element $y \in S$ is said to be reachable from x if there is a path $x \rightarrow y$ in this graph.

Given f and x , this method computes the list of all elements of S reachable from x .

Note that if there are infinitely many such elements, then this method will never halt.

For more powerful versions, see `sage.combinat.backtrack`

EXAMPLES:

```
sage: f = lambda x: [x-1] if x > 0 else []
sage: sage.combinat.tools.transitive_ideal(f, 10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

5.1.348 Tuples

`class sage.combinat.tuple.Tuples(S, k)`

Bases: `sage.structure.parent.Parent`, `sage.structure.unique_representation.UniqueRepresentation`

Return the enumerated set of ordered tuples of S of length k .

An ordered tuple of length k of set is an ordered selection with repetition and is represented by a list of length k containing elements of set.

EXAMPLES:

```
sage: S = [1,2]
sage: Tuples(S,3).list()
[[1, 1, 1], [2, 1, 1], [1, 2, 1], [2, 2, 1], [1, 1, 2],
 [2, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: mset = ["s","t","e","i","n"]
sage: Tuples(mset,2).list()
[['s', 's'], ['t', 's'], ['e', 's'], ['i', 's'], ['n', 's'],
 ['s', 't'], ['t', 't'], ['e', 't'], ['i', 't'], ['n', 't'],
 ['s', 'e'], ['t', 'e'], ['e', 'e'], ['i', 'e'], ['n', 'e'],
 ['s', 'i'], ['t', 'i'], ['e', 'i'], ['i', 'i'], ['n', 'i'],
 ['s', 'n'], ['t', 'n'], ['e', 'n'], ['i', 'n'], ['n', 'n']]
```

```
sage: K.<a> = GF(4, 'a')
sage: mset = [x for x in K if x != 0]
sage: Tuples(mset,2).list()
[[a, a], [a + 1, a], [1, a], [a, a + 1], [a + 1, a + 1], [1, a + 1],
 [a, 1], [a + 1, 1], [1, 1]]
```

cardinality()

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
sage: S = [1,1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
```

sage.combinat.tuple.Tuples_skalias of *sage.combinat.tuple.Tuples***class sage.combinat.tuple.UnorderedTuples(S, k)**Bases: *sage.structure.parent.Parent*, *sage.structure.unique_representation.UniqueRepresentation*

Return the enumerated set of unordered tuples of S of length k.

An unordered tuple of length k of set is a unordered selection with repetitions of set and is represented by a sorted list of length k containing elements from set.

EXAMPLES:

```
sage: S = [1,2]
sage: UnorderedTuples(S,3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: UnorderedTuples(["a","b","c"],2).list()
[['a', 'a'], ['a', 'b'], ['a', 'c'], ['b', 'b'], ['b', 'c'],
 ['c', 'c']]
```

cardinality()

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: UnorderedTuples(S,2).cardinality()
15
```

list()

EXAMPLES:

```
sage: S = [1,2]
sage: UnorderedTuples(S,3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: UnorderedTuples(["a","b","c"],2).list()
[['a', 'a'], ['a', 'b'], ['a', 'c'], ['b', 'b'], ['b', 'c'],
 ['c', 'c']]
```

5.1.349 Introduction to combinatorics in Sage

This thematic tutorial is a translation by Hugh Thomas of the combinatorics chapter written by Nicolas M. Thiéry in the book “Calcul Mathématique avec Sage” [CMS2012]. It covers mainly the treatment in Sage of the following combinatorial problems: enumeration (how many elements are there in a set S ?), listing (generate all the elements of S , or iterate through them), and random selection (choosing an element at random from a set S according to a given distribution, for example the uniform distribution). These questions arise naturally in the calculation of probabilities (what is the probability in poker of obtaining a straight or a four-of-a-kind of aces?), in statistical physics, and also in computer algebra (the number of elements in a finite field), or in the analysis of algorithms. Combinatorics covers a much wider domain (partial orders, representation theory, ...) for which we only give a few pointers towards the possibilities offered by Sage.

Todo: Add link to some thematic tutorial on graphs

A characteristic of computational combinatorics is the profusion of types of objects and sets that one wants to manipulate. It would be impossible to describe them all or, a fortiori, to implement them all. After some *Initial examples*, this chapter illustrates the underlying method: supplying the basic building blocks to describe common combinatorial sets *Common enumerated sets*, tools for combining them to construct new examples *Constructions*, and generic algorithms for solving uniformly a large class of problems *Generic algorithms*.

This is a domain in which Sage has much more extensive capabilities than most computer algebra systems, and it is rapidly expanding; at the same time, it is still quite new, and has many unnecessary limitations and incoherences.

Initial examples

Poker and probability

We begin by solving a classic problem: enumerating certain combinations of cards in the game of poker, in order to deduce their probability.

A card in a poker deck is characterized by a suit (hearts, diamonds, spades, or clubs) and a value (2, 3, ..., 10, jack, queen, king, ace). The game is played with a full deck, which consists of the Cartesian product of the set of suits and the set of values:

$$\text{Cards} = \text{Suits} \times \text{Values} = \{(s, v) \mid s \in \text{Suits et } v \in \text{Values}\}.$$

We construct these examples in Sage:

```
sage: Suits = Set(["Hearts", "Diamonds", "Spades", "Clubs"])
sage: Values = Set([2, 3, 4, 5, 6, 7, 8, 9, 10,
.....:             "Jack", "Queen", "King", "Ace"])
sage: Cards = cartesian_product([Values, Suits])
```

There are 4 suits and 13 possible values, and therefore $4 \times 13 = 52$ cards in the poker deck:

```
sage: Suits.cardinality()
4
sage: Values.cardinality()
13
sage: Cards.cardinality()
52
```

Draw a card at random:

```
sage: Cards.random_element() # random
(6, 'Clubs')
```

Now we can define a set of cards:

```
sage: Set([Cards.random_element(), Cards.random_element()]) # random
{(2, 'Hearts'), (4, 'Spades')}
```

This problem should eventually disappear: it is planned to change the implementation of Cartesian products so that their elements are immutable by default.

Returning to our main topic, we will be considering a simplified version of poker, in which each player directly draws five cards, which form his *hand*. The cards are all distinct and the order in which they are drawn is irrelevant; a hand is therefore a subset of size 5 of the set of cards. To draw a hand at random, we first construct the set of all possible hands, and then we ask for a randomly chosen element:

```
sage: Hands = Subsets(Cards, 5)
sage: Hands.random_element() # random
{(4, 'Hearts', 4), (9, 'Diamonds'), (8, 'Spades'),
 (9, 'Clubs'), (7, 'Hearts')}
```

The total number of hands is given by the number of subsets of size 5 of a set of size 52, which is given by the binomial coefficient $\binom{52}{5}$:

```
sage: binomial(52, 5)
2598960
```

One can also ignore the method of calculation, and simply ask for the size of the set of hands:

```
sage: Hands.cardinality()
2598960
```

The strength of a poker hand depends on the particular combination of cards present. One such combination is the *flush*; this is a hand all of whose cards have the same suit. (In principle, straight flushes should be excluded; this will be the goal of an exercise given below.) Such a hand is therefore characterized by the choice of five values from among the thirteen possibilities, and the choice of one of four suits. We will construct the set of all flushes, so as to determine how many there are:

```
sage: Flushes = cartesian_product([Subsets(Values, 5), Suits])
sage: Flushes.cardinality()
5148
```

The probability of obtaining a flush when drawing a hand at random is therefore:

```
sage: Flushes.cardinality() / Hands.cardinality()
33/16660
```

or about two in a thousand:

```
sage: 1000.0 * Flushes.cardinality() / Hands.cardinality()
1.98079231692677
```

We will now attempt a little numerical simulation. The following function tests whether a given hand is a flush or not:

```
sage: def is_flush(hand):
.....:     return len(set(suit for (val, suit) in hand)) == 1
```

We now draw 10000 hands at random, and count the number of flushes obtained (this takes about 10 seconds):

```
sage: n = 10000
sage: nflush = 0
sage: for i in range(n):                               # long time
.....:     hand = Hands.random_element()
.....:     if is_flush(hand):
.....:         nflush += 1
sage: n, nflush                                       # random
(10000, 18)
```

Exercises

A hand containing four cards of the same value is called a *four of a kind*. Construct the set of four of a kind hands (Hint: use `Arrangements` to choose a pair of distinct values at random, then choose a suit for the first value). Calculate the number of four of a kind hand, list them, and then determine the probability of obtaining a four of a kind when drawing a hand at random.

A hand all of whose cards have the same suit, and whose values are consecutive, is called a *straight flush* rather than a *flush*. Count the number of straight flushes, and then deduce the correct probability of obtaining a flush when drawing a hand at random.

Calculate the probability of each of the poker hands (see [Wikipedia article Poker_hands](#)), and compare them with the results of simulations.

Enumeration of trees using generating functions

In this section, we discuss the example of complete binary trees, and illustrate in this context many techniques of enumeration in which formal power series play a natural role. These techniques are quite general, and can be applied whenever the combinatorial objects in question admit a recursive definition (grammar) (see *Species, decomposable combinatorial classes* for an automated treatment). The goal is not a formal presentation of these methods; the calculations are rigorous, but most of the justifications will be skipped.

A *complete binary tree* is either a leaf L , or a node to which two complete binary trees are attached (see *Figure: The five complete binary trees with four leaves*).

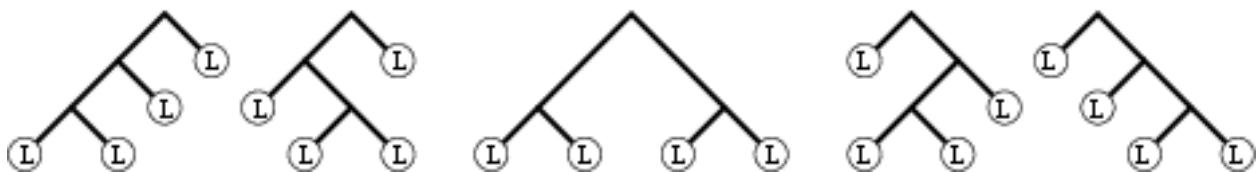

Fig. 1: Figure: The five complete binary trees with four leaves

Exercise: enumeration of binary trees

Find by hand all the complete binary trees with $n = 1, 2, 3, 4, 5$ leaves (see *Exercise: complete binary tree iterator* to find them using Sage).

Our goal is to determine the number c_n of complete binary trees with n leaves (in this section, except when explicitly stated otherwise, “trees” always means complete binary trees). This is a typical situation in which one is not only interested in a single set, but in a family of sets, typically parameterized by $n \in \mathbb{N}$.

According to the solution of *Exercise: enumeration of binary trees*, the first terms are given by $c_1, \dots, c_5 = 1, 1, 2, 5, 14$. The simple fact of knowing these few numbers is already very valuable. In fact, this permits research in a gold mine of information: the [Online Encyclopedia of Integer Sequences](#), commonly called “Sloane”, the name of its principal author, which contains more than 190000 sequences of integers:

```
sage: oeis([1,1,2,5,14]) # optional -- internet
0: A000108: Catalan numbers: ...
1: ...
2: ...
```

The result suggests that the trees are counted by one of the most famous sequences, the Catalan numbers. Looking through the references supplied by the Encyclopedia, we see that this is really the case: the few numbers above form a digital fingerprint of our objects, which enable us to find, in a few seconds, a precise result from within an abundant literature.

Our next goal is to recover this result using Sage. Let C_n be the set of trees with n leaves, so that $c_n = |C_n|$; by convention, we will define $C_0 = \emptyset$ and $c_0 = 0$. The set of all trees is then the disjoint union of the sets C_n :

$$C = \bigsqcup_{n \in \mathbb{N}} C_n.$$

Having named the set C of all trees, we can translate the recursive definition of trees into a set-theoretic equation:

$$C \approx \{L\} \uplus C \times C.$$

In words: a tree t (which is by definition in C) is either a leaf (so in $\{L\}$) or a node to which two trees t_1 and t_2 have been attached, and which we can therefore identify with the pair (t_1, t_2) (in the Cartesian product $C \times C$).

The founding idea of algebraic combinatorics, introduced by Euler in a letter to Goldbach of 1751 to treat a similar problem, is to manipulate all the numbers c_n simultaneously, by encoding them as coefficients in a formal power series, called the *generating function* of the c_n 's:

$$C(z) = \sum_{n \in \mathbb{N}} c_n z^n,$$

where z is a formal variable (which means that we do not have to worry about questions of convergence). The beauty of this idea is that set-theoretic operations ($A \uplus B$, $A \times B$) translate naturally into algebraic operations on the corresponding series ($A(z) + B(z)$, $A(z) \cdot B(z)$), in such a way that the set-theoretic equation satisfied by C can be translated directly into an algebraic equation satisfied by $C(z)$:

$$C(z) = z + C(z) \cdot C(z).$$

Now we can solve this equation with Sage. In order to do so, we introduce two variables, C and z , and we define the equation:

```
sage: C, z = var('C,z')
sage: sys = [ C == z + C*C ]
```

There are two solutions, which happen to have closed forms:

```
sage: sol = solve(sys, C, solution_dict=True); sol
[ {C: -1/2*sqrt(-4*z + 1) + 1/2}, {C: 1/2*sqrt(-4*z + 1) + 1/2} ]
sage: s0 = sol[0][C]; s1 = sol[1][C]
```

and whose Taylor series begin as follows:

```
sage: s0.series(z, 6)
1*z + 1*z^2 + 2*z^3 + 5*z^4 + 14*z^5 + Order(z^6)
sage: s1.series(z, 6)
1 + (-1)*z + (-1)*z^2 + (-2)*z^3 + (-5)*z^4 + (-14)*z^5
+ Order(z^6)
```

The second solution is clearly aberrant, while the first one gives the expected coefficients. Therefore, we set:

```
sage: C = s0
```

We can now calculate the next terms:

```
sage: C.series(z, 11)
1*z + 1*z^2 + 2*z^3 + 5*z^4 + 14*z^5 + 42*z^6 +
132*z^7 + 429*z^8 + 1430*z^9 + 4862*z^10 + Order(z^11)
```

or calculate, more or less instantaneously, the 100-th coefficient:

```
sage: C.series(z, 101).coefficient(z,100)
227508830794229349661819540395688853956041682601541047340
```

It is unfortunate to have to recalculate everything if at some point we wanted the 101-st coefficient. Lazy power series (see [sage.combinat.species.series](#)) come into their own here, in that one can define them from a system of equations without solving it, and, in particular, without needing a closed form for the answer. We begin by defining the ring of lazy power series:

```
sage: L.<z> = LazyPowerSeriesRing(QQ)
```

Then we create a “free” power series, which we name, and which we then define by a recursive equation:

```
sage: C = L()
sage: C._name = 'C'
sage: C.define( z + C * C )
```

```
sage: [C.coefficient(i) for i in range(11)]
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

At any point, one can ask for any coefficient without having to redefine C :

```
sage: C.coefficient(100)
227508830794229349661819540395688853956041682601541047340
sage: C.coefficient(200)
1290131580644291140012229076696766751343495305527288824998108515989014190133483190455345808508477355282
```

We now return to the closed form of $C(z)$:

```
sage: z = var('z')
sage: C = s0; C
-1/2*sqrt(-4*z + 1) + 1/2
```

The n -th coefficient in the Taylor series for $C(z)$ being given by $\frac{1}{n!}C(z)^{(n)}(0)$, we look at the successive derivatives $C(z)^{(n)}(z)$:

```
sage: derivative(C, z, 1)
1/sqrt(-4*z + 1)
sage: derivative(C, z, 2)
2/(-4*z + 1)^(3/2)
sage: derivative(C, z, 3)
12/(-4*z + 1)^(5/2)
```

This suggests the existence of a simple explicit formula, which we will now seek. The following small function returns $d_n = n! c_n$:

```
sage: def d(n): return derivative(s0, n).subs(z=0)
```

Taking successive quotients:

```
sage: [ (d(n+1) / d(n)) for n in range(1,17) ]
[2, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62]
```

we observe that d_n satisfies the recurrence relation $d_{n+1} = (4n - 2)d_n$, from which we deduce that c_n satisfies the recurrence relation $c_{n+1} = \frac{(4n-2)}{n+1}c_n$. Simplifying, we find that c_n is the $(n - 1)$ -th Catalan number:

$$c_n = \text{Catalan}(n - 1) = \frac{1}{n} \binom{2(n - 1)}{n - 1}.$$

We check this:

```
sage: n = var('n')
sage: c = 1/n*binomial(2*(n-1),n-1)
sage: [c.subs(n=k) for k in range(1, 11)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
sage: [catalan_number(k-1) for k in range(1, 11)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

We can now calculate coefficients much further; here we calculate c_{100000} which has more than 60000 digits:

```
sage: cc = c(n = 100000)
```

This takes a couple of seconds:

```
sage: %time cc = c(100000) # not tested
CPU times: user 2.34 s, sys: 0.00 s, total: 2.34 s
Wall time: 2.34 s
sage: ZZ(cc).ndigits()
60198
```

The methods which we have used generalize to all recursively defined objects: the system of set-theoretic equations can be translated into a system of equations on the generating function, which enables the recursive calculation of its coefficients. If the set-theoretic equations are simple enough (for example, if they only involve Cartesian products and disjoint unions), the equation for $C(z)$ is algebraic. This equation has, in general, no closed-form solution. However, using *confinement*, one can deduce a *linear* differential equation which $C(z)$ satisfies. This differential equation, in turn, can be translated into a recurrence relation of fixed length on its coefficients c_n . In this case, the series is called *D-finite*. After the initial calculation of this recurrence relation, the calculation of coefficients is very fast. All these steps are purely algorithmic, and it is planned to port into Sage the implementations which exist in Maple (the `gfun` and `combstruct` packages) or MuPAD-Combinat (the `decomposableObjects` library).

For the moment, we illustrate this general procedure in the case of complete binary trees. The generating function $C(z)$ is a solution to an algebraic equation $P(z, C(z)) = 0$, where $P = P(x, y)$ is a polynomial with coefficients in \mathbf{Q} . In the present case, $P = y^2 - y + x$. We formally differentiate this equation with respect to z :

```
sage: x, y, z = var('x, y, z')
sage: P = function('P')(x, y)
sage: C = function('C')(z)
sage: equation = P(x=z, y=C) == 0
sage: diff(equation, z)
diff(C(z), z)*D[1](P)(z, C(z)) + D[0](P)(z, C(z)) == 0
```

or, in a more readable format,

$$\frac{dC(z)}{dz} \frac{\partial P}{\partial y}(z, C(z)) + \frac{\partial P}{\partial x}(z, C(z)) = 0$$

From this we deduce:

$$\frac{dC(z)}{dz} = -\frac{\frac{\partial P}{\partial x}}{\frac{\partial P}{\partial y}}(z, C(z)).$$

In the case of complete binary trees, this gives:

```
sage: P = y^2 - y + x
sage: Px = diff(P, x); Py = diff(P, y)
sage: - Px / Py
-1/(2*y - 1)
```

Recall that $P(z, C(z)) = 0$. Thus, we can calculate this fraction mod P and, in this way, express the derivative of $C(z)$ as a *polynomial in $C(z)$ with coefficients in $\mathbf{Q}(z)$* . In order to achieve this, we construct the quotient ring $R = \mathbf{Q}(x)[y]/(P)$:

```
sage: Qx = QQ['x'].fraction_field()
sage: Qxy = Qx['y']
sage: R = Qxy.quo(P); R
Univariate Quotient Polynomial Ring in ybar
over Fraction Field of Univariate Polynomial Ring in x
over Rational Field with modulus y^2 - y + x
```

Note: $ybar$ is the name of the variable y in the quotient ring.

Todo: add link to some tutorial on quotient rings

We continue the calculation of this fraction in R :

```
sage: fraction = - R(Px) / R(Py); fraction
(1/2/(x - 1/4))*ybar - 1/4/(x - 1/4)
```

Note: The following variant does not work yet:

```
sage: fraction = R(- Px / Py ); fraction # todo: not implemented
Traceback (most recent call last):
...
TypeError: denominator must be a unit
```

We lift the result to $\mathbf{Q}(x)[y]$ and then substitute z and $C(z)$ to obtain an expression for $\frac{d}{dz}C(z)$:

```
sage: fraction = fraction.lift(); fraction
(1/2/(x - 1/4))*y - 1/4/(x - 1/4)
sage: fraction(x=z, y=C)
2*C(z)/(4*z - 1) - 1/(4*z - 1)
```

or, more legibly,

$$\frac{\partial C(z)}{\partial z} = \frac{1}{1-4z} - \frac{2}{1-4z}C(z).$$

In this simple case, we can directly deduce from this expression a linear differential equation with coefficients in $\mathbf{Q}[z]$:

```
sage: equadiff = diff(C,z) == fraction(x=z, y=C)
sage: equadiff
diff(C(z), z) == 2*C(z)/(4*z - 1) - 1/(4*z - 1)
sage: equadiff = equadiff.simplify_rational()
sage: equadiff = equadiff * equadiff.rhs().denominator()
sage: equadiff = equadiff - equadiff.rhs()
sage: equadiff
(4*z - 1)*diff(C(z), z) - 2*C(z) + 1 == 0
```

or, more legibly,

$$(1-4z)\frac{\partial C(z)}{\partial z} + 2C(z) - 1 = 0.$$

It is trivial to verify this equation on the closed form:

```
sage: Cf = sage.symbolic.function_factory.function('C')
sage: equadiff.substitute_function(Cf, s0.function(z))
(4*z - 1)/sqrt(-4*z + 1) + sqrt(-4*z + 1) == 0
sage: bool(equadiff.substitute_function(Cf, s0.function(z)))
True
```

In the general case, one continues to calculate successive derivatives of $C(z)$. These derivatives are *confined* in the quotient ring $\mathbf{Q}(z)[C]/(P)$ which is of finite dimension $\deg P$ over $\mathbf{Q}(z)$. Therefore, one will eventually find a linear relation among the first $\deg P$ derivatives of $C(z)$. Putting it over a single denominator, we obtain a linear differential equation of degree $\leq \deg P$ with coefficients in $\mathbf{Q}[z]$. By extracting the coefficient of z^n in the differential equation, we obtain the desired recurrence relation on the coefficients; in this case we recover the relation we had already found, based on the closed form:

$$c_{n+1} = \frac{(4n-2)}{n+1}c_n$$

After fixing the correct initial conditions, it becomes possible to calculate the coefficients of $C(z)$ recursively:

```
sage: def C(n): return 1 if n <= 1 else (4*n-6)/n * C(n-1)
sage: [ C(i) for i in range(10) ]
[1, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
```

If n is too large for the explicit calculation of c_n , a sequence asymptotically equivalent to the sequence of coefficients c_n may be sought. Here again, there are generic techniques. The central tool is complex analysis, specifically, the study of the generating function around its singularities. In the present instance, the singularity is at $z_0 = 1/4$ and one would obtain $c_n \sim \frac{4^n}{n^{3/2}\sqrt{\pi}}$.

Summary

We see here a general phenomenon of computer algebra: the best *data structure* to describe a complicated mathematical object (a real number, a sequence, a formal power series, a function, a set) is often an equation defining the object (or a system of equations, typically with some initial conditions). Attempting to find a closed-form solution to this equation is not necessarily of interest: on the one hand, such a closed form rarely exists (e.g., the problem of solving a polynomial by radicals), and on the other hand, the equation, in itself, contains all the necessary information to calculate algorithmically the properties of the object under consideration (e.g., a numerical approximation, the initial terms or elements, an asymptotic equivalent), or to calculate with the object itself (e.g., performing arithmetic on power series). Therefore, instead of solving the equation, we look for the equation describing the object which is best suited to the problem we want to solve.

As we saw in our example, confinement (for example, in a finite dimensional vector space) is a fundamental tool for studying such equations. This notion of confinement is widely applicable in elimination techniques (linear algebra, Gröbner bases, and their algebro-differential generalizations). The same tool is central in algorithms for automatic summation and automatic verification of identities (Gosper's algorithm, Zeilberger's algorithm, and their generalizations; see also *Exercise: alternating sign matrices*).

Todo: add link to some tutorial on summation

All these techniques and their many generalizations are at the heart of very active topics of research: automatic combinatorics and analytic combinatorics, with major applications in the analysis of algorithms. It is likely, and desirable, that they will be progressively implemented in Sage.

Common enumerated sets

First example: the subsets of a set

Fix a set E of size n and consider the subsets of E of size k . We know that these subsets are counted by the binomial coefficients $\binom{n}{k}$. We can therefore calculate the number of subsets of size $k = 2$ of $E = \{1, 2, 3, 4\}$ with the function `binomial`:

```
sage: binomial(4, 2)
6
```

Alternatively, we can *construct* the set $\mathcal{P}_2(E)$ of all the subsets of size 2 of E , then ask its cardinality:

```
sage: S = Subsets([1,2,3,4], 2)
sage: S.cardinality()
6
```

Once S has been constructed, we can also obtain the list of its elements:

```
sage: S.list()
[ $\{1, 2\}$ ,  $\{1, 3\}$ ,  $\{1, 4\}$ ,  $\{2, 3\}$ ,  $\{2, 4\}$ ,  $\{3, 4\}$ ]
```

or select an element at random:

```
sage: S.random_element() # random
 $\{1, 4\}$ 
```

More precisely, the object S models the set $\mathcal{P}_2(E)$ equipped with a fixed order (here, lexicographic order). It is therefore possible to ask for its 5-th element, keeping in mind that, as with Python lists, the first element is numbered zero:

```
sage: S.unrank(4)
{2, 4}
```

As a shortcut, in this setting, one can also use the notation:

```
sage: S[4]
{2, 4}
```

but this should be used with care because some sets have a natural indexing other than by $(0, 1, \dots)$.

Conversely, one can calculate the position of an object in this order:

```
sage: s = S([2,4]); s
{2, 4}
sage: S.rank(s)
4
```

Note that S is *not* the list of its elements. One can, for example, model the set $\mathcal{P}(\mathcal{P}(\mathcal{P}(E)))$ and calculate its cardinality ($2^{2^{2^4}}$):

```
sage: E = Set([1,2,3,4])
sage: S = Subsets(Subsets(Subsets(E))); S
Subsets of Subsets of Subsets of {1, 2, 3, 4}
sage: n = S.cardinality(); n
2003529930406846464979072351560255750447825475569751419265016973...
```

which is roughly $2 \cdot 10^{19728}$:

```
sage: n.ndigits()
19729
```

or ask for its 237102124-th element:

```
sage: S.unrank(237102123) # random print output
{{{2, 4}, {1, 4}, {}}, {1, 3, 4}, {1, 2, 4}, {4}, {2, 3}, {1, 3}, {2}},
{{1, 3}, {2, 4}, {1, 2, 4}, {}, {3, 4}}}
```

It would be physically impossible to construct explicitly all the elements of S , as there are many more of them than there are particles in the universe (estimated at 10^{82}).

Remark: it would be natural in Python to use `len(S)` to ask for the cardinality of S . This is not possible because Python requires that the result of `len` be an integer of type `int`; this could cause overflows, and would not permit the return of `{Infinity}` for infinite sets:

```
sage: len(S)
Traceback (most recent call last):
...
OverflowError: cannot fit 'int' into an index-sized integer
```

Partitions of integers

We now consider another classic problem: given a positive integer n , in how many ways can it be written in the form of a sum $n = i_1 + i_2 + \dots + i_\ell$, where i_1, \dots, i_ℓ are positive integers? There are two cases to distinguish:

- the order of the elements in the sum is not important, in which case we call (i_1, \dots, i_ℓ) a *partition* of n ;
- the order of the elements in the sum is important, in which case we call (i_1, \dots, i_ℓ) a *composition* of n .

We will begin with the partitions of $n = 5$; as before, we begin by constructing the set of these partitions:

```
sage: P5 = Partitions(5); P5
Partitions of the integer 5
```

then we ask for its cardinality:

```
sage: P5.cardinality()
7
```

We look at these 7 partitions; the order being irrelevant, the entries are ordered, by convention, in decreasing order.

```
sage: P5.list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1],
 [1, 1, 1, 1, 1]]
```

The calculation of the number of partitions uses the Rademacher formula ([Wikipedia article Partition_\(number_theory\)](#)), implemented in C and highly optimized, which makes it very fast:

```
sage: Partitions(100000).cardinality()
2749351056977569651267751632098635268817342931598005475820312598430214732811496417305505074166073662159
```

Partitions of integers are combinatorial objects naturally equipped with many operations. They are therefore returned as objects that are richer than simple lists:

```
sage: P7 = Partitions(7)
sage: p = P7.unrank(5); p
[4, 2, 1]
sage: type(p)
<class 'sage.combinat.partition.Partitions_n_with_category.element_class'>
```

For example, they can be represented graphically by a Ferrers diagram:

```
sage: print(p.ferrers_diagram())
****
**
*
```

We leave it to the user to explore by introspection the available operations.

Note that we can also construct a partition directly by:

```
sage: Partition([4,2,1])
[4, 2, 1]
```

or:

```
sage: P7([4,2,1])
[4, 2, 1]
```

If one wants to restrict the possible values of the parts i_1, \dots, i_ℓ of the partition as, for example, when giving change, one can use `WeightedIntegerVectors`. For example, the following calculation:

```
sage: WeightedIntegerVectors(8, [2,3,5]).list()
[[0, 1, 1], [1, 2, 0], [4, 0, 0]]
```

shows that to make 8 dollars using 2, 3, and 5 dollar bills, one can use a 3 and a 5 dollar bill, or a 2 and two 3 dollar bills, or four 2 dollar bills.

Compositions of integers are manipulated the same way:

```
sage: C5 = Compositions(5); C5
Compositions of 5
sage: C5.cardinality()
16
sage: C5.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 2, 1], [1, 1, 3],
 [1, 2, 1, 1], [1, 2, 2], [1, 3, 1], [1, 4], [2, 1, 1, 1],
 [2, 1, 2], [2, 2, 1], [2, 3], [3, 1, 1], [3, 2], [4, 1], [5]]
```

The number 16 above seems significant and suggests the existence of a formula. We look at the number of compositions of n ranging from 0 to 9:

```
sage: [ Compositions(n).cardinality() for n in range(10) ]
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256]
```

Similarly, if we consider the number of compositions of 5 by length, we find a line of Pascal's triangle:

```
sage: x = var('x')
sage: sum( x^len(c) for c in C5 )
x^5 + 4*x^4 + 6*x^3 + 4*x^2 + x
```

The above example uses a functionality which we have not seen yet: `C5` being iterable, it can be used like a list in a `for` loop or a comprehension (*Set comprehension and iterators*).

Prove the formulas suggested by the above examples for the number of compositions of n and the number of compositions of n of length k ; investigate by introspection whether Sage uses these formulas for calculating cardinalities.

Some other finite enumerated sets

Essentially, the principle is the same for all the finite sets with which one wants to do combinatorics in Sage; begin by constructing an object which models this set, and then supply appropriate methods, following a uniform interface¹. We now give a few more typical examples.

Intervals of integers:

```
sage: C = IntegerRange(3, 21, 2); C
{3, 5, ..., 19}
sage: C.cardinality()
```

(continues on next page)

¹ Or at least that should be the case; there are still many corners to clean up.

(continued from previous page)

```
9
sage: C.list()
[3, 5, 7, 9, 11, 13, 15, 17, 19]
```

Permutations:

```
sage: C = Permutations(4); C
Standard permutations of 4
sage: C.cardinality()
24
sage: C.list()
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 3, 2, 4], [1, 3, 4, 2],
 [1, 4, 2, 3], [1, 4, 3, 2], [2, 1, 3, 4], [2, 1, 4, 3],
 [2, 3, 1, 4], [2, 3, 4, 1], [2, 4, 1, 3], [2, 4, 3, 1],
 [3, 1, 2, 4], [3, 1, 4, 2], [3, 2, 1, 4], [3, 2, 4, 1],
 [3, 4, 1, 2], [3, 4, 2, 1], [4, 1, 2, 3], [4, 1, 3, 2],
 [4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 1, 2], [4, 3, 2, 1]]
```

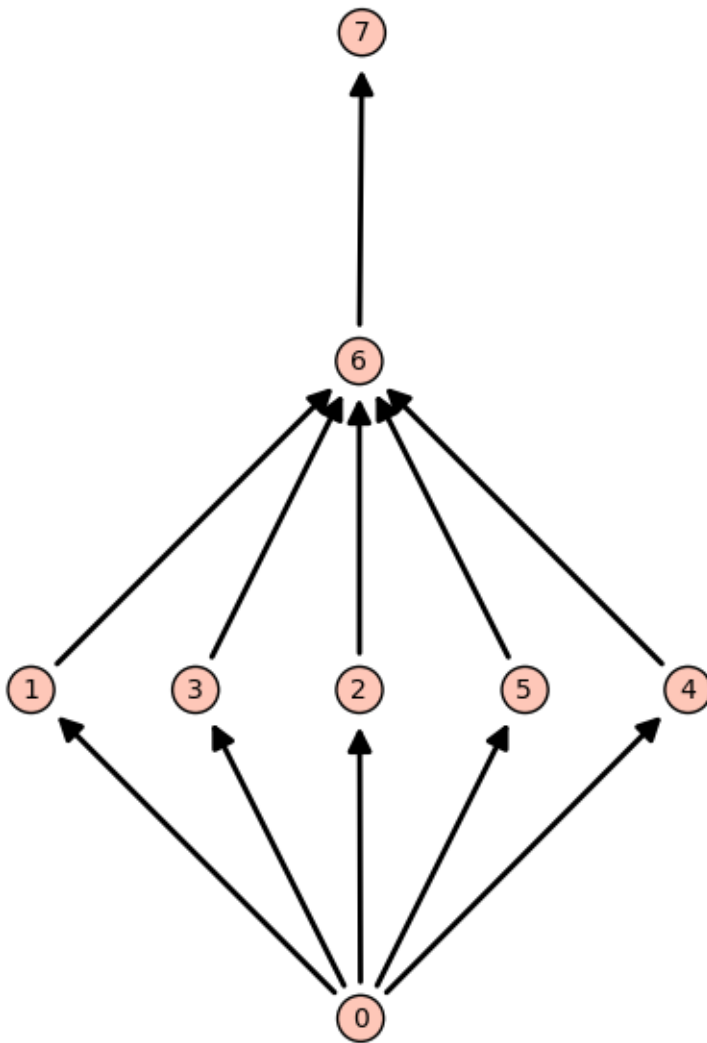

Set partitions:

```
sage: C = SetPartitions(["a", "b", "c"])
sage: C # random print output
Set partitions of {'a', 'c', 'b'}
sage: C.cardinality()
5
sage: C.list()
[{'a', 'b', 'c'},
 {'a', 'b'}, {'c'},
 {'a', 'c'}, {'b'},
 {'a'}, {'b', 'c'},
 {'a'}, {'b'}, {'c'}]
```

Partial orders on a set of 8 elements, up to isomorphism:

```
sage: C = Posets(8); C
Posets containing 8 elements
sage: C.cardinality()
16999
```

```
sage: C.unrank(20).plot()
Graphics object consisting of 20 graphics primitives
```

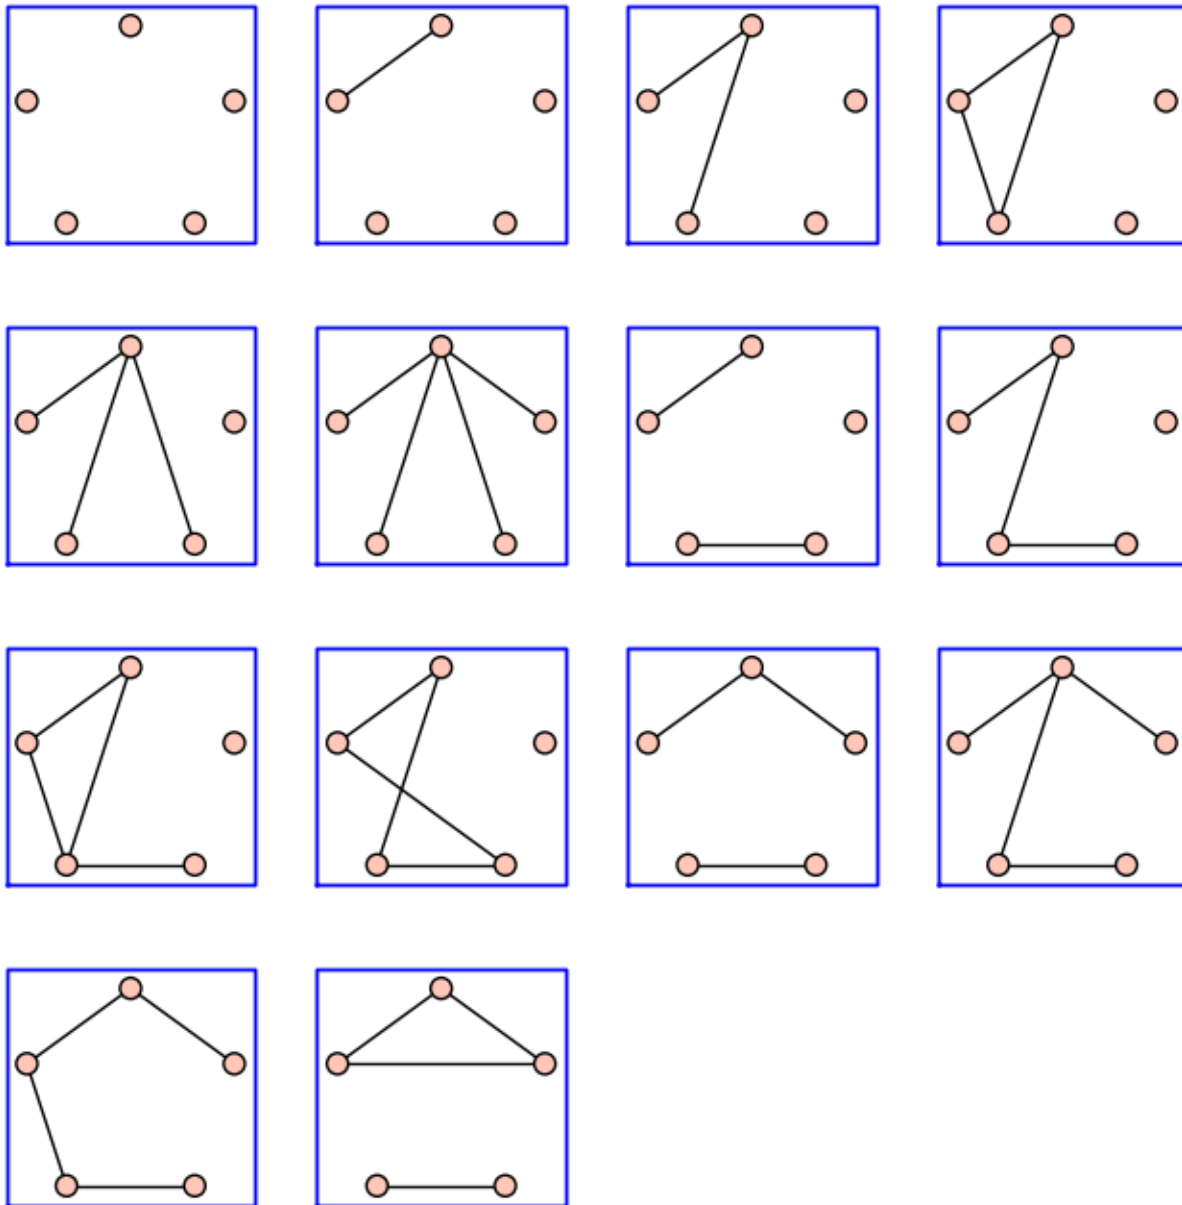

One can iterate through all graphs up to isomorphism. For example, there are 34 simple graphs with 5 vertices:

```
sage: len(list(graphs(5)))  
34
```

Here are those with at most 4 edges:

```
sage: up_to_four_edges = list(graphs(5, lambda G: G.size() <= 4))  
sage: pretty_print(*up_to_four_edges)
```

However, the *set* C of these graphs is not yet available in Sage; as a result, the following commands are not yet implemented:

```
sage: C = Graphs(5)           # todo: not implemented
sage: C.cardinality()        # todo: not implemented
34
sage: Graphs(19).cardinality() # todo: not implemented
24637809253125004524383007491432768
sage: Graphs(19).random_element() # todo: not implemented
Graph on 19 vertices
```

What we have seen so far also applies, in principle, to finite algebraic structures like the dihedral groups:

```

sage: G = DihedralGroup(4); G
Dihedral group of order 8 as a permutation group
sage: G.cardinality()
8
sage: G.list()
[(), (1,3)(2,4), (1,4,3,2), (1,2,3,4), (2,4), (1,3), (1,4)(2,3), (1,2)(3,4)]

```

or the algebra of 2×2 matrices over the finite field $\mathbf{Z}/2\mathbf{Z}$:

```

sage: C = MatrixSpace(GF(2), 2)
sage: C.list()
[
[0 0] [1 0] [0 1] [0 0] [0 0] [1 1] [1 0] [1 0] [0 1] [0 1]
[0 0], [0 0], [0 0], [1 0], [0 1], [0 0], [1 0], [0 1], [1 0], [0 1],
[0 0] [1 1] [1 1] [1 0] [0 1] [1 1]
[1 1], [1 0], [0 1], [1 1], [1 1], [1 1]
]
sage: C.cardinality()
16

```

Exercise

List all the monomials of degree 5 in three variables (see `IntegerVectors`). Manipulate the ordered set partitions `OrderedSetPartitions` and standard tableaux (`StandardTableaux`).

Exercise

List the alternating sign matrices of size 3, 4, and 5 (`AlternatingSignMatrices`), and try to guess the definition. The discovery and proof of the formula for the enumeration of these matrices (see the method `cardinality`), motivated by calculations of determinants in physics, is quite a story. In particular, the first proof, given by Zeilberger in 1992 was automatically produced by a computer program. It was 84 pages long, and required nearly a hundred people to verify it.

Exercise

Calculate by hand the number of vectors in $(\mathbf{Z}/2\mathbf{Z})^5$, and the number of matrices in $GL_3(\mathbf{Z}/2\mathbf{Z})$ (that is to say, the number of invertible 3×3 matrices with coefficients in $\mathbf{Z}/2\mathbf{Z}$). Verify your answer with Sage. Generalize to $GL_n(\mathbf{Z}/q\mathbf{Z})$.

Set comprehension and iterators

We will now show some of the possibilities offered by Python for constructing (and iterating through) sets, with a notation that is flexible and close to usual mathematical usage, and in particular the benefits this yields in combinatorics.

We begin by constructing the finite set $\{i^2 \mid i \in \{1, 3, 7\}\}$:

```
sage: [ i^2 for i in [1, 3, 7] ]
[1, 9, 49]
```

and then the same set, but with i running from 1 to 9:

```
sage: [ i^2 for i in range(1,10) ]
[1, 4, 9, 16, 25, 36, 49, 64, 81]
```

A construction of this form in Python is called *set comprehension*. A clause can be added to keep only those elements with i prime:

```
sage: [ i^2 for i in range(1,10) if is_prime(i) ]
[4, 9, 25, 49]
```

Combining more than one set comprehension, it is possible to construct the set $\{(i, j) \mid 1 \leq j < i < 5\}$:

```
sage: [ (i,j) for i in range(1,6) for j in range(1,i) ]
[(2, 1), (3, 1), (3, 2), (4, 1), (4, 2), (4, 3),
