INTRODUCTORY MATERIAL

- *Combinatorics quickref*
- *Introduction to combinatorics in Sage*

THEMATIC INDEXES

- *Algebraic combinatorics*
 - *Combinatorial Hopf algebras*
 - *Cluster algebras and quivers*
 - *Crystals*
 - *Root Systems*
 - *Symmetric Functions*
 - *FullyCommutativeElements*
- *Counting*
- *Enumerated sets and combinatorial objects*
- *Enumerated sets of partitions, tableaux, ...*
- *Finite state machines, automata, transducers*
- *Combinatorial species*
- *Combinatorial designs and incidence structures*
- *Posets*
- *Combinatorics on words*

UTILITIES

- *Output functions*
- *Rankers*
- *Combinatorial maps*
- *Miscellaneous*

RELATED TOPICS

- Coding Theory
- Discrete dynamics
- Graph Theory

COMPREHENSIVE MODULE LIST

5.1 Comprehensive Module List

Note: This list is currently sorted in alphabetical order w.r.t. the module names. It can be updated semi-automatically by running in `src/sage/combinat`:

```
find -name "*.py*" | sed 's|\.pyx\?$||; s|\./| sage/combinat/|' | LANG=en_US.UTF-8 LC_
↪COLLATE=C sort > /tmp/module_list.rst
```

and copy pasting the result back there.

Todo: See [trac ticket #17421](#) for desirable improvements.

5.1.1 Abstract Recursive Trees

The purpose of this class is to help implement trees with a specific structure on the children of each node. For instance, one could want to define a tree in which each node sees its children as linearly (see the *Ordered Trees* module) or cyclically ordered.

Tree structures

Conceptually, one can define a tree structure from any object that can contain others. Indeed, a list can contain lists which contain lists which contain lists, and thus define a tree ... The same can be done with sets, or any kind of iterable objects.

While any iterable is sufficient to encode trees, it can prove useful to have other methods available like isomorphism tests (see next section), conversions to DiGraphs objects (see *as_digraph()*) or computation of the number of automorphisms constrained by the structure on children. Providing such methods is the whole purpose of the *AbstractTree* class.

As a result, the *AbstractTree* class is not meant to be instantiated, but extended. It is expected that classes extending this one may also inherit from classes representing iterables, for instance *ClonableArray* or *ClonableList*

Constrained Trees

The tree built from a specific container will reflect the properties of the container. Indeed, if *A* is an iterable class whose elements are linearly ordered, a class *B* extending both of *AbstractTree* and *A* will be such that the children of a node will be linearly ordered. If *A* behaves like a set (i.e. if there is no order on the elements it contains), then two trees will be considered as equal if one can be obtained from the other through permutations between the children of a same node (see next section).

Paths and ID

It is expected that each element of a set of children should be identified by its index in the container. This way, any node of the tree can be identified by a word describing a path from the root node.

Canonical labellings

Equality between instances of classes extending both *AbstractTree* and A is entirely defined by the equality defined on the elements of A. A canonical labelling of such a tree, however, should be such that two trees a and b satisfying `a == b` have the same canonical labellings. On the other hand, the canonical labellings of trees a and b satisfying `a != b` are expected to be different.

For this reason, the values returned by the *canonical_labelling* method heavily depend on the data structure used for a node's children and **should be overridden** by most of the classes extending *AbstractTree* if it is incoherent with the data structure.

Authors

- Florent Hivert (2010-2011): initial revision
- Frédéric Chapoton (2011): contributed some methods

class `sage.combinat.abstract_tree.AbstractClonableTree`

Bases: `sage.combinat.abstract_tree.AbstractTree`

Abstract Clonable Tree.

An abstract class for trees with clone protocol (see `list_clone`). It is expected that classes extending this one may also inherit from classes like `ClonableArray` or `ClonableList` depending whether one wants to build trees where adding a child is allowed.

Note: Due to the limitation of Cython inheritance, one cannot inherit here from `ClonableElement`, because it would prevent us from later inheriting from `ClonableArray` or `ClonableList`.

How should this class be extended ?

A class extending *AbstractClonableTree* should satisfy the following assumptions:

- An instantiable class extending *AbstractClonableTree* should also extend the `ClonableElement` class or one of its subclasses generally, at least `ClonableArray`.
- To respect the Clone protocol, the *AbstractClonableTree*.`check()` method should be overridden by the new class.

See also the assumptions in *AbstractTree*.

check()

Check that `self` is a correct tree.

This method does nothing. It is implemented here because many extensions of *AbstractClonableTree* also extend `sage.structure.list_clone.ClonableElement`, which requires it.

It should be overridden in subclasses in order to check that the characterizing property of the respective kind of tree holds (eg: two children for binary trees).

EXAMPLES:

```
sage: OrderedTree([[[]],[[]]]).check()
sage: BinaryTree([[[]],[[]],[[]]]).check()
```

class sage.combinat.abstract_tree.**AbstractLabelledClonableTree**(parent, children, label=None, check=True)

Bases: [sage.combinat.abstract_tree.AbstractLabelledTree](#), [sage.combinat.abstract_tree.AbstractClonableTree](#)

Abstract Labelled Clonable Tree

This class takes care of modification for the label by the clone protocol.

Note: Due to the limitation of Cython inheritance, one cannot inherit here from [ClonableArray](#), because it would prevent us to inherit later from [ClonableList](#).

map_labels(*f*)

Apply the function *f* to the labels of `self`

This method returns a copy of `self` on which the function *f* has been applied on all labels (a label *x* is replaced by *f*(*x*)).

EXAMPLES:

```
sage: LT = LabelledOrderedTree
sage: t = LT([LT([],label=1),LT([],label=7)],label=3); t
3[1[], 7[]]
sage: t.map_labels(lambda z:z+1)
4[2[], 8[]]

sage: LBT = LabelledBinaryTree
sage: bt = LBT([LBT([],label=1),LBT([],label=4)],label=2); bt
2[1[., .], 4[., .]]
sage: bt.map_labels(lambda z:z+1)
3[2[., .], 5[., .]]
```

set_label(*path*, *label*)

Change the label of subtree indexed by path to label.

INPUT:

- **path** – None (default) or a path (list or tuple of children index in the tree)
- **label** – any sage object

OUTPUT: Nothing, `self` is modified in place

Note: `self` must be in a mutable state. See [sage.structure.list_clone](#) for more details about mutability.

EXAMPLES:

```
sage: t = LabelledOrderedTree([[],[[]],[[]]])
sage: t.set_label((0,), 4)
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t:
.....:     t.set_label((0,), 4)
```

(continues on next page)

(continued from previous page)

```

sage: t
None[4[], None[None[], None[]]]
sage: with t.clone() as t:
.....:     t.set_label((1,0), label = 42)
sage: t
None[4[], None[42[], None[]]]

```

Todo: Do we want to implement the following syntactic sugar:

```

with t.clone() as tt:
    tt.labels[1,2] = 3 ?

```

`set_root_label(label)`

Set the label of the root of `self`.

INPUT: `label` – any Sage object

OUTPUT: `None`, `self` is modified in place

Note: `self` must be in a mutable state. See `sage.structure.list_clone` for more details about mutability.

EXAMPLES:

```

sage: t = LabelledOrderedTree([[[]],[[]],[[]]])
sage: t.set_root_label(3)
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t:
.....:     t.set_root_label(3)
sage: t.label()
3
sage: t
3[None[], None[None[], None[]]]

```

This also works for binary trees:

```

sage: bt = LabelledBinaryTree([[[]],[[]]])
sage: bt.set_root_label(3)
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
sage: with bt.clone() as bt:
.....:     bt.set_root_label(3)
sage: bt.label()
3
sage: bt
3[None[., .], None[., .]]

```

class `sage.combinat.abstract_tree.AbstractLabelledTree`(*parent, children, label=None, check=True*)
 Bases: `sage.combinat.abstract_tree.AbstractTree`

Abstract Labelled Tree.

Typically a class for labelled trees is constructed by inheriting from a class for unlabelled trees and `AbstractLabelledTree`.

How should this class be extended ?

A class extending `AbstractLabelledTree` should respect the following assumptions:

- For a labelled tree `T` the call `T.parent().unlabelled_trees()` should return a parent for unlabelled trees of the same kind: for example,
 - if `T` is a binary labelled tree, `T.parent()` is `LabelledBinaryTrees()` and `T.parent().unlabelled_trees()` is `BinaryTrees()`
 - if `T` is an ordered labelled tree, `T.parent()` is `LabelledOrderedTrees()` and `T.parent().unlabelled_trees()` is `OrderedTrees()`
- In the same vein, the class of `T` should contain an attribute `_UnLabelled` which should be the class for the corresponding unlabelled trees.

See also the assumptions in `AbstractTree`.

See also:

`AbstractTree`

as_digraph()

Return a directed graph version of `self`.

Warning: At this time, the output makes sense only if `self` is a labelled binary tree with no repeated labels and no `None` labels.

EXAMPLES:

```
sage: LT = LabelledOrderedTrees()
sage: t1 = LT([LT([],label=6),LT([],label=1)],label=9)
sage: t1.as_digraph()
Digraph on 3 vertices

sage: t = BinaryTree([[None, None], [[], None]])
sage: lt = t.canonical_labelling()
sage: lt.as_digraph()
Digraph on 4 vertices
```

label(*path=None*)

Return the label of `self`.

INPUT:

- `path` – `None` (default) or a path (list or tuple of children index in the tree)

OUTPUT: the label of the subtree indexed by `path`

EXAMPLES:

```

sage: t = LabelledOrderedTree([],[], label = 3)
sage: t.label()
3
sage: t[0].label()
sage: t = LabelledOrderedTree([LabelledOrderedTree([], 5),[]], label = 3)
sage: t.label()
3
sage: t[0].label()
5
sage: t[1].label()
sage: t.label([0])
5

```

labels()

Return the list of labels of `self`.

EXAMPLES:

```

sage: LT = LabelledOrderedTree
sage: t = LT([LT([],label='b'),LT([],label='c')],label='a')
sage: t.labels()
['a', 'b', 'c']

sage: LBT = LabelledBinaryTree
sage: LBT([LBT([],label=1),LBT([],label=4)],label=2).labels()
[2, 1, 4]

```

leaf_labels()

Return the list of labels of the leaves of `self`.

In case of a labelled binary tree, these “leaves” are not actually the leaves of the binary trees, but the nodes whose both children are leaves!

EXAMPLES:

```

sage: LT = LabelledOrderedTree
sage: t = LT([LT([],label='b'),LT([],label='c')],label='a')
sage: t.leaf_labels()
['b', 'c']

sage: LBT = LabelledBinaryTree
sage: bt = LBT([LBT([],label='b'),LBT([],label='c')],label='a')
sage: bt.leaf_labels()
['b', 'c']
sage: LBT([], label='1').leaf_labels()
['1']
sage: LBT(None).leaf_labels()
[]

```

shape()

Return the unlabelled tree associated to `self`.

EXAMPLES:

```

sage: t = LabelledOrderedTree([[[]],[[]]], label = 25).shape(); t
[[[]], [[]]]

sage: LabelledBinaryTree([[[]],[[]],[[]]], label = 25).shape()
[[., .], [[., .], [., .]]]

sage: LRT = LabelledRootedTree
sage: tb = LRT([],label='b')
sage: LRT([tb, tb], label='a').shape()
[[[]], [[]]]

```

class sage.combinat.abstract_tree.**AbstractTree**

Bases: object

Abstract Tree.

There is no data structure defined here, as this class is meant to be extended, not instantiated.

How should this class be extended?

A class extending *AbstractTree* should respect several assumptions:

- For a tree T , the call `iter(T)` should return an iterator on the children of the root T .
- The *canonical_labelling* method should return the same value for trees that are considered equal (see the “canonical labellings” section in the documentation of the *AbstractTree* class).
- For a tree T the call `T.parent().labelled_trees()` should return a parent for labelled trees of the same kind: for example,
 - if T is a binary tree, `T.parent()` is `BinaryTrees()` and `T.parent().labelled_trees()` is `LabelledBinaryTrees()`
 - if T is an ordered tree, `T.parent()` is `OrderedTrees()` and `T.parent().labelled_trees()` is `LabelledOrderedTrees()`

breadth_first_order_traversal(*action=None*)

Run the breadth-first post-order traversal algorithm and subject every node encountered to some procedure *action*. The algorithm is:

```

queue <- [ root ];
while the queue is not empty:
  node <- pop( queue );
  manipulate the node;
  prepend to the queue the list of all subtrees of
    the node (from the rightmost to the leftmost).

```

INPUT:

- *action* – (optional) a function which takes a node as input, and does something during the exploration

OUTPUT:

None. (This is *not* an iterator.)

EXAMPLES:

For example, on the following binary tree b :

the breadth-first order traversal algorithm explores b in the following order of nodes: 3, 1, 7, 2, 5, 8, 4, 6.

canonical_labelling(*shift=1*)

Return a labelled version of `self`.

The actual canonical labelling is currently unspecified. However, it is guaranteed to have labels in $1..n$ where n is the number of nodes of the tree. Moreover, two (unlabelled) trees compare as equal if and only if their canonical labelled trees compare as equal.

EXAMPLES:

```

sage: t = OrderedTree([], [], [], [], [], [], [], [])
sage: t.canonical_labelling()
1[2[], 3[4[], 5[6[], 7[], 8[9[], 10[[], 11[12[], 13[[]]]]]]]

sage: BinaryTree().canonical_labelling()
1[., .]

sage: BinaryTree([], [], []).canonical_labelling()
2[1[., .], 4[3[., .], 5[., .]]]
  
```

depth()

Return the depth of `self`.

EXAMPLES:

```

sage: OrderedTree().depth()
1
sage: OrderedTree([]).depth()
1
sage: OrderedTree([], []).depth()
2
sage: OrderedTree([], []).depth()
3
sage: OrderedTree([], [], [], [], [], [], [], []).depth()
4

sage: BinaryTree().depth()
0
sage: BinaryTree([], [], []).depth()
3
  
```

iterative_post_order_traversal(*action=None*)

Run the depth-first post-order traversal algorithm (iterative implementation) and subject every node encountered to some procedure `action`. The algorithm is:

```

explore each subtree (by the algorithm) from the
  leftmost one to the rightmost one;
  
```

(continues on next page)

(continued from previous page)

then manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf).

INPUT:

- `action` – (optional) a function which takes a node as input, and does something during the exploration

OUTPUT:

None. (This is *not* an iterator.)

See also:

- [`post_order_traversal_iter\(\)`](#)

iterative_pre_order_traversal(*action=None*)

Run the depth-first pre-order traversal algorithm (iterative implementation) and subject every node encountered to some procedure `action`. The algorithm is:

manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf); then explore each subtree (by the algorithm) from the leftmost one to the rightmost one.

INPUT:

- `action` – (optional) a function which takes a node as input, and does something during the exploration

OUTPUT:

None. (This is *not* an iterator.)

See also:

- [`pre_order_traversal_iter\(\)`](#)
- [`pre_order_traversal\(\)`](#)

node_number()

Return the number of nodes of `self`.

See also:

[`node_number_at_depth\(\)`](#), [`node_number_to_the_right\(\)`](#)

EXAMPLES:

```
sage: OrderedTree().node_number()
1
sage: OrderedTree([]).node_number()
1
sage: OrderedTree([], []).node_number()
3
sage: OrderedTree([], [[]]).node_number()
4
sage: OrderedTree([], [], [], [], [], [], [], []).node_number()
13
```

EXAMPLES:

```

sage: BinaryTree(None).node_number()
0
sage: BinaryTree([]).node_number()
1
sage: BinaryTree([], None).node_number()
2
sage: BinaryTree([[None], [], []], None).node_number()
5

```

node_number_at_depth(*depth*)

Return the number of nodes at a given depth.

This counts all nodes that are at the given depth.

Here the root is considered to have depth 0.

INPUT:

- *depth* – an integer

See also:

[*node_number\(\)*](#), [*node_number_to_the_right\(\)*](#), [*paths_at_depth\(\)*](#)

EXAMPLES:

```

sage: T = OrderedTree([[[[]], [[]]], [[], [[]]]], [])
sage: ascii_art(T)
  ---o---
 /   / /
o_  o_ o
 / / / /
o o o o
 |  |
  o  o
      |
      o
sage: [T.node_number_at_depth(i) for i in range(6)]
[1, 3, 4, 2, 1, 0]

```

node_number_to_the_right(*path*)

Return the number of nodes at the same depth and to the right of the node identified by *path*.

This counts the nodes that are at the same depth as the given one, and strictly to its right.

See also:

[*node_number\(\)*](#), [*node_number_at_depth\(\)*](#), [*paths_to_the_right\(\)*](#)

EXAMPLES:

```

sage: T = OrderedTree([[[[]], [[]]], [[], [[]]]], [])
sage: ascii_art(T)
  ---o---
 /   / /
o_  o_ o
 / / / /
o o o o

```

(continues on next page)

(continued from previous page)

```

|   |
o   o
    |
    o
sage: T.node_number_to_the_right(())
0
sage: T.node_number_to_the_right((0,))
2
sage: T.node_number_to_the_right((0,1))
2
sage: T.node_number_to_the_right((0,1,0))
1

sage: T = OrderedTree([])
sage: T.node_number_to_the_right(())
0

```

paths()

Return a generator for all paths to nodes of `self`.

OUTPUT:

This method returns a list of sequences of integers. Each of these sequences represents a path from the root node to some node. For instance, `(1, 3, 2, 5, 0, 3)` represents the node obtained by choosing the 1st child of the root node (in the ordering returned by `iter`), then the 3rd child of its child, then the 2nd child of the latter, etc. (where the labelling of the children is zero-based).

The root element is represented by the empty tuple `()`.

See also:

[`paths_at_depth\(\)`](#), [`paths_to_the_right\(\)`](#)

EXAMPLES:

```

sage: list(OrderedTree([]).paths())
[()]
sage: list(OrderedTree([[[]],[[]]]).paths())
[(), (0,), (1,), (1, 0)]

sage: list(BinaryTree([[[]],[[]],[[]]]).paths())
[(), (0,), (1,), (1, 0), (1, 1)]

```

paths_at_depth(*depth*, *path*=[])

Return a generator for all paths at a fixed depth.

This iterates over all paths for nodes that are at the given depth.

Here the root is considered to have depth 0.

INPUT:

- `depth` – an integer
- `path` – optional given path (as a list) used in the recursion

Warning: The path option should not be used directly.

See also:

`paths()`, `paths_to_the_right()`, `node_number_at_depth()`

EXAMPLES:

```
sage: T = OrderedTree([[[]], [[]], [[]]]), [], [[[]],[[]]], [], [])
sage: ascii_art(T)
      o
     / / / /
    _o_ o o o o
   / /   |
  o  o_  o_
   / /   / /
  o o   o o
   |
  o

sage: list(T.paths_at_depth(0))
[()]
sage: list(T.paths_at_depth(2))
[(0, 0), (0, 1), (2, 0)]
sage: list(T.paths_at_depth(4))
[(0, 1, 1, 0)]
sage: list(T.paths_at_depth(5))
[]

sage: T2 = OrderedTree([])
sage: list(T2.paths_at_depth(0))
[()]
```

`paths_to_the_right(path)`

Return a generator of paths for all nodes at the same depth and to the right of the node identified by `path`.

This iterates over the paths for nodes that are at the same depth as the given one, and strictly to its right.

INPUT:

- `path` – any path in the tree

See also:

`paths()`, `paths_at_depth()`, `node_number_to_the_right()`

EXAMPLES:

```
sage: T = OrderedTree([[[]], [[]]], [[]], [[[]]]), []
sage: ascii_art(T)
      o
     / / /
    o_ o_ o
   / / / /
  o o o o
   | |
  o o
```

(continues on next page)

(continued from previous page)

```

      |
      o
sage: g = T.paths_to_the_right(())
sage: list(g)
[]

sage: g = T.paths_to_the_right((0,))
sage: list(g)
[(1,)]

sage: g = T.paths_to_the_right((0,1))
sage: list(g)
[(1, 0), (1, 1)]

sage: g = T.paths_to_the_right((0,1,0))
sage: list(g)
[(1, 1, 0)]

sage: g = T.paths_to_the_right((1,2))
sage: list(g)
[]

```

post_order_traversal (*action=None*)

Run the depth-first post-order traversal algorithm (recursive implementation) and subject every node encountered to some procedure *action*. The algorithm is:

```

explore each subtree (by the algorithm) from the
  leftmost one to the rightmost one;
then manipulate the root with function `action` (in the
  case of a binary tree, only if the root is not a leaf).

```

INPUT:

- *action* – (optional) a function which takes a node as input, and does something during the exploration

OUTPUT:

None. (This is *not* an iterator.)

See also:

- [post_order_traversal_iter\(\)](#)
- [iterative_post_order_traversal\(\)](#)

post_order_traversal_iter()

The depth-first post-order traversal iterator.

This method iters each node following the depth-first post-order traversal algorithm (recursive implementation). The algorithm is:

```

explore each subtree (by the algorithm) from the
  leftmost one to the rightmost one;
then yield the root (in the case of binary trees, only if
  it is not a leaf).

```

EXAMPLES:

For example on the following binary tree *b*:

(only the nodes are shown), the depth-first post-order traversal algorithm explores *b* in the following order of nodes: 2, 1, 4, 6, 5, 8, 7, 3.

For another example, consider the labelled tree:

The algorithm explores this tree in the following order: 4, 5, 3, 2, 7, 6, 9, 10, 8, 1.

pre_order_traversal(*action=None*)

Run the depth-first pre-order traversal algorithm (recursive implementation) and subject every node encountered to some procedure *action*. The algorithm is:

```

manipulate the root with function `action` (in the case
of a binary tree, only if the root is not a leaf);
then explore each subtree (by the algorithm) from the
leftmost one to the rightmost one.
    
```

INPUT:

- *action* – (optional) a function which takes a node as input, and does something during the exploration

OUTPUT:

None. (This is *not* an iterator.)

EXAMPLES:

For example, on the following binary tree *b*:

the depth-first pre-order traversal algorithm explores *b* in the following order of nodes: 3, 1, 2, 7, 5, 4, 6, 8.

Another example:

The algorithm explores this tree in the following order: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

See also:

- `pre_order_traversal_iter()`
- `iterative_pre_order_traversal()`

`pre_order_traversal_iter()`

The depth-first pre-order traversal iterator.

This method iters each node following the depth-first pre-order traversal algorithm (recursive implementation). The algorithm is:

```

yield the root (in the case of binary trees, if it is not
  a leaf);
then explore each subtree (by the algorithm) from the
  leftmost one to the rightmost one.

```

EXAMPLES:

For example, on the following binary tree *b*:

(only the nodes shown), the depth-first pre-order traversal algorithm explores *b* in the following order of nodes: 3, 1, 2, 7, 5, 4, 6, 8.

Another example:

The algorithm explores this labelled tree in the following order: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

`subtrees()`

Return a generator for all nonempty subtrees of `self`.

The number of nonempty subtrees of a tree is its number of nodes. (The word “nonempty” makes a difference only in the case of binary trees. For ordered trees, for example, all trees are nonempty.)

EXAMPLES:

```
sage: list(OrderedTree([]).subtrees())
[[]]
sage: list(OrderedTree([[[]],[[]]]).subtrees())
[[[]], [[[]]], [], [[[]], []]
sage: list(OrderedTree([[[]],[[]]]).canonical_labelling().subtrees())
[1[2[], 3[4[[]]]], 2[], 3[4[[]]], 4[]]
sage: list(BinaryTree([[[]],[[]],[[]]]).subtrees())
[[[., .], [[., .], [., .]], [., .], [[., .], [., .]], [., .], [., .]]
sage: v = BinaryTree([[[]],[[]])
sage: list(v.canonical_labelling().subtrees())
[2[1[., .], 3[., .]], 1[., .], 3[., .]]
```

to_hexacode()

Transform a tree into an hexadecimal string.

The definition of the hexacode is recursive. The first letter is the valence of the root as an hexadecimal (up to 15), followed by the concatenation of the hexacodes of the subtrees.

This method only works for trees where every vertex has valency at most 15.

See [from_hexacode\(\)](#) for the reverse transformation.

EXAMPLES:

```
sage: from sage.combinat.abstract_tree import from_hexacode
sage: LT = LabelledOrderedTrees()
sage: from_hexacode('2010', LT).to_hexacode()
'2010'
sage: LT.an_element().to_hexacode()
'3020010'
sage: t = from_hexacode('a00000000000000000', LT)
sage: t.to_hexacode()
'a00000000000'
sage: OrderedTrees(6).an_element().to_hexacode()
'500000'
```

tree_factorial()

Return the tree-factorial of self.

Definition:

The tree-factorial $T!$ of a tree T is the product $\prod_{v \in T} \#\text{children}(v)$.

EXAMPLES:

```
sage: LT = LabelledOrderedTrees()
sage: t = LT([LT([], label=6), LT([], label=1)], label=9)
sage: t.tree_factorial()
3
```

(continues on next page)

(continued from previous page)

```
sage: BinaryTree([[[]],[[], [[]]]]).tree_factorial()
15
```

`sage.combinat.abstract_tree.from_hexacode(ch, parent=None, label='@')`

Transform an hexadecimal string into a tree.

INPUT:

- `ch` – an hexadecimal string
- `parent` – kind of trees to be produced. If `None`, this will be `LabelledOrderedTrees`
- `label` – a label (default: '@') to be used for every vertex of the tree

See [AbstractTree.to_hexacode\(\)](#) for the description of the encoding

See `_from_hexacode_aux()` for the actual code

EXAMPLES:

```
sage: from sage.combinat.abstract_tree import from_hexacode
sage: from_hexacode('12000', LabelledOrderedTrees())
@@[@[], @[]]
sage: from_hexacode('12000')
@@[@[], @[]]

sage: from_hexacode('1200', LabelledOrderedTrees())
@@[@[], @[]]
```

It can happen that only a prefix of the word is used:

```
sage: from_hexacode('a'+14*'0', LabelledOrderedTrees())
@[@[], @[], @[], @[], @[], @[], @[], @[], @[], @[]]
```

One can choose the label:

```
sage: from_hexacode('1200', LabelledOrderedTrees(), label='o')
o[o[o[], o[]]]
```

One can also create other kinds of trees:

```
sage: from_hexacode('1200', OrderedTrees())
[[[], []]]
```

5.1.2 Affine Permutations

`class sage.combinat.affine_permutation.AffinePermutation(parent, lst, check=True)`

Bases: `sage.structure.list_clone.ClonableArray`

An affine permutation, represented in the window notation, and considered as a bijection from \mathbf{Z} to \mathbf{Z} .

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]

```

apply_simple_reflection(*i, side='right'*)

Apply a simple reflection.

INPUT:

- *i* – an integer
- *side* – (default: 'right') determines whether to apply the reflection on the 'right' or 'left'

EXAMPLES:

```

sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.apply_simple_reflection(3)
Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
sage: p.apply_simple_reflection(11)
Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
sage: p.apply_simple_reflection(3, 'left')
Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]
sage: p.apply_simple_reflection(11, 'left')
Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]

```

grassmannian_quotient(*i=0, side='right'*)

Return the Grassmannian quotient.

Factors `self` into a unique product of a Grassmannian and a finite-type element. Returns a tuple containing the Grassmannian and finite elements, in order according to *side*.

INPUT:

- *i* – (default: 0) an element of the index set; the descent checked for

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: gq=p.grassmannian_quotient()
sage: gq
(Type A affine permutation with window [-1, 0, 3, 4, 5, 6, 9, 10],
 Type A affine permutation with window [3, 1, 2, 6, 5, 4, 8, 7])
sage: gq[0].is_i_grassmannian()
True
sage: 0 not in gq[1].reduced_word()
True
sage: prod(gq)==p
True

sage: gqLeft=p.grassmannian_quotient(side='left')
sage: 0 not in gqLeft[0].reduced_word()
True
sage: gqLeft[1].is_i_grassmannian(side='left')
True

```

(continues on next page)

(continued from previous page)

```
sage: prod(gqLeft)==p
True
```

index_set()

Index set of the affine permutation group.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: A.index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

inverse()

Return the inverse affine permutation.

EXAMPLES:

```
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.inverse()
Type A affine permutation with window [0, -1, 1, 6, 5, 4, 10, 11]
```

is_i_grassmannian(*i=0, side='right'*)

Test whether self is *i*-grassmannian, i.e., either is the identity or has *i* as the sole descent.

INPUT:

- *i* – an element of the index set
- *side* – determines the side on which to check the descents

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_i_grassmannian()
False
sage: q=A.from_word([3,2,1,0])
sage: q.is_i_grassmannian()
True
sage: q=A.from_word([2,3,4,5])
sage: q.is_i_grassmannian(5)
True
sage: q.is_i_grassmannian(2, side='left')
True
```

is_one()

Tests whether the affine permutation is the identity.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_one()
False
sage: q=A.one()
sage: q.is_one()
True
```

lower_covers(*side='right'*)

Return lower covers of `self`.

The set of affine permutations of one less length related by multiplication by a simple transposition on the indicated side. These are the elements that `self` covers in weak order.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.lower_covers()
[Type A affine permutation with window [-1, 3, 0, 6, 5, 4, 10, 9],
Type A affine permutation with window [3, -1, 0, 5, 6, 4, 10, 9],
Type A affine permutation with window [3, -1, 0, 6, 4, 5, 10, 9],
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 9, 10]]
```

reduced_word()

Returns a reduced word for the affine permutation.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.reduced_word()
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
```

signature()

Signature of the affine permutation, $(-1)^l$, where l is the length of the permutation.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.signature()
1
```

to_weyl_group_element()

The affine Weyl group element corresponding to the affine permutation.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_weyl_group_element()
[ 0 -1  0  1  0  0  1  0]
[ 1 -1  0  1  0  0  1 -1]
[ 1 -1  0  1  0  0  0  0]
[ 0  0  0  1  0  0  0  0]
[ 0  0  0  1  0 -1  1  0]
[ 0  0  0  1 -1  0  1  0]
[ 0  0  0  0  0  0  1  0]
[ 0 -1  1  0  0  0  1  0]
```

sage.combinat.affine_permutation.AffinePermutationGroup(*cartan_type*)

Wrapper function for specific affine permutation groups.

These are combinatorial implementations of the affine Weyl groups of types A , B , C , D , and G as permutations of the set of all integers. the basic algorithms are derived from [BB2005] and [Eri1995].

EXAMPLES:

```
sage: ct = CartanType(['A',7,1])
sage: A = AffinePermutationGroup(ct)
sage: A
The group of affine permutations of type ['A', 7, 1]
```

We define an element of A:

```
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
```

We find the value $p(1)$, considering p as a bijection on the integers. This is the same as calling the `value()` method:

```
sage: p.value(1)
3
sage: p(1) == p.value(1)
True
```

We can also find the position of the integer 3 in p considered as a sequence, equivalent to finding $p^{-1}(3)$:

```
sage: p.position(3)
1
sage: (p^-1)(3)
1
```

Since the affine permutation group is a group, we demonstrate its group properties:

```
sage: A.one()
Type A affine permutation with window [1, 2, 3, 4, 5, 6, 7, 8]

sage: q = A([0, 2, 3, 4, 5, 6, 7, 9])
sage: p * q
Type A affine permutation with window [1, -1, 0, 6, 5, 4, 10, 11]
sage: q * p
Type A affine permutation with window [3, -1, 1, 6, 5, 4, 10, 8]

sage: p^-1
Type A affine permutation with window [0, -1, 1, 6, 5, 4, 10, 11]
sage: p^-1 * p == A.one()
True
sage: p * p^-1 == A.one()
True
```

If we decide we prefer the Weyl Group implementation of the affine Weyl group, we can easily get it:

```
sage: p.to_weyl_group_element()
[ 0 -1  0  1  0  0  1  0]
[ 1 -1  0  1  0  0  1 -1]
[ 1 -1  0  1  0  0  0  0]
[ 0  0  0  1  0  0  0  0]
[ 0  0  0  1  0 -1  1  0]
```

(continues on next page)

(continued from previous page)

```
[ 0  0  0  1 -1  0  1  0]
[ 0  0  0  0  0  0  1  0]
[ 0 -1  1  0  0  0  1  0]
```

We can find a reduced word and do all of the other things one expects in a Coxeter group:

```
sage: p.has_right_descent(1)
True
sage: p.apply_simple_reflection(1)
Type A affine permutation with window [-1, 3, 0, 6, 5, 4, 10, 9]
sage: p.apply_simple_reflection(0)
Type A affine permutation with window [1, -1, 0, 6, 5, 4, 10, 11]
sage: p.reduced_word()
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
sage: p.length()
10
```

The following methods are particular to type A . We can check if the element is fully commutative:

```
sage: p.is_fully_commutative()
False
sage: q.is_fully_commutative()
True
```

We can also compute the affine Lehmer code of the permutation, a weak composition with $k + 1$ entries:

```
sage: p.to_lehmer_code()
[0, 3, 3, 0, 1, 2, 0, 1]
```

Once we have the Lehmer code, we can obtain a k -bounded partition by sorting the Lehmer code, and then reading the row lengths. There is a unique 0-Grassmanian (dominant) affine permutation associated to this k -bounded partition, and a k -core as well.

```
sage: p.to_bounded_partition()
[5, 3, 2]
sage: p.to_dominant()
Type A affine permutation with window [-2, -1, 1, 3, 4, 8, 10, 13]
sage: p.to_core()
[5, 3, 2]
```

Finally, we can take a reduced word for p and insert it to find a standard composition tableau associated uniquely to that word:

```
sage: p.tableau_of_word(p.reduced_word())
[[], [1, 6, 9], [2, 7, 10], [], [3], [4, 8], [], [5]]
```

We can also form affine permutation groups in types B , C , D , and G :

```
sage: B = AffinePermutationGroup(['B',4,1])
sage: B.an_element()
Type B affine permutation with window [-1, 3, 4, 11]

sage: C = AffinePermutationGroup(['C',4,1])
```

(continues on next page)

(continued from previous page)

```

sage: C.an_element()
Type C affine permutation with window [2, 3, 4, 10]

sage: D = AffinePermutationGroup(['D',4,1])
sage: D.an_element()
Type D affine permutation with window [-1, 3, 11, 5]

sage: G = AffinePermutationGroup(['G',2,1])
sage: G.an_element()
Type G affine permutation with window [0, 4, -1, 8, 3, 7]

```

class `sage.combinat.affine_permutation.AffinePermutationGroupGeneric`(*cartan_type*)
 Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The generic affine permutation group class, in which we define all type-free methods for the specific affine permutation groups.

cartan_matrix()
 Returns the Cartan matrix of `self`.

EXAMPLES:

```

sage: AffinePermutationGroup(['A',7,1]).cartan_matrix()
[ 2 -1  0  0  0  0  0 -1]
[-1  2 -1  0  0  0  0  0]
[ 0 -1  2 -1  0  0  0  0]
[ 0  0 -1  2 -1  0  0  0]
[ 0  0  0 -1  2 -1  0  0]
[ 0  0  0  0 -1  2 -1  0]
[ 0  0  0  0  0 -1  2 -1]
[-1  0  0  0  0  0 -1  2]

```

cartan_type()
 Returns the Cartan type of `self`.

EXAMPLES:

```

sage: AffinePermutationGroup(['A',7,1]).cartan_type()
['A', 7, 1]

```

classical()
 Returns the finite permutation group.

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: A.classical()
Symmetric group of order 8! as a permutation group

```

from_word(*w*)
 Builds an affine permutation from a given word. Note: Already in category as `from_reduced_word`, but this is less typing!

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: A.from_word([0, 7, 4, 1, 0, 7, 5, 4, 2, 1])
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]

```

index_set()

EXAMPLES:

```

sage: AffinePermutationGroup(['A',7,1]).index_set()
(0, 1, 2, 3, 4, 5, 6, 7)

```

is_crystallographic()

Tells whether the affine permutation group is crystallographic.

EXAMPLES:

```

sage: AffinePermutationGroup(['A',7,1]).is_crystallographic()
True

```

random_element(*n=None*)Return a random affine permutation of length n .If n is not specified, then n is chosen as a random non-negative integer in $[0, 1000]$.Starts at the identity, then chooses an upper cover at random. Not very uniform: actually constructs a uniformly random reduced word of length n . Thus we most likely get elements with lots of reduced words!For the actual code, see `sage.categories.coxeter_group.random_element_of_length()`.

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: A.random_element() # random
Type A affine permutation with window [-12, 16, 19, -1, -2, 10, -3, 9]
sage: p = A.random_element(10)
sage: p.length() == 10
True

```

rank()Rank of the affine permutation group, equal to $k + 1$.

EXAMPLES:

```

sage: AffinePermutationGroup(['A',7,1]).rank()
8

```

reflection_index_set()

EXAMPLES:

```

sage: AffinePermutationGroup(['A',7,1]).reflection_index_set()
(0, 1, 2, 3, 4, 5, 6, 7)

```

weyl_group()Returns the Weyl Group of the same type as `self`.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: A.weyl_group()
Weyl Group of type ['A', 7, 1] (as a matrix group acting on the root space)
```

```
class sage.combinat.affine_permutation.AffinePermutationGroupTypeA(cartan_type)
Bases: sage.combinat.affine_permutation.AffinePermutationGroupGeneric
```

Element

alias of *AffinePermutationTypeA*

```
from_lehmer_code(C, typ='decreasing', side='right')
```

Return the affine permutation with the supplied Lehmer code (a weak composition with $k + 1$ parts, at least one of which is 0).

INPUT:

- *typ* – 'increasing' or 'decreasing' (default: 'decreasing'); type of product
- *side* – 'right' or 'left' (default: 'right'); whether the decomposition is from the right or left

EXAMPLES:

```
sage: import itertools
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_lehmer_code()
[0, 3, 3, 0, 1, 2, 0, 1]
sage: A.from_lehmer_code(p.to_lehmer_code()) == p
True
sage: orders = ('increasing', 'decreasing')
sage: sides = ('left', 'right')
sage: all(A.from_lehmer_code(p.to_lehmer_code(o,s),o,s) == p
.....:         for o,s in itertools.product(orders,sides))
True
```

```
one()
```

Return the identity element.

EXAMPLES:

```
sage: AffinePermutationGroup(['A',7,1]).one()
Type A affine permutation with window [1, 2, 3, 4, 5, 6, 7, 8]
```

```
class sage.combinat.affine_permutation.AffinePermutationGroupTypeB(cartan_type)
Bases: sage.combinat.affine_permutation.AffinePermutationGroupTypeC
```

Element

alias of *AffinePermutationTypeB*

```
class sage.combinat.affine_permutation.AffinePermutationGroupTypeC(cartan_type)
Bases: sage.combinat.affine_permutation.AffinePermutationGroupGeneric
```

Element

alias of *AffinePermutationTypeC*

```
one()
```

Return the identity element.

EXAMPLES:

```

sage: ct=CartanType(['C',4,1])
sage: C = AffinePermutationGroup(ct)
sage: C.one()
Type C affine permutation with window [1, 2, 3, 4]
sage: C.one()*C.one()==C.one()
True

```

```

class sage.combinat.affine_permutation.AffinePermutationGroupTypeD(cartan_type)
    Bases: sage.combinat.affine_permutation.AffinePermutationGroupTypeC

```

Element

alias of *AffinePermutationTypeD*

```

class sage.combinat.affine_permutation.AffinePermutationGroupTypeG(cartan_type)
    Bases: sage.combinat.affine_permutation.AffinePermutationGroupGeneric

```

Element

alias of *AffinePermutationTypeG*

one()

Return the identity element.

EXAMPLES:

```

sage: AffinePermutationGroup(['G',2,1]).one()
Type G affine permutation with window [1, 2, 3, 4, 5, 6]

```

```

class sage.combinat.affine_permutation.AffinePermutationTypeA(parent, lst, check=True)
    Bases: sage.combinat.affine_permutation.AffinePermutation

```

apply_simple_reflection_left(*i*)

Apply the simple reflection to the values $i, i + 1$.

EXAMPLES:

```

sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.apply_simple_reflection_left(3)
Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]
sage: p.apply_simple_reflection_left(11)
Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]

```

apply_simple_reflection_right(*i*)

Apply the simple reflection to positions $i, i + 1$.

INPUT:

- i – an integer

EXAMPLES:

```

sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.apply_simple_reflection_right(3)
Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
sage: p.apply_simple_reflection_right(11)
Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]

```

check()

Check that self is an affine permutation.

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
sage: q = A([1,2,3]) # indirect doctest
Traceback (most recent call last):
...
ValueError: length of list must be k+1=8
sage: q = A([1,2,3,4,5,6,7,0]) # indirect doctest
Traceback (most recent call last):
...
ValueError: window does not sum to 36
sage: q = A([1,1,3,4,5,6,7,9]) # indirect doctest
Traceback (most recent call last):
...
ValueError: entries must have distinct residues

```

flip_automorphism()

The Dynkin diagram automorphism which fixes s_0 and reverses all other indices.

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.flip_automorphism()
Type A affine permutation with window [0, -1, 5, 4, 3, 9, 10, 6]

```

has_left_descent(i)

Determine whether there is a descent at i .

INPUT:

- i – an integer

EXAMPLES:

```

sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.has_left_descent(1)
True
sage: p.has_left_descent(9)
True
sage: p.has_left_descent(0)
True

```

has_right_descent(i)

Determine whether there is a descent at i .

INPUT:

- i – an integer

EXAMPLES:

```

sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.has_right_descent(1)
True
sage: p.has_right_descent(9)

```

(continues on next page)

(continued from previous page)

```
True
sage: p.has_right_descent(0)
False
```

is_fully_commutative()

Determine whether `self` is fully commutative, i.e., has no reduced words with a braid.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_fully_commutative()
False
sage: q=A([-3, -2, 0, 7, 9, 2, 11, 12])
sage: q.is_fully_commutative()
True
```

maximal_cyclic_decomposition(*typ='decreasing', side='right', verbose=False*)

Find the unique maximal decomposition of `self` into cyclically decreasing/increasing elements.

INPUT:

- `typ` – 'increasing' or 'decreasing' (default: 'decreasing'); chooses whether to find increasing or decreasing sets
- `side` – 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right
- `verbose` – (default: False) print extra information while finding the decomposition

EXAMPLES:

```
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.maximal_cyclic_decomposition()
[[0, 7], [4, 1, 0], [7, 5, 4, 2, 1]]
sage: p.maximal_cyclic_decomposition(side='left')
[[1, 0, 7, 5, 4], [1, 0, 5], [2, 1]]
sage: p.maximal_cyclic_decomposition(typ='increasing', side='right')
[[1], [5, 0, 1, 2], [4, 5, 7, 0, 1]]
sage: p.maximal_cyclic_decomposition(typ='increasing', side='left')
[[0, 1, 2, 4, 5], [4, 7, 0, 1], [7]]
```

maximal_cyclic_factor(*typ='decreasing', side='right', verbose=False*)

For an affine permutation x , find the unique maximal subset A of the index set such that $x = yd_A$ is a reduced product.

INPUT:

- `typ` – 'increasing' or 'decreasing' (default: 'decreasing'); chooses whether to find increasing or decreasing sets
- `side` – 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right
- `verbose` – True or False. If True, outputs information about how the cyclically increasing element was found.

EXAMPLES:

```

sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.maximal_cyclic_factor()
[7, 5, 4, 2, 1]
sage: p.maximal_cyclic_factor(side='left')
[1, 0, 7, 5, 4]
sage: p.maximal_cyclic_factor('increasing', 'right')
[4, 5, 7, 0, 1]
sage: p.maximal_cyclic_factor('increasing', 'left')
[0, 1, 2, 4, 5]

```

position(*i*)

Find the position j such the `self.value(j) == i`.

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.position(3)
1
sage: p.position(11)
9

```

promotion()

The Dynkin diagram automorphism which sends s_i to s_{i+1} .

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.promotion()
Type A affine permutation with window [2, 4, 0, 1, 7, 6, 5, 11]

```

tableau_of_word(*w*, *typ*='decreasing', *side*='right', *alpha*=None)

Finds a tableau on the Lehmer code of `self` corresponding to the given reduced word.

For a full description of this algorithm, see [Den2012].

INPUT:

- `w` – a reduced word for `self`
- `typ` – 'increasing' or 'decreasing'; the type of Lehmer code used
- `side` – 'right' or 'left'
- `alpha` – a content vector; `w` should be of type `alpha`; specifying `alpha` produces semistandard tableaux

EXAMPLES:

```

sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.tableau_of_word(p.reduced_word())
[[], [1, 6, 9], [2, 7, 10], [], [3], [4, 8], [], [5]]
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: w=p.reduced_word()
sage: w

```

(continues on next page)

(continued from previous page)

```
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
sage: alpha=[5,3,2]
sage: p.tableau_of_word(p.reduced_word(), alpha=alpha)
[[], [1, 2, 3], [1, 2, 3], [], [1], [1, 2], [], [1]]
sage: p.tableau_of_word(p.reduced_word(), side='left')
[[1, 4, 9], [6], [], [], [3, 7], [8], [], [2, 5, 10]]
sage: p.tableau_of_word(p.reduced_word(), typ='increasing', side='right')
[[9, 10], [1, 2], [], [], [3, 4], [8], [], [5, 6, 7]]
sage: p.tableau_of_word(p.reduced_word(), typ='increasing', side='left')
[[1, 2], [4, 5, 6], [9, 10], [], [3], [7, 8], [], []]
```

to_bounded_partition(*typ='decreasing', side='right'*)

Return the k -bounded partition associated to the dominant element obtained by sorting the Lehmer code.

INPUT:

- *typ* – ‘increasing’ or ‘decreasing’ (default: ‘decreasing’.) Chooses whether to find increasing or decreasing sets.
- *side* – ‘right’ or ‘left’ (default: ‘right’.) Chooses whether to find maximal sets starting from the left or the right.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A', 2, 1])
sage: p=A.from_lehmer_code([4,1,0])
sage: p.to_bounded_partition()
[2, 1, 1, 1]
```

to_core(*typ='decreasing', side='right'*)

Returns the core associated to the dominant element obtained by sorting the Lehmer code.

INPUT:

- *typ* – ‘increasing’ or ‘decreasing’ (default: ‘decreasing’.)
- *side* – ‘right’ or ‘left’ (default: ‘right’.) Chooses whether to find maximal sets starting from the left or the right.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A', 2, 1])
sage: p=A.from_lehmer_code([4,1,0])
sage: p.to_bounded_partition()
[2, 1, 1, 1]
sage: p.to_core()
[4, 2, 1, 1]
```

to_dominant(*typ='decreasing', side='right'*)

Finds the Lehmer code and then sorts it. Returns the affine permutation with the given sorted Lehmer code; this element is 0-dominant.

INPUT:

- *typ* – ‘increasing’ or ‘decreasing’ (default: ‘decreasing’) chooses whether to find increasing or decreasing sets
- *side* – ‘right’ or ‘left’ (default: ‘right’) chooses whether to find maximal sets starting from the left or the right

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_dominant()
Type A affine permutation with window [-2, -1, 1, 3, 4, 8, 10, 13]
sage: p.to_dominant(typ='increasing', side='left')
Type A affine permutation with window [3, 4, -1, 5, 0, 9, 6, 10]
```

to_lehmer_code(*typ='decreasing', side='right'*)

Return the affine Lehmer code.

There are four such codes; the options *typ* and *side* determine which code is generated. The codes generated are the shape of the maximal cyclic decompositions of *self* according to the given *typ* and *side* options.

INPUT:

- *typ* – 'increasing' or 'decreasing' (default: 'decreasing'); chooses whether to find increasing or decreasing sets
- *side* – 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right

EXAMPLES:

```
sage: import itertools
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: orders = ('increasing', 'decreasing')
sage: sides = ('left', 'right')
sage: for o,s in itertools.product(orders, sides):
.....:     p.to_lehmer_code(o,s)
[2, 3, 2, 0, 1, 2, 0, 0]
[2, 2, 0, 0, 2, 1, 0, 3]
[3, 1, 0, 0, 2, 1, 0, 3]
[0, 3, 3, 0, 1, 2, 0, 1]
sage: for a in itertools.product(orders, sides):
.....:     A.from_lehmer_code(p.to_lehmer_code(a[0],a[1]), a[0],a[1])==p
True
True
True
True
```

to_type_a()

Return an embedding of *self* into the affine permutation group of type *A*. (For type *A*, just returns *self*.)

EXAMPLES:

```
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_type_a() is p
True
```

value(*i, base_window=False*)

Return the image of the integer *i* under this permutation.

INPUT:

- `base_window` – boolean; indicating whether `i` is in the base window; if `True`, will run a bit faster, but the method will screw up if `i` is not actually in the index set

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.value(1)
3
sage: p.value(9)
11
```

class `sage.combinat.affine_permutation.AffinePermutationTypeB`(*parent, lst, check=True*)
 Bases: `sage.combinat.affine_permutation.AffinePermutationTypeC`

apply_simple_reflection_left(*i*)

Apply the simple reflection indexed by `i` on values.

EXAMPLES:

```
sage: B = AffinePermutationGroup(['B',4,1])
sage: p=B([-5,1,6,-2])
sage: p.apply_simple_reflection_left(0)
Type B affine permutation with window [-5, -2, 6, 1]
sage: p.apply_simple_reflection_left(2)
Type B affine permutation with window [-5, 1, 7, -3]
sage: p.apply_simple_reflection_left(4)
Type B affine permutation with window [-4, 1, 6, -2]
```

apply_simple_reflection_right(*i*)

Apply the simple reflection indexed by `i` on positions.

EXAMPLES:

```
sage: B = AffinePermutationGroup(['B',4,1])
sage: p=B([-5,1,6,-2])
sage: p.apply_simple_reflection_right(1)
Type B affine permutation with window [1, -5, 6, -2]
sage: p.apply_simple_reflection_right(0)
Type B affine permutation with window [-1, 5, 6, -2]
sage: p.apply_simple_reflection_right(4)
Type B affine permutation with window [-5, 1, 6, 11]
```

check()

Check that `self` is an affine permutation.

EXAMPLES:

```
sage: B = AffinePermutationGroup(['B',4,1])
sage: x = B([-5,1,6,-2])
sage: x
Type B affine permutation with window [-5, 1, 6, -2]
```

has_left_descent(*i*)

Determines whether there is a descent at `i`.

INPUT:

- i – an integer

EXAMPLES:

```
sage: B = AffinePermutationGroup(['B',4,1])
sage: p=B([-5,1,6,-2])
sage: [p.has_left_descent(i) for i in B.index_set()]
[True, True, False, False, True]
```

has_right_descent(i)

Determines whether there is a descent at index i .

INPUT:

- i – an integer

EXAMPLES:

```
sage: B = AffinePermutationGroup(['B',4,1])
sage: p = B([-5,1,6,-2])
sage: [p.has_right_descent(i) for i in B.index_set()]
[True, False, False, True, False]
```

class sage.combinat.affine_permutation.**AffinePermutationTypeC**(*parent, lst, check=True*)

Bases: *sage.combinat.affine_permutation.AffinePermutation*

apply_simple_reflection_left(i)

Apply the simple reflection indexed by i on values.

EXAMPLES:

```
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: for i in C.index_set(): x.apply_simple_reflection_left(i)
Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [-2, 5, 3, 8]
Type C affine permutation with window [-1, 5, 2, 6]
Type C affine permutation with window [-1, 6, 4, 7]
Type C affine permutation with window [-1, 4, 3, 7]
```

apply_simple_reflection_right(i)

Apply the simple reflection indexed by i on positions.

EXAMPLES:

```
sage: C = AffinePermutationGroup(['C',4,1])
sage: x=C([-1,5,3,7])
sage: for i in C.index_set(): x.apply_simple_reflection_right(i)
Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [5, -1, 3, 7]
Type C affine permutation with window [-1, 3, 5, 7]
Type C affine permutation with window [-1, 5, 7, 3]
Type C affine permutation with window [-1, 5, 3, 2]
```

check()

Check that self is an affine permutation.

EXAMPLES:

```

sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: x
Type C affine permutation with window [-1, 5, 3, 7]

```

has_left_descent(*i*)

Determine whether there is a descent at *i*.

INPUT:

- *i* – an integer

EXAMPLES:

```

sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: for i in C.index_set(): x.has_left_descent(i)
True
False
True
False
True

```

has_right_descent(*i*)

Determine whether there is a descent at index *i*.

INPUT:

- *i* – an integer

EXAMPLES:

```

sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: for i in C.index_set(): x.has_right_descent(i)
True
False
True
False
True

```

position(*i*)

Find the position *j* such the `self.value(j)=i`

EXAMPLES:

```

sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C.one()
sage: [x.position(i) for i in range(-10,10)] == list(range(-10,10))
True

```

to_type_a()

Return an embedding of `self` into the affine permutation group of type *A*.

EXAMPLES:

```

sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: x.to_type_a()
Type A affine permutation with window [-1, 5, 3, 7, 2, 6, 4, 10, 9]

```

value(*i*)

Return the image of the integer *i* under this permutation.

EXAMPLES:

```

sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C.one()
sage: [x.value(i) for i in range(-10,10)] == list(range(-10,10))
True

```

class sage.combinat.affine_permutation.**AffinePermutationTypeD**(*parent, lst, check=True*)

Bases: *sage.combinat.affine_permutation.AffinePermutationTypeC*

apply_simple_reflection_left(*i*)

Apply simple reflection indexed by *i* on values.

EXAMPLES:

```

sage: D = AffinePermutationGroup(['D',4,1])
sage: p=D([1,-6,5,-2])
sage: p.apply_simple_reflection_left(0)
Type D affine permutation with window [-2, -6, 5, 1]
sage: p.apply_simple_reflection_left(1)
Type D affine permutation with window [2, -6, 5, -1]
sage: p.apply_simple_reflection_left(4)
Type D affine permutation with window [1, -4, 3, -2]

```

apply_simple_reflection_right(*i*)

Apply the simple reflection indexed by *i* on positions.

EXAMPLES:

```

sage: D = AffinePermutationGroup(['D',4,1])
sage: p=D([1,-6,5,-2])
sage: p.apply_simple_reflection_right(0)
Type D affine permutation with window [6, -1, 5, -2]
sage: p.apply_simple_reflection_right(1)
Type D affine permutation with window [-6, 1, 5, -2]
sage: p.apply_simple_reflection_right(4)
Type D affine permutation with window [1, -6, 11, 4]

```

check()

Check that self is an affine permutation.

EXAMPLES:

```

sage: D = AffinePermutationGroup(['D',4,1])
sage: p = D([1,-6,5,-2])
sage: p
Type D affine permutation with window [1, -6, 5, -2]

```

has_left_descent(*i*)

Determine whether there is a descent at *i*.

INPUT:

- *i* – an integer

EXAMPLES:

```
sage: D = AffinePermutationGroup(['D',4,1])
sage: p=D([1,-6,5,-2])
sage: [p.has_left_descent(i) for i in D.index_set()]
[True, True, False, True, True]
```

has_right_descent(*i*)

Determine whether there is a descent at index *i*.

INPUT:

- *i* – an integer

EXAMPLES:

```
sage: D = AffinePermutationGroup(['D',4,1])
sage: p=D([1,-6,5,-2])
sage: [p.has_right_descent(i) for i in D.index_set()]
[True, True, False, True, False]
```

class sage.combinat.affine_permutation.**AffinePermutationTypeG**(*parent, lst, check=True*)

Bases: *sage.combinat.affine_permutation.AffinePermutation*

apply_simple_reflection_left(*i*)

Apply simple reflection indexed by *i* on values.

EXAMPLES:

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p=G([2, 10, -5, 12, -3, 5])
sage: p.apply_simple_reflection_left(0)
Type G affine permutation with window [0, 10, -7, 14, -3, 7]
sage: p.apply_simple_reflection_left(1)
Type G affine permutation with window [1, 9, -4, 11, -2, 6]
sage: p.apply_simple_reflection_left(2)
Type G affine permutation with window [3, 11, -5, 12, -4, 4]
```

apply_simple_reflection_right(*i*)

Apply the simple reflection indexed by *i* on positions.

EXAMPLES:

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: p.apply_simple_reflection_right(0)
Type G affine permutation with window [-9, -1, -5, 12, 8, 16]
sage: p.apply_simple_reflection_right(1)
Type G affine permutation with window [10, 2, 12, -5, 5, -3]
sage: p.apply_simple_reflection_right(2)
Type G affine permutation with window [2, -5, 10, -3, 12, 5]
```

check()

Check that `self` is an affine permutation.

EXAMPLES:

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: p
Type G affine permutation with window [2, 10, -5, 12, -3, 5]
```

has_left_descent(i)

Determines whether there is a descent at `i`.

INPUT:

- `i` – an integer

EXAMPLES:

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: [p.has_left_descent(i) for i in G.index_set()]
[False, True, False]
```

has_right_descent(i)

Determines whether there is a descent at index `i`.

INPUT:

- `i` – an integer

EXAMPLES:

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: [p.has_right_descent(i) for i in G.index_set()]
[False, False, True]
```

position(i)

Find the position `j` such the `self.value(j) == i`.

EXAMPLES:

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: [p.position(i) for i in p]
[1, 2, 3, 4, 5, 6]
```

to_type_a()

Return an embedding of `self` into the affine permutation group of type `A`.

EXAMPLES:

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: p.to_type_a()
Type A affine permutation with window [2, 10, -5, 12, -3, 5]
```

value(i, base_window=False)

Return the image of the integer `i` under this permutation.

INPUT:

- `base_window` – boolean indicating whether `i` is between 1 and $k + 1$; if `True`, will run a bit faster, but the method will screw up if `i` is not actually in the index set

EXAMPLES:

```
sage: G = AffinePermutationGroup(['G',2,1])
sage: p=G([2, 10, -5, 12, -3, 5])
sage: [p.value(i) for i in [1..12]]
[2, 10, -5, 12, -3, 5, 8, 16, 1, 18, 3, 11]
```

5.1.5 Alternating Sign Matrices

AUTHORS:

- Mike Hansen (2007): Initial version
- Pierre Cange, Luis Serrano (2012): Added monotone triangles
- Travis Scrimshaw (2013-28-03): Added element class for ASM's and made *MonotoneTriangles* inherit from *GelfandTsetlinPatterns*
- Jessica Striker (2013): Added additional methods
- Vincent Delecroix (2017): cleaning

class `sage.combinat.alternating_sign_matrix.AlternatingSignMatrices(n)`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Class of all $n \times n$ alternating sign matrices.

An alternating sign matrix of size n is an $n \times n$ matrix of 0's, 1's and -1 's such that the sum of each row and column is 1 and the non-zero entries in each row and column alternate in sign.

Alternating sign matrices of size n are in bijection with *monotone triangles* with n rows.

INPUT:

- n – an integer, the size of the matrices.

EXAMPLES:

This will create an instance to manipulate the alternating sign matrices of size 3:

```
sage: A = AlternatingSignMatrices(3)
sage: A
Alternating sign matrices of size 3
sage: A.cardinality()
7
```

Notably, this implementation allows to make a lattice of it:

```

sage: L = A.lattice()
sage: L
Finite lattice containing 7 elements
sage: L.category()
Category of facade finite enumerated lattice posets

```

Element

alias of *AlternatingSignMatrix*

cardinality()

Return the cardinality of self.

The number of $n \times n$ alternating sign matrices is equal to

$$\prod_{k=0}^{n-1} \frac{(3k+1)!}{(n+k)!} = \frac{1!4!7!10! \cdots (3n-2)!}{n!(n+1)!(n+2)!(n+3)! \cdots (2n-1)!}$$

EXAMPLES:

```

sage: [AlternatingSignMatrices(n).cardinality() for n in range(11)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]

```

cover_relations()

Iterate on the cover relations between the alternating sign matrices.

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: for (a,b) in A.cover_relations():
.....:     eval('a, b')
(
[1 0 0]  [0 1 0]
[0 1 0]  [1 0 0]
[0 0 1], [0 0 1]
)
(
[1 0 0]  [1 0 0]
[0 1 0]  [0 0 1]
[0 0 1], [0 1 0]
)
(
[0 1 0]  [ 0 1 0]
[1 0 0]  [ 1 -1 1]
[0 0 1], [ 0 1 0]
)
(
[1 0 0]  [ 0 1 0]
[0 0 1]  [ 1 -1 1]
[0 1 0], [ 0 1 0]
)
(
[ 0 1 0]  [0 0 1]
[ 1 -1 1]  [1 0 0]
[ 0 1 0], [0 1 0]
)

```

(continues on next page)

(continued from previous page)

```
(
[ 0  1  0] [0  1  0]
[ 1 -1  1] [0  0  1]
[ 0  1  0], [1  0  0]
)
(
[0  0  1] [0  0  1]
[1  0  0] [0  1  0]
[0  1  0], [1  0  0]
)
(
[0  1  0] [0  0  1]
[0  0  1] [0  1  0]
[1  0  0], [1  0  0]
)
)
```

first()

Return the first alternating sign matrix.

EXAMPLES:

```
sage: AlternatingSignMatrices(5).first()
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

from_contre_tableau(*comps*)

Return an alternating sign matrix from a contre-tableau.

EXAMPLES:

```
sage: ASM = AlternatingSignMatrices(3)
sage: ASM.from_contre_tableau([[1, 2, 3], [1, 2], [1]])
[0 0 1]
[0 1 0]
[1 0 0]
sage: ASM.from_contre_tableau([[1, 2, 3], [2, 3], [3]])
[1 0 0]
[0 1 0]
[0 0 1]
```

from_corner_sum(*corner*)

Return an alternating sign matrix from a corner sum matrix.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A.from_corner_sum(matrix([[0,0,0,0], [0,1,1,1], [0,1,2,2], [0,1,2,3]]))
[1 0 0]
[0 1 0]
[0 0 1]
sage: A.from_corner_sum(matrix([[0,0,0,0], [0,0,1,1], [0,1,1,2], [0,1,2,3]]))
```

(continues on next page)

(continued from previous page)

```
[ 0  1  0]
[ 1 -1  1]
[ 0  1  0]
```

from_height_function(*height*)

Return an alternating sign matrix from a height function.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A.from_height_function(matrix([[0,1,2,3],[1,2,1,2],[2,3,2,1],[3,2,1,0]]))
[0 0 1]
[1 0 0]
[0 1 0]
sage: A.from_height_function(matrix([[0,1,2,3],[1,2,1,2],[2,1,2,1],[3,2,1,0]]))
[ 0  1  0]
[ 1 -1  1]
[ 0  1  0]
```

from_monotone_triangle(*triangle*, *check=True*)

Return an alternating sign matrix from a monotone triangle.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A.from_monotone_triangle([[3, 2, 1], [2, 1], [1]])
[1 0 0]
[0 1 0]
[0 0 1]
sage: A.from_monotone_triangle([[3, 2, 1], [3, 2], [3]])
[0 0 1]
[0 1 0]
[1 0 0]

sage: A.from_monotone_triangle([[3, 2, 1], [2, 2], [1]])
Traceback (most recent call last):
...
ValueError: not a valid triangle
```

gyration_orbit_sizes()

Return the sizes of gyration orbits of self.

EXAMPLES:

```
sage: AlternatingSignMatrices(3).gyration_orbit_sizes()
[3, 2, 2]
sage: AlternatingSignMatrices(4).gyration_orbit_sizes()
[4, 8, 2, 8, 8, 8, 2, 2]

sage: A = AlternatingSignMatrices(5)
sage: li = [5,10,10,10,10,10,2,5,10,10,10,10,10,10,10,10,10,10,10,10,10,
.....: 4,10,10,10,10,10,10,4,5,10,10,10,10,10,10,2,4,5,10,10,10,10,10,10,
.....: 4,5,10,10,2,2]
```

(continues on next page)

(continued from previous page)

```
sage: A.gyration_orbit_sizes() == li
True
```

gyration_orbits()

Return the list of gyration orbits of `self`.

EXAMPLES:

```
sage: AlternatingSignMatrices(3).gyration_orbits()
((
  [1 0 0] [0 0 1] [ 0  1  0]
  [0 1 0] [0 1 0] [ 1 -1  1]
  [0 0 1], [1 0 0], [ 0  1  0]
),
 (
  [0 1 0] [1 0 0]
  [1 0 0] [0 0 1]
  [0 0 1], [0 1 0]
),
 (
  [0 0 1] [0 1 0]
  [1 0 0] [0 0 1]
  [0 1 0], [1 0 0]
))
```

last()

Return the last alternating sign matrix.

EXAMPLES:

```
sage: AlternatingSignMatrices(5).last()
[0 0 0 0 1]
[0 0 0 1 0]
[0 0 1 0 0]
[0 1 0 0 0]
[1 0 0 0 0]
```

lattice()

Return the lattice of the alternating sign matrices of size n , created by `LatticePoset`.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: L = A.lattice()
sage: L
Finite lattice containing 7 elements
```

matrix_space()

Return the underlying matrix space.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A.matrix_space()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
```

random_element()

Return a uniformly random alternating sign matrix.

EXAMPLES:

```
sage: AlternatingSignMatrices(7).random_element() # random
[ 0 0 0 0 1 0 0]
[ 0 0 1 0 -1 0 1]
[ 0 0 0 0 1 0 0]
[ 0 1 -1 0 0 1 0]
[ 1 -1 1 0 0 0 0]
[ 0 0 0 1 0 0 0]
[ 0 1 0 0 0 0 0]
sage: a = AlternatingSignMatrices(5).random_element()
sage: bool(a.number_negative_ones()) or a.is_permutation()
True
```

This is done using a modified version of Propp and Wilson’s “coupling from the past” algorithm. It creates a uniformly random Gelfand-Tsetlin triangle with top row $[n, n - 1, \dots, 2, 1]$, and then converts it to an alternating sign matrix.

size()

Return the size of the matrices in `self`.

class `sage.combinat.alternating_sign_matrix.AlternatingSignMatrix`(*parent, asm*)

Bases: `sage.structure.element.Element`

An alternating sign matrix.

An alternating sign matrix is a square matrix of 0’s, 1’s and -1 ’s such that the sum of each row and column is 1 and the non-zero entries in each row and column alternate in sign.

These were introduced in [MRR1983].

ASM_compatible(B)

Return True if `self` and `B` are compatible alternating sign matrices in the sense of [EKLP1992]. (If `self` is of size n , `B` must be of size $n + 1$.)

In [EKLP1992], there is a notion of a pair of ASM’s with sizes differing by 1 being compatible, in the sense that they can be combined to encode a tiling of the Aztec Diamond.

EXAMPLES:

```
sage: A = AlternatingSignMatrix(matrix([[0,0,1,0],[0,1,-1,1],[1,0,0,0],[0,0,1,-0]]))
sage: B = AlternatingSignMatrix(matrix([[0,0,1,0,0],[0,0,0,1,0],[1,0,0,-1,1],[0,-1,0,0,0],[0,0,0,1,0]]))
sage: A.ASM_compatible(B)
True
sage: A = AlternatingSignMatrix(matrix([[0,1,0],[1,-1,1],[0,1,0]]))
sage: B = AlternatingSignMatrix(matrix([[0,0,1,0],[0,0,0,1],[1,0,0,0],[0,1,0,-0]]))
sage: A.ASM_compatible(B)
False
```

ASM_compatible_bigger()

Return all ASM’s compatible with `self` that are of size one greater than `self`.

Given an $n \times n$ alternating sign matrix A , there are as many ASM's of size $n + 1$ compatible with A as 2 raised to the power of the number of 1's in A [EKLP1992].

EXAMPLES:

```
sage: A = AlternatingSignMatrix([[1,0],[0,1]])
sage: A.ASM_compatible_bigger()
[
[ 0  1  0] [1 0 0] [0 1 0] [1 0 0]
[ 1 -1  1] [0 0 1] [1 0 0] [0 1 0]
[ 0  1  0], [0 1 0], [0 0 1], [0 0 1]
]
sage: B = AlternatingSignMatrix([[0,1],[1,0]])
sage: B.ASM_compatible_bigger()
[
[0 0 1] [0 0 1] [0 1 0] [ 0  1  0]
[0 1 0] [1 0 0] [0 0 1] [ 1 -1  1]
[1 0 0], [0 1 0], [1 0 0], [ 0  1  0]
]
sage: B = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
sage: len(B.ASM_compatible_bigger()) == 2**4
True
```

ASM_compatible_smaller()

Return the list of all ASMs compatible with `self` that are of size one smaller than `self`.

Given an alternating sign matrix A of size n , there are as many ASM's of size $n - 1$ compatible with it as 2 raised to the power of the number of -1 's in A [EKLP1992].

EXAMPLES:

```
sage: A = AlternatingSignMatrix(matrix([[0,0,1,0],[0,1,-1,1],[1,0,0,0],[0,0,1,-0]]))
sage: A.ASM_compatible_smaller()
[
[0 0 1] [ 0  1  0]
[1 0 0] [ 1 -1  1]
[0 1 0], [ 0  1  0]
]
sage: B = AlternatingSignMatrix(matrix([[1,0,0],[0,0,1],[0,1,0]]))
sage: B.ASM_compatible_smaller()
[
[1 0]
[0 1]
]
```

corner_sum_matrix()

Return the corner sum matrix of `self`.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]) .corner_sum_matrix()
[0 0 0 0]
[0 1 1 1]
```

(continues on next page)

(continued from previous page)

```

[0 1 2 2]
[0 1 2 3]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.corner_sum_matrix()
[0 0 0 0]
[0 0 1 1]
[0 1 1 2]
[0 1 2 3]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.corner_sum_matrix()
[0 0 0 0]
[0 0 0 1]
[0 1 1 2]
[0 1 2 3]

```

gyration()

Return the alternating sign matrix obtained by applying gyration to the height function in bijection with self.

Gyration acts on height functions as follows. Go through the entries of the matrix, first those for which the sum of the row and column indices is even, then for those for which it is odd, and increment or decrement the squares by 2 wherever possible such that the resulting matrix is still a height function. Gyration was first defined in [Wie2000] as an action on fully-packed loops.

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).gyration()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.gyration()
[1 0 0]
[0 1 0]
[0 0 1]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.gyration()
[0 1 0]
[0 0 1]
[1 0 0]
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).gyration().gyration()
[ 0 1 0]
[ 1 -1 1]
[ 0 1 0]
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).gyration().gyration().gyration()
[1 0 0]
[0 1 0]
[0 0 1]

sage: A = AlternatingSignMatrices(4)
sage: M = A([[0,0,1,0],[1,0,0,0],[0,1,-1,1],[0,0,1,0]])

```

(continues on next page)

(continued from previous page)

```

sage: for i in range(5):
.....:     M = M.gyration()
sage: M
[1 0 0 0]
[0 0 0 1]
[0 1 0 0]
[0 0 1 0]

sage: a0 = a = AlternatingSignMatrices(5).random_element()
sage: for i in range(20):
.....:     a = a.gyration()
sage: a == a0
True

```

gyration_orbit()

Return the gyration orbit of `self` (including `self`).

EXAMPLES:

```

sage: AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]]).gyration_orbit()
[
 [ 0  1  0] [1 0 0] [0 0 1]
 [ 1 -1  1] [0 1 0] [0 1 0]
 [ 0  1  0], [0 0 1], [1 0 0]
]

sage: AlternatingSignMatrix([[0,1,0,0],[1,-1,1,0],[0,1,-1,1],[0,0,1,0]]).
↳gyration_orbit()
[
 [ 0  1  0  0] [1 0 0 0] [ 0  0  1  0] [0 0 0 1]
 [ 1 -1  1  0] [0 1 0 0] [ 0  1 -1  1] [0 0 1 0]
 [ 0  1 -1  1] [0 0 1 0] [ 1 -1  1  0] [0 1 0 0]
 [ 0  0  1  0], [0 0 0 1], [ 0  1  0  0], [1 0 0 0]
]

sage: len(AlternatingSignMatrix([[0,1,0,0,0,0],[0,0,1,0,0,0],[1,-1,0,0,0,1],
.....: [0,1,0,0,0,0],[0,0,0,1,0,0],[0,0,0,0,1,0]]).gyration_orbit())
12

```

height_function()

Return the height function from `self`.

A height function corresponding to an $n \times n$ ASM is an $(n+1) \times (n+1)$ matrix such that the first row is $0, 1, \dots, n$, the last row is $n, n-1, \dots, 1, 0$, and the difference between adjacent entries is 1.

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).height_function()
[0 1 2 3]
[1 0 1 2]
[2 1 0 1]
[3 2 1 0]

sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])

```

(continues on next page)

(continued from previous page)

```

sage: asm.height_function()
[0 1 2 3]
[1 2 1 2]
[2 1 2 1]
[3 2 1 0]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.height_function()
[0 1 2 3]
[1 2 1 2]
[2 3 2 1]
[3 2 1 0]

sage: A = AlternatingSignMatrices(4)
sage: all(A.from_height_function(a.height_function()) == a for a in A)
True

```

inversion_number()

Return the inversion number of self.

If we denote the entries of the alternating sign matrix as $a_{i,j}$, the inversion number is defined as $\sum_{i>k} \sum_{j<l} a_{i,j} a_{k,l}$. When restricted to permutation matrices, this gives the usual inversion number of the permutation.

This definition is equivalent to the one given in [MRR1983].

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).inversion_number()
0
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.inversion_number()
2
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.inversion_number()
2
sage: P = Permutations(5)
sage: all(p.number_of_inversions()==AlternatingSignMatrix(p.to_matrix()).
↪inversion_number() for p in P)
True

```

is_permutation()

Return True if self is a permutation matrix and False otherwise.

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0,1,0],[1,0,0],[0,0,1]])
sage: asm.is_permutation()
True
sage: asm = A([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.is_permutation()
False

```

left_key()

Return the left key of the alternating sign matrix `self`.

The left key of an alternating sign matrix was defined by Lascoux in [Lasc] and is obtained by successively removing all the -1 's until what remains is a permutation matrix. This notion corresponds to the notion of left key for semistandard tableaux. So our algorithm proceeds as follows: we map `self` to its corresponding monotone triangle, view that monotone triangle as a semistandard tableau, take its left key, and then map back through monotone triangles to the permutation matrix which is the left key.

See also [Ava2007].

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A([[0,0,1],[1,0,0],[0,1,0]]).left_key()
[0 0 1]
[1 0 0]
[0 1 0]
sage: t = A([[0,1,0],[1,-1,1],[0,1,0]]).left_key(); t
[1 0 0]
[0 0 1]
[0 1 0]
sage: parent(t)
Alternating sign matrices of size 3
```

left_key_as_permutation()

Return the permutation of the left key of `self`.

See also:

- [left_key\(\)](#)

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A([[0,0,1],[1,0,0],[0,1,0]]).left_key_as_permutation()
[3, 1, 2]
sage: t = A([[0,1,0],[1,-1,1],[0,1,0]]).left_key_as_permutation(); t
[1, 3, 2]
sage: parent(t)
Standard permutations
```

link_pattern()

Return the link pattern corresponding to the fully packed loop corresponding to `self`.

EXAMPLES:

We can extract the underlying link pattern (a non-crossing partition) from a fully packed loop:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: A.link_pattern()
[(1, 2), (3, 6), (4, 5)]
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: B.link_pattern()
[(1, 6), (2, 5), (3, 4)]
```

number_negative_ones()

Return the number of entries in `self` equal to -1.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0, 1, 0], [1, 0, 0], [0, 0, 1]])
sage: asm.number_negative_ones()
0
sage: asm = A([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: asm.number_negative_ones()
1
```

rotate_ccw()

Return the counterclockwise quarter turn rotation of `self`.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0], [0, 1, 0], [0, 0, 1]]).rotate_ccw()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = A([[0, 0, 1], [1, 0, 0], [0, 1, 0]])
sage: asm.rotate_ccw()
[1 0 0]
[0 0 1]
[0 1 0]
```

rotate_cw()

Return the clockwise quarter turn rotation of `self`.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0], [0, 1, 0], [0, 0, 1]]).rotate_cw()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = A([[0, 0, 1], [1, 0, 0], [0, 1, 0]])
sage: asm.rotate_cw()
[0 1 0]
[1 0 0]
[0 0 1]
```

to_dyck_word(*algorithm*)

Return a Dyck word determined by the specified algorithm.

The algorithm `'last_diagonal'` uses the last diagonal of the monotone triangle corresponding to `self`. The algorithm `'link_pattern'` returns the Dyck word in bijection with the link pattern of the fully packed loop.

Note that these two algorithms in general yield different Dyck words for a given alternating sign matrix.

INPUT:

- `algorithm` - either `'last_diagonal'` or `'link_pattern'`

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: A([[0,1,0],[1,0,0],[0,0,1]].to_dyck_word(algorithm = 'last_diagonal')
[1, 1, 0, 0, 1, 0]
sage: d = A([[0,1,0],[1,-1,1],[0,1,0]].to_dyck_word(algorithm = 'last_diagonal
↔'); d
[1, 1, 0, 1, 0, 0]
sage: parent(d)
Complete Dyck words
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0,1,0],[1,0,0],[0,0,1]])
sage: asm.to_dyck_word(algorithm = 'link_pattern')
[1, 0, 1, 0, 1, 0]
sage: asm = A([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.to_dyck_word(algorithm = 'link_pattern')
[1, 0, 1, 1, 0, 0]
sage: A = AlternatingSignMatrices(4)
sage: asm = A([[0,0,1,0],[1,0,0,0],[0,1,-1,1],[0,0,1,0]])
sage: asm.to_dyck_word(algorithm = 'link_pattern')
[1, 1, 1, 0, 1, 0, 0, 0]
sage: asm.to_dyck_word()
Traceback (most recent call last):
...
TypeError: ...to_dyck_word() ...argument...
sage: asm.to_dyck_word(algorithm = 'notamethod')
Traceback (most recent call last):
...
ValueError: unknown algorithm 'notamethod'

```

to_fully_packed_loop()

Return the fully packed loop configuration from self.

See also:

[FullyPackedLoop](#)

EXAMPLES:

```

sage: asm = AlternatingSignMatrix([[1,0,0],[0,1,0],[0,0,1]])
sage: fpl = asm.to_fully_packed_loop()
sage: fpl
  |           |
  |           |
  +   +  -- +
  |   |
  |   |
-- +   +   +  --
      |   |
      |   |
  +  -- +   +
  |           |
  |           |

```

to_matrix()

Return self as a regular matrix.

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: asm = A([[1, 0, 0],[0, 1, 0],[0, 0, 1]])
sage: m = asm.to_matrix(); m
[1 0 0]
[0 1 0]
[0 0 1]
sage: m.parent()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

```

to_monotone_triangle()

Return a monotone triangle from self.

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).to_monotone_triangle()
[[3, 2, 1], [2, 1], [1]]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.to_monotone_triangle()
[[3, 2, 1], [3, 1], [2]]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.to_monotone_triangle()
[[3, 2, 1], [3, 1], [3]]
sage: A.from_monotone_triangle(asm.to_monotone_triangle()) == asm
True

```

to_permutation()

Return the corresponding permutation if self is a permutation matrix.

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0, 1, 0],[1, 0, 0],[0, 0, 1]])
sage: p = asm.to_permutation(); p
[2, 1, 3]
sage: parent(p)
Standard permutations
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.to_permutation()
Traceback (most recent call last):
...
ValueError: Not a permutation matrix

```

to_semistandard_tableau()

Return the semistandard tableau corresponding the monotone triangle corresponding to self.

EXAMPLES:

```

sage: A = AlternatingSignMatrices(3)
sage: A([[0, 0, 1],[1, 0, 0],[0, 1, 0]]).to_semistandard_tableau()
[[1, 1, 3], [2, 3], [3]]
sage: t = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]]).to_semistandard_tableau(); t
[[1, 1, 2], [2, 3], [3]]
sage: parent(t)
Semistandard tableaux

```

to_six_vertex_model()

Return the six vertex model configuration from self.

This method calls `sage.combinat.six_vertex_model.from_alternating_sign_matrix()`.

EXAMPLES:

```
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.to_six_vertex_model()
  ^   ^   ^
  |   |   |
--> # -> # <- # <--
  ^   |   ^
  |   V   |
--> # <- # -> # <--
  |   ^   |
  V   |   V
--> # -> # <- # <--
  |   |   |
  V   V   V
```

transpose()

Return self transposed.

EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).transpose()
[1 0 0]
[0 1 0]
[0 0 1]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.transpose()
[0 1 0]
[0 0 1]
[1 0 0]
```

class sage.combinat.alternating_sign_matrix.ContreTableaux

Bases: `sage.structure.parent.Parent`

Factory class for the combinatorial class of contre tableaux of size n .

EXAMPLES:

```
sage: ct4 = ContreTableaux(4); ct4
Contre tableaux of size 4
sage: ct4.cardinality()
42
```

class sage.combinat.alternating_sign_matrix.ContreTableaux_n(n)

Bases: `sage.combinat.alternating_sign_matrix.ContreTableaux`

cardinality()

EXAMPLES:

```
sage: [ContreTableaux(n).cardinality() for n in range(11)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]
```

class sage.combinat.alternating_sign_matrix.**MonotoneTriangles**(*n*)

Bases: *sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPatternsTopRow*

Monotone triangles with *n* rows.

A monotone triangle is a number triangle $(a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq i}$ on $\{1, \dots, n\}$ such that:

- $a_{i,j} < a_{i,j+1}$
- $a_{i+1,j} < a_{i,j} \leq a_{i+1,j+1}$

This notably requires that the bottom column is $[1, \dots, n]$.

Alternatively a monotone triangle is a strict Gelfand-Tsetlin pattern with top row $(n, \dots, 2, 1)$.

INPUT:

- *n* – The number of rows in the monotone triangles

EXAMPLES:

This represents the monotone triangles with base $[3, 2, 1]$:

```
sage: M = MonotoneTriangles(3)
sage: M
Monotone triangles with 3 rows
sage: M.cardinality()
7
```

The monotone triangles are a lattice:

```
sage: M.lattice()
Finite lattice containing 7 elements
```

Monotone triangles can be converted to alternating sign matrices and back:

```
sage: M = MonotoneTriangles(5)
sage: A = AlternatingSignMatrices(5)
sage: all(A.from_monotone_triangle(m).to_monotone_triangle() == m for m in M)
True
```

cardinality()

Cardinality of self.

The number of monotone triangles with *n* rows is equal to

$$\prod_{k=0}^{n-1} \frac{(3k+1)!}{(n+k)!} = \frac{1!4!7!10! \cdots (3n-2)!}{n!(n+1)!(n+2)!(n+3)! \cdots (2n-1)!}$$

EXAMPLES:

```
sage: M = MonotoneTriangles(4)
sage: M.cardinality()
42
```

cover_relations()

Iterate on the cover relations in the set of monotone triangles with *n* rows.

EXAMPLES:

```

sage: M = MonotoneTriangles(3)
sage: for (a,b) in M.cover_relations():
.....:     eval('a, b')
([[3, 2, 1], [2, 1], [1]], [[3, 2, 1], [2, 1], [2]])
([[3, 2, 1], [2, 1], [1]], [[3, 2, 1], [3, 1], [1]])
([[3, 2, 1], [2, 1], [2]], [[3, 2, 1], [3, 1], [2]])
([[3, 2, 1], [3, 1], [1]], [[3, 2, 1], [3, 1], [2]])
([[3, 2, 1], [3, 1], [2]], [[3, 2, 1], [3, 1], [3]])
([[3, 2, 1], [3, 1], [2]], [[3, 2, 1], [3, 2], [2]])
([[3, 2, 1], [3, 1], [3]], [[3, 2, 1], [3, 2], [3]])
([[3, 2, 1], [3, 2], [2]], [[3, 2, 1], [3, 2], [3]])

```

lattice()

Return the lattice of the monotone triangles with n rows.

EXAMPLES:

```

sage: M = MonotoneTriangles(3)
sage: P = M.lattice()
sage: P
Finite lattice containing 7 elements

```

class sage.combinat.alternating_sign_matrix.TruncatedStaircases

Bases: [sage.structure.parent.Parent](#)

Factory class for the combinatorial class of truncated staircases of size n with last column `last_column`.

EXAMPLES:

```

sage: t4 = TruncatedStaircases(4, [2,3]); t4
Truncated staircases of size 4 with last column [2, 3]
sage: t4.cardinality()
4

```

class sage.combinat.alternating_sign_matrix.TruncatedStaircases_nlastcolumn(n , $last_column$)

Bases: [sage.combinat.alternating_sign_matrix.TruncatedStaircases](#)

cardinality()

EXAMPLES:

```

sage: T = TruncatedStaircases(4, [2,3])
sage: T.cardinality()
4

```

5.1.6 Backtracking

This library contains a generic tool for constructing large sets whose elements can be enumerated by exploring a search space with a (lazy) tree or graph structure.

- *GenericBacktracker*: Depth first search through a tree described by a children function, with branch pruning, etc.

This module has mostly been superseded by `RecursivelyEnumeratedSet`.

class sage.combinat.backtrack.GenericBacktracker($initial_data$, $initial_state$)

Bases: `object`

A generic backtrack tool for exploring a search space organized as a tree, with branch pruning, etc.

See also `RecursivelyEnumeratedSet_forest` for handling simple special cases.

class `sage.combinat.backtrack.PositiveIntegerSemigroup`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.sets.recursively_enumerated_set.RecursivelyEnumeratedSet_forest`

The commutative additive semigroup of positive integers.

This class provides an example of algebraic structure which inherits from `RecursivelyEnumeratedSet_forest`. It builds the positive integers a la Peano, and endows it with its natural commutative additive semigroup structure.

EXAMPLES:

```
sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
sage: PP = PositiveIntegerSemigroup()
sage: PP.category()
Join of Category of monoids and Category of commutative additive semigroups and
↳Category of infinite enumerated sets and Category of facade sets
sage: PP.cardinality()
+Infinity
sage: PP.one()
1
sage: PP.an_element()
1
sage: some_elements = list(PP.some_elements()); some_elements
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23,
↳24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43,
↳44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63,
↳64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83,
↳84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100]
```

children(x)

Return the single child $x+1$ of the integer x

EXAMPLES:

```
sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
sage: PP = PositiveIntegerSemigroup()
sage: list(PP.children(1))
[2]
sage: list(PP.children(42))
[43]
```

one()

Return the unit of self.

EXAMPLES:

```
sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
sage: PP = PositiveIntegerSemigroup()
sage: PP.one()
1
```

roots()

Return the single root of self.

EXAMPLES:

```
sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
sage: PP = PositiveIntegerSemigroup()
sage: list(PP.roots())
[1]
```

5.1.7 Baxter permutations

class `sage.combinat.baxter_permutations.BaxterPermutations`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The combinatorial class of Baxter permutations.

A Baxter permutation is a permutation avoiding the generalized permutation patterns $2-41-3$ and $3-14-2$. In other words, a permutation σ is a Baxter permutation if for any subword $u := u_1u_2u_3u_4$ of σ such that the letters u_2 and u_3 are adjacent in σ , the standardized version of u is neither 2413 nor 3142 .

See [Gir2012] for a study of Baxter permutations.

INPUT:

- n – (default: None) a nonnegative integer, the size of the permutations.

OUTPUT:

Return the combinatorial class of the Baxter permutations of size n if n is not None. Otherwise, return the combinatorial class of all Baxter permutations.

EXAMPLES:

```
sage: BaxterPermutations(5)
Baxter permutations of size 5
sage: BaxterPermutations()
Baxter permutations
```

class `sage.combinat.baxter_permutations.BaxterPermutations_all` ($n=None$)

Bases: `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`, `sage.combinat.baxter_permutations.BaxterPermutations`

The enumerated set of all Baxter permutations.

See *BaxterPermutations* for the definition of Baxter permutations.

EXAMPLES:

```
sage: from sage.combinat.baxter_permutations import BaxterPermutations_all
sage: BaxterPermutations_all()
Baxter permutations
```

to_pair_of_twin_binary_trees(p)

Apply a bijection between Baxter permutations of size `self._n` and the set of pairs of twin binary trees with `self._n` nodes.

INPUT:

- p – a Baxter permutation.

OUTPUT:

The pair of twin binary trees (T_L, T_R) where T_L (resp. T_R) is obtained by inserting the letters of p from left to right (resp. right to left) following the binary search tree insertion algorithm. This is called the *Baxter P-symbol* in [Gir2012] Definition 4.1.

Note: This method only works when p is a permutation. For words with repeated letters, it would return two “right binary search trees” (in the terminology of [Gir2012]), which conflicts with the definition in [Gir2012].

EXAMPLES:

```
sage: BaxterPermutations().to_pair_of_twin_binary_trees(Permutation([]))
(., .)
sage: BaxterPermutations().to_pair_of_twin_binary_trees(Permutation([1, 2, 3]))
(1[., 2[., 3[., .]], 3[2[1[., .], .], .])
sage: BaxterPermutations().to_pair_of_twin_binary_trees(Permutation([3, 4, 1, 2]))
(3[1[., 2[., .]], 4[., .]], 2[1[., .], 4[3[., .], .]])
```

class `sage.combinat.baxter_permutations.BaxterPermutations_size`(n)

Bases: `sage.combinat.baxter_permutations.BaxterPermutations`

The enumerated set of Baxter permutations of a given size.

See `BaxterPermutations` for the definition of Baxter permutations.

EXAMPLES:

```
sage: from sage.combinat.baxter_permutations import BaxterPermutations_size
sage: BaxterPermutations_size(5)
Baxter permutations of size 5
```

cardinality()

Return the number of Baxter permutations of size `self._n`.

For any positive integer n , the number of Baxter permutations of size n equals

$$\sum_{k=1}^n \frac{\binom{n+1}{k-1} \binom{n+1}{k} \binom{n+1}{k+1}}{\binom{n+1}{1} \binom{n+1}{2}}.$$

This is OEIS sequence A001181.

EXAMPLES:

```
sage: [BaxterPermutations(n).cardinality() for n in range(13)]
[1, 1, 2, 6, 22, 92, 422, 2074, 10754, 58202, 326240, 1882960, 11140560]

sage: BaxterPermutations(3r).cardinality()
6
sage: parent(_)
Integer Ring
```

5.1.8 Binary Recurrence Sequences

This class implements several methods relating to general linear binary recurrence sequences, including a sieve to find perfect powers in integral linear binary recurrence sequences.

EXAMPLES:

```

sage: R = BinaryRecurrenceSequence(1,1)      #the Fibonacci sequence
sage: R(137)      #the 137th term of the Fibonacci sequence
19134702400093278081449423917
sage: R(137) == fibonacci(137)
True
sage: [R(i) % 4 for i in range(12)]
[0, 1, 1, 2, 3, 1, 0, 1, 1, 2, 3, 1]
sage: R.period(4)      #the period of the fibonacci sequence modulo 4
6
sage: R.pthpowers(2, 10**10)      # long time (7 seconds) -- in fact these are all
↪ squares, c.f. [BMS06]
[0, 1, 2, 12]

sage: S = BinaryRecurrenceSequence(8,1) #a Lucas sequence
sage: S.period(73)
148
sage: S(5) % 73 == S(5 +148) %73
True
sage: S.pthpowers(3,10**10)      # long time (3 seconds) -- provably finds the indices of
↪ all 3rd powers less than 10^10
[0, 1, 2]

sage: T = BinaryRecurrenceSequence(2,0,1,2)
sage: [T(i) for i in range(10)]
[1, 2, 4, 8, 16, 32, 64, 128, 256, 512]
sage: T.is_degenerate()
True
sage: T.is_geometric()
True
sage: T.pthpowers(7,10**30)
Traceback (most recent call last):
...
ValueError: the degenerate binary recurrence sequence is geometric or quasigeometric and
↪ has many pth powers

```

AUTHORS:

- Isabel Vogt (2013): initial version

See [SV2013], [BMS2006], and [SS1983].

class `sage.combinat.binary_recurrence_sequences.BinaryRecurrenceSequence`($b, c, u_0=0, u_1=1$)
 Bases: `sage.structure.sage_object.SageObject`

Create a linear binary recurrence sequence defined by initial conditions u_0 and u_1 and recurrence relation $u_{n+2} = b * u_{n+1} + c * u_n$.

INPUT:

- b – an integer (partially determining the recurrence relation)

- c – an integer (partially determining the recurrence relation)
- u_0 – an integer (the 0th term of the binary recurrence sequence)
- u_1 – an integer (the 1st term of the binary recurrence sequence)

OUTPUT:

- An integral linear binary recurrence sequence defined by u_0 , u_1 , and $u_{n+2} = b * u_{n+1} + c * u_n$

See also:

`fibonacci()`, `lucas_number1()`, `lucas_number2()`

EXAMPLES:

```
sage: R = BinaryRecurrenceSequence(3,3,2,1)
sage: R
Binary recurrence sequence defined by: u_n = 3 * u_{n-1} + 3 * u_{n-2};
With initial conditions: u_0 = 2, and u_1 = 1
```

is_arithmetic()

Decide whether the sequence is degenerate and an arithmetic sequence.

The sequence is arithmetic if and only if $u_1 - u_0 = u_2 - u_1 = u_3 - u_2$.

This corresponds to the matrix $F = \begin{bmatrix} 0 & 1 \\ c & b \end{bmatrix}$ being nondiagonalizable and $\alpha/\beta = 1$.

EXAMPLES:

```
sage: S = BinaryRecurrenceSequence(2,-1)
sage: [S(i) for i in range(10)]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: S.is_arithmetic()
True
```

is_degenerate()

Decide whether the binary recurrence sequence is degenerate.

Let α and β denote the roots of the characteristic polynomial $p(x) = x^2 - bx - c$. Let $a = u_1 - u_0\beta/(\beta - \alpha)$ and $b = u_1 - u_0\alpha/(\beta - \alpha)$. The sequence is, thus, given by $u_n = a\alpha^n - b\beta^n$. Then we say that the sequence is nondegenerate if and only if $a * b * \alpha * \beta \neq 0$ and α/β is not a root of unity.

More concretely, there are 4 classes of degeneracy, that can all be formulated in terms of the matrix $F = \begin{bmatrix} 0 & 1 \\ c & b \end{bmatrix}$.

- F is singular – this corresponds to $c = 0$, and thus $\alpha * \beta = 0$. This sequence is geometric after term u_0 and so we call it **quasigeometric**.
- $v = \begin{bmatrix} u_0 \\ u_1 \end{bmatrix}$ is an eigenvector of F – this corresponds to a **geometric** sequence with $a * b = 0$.
- F is nondiagonalizable – this corresponds to $\alpha = \beta$. This sequence will be the point-wise product of an arithmetic and geometric sequence.
- F^k is scalar, for some $k > 1$ – this corresponds to α/β a k th root of unity. This sequence is a union of several geometric sequences, and so we again call it **quasigeometric**.

EXAMPLES:

```
sage: S = BinaryRecurrenceSequence(0,1)
sage: S.is_degenerate()
True
```

(continues on next page)

(continued from previous page)

```

sage: S.is_geometric()
False
sage: S.is_quasigeometric()
True

sage: R = BinaryRecurrenceSequence(3,-2)
sage: R.is_degenerate()
False

sage: T = BinaryRecurrenceSequence(2,-1)
sage: T.is_degenerate()
True
sage: T.is_arithmetic()
True

```

is_geometric()

Decide whether the binary recurrence sequence is geometric - ie a geometric sequence.

This is a subcase of a degenerate binary recurrence sequence, for which $ab = 0$, i.e. $u_n/u_{n-1} = r$ for some value of r .

See `is_degenerate()` for a description of degeneracy and definitions of a and b .

EXAMPLES:

```

sage: S = BinaryRecurrenceSequence(2,0,1,2)
sage: [S(i) for i in range(10)]
[1, 2, 4, 8, 16, 32, 64, 128, 256, 512]
sage: S.is_geometric()
True

```

is_quasigeometric()

Decide whether the binary recurrence sequence is degenerate and similar to a geometric sequence, i.e. the union of multiple geometric sequences, or geometric after term u_0 .

If α/β is a k th root of unity, where $k > 1$, then necessarily $k = 2, 3, 4, 6$. Then $F = \begin{bmatrix} 0 & 1 \\ c & b \end{bmatrix}$ is diagonalizable, and $F^k = \begin{bmatrix} \alpha^k & 0 \\ 0 & \beta^k \end{bmatrix}$ is scalar matrix. Thus for all values of $j \pmod k$, the $j \pmod k$ terms of u_n form a geometric series.

If α or β is zero, this implies that $c = 0$. This is the case when F is singular. In this case, u_1, u_2, u_3, \dots is geometric.

EXAMPLES:

```

sage: S = BinaryRecurrenceSequence(0,1)
sage: [S(i) for i in range(10)]
[0, 1, 0, 1, 0, 1, 0, 1, 0, 1]
sage: S.is_quasigeometric()
True

sage: R = BinaryRecurrenceSequence(3,0)
sage: [R(i) for i in range(10)]
[0, 1, 3, 9, 27, 81, 243, 729, 2187, 6561]
sage: R.is_quasigeometric()
True

```

period(*m*)

Return the period of the binary recurrence sequence modulo an integer *m*.

If n_1 is congruent to n_2 modulo `period(m)`, then u_{n_1} is congruent to u_{n_2} modulo *m*.

INPUT:

- *m* – an integer (modulo which the period of the recurrence relation is calculated).

OUTPUT:

- The integer (the period of the sequence modulo *m*)

EXAMPLES:

If $p = \pm 1 \pmod{5}$, then the period of the Fibonacci sequence mod *p* is $p - 1$ (c.f. Lemma 3.3 of [BMS2006]).

```
sage: R = BinaryRecurrenceSequence(1,1)
sage: R.period(31)
30
sage: [R(i) % 4 for i in range(12)]
[0, 1, 1, 2, 3, 1, 0, 1, 1, 2, 3, 1]
sage: R.period(4)
6
```

This function works for degenerate sequences as well.

```
sage: S = BinaryRecurrenceSequence(2,0,1,2)
sage: S.is_degenerate()
True
sage: S.is_geometric()
True
sage: [S(i) % 17 for i in range(16)]
[1, 2, 4, 8, 16, 15, 13, 9, 1, 2, 4, 8, 16, 15, 13, 9]
sage: S.period(17)
8
```

Note: The answer is cached.

pthpowers(*p*, *Bound*)

Find the indices of provably all *p*th powers in the recurrence sequence bounded by *Bound*.

Let u_n be a binary recurrence sequence. A *p*th power in u_n is a solution to $u_n = y^p$ for some integer *y*. There are only finitely many *p*th powers in any recurrence sequence [SS1983].

INPUT:

- *p* - a rational prime integer (the fixed *p* in $u_n = y^p$)
- *Bound* - a natural number (the maximum index *n* in $u_n = y^p$ that is checked).

OUTPUT:

- A list of the indices of all *p*th powers less bounded by *Bound*. If the sequence is degenerate and there are many *p*th powers, raises `ValueError`.

EXAMPLES:

```

sage: R = BinaryRecurrenceSequence(1,1)      #the Fibonacci sequence
sage: R.pthpowers(2, 10**10)                # long time (7 seconds) -- in fact these
↪are all squares, c.f. [BMS2006]_
[0, 1, 2, 12]

sage: S = BinaryRecurrenceSequence(8,1) #a Lucas sequence
sage: S.pthpowers(3,10**10)                # long time (3 seconds) -- provably finds the
↪indices of all 3rd powers less than 10^10
[0, 1, 2]

sage: Q = BinaryRecurrenceSequence(3,3,2,1)
sage: Q.pthpowers(11,10**10)                # long time (7.5 seconds)
[1]

```

If the sequence is degenerate, and there are no p th powers, returns []. Otherwise, if there are many p th powers, raises `ValueError`.

```

sage: T = BinaryRecurrenceSequence(2,0,1,2)
sage: T.is_degenerate()
True
sage: T.is_geometric()
True
sage: T.pthpowers(7,10**30)
Traceback (most recent call last):
...
ValueError: the degenerate binary recurrence sequence is geometric or
↪quasigeometric and has many pth powers

sage: L = BinaryRecurrenceSequence(4,0,2,2)
sage: [L(i).factor() for i in range(10)]
[2, 2, 2^3, 2^5, 2^7, 2^9, 2^11, 2^13, 2^15, 2^17]
sage: L.is_quasigeometric()
True
sage: L.pthpowers(2,10**30)
[]

```

Note: This function is primarily optimized in the range where `Bound` is much larger than `p`.

5.1.9 Binary Trees

This module deals with binary trees as mathematical (in particular immutable) objects.

Note: If you need the data-structure for example to represent sets or hash tables with AVL trees, you should have a look at `sage.misc.sagex_ds`.

AUTHORS:

- Florent Hivert (2010-2011): initial implementation.
- Adrien Boussicault (2015): Hook statistics.

```
class sage.combinat.binary_tree.BinaryTree(parent, children=None, check=True)
Bases: sage.combinat.abstract_tree.AbstractClonableTree, sage.structure.list_clone.ClonableArray
```

Binary trees.

Binary trees here mean ordered (a.k.a. plane) finite binary trees, where “ordered” means that the children of each node are ordered.

Binary trees contain nodes and leaves, where each node has two children while each leaf has no children. The number of leaves of a binary tree always equals the number of nodes plus 1.

INPUT:

- `children` – `None` (default) or a list, tuple or iterable of length 2 of binary trees or convertible objects. This corresponds to the standard recursive definition of a binary tree as either a leaf or a pair of binary trees. Syntactic sugar allows leaving out all but the outermost calls of the `BinaryTree()` constructor, so that, e. g., `BinaryTree([BinaryTree(None), BinaryTree(None)])` can be shortened to `BinaryTree([None, None])`. It is also allowed to abbreviate `[None, None]` by `[]`.
- `check` – (default: `True`) whether check for binary should be performed or not.

EXAMPLES:

```
sage: BinaryTree()
.
sage: BinaryTree(None)
.
sage: BinaryTree([])
[., .]
sage: BinaryTree([None, None])
[., .]
sage: BinaryTree([None, []])
[., [., .]]
sage: BinaryTree([], None)
[[., .], .]
sage: BinaryTree("[[], .]")
[[., .], .]
sage: BinaryTree([None, BinaryTree([None, None]])]
[., [., .]]

sage: BinaryTree([], None, [])
Traceback (most recent call last):
...
ValueError: this is not a binary tree
```

`as_ordered_tree` (*with_leaves=True*)

Return the same tree seen as an ordered tree. By default, leaves are transformed into actual nodes, but this can be avoided by setting the optional variable `with_leaves` to `False`.

EXAMPLES:

```
sage: bt = BinaryTree([]); bt
[., .]
sage: bt.as_ordered_tree()
[[], []]
sage: bt.as_ordered_tree(with_leaves = False)
[]
```

(continues on next page)

(continued from previous page)

```

sage: bt = bt.canonical_labelling(); bt
1[., .]
sage: bt.as_ordered_tree()
1[None[], None[]]
sage: bt.as_ordered_tree(with_leaves=False)
1[]

```

canonical_labelling(*shift=1*)

Return a labelled version of `self`.

The canonical labelling of a binary tree is a certain labelling of the nodes (not the leaves) of the tree. The actual canonical labelling is currently unspecified. However, it is guaranteed to have labels in $1..n$ where n is the number of nodes of the tree. Moreover, two (unlabelled) trees compare as equal if and only if their canonical labelled trees compare as equal.

EXAMPLES:

```

sage: BinaryTree().canonical_labelling()
.
sage: BinaryTree([]).canonical_labelling()
1[., .]
sage: BinaryTree([[[]], [[]], None], [[], []]).canonical_labelling()
5[2[1[., .], 4[3[., .], .]], 7[6[., .], 8[., .]]]

```

canopee()

Return the canopee of `self`.

The *canopee* of a non-empty binary tree T with n internal nodes is the list l of 0 and 1 of length $n - 1$ obtained by going along the leaves of T from left to right except the two extremal ones, writing 0 if the leaf is a right leaf and 1 if the leaf is a left leaf.

EXAMPLES:

```

sage: BinaryTree([]).canopee()
[]
sage: BinaryTree([None, []]).canopee()
[1]
sage: BinaryTree([[[]], None]).canopee()
[0]
sage: BinaryTree([[[]], []]).canopee()
[0, 1]
sage: BinaryTree([[[]], [[]], None], [[], []]).canopee()
[0, 1, 0, 0, 1, 0, 1]

```

The number of pairs (t_1, t_2) of binary trees of size n such that the canopee of t_1 is the complementary of the canopee of t_2 is also the number of Baxter permutations (see [DG1994], see also [OEIS sequence A001181](#)). We check this in small cases:

```

sage: [len([(u,v) for u in BinaryTrees(n) for v in BinaryTrees(n)
.....:         if [1 - x for x in u.canopee()] == v.canopee()])
.....:      for n in range(1, 5)]
[1, 2, 6, 22]

```

Here is a less trivial implementation of this:

```

sage: from sage.sets.finite_set_map_cy import fibers
sage: def baxter(n):
.....:     f = fibers(lambda t: tuple(t.canopee()),
.....:                 BinaryTrees(n))
.....:     return sum(len(f[i])*len(f[tuple(1-x for x in i)])
.....:                for i in f)
sage: [baxter(n) for n in range(1, 7)]
[1, 2, 6, 22, 92, 422]

```

check()

Check that self is a binary tree.

EXAMPLES:

```

sage: BinaryTree([[[]], [[]]) # indirect doctest
[[., .], [., .]]
sage: BinaryTree([[[]], [], [[]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: this is not a binary tree
sage: BinaryTree([[[]]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: this is not a binary tree

```

comb(side='left')

Return the comb of a tree.

There are two combs in a binary tree: a left comb and a right comb.

Consider all the vertices of the leftmost (resp. rightmost) branch of the root. The left (resp. right) comb is the list of right (resp. left) subtrees of each of these vertices.

INPUT:

- side – (default: 'left') set to 'left' to obtain a left comb, and to 'right' to obtain a right comb.

OUTPUT:

A list of binary trees.

See also:

[over_decomposition\(\)](#), [under_decomposition\(\)](#)

EXAMPLES:

```

sage: BT = BinaryTree( '.' )
sage: [BT.comb('left'), BT.comb('right')]
[[[]], [[]]
sage: BT = BinaryTree( '[.,.]' )
sage: [BT.comb('left'), BT.comb('right')]
[[[]], [[]]
sage: BT = BinaryTree( '[[[.,.], .], [.,.]]' )
sage: BT.comb('left')
[., .]
sage: BT.comb('right')
[.]

```

(continues on next page)

(continued from previous page)

```

sage: BT = BinaryTree( '[[[[[., [., .]], .], [[., .], [[., .], [., .]], [., .
↪]]]], [., [[., .], [[., .], [., .]], .]], .]]' )
sage: ascii_art(BT)
      o
     / \
    /   \
   /     \
  /       \
 /         \
o           o
 \         /
  \       /
   \     /
    \   /
     \ /
      o
sage: BT.comb('left')
[[[., .], [[., .], [., .]], [., .]], ., [., .]]
sage: ascii_art(BT.comb('left'))
[  --o--   , , o ]
[ /       \ ]
[ o       o ]
[ /       \ ]
[  o     o ]
[ /       \ ]
[  o     o ]
sage: BT.comb('right')
[., [[., .], [[., .], [., .]], .]]
sage: ascii_art(BT.comb('right'))
[ ,  --o-- ]
[ /       \ ]
[  o     o ]
[ /       \ ]
[  o     o ]
[ /       \ ]
[  o     o ]

```

dendriform_shuffle(*other*)

Return the list of terms in the dendriform product.

This is the list of all binary trees that can be obtained by identifying the rightmost path in `self` and the leftmost path in `other`. Every term corresponds to a shuffle of the vertices on the rightmost path in `self` and the vertices on the leftmost path in `other`.

EXAMPLES:

```

sage: u = BinaryTree()
sage: g = BinaryTree([])
sage: l = BinaryTree([g, u])
sage: r = BinaryTree([u, g])

sage: list(g.dendriform_shuffle(g))
[[[., .], .], [., [., .]]]

```

(continues on next page)

(continued from previous page)

```

sage: list(l.dendriform_shuffle(l))
[[[[[., .], .], .], .], [[[., .], [., .]], .],
[[., .], [[., .], .]]]

sage: list(l.dendriform_shuffle(r))
[[[[[., .], .], [., .]], [[., .], [., [., .]]]]]

```

graph(with_leaves=True)

Convert self to a digraph.

By default, this graph contains both nodes and leaves, hence is never empty. To obtain a graph which contains only the nodes, the with_leaves optional keyword variable has to be set to False.

The resulting digraph is endowed with a combinatorial embedding, in order to be displayed correctly.

INPUT:

- with_leaves – (default: True) a Boolean, determining whether the resulting graph will be formed from the leaves and the nodes of self (if True), or only from the nodes of self (if False)

EXAMPLES:

```

sage: t1 = BinaryTree([], None)
sage: t1.graph()
Digraph on 5 vertices
sage: t1.graph(with_leaves=False)
Digraph on 2 vertices

sage: t1 = BinaryTree([], [[], None])
sage: t1.graph()
Digraph on 9 vertices
sage: t1.graph().edges(sort=True)
[(0, 1, None), (0, 4, None), (1, 2, None), (1, 3, None), (4, 5, None), (4, 8, None), (5, 6, None), (5, 7, None)]
sage: t1.graph(with_leaves=False)
Digraph on 4 vertices
sage: t1.graph(with_leaves=False).edges(sort=True)
[(0, 1, None), (0, 2, None), (2, 3, None)]

sage: t1 = BinaryTree()
sage: t1.graph()
Digraph on 1 vertex
sage: t1.graph(with_leaves=False)
Digraph on 0 vertices

sage: BinaryTree().graph()
Digraph on 3 vertices
sage: BinaryTree().graph(with_leaves=False)
Digraph on 1 vertex

sage: t1 = BinaryTree([], [[], []])
sage: t1.graph(with_leaves=False)
Digraph on 5 vertices

```

(continues on next page)

(continued from previous page)

```
sage: t1.graph(with_leaves=False).edges(sort=True)
[(0, 1, None), (0, 2, None), (2, 3, None), (2, 4, None)]
```

hook_number()

Return the number of hooks.

Recalling that a branch is a path from a vertex of the tree to a leaf, the leftmost (resp. rightmost) branch of a vertex v is the branch from v made only of left (resp. right) edges.

The hook of a vertex v is a set of vertices formed by the union of v , and the vertices of its leftmost and rightmost branches.

There is a unique way to partition the set of vertices in hooks. The number of hooks in such a partition is the hook number of the tree.

We can obtain this partition recursively by extracting the root's hook and iterating the process on each tree of the remaining forest.

EXAMPLES:

```
sage: BT = BinaryTree( '.' )
sage: BT.hook_number()
0
sage: BT = BinaryTree( '[...]' )
sage: BT.hook_number()
1
sage: BT = BinaryTree( '[[[...], .], [...]]' ); ascii_art(BT)
  o
 / \
o   o
 /
o
sage: BT.hook_number()
1
sage: BT = BinaryTree( '[[[[[., [., .]], .], [[., .], [[[, .], [., .]], [., .
↪]]], [., [[[, .], [[[, .], [., .]], .]], .]]]' )
sage: ascii_art(BT)
      o-----o-----
     /         \
  o-----o-----o
 /         \         \
o         o         o
 /         \         / \
o         o         o   o
 \         /         / \
  o       o         o   o
   \     /         / \
    o   o         o   o
     \ /         / \
      o o         o o
sage: BT.hook_number()
6
```

in_order_traversal(*node_action=None, leaf_action=None*)

Explore the binary tree `self` using the depth-first infix-order traversal algorithm, executing the

`node_action` function whenever traversing a node and executing the `leaf_action` function whenever traversing a leaf.

In more detail, what this method does to a tree T is the following:

```

if the root of `T` is a node:
    apply in_order_traversal to the left subtree of `T`
        (with the same node_action and leaf_action);
    apply node_action to the root of `T`;
    apply in_order_traversal to the right subtree of `T`
        (with the same node_action and leaf_action);
else:
    apply leaf_action to the root of `T`.

```

For example on the following binary tree T , where we denote leaves by a, b, c, \dots and nodes by $1, 2, 3, \dots$:

this method first applies `leaf_action` to a , then applies `node_action` to 1, then `leaf_action` to b , then `node_action` to 2, etc., with the vertices being traversed in the order $a, 1, b, 2, c, 3, d, 4, e, 5, f, 6, g, 7, h, 8, i$.

See [in_order_traversal_iter\(\)](#) for a version of this algorithm which only iterates through the vertices rather than applying any function to them.

INPUT:

- `node_action` – (optional) a function which takes a node in input and does something during the exploration
- `leaf_action` – (optional) a function which takes a leaf in input and does something during the exploration

in_order_traversal_iter()

The depth-first infix-order traversal iterator for the binary tree `self`.

This method iters each vertex (node and leaf alike) of the given binary tree following the depth-first infix order traversal algorithm.

The *depth-first infix order traversal algorithm* iterates through a binary tree as follows:

```

iterate through the left subtree (by the depth-first infix
    order traversal algorithm);
yield the root;
iterate through the right subtree (by the depth-first infix
    order traversal algorithm).

```

For example on the following binary tree T , where we denote leaves by a, b, c, \dots and nodes by $1, 2, 3, \dots$:

the depth-first infix-order traversal algorithm iterates through the vertices of T in the following order: $a, 1, b, 2, c, 3, d, 4, e, 5, f, 6, g, 7, h, 8, i$.

See `in_order_traversal()` for a version of this algorithm which not only iterates through, but actually does something at the vertices of tree.

is_complete()

Return True if `self` is complete, else return False.

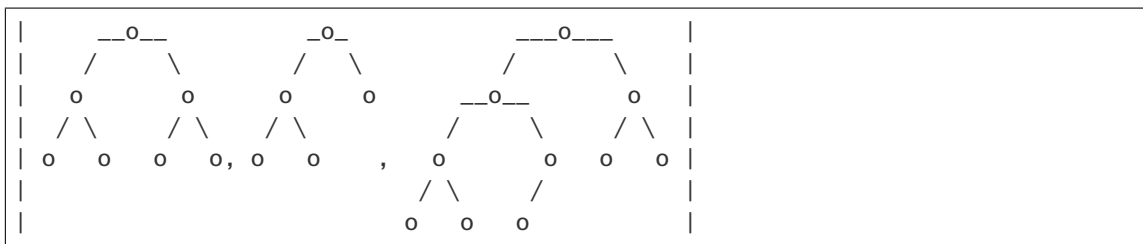

In a nutshell, a complete binary tree is a perfect binary tree except possibly in the last level, with all nodes in the last level “flush to the left”.

In more detail: A complete binary tree (also called binary heap) is a binary tree in which every level, except possibly the last one (the deepest), is completely filled. At depth n , all nodes must be as far left as possible.

For example:

is not complete but the following ones are:

EXAMPLES:

```
sage: def lst(i):
....:     return [bt for bt in BinaryTrees(i) if bt.is_complete()]
sage: for i in range(8): ascii_art(lst(i)) # long time
[ ]
[ o ]
[ o ]
[ / ]
[ o ]
[ o ]
```

(continues on next page)

(continued from previous page)

**is_empty()**

Return whether `self` is empty.

The notion of emptiness employed here is the one which defines a binary tree to be empty if its root is a leaf. There is precisely one empty binary tree.

EXAMPLES:

```

sage: BinaryTree().is_empty()
True
sage: BinaryTree([]).is_empty()
False
sage: BinaryTree([], None).is_empty()
False

```

is_full()

Return True if `self` is full, else return False.

A full binary tree is a tree in which every node either has two child nodes or has two child leaves.

This is also known as *proper binary tree* or *2-tree* or *strictly binary tree*.

For example:

is not full but the next one is:

EXAMPLES:

```

sage: BinaryTree([[[[],None],[None,[]]], []).is_full()
False
sage: BinaryTree([[[[],[]],[[],[]]], []).is_full()
True
sage: ascii_art([bt for bt in BinaryTrees(5) if bt.is_full()])
[  _o_   ,  _o_   ]
[ /   \   /   \ ]
[ o     o o     o ]
[   / \   / \   ]
[   o  o o  o   ]

```

is_perfect()

Return True if self is perfect, else return False.

A perfect binary tree is a full tree in which all leaves are at the same depth.

For example:

is not perfect but the next one is:

EXAMPLES:

```

sage: def lst(i):
....:     return [bt for bt in BinaryTrees(i) if bt.is_perfect()]
sage: for i in range(8): ascii_art(lst(i)) # long time
[ ]
[ o ]
[ ]
[ o ]
[ / \ ]

```

(continues on next page)

(continued from previous page)

```

[ o  o ]
[   ]
[   ]
[   ]
[   --o--   ]
[  /      \ ]
[ o        o ]
[ / \    / \ ]
[ o  o  o  o ]

```

left_border_symmetry()

Return the tree where a symmetry has been applied recursively on all left borders. If a tree is made of three trees $[T_1, T_2, T_3]$ on its left border, it becomes $[T'_1, T'_2, T'_3]$ where same symmetry has been applied to T_1, T_2, T_3 .

EXAMPLES:

```

sage: BinaryTree().left_border_symmetry()
.
sage: BinaryTree([]).left_border_symmetry()
[., .]
sage: BinaryTree([[None, []], None]).left_border_symmetry()
[[., .], [., .]]
sage: BinaryTree([[None, [None, []]], None]).left_border_symmetry()
[[., .], [., [., .]]]
sage: bt = BinaryTree([[None, [None, []]], None]).canonical_labelling()
sage: bt
4[1[., 2[., 3[., .]], .]
sage: bt.left_border_symmetry()
1[4[., .], 2[., 3[., .]]]

```

left_children_node_number(*direction='left'*)

Return the number of nodes which are left children in *self*.

Every node (except the root) is either the left child or the right child of its parent node. The total number of nodes is 1 plus the number of left-children nodes plus the number of right-children nodes.

INPUT:

- *direction* – either 'left' (default) or 'right' ; if set to 'right', instead count nodes that are right children

EXAMPLES:

```

sage: bt = BinaryTree([[None, [[]], [None, [[]], None]])
sage: ascii_art(bt)
  --o--
 /      \
o        o
 \      /
  o    o
 / \  / \
o  o o  o
sage: bt.left_children_node_number('left')
3

```

(continues on next page)

(continued from previous page)

```

sage: bt.left_children_node_number('right')
4
sage: all(5 == 1 + bt.left_children_node_number()
.....:      + bt.left_children_node_number('right')
.....:      for bt in BinaryTrees(5))
True

```

left_right_symmetry()

Return the left-right symmetrized tree of self.

EXAMPLES:

```

sage: BinaryTree().left_right_symmetry()
.
sage: BinaryTree([]).left_right_symmetry()
[., .]
sage: BinaryTree([[None]).left_right_symmetry()
[., [., .]]
sage: BinaryTree([[None, []], None]).left_right_symmetry()
[., [[., .], .]]

```

left_rotate()

Return the result of left rotation applied to the binary tree self.

Left rotation on binary trees is defined as follows: Let T be a binary tree such that the right child of the root of T is a node. Let A be the left child of the root of T , and let B and C be the left and right children of the right child of the root of T . (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Then, the left rotation of T is the binary tree in which the right child of the root is C , whereas the left child of the root is a node whose left and right children are A and B . In pictures:

```

|   *           *   |
|  / \         / \  |
| A  *  -left-rotate-> *  C |
|   / \         / \  |
|  B  C         A  B  |

```

where asterisks signify a single node each (but A , B and C might be empty).

For example,

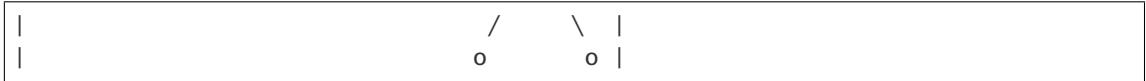

```

|   _o_         o   |
|  / \         / \  |
| o   o  -left-rotate-> o   |
|   /         / \  |
|  o         o   o  |
|
|<BLANKLINE>
|   _o_         o   |
|  / \         / \  |
| o   o  -left-rotate-> o   |
|   / \         / \  |
|  o   o         o   o  |
|   / \         / \  |
|  o   o         o   o  |

```

(continues on next page)

(continued from previous page)

Left rotation is the inverse operation to right rotation (*right_rotate()*).

See also:

right_rotate()

EXAMPLES:

```

sage: b = BinaryTree([[[]],[[],None]]); ascii_art([b])
[  _o_ ]
[ /   \ ]
[ o     o ]
[     / ]
[     o ]
sage: ascii_art([b.left_rotate()])
[     o ]
[     / ]
[     o ]
[ /   \ ]
[ o     o ]
sage: b.left_rotate().right_rotate() == b
True

```

make_leaf()

Modify self so that it becomes a leaf (i. e., an empty tree).

Note: self must be in a mutable state.

See also:

make_node

EXAMPLES:

```

sage: t = BinaryTree([None, None])
sage: t.make_leaf()
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t1:
.....:     t1.make_leaf()
sage: t, t1
([., .], .)

```

make_node(*child_list*=[None, None])

Modify self so that it becomes a node with children *child_list*.

INPUT:

- *child_list* – a pair of binary trees (or objects convertible to)

Note: `self` must be in a mutable state.

See also:

[*make_leaf*](#)

EXAMPLES:

```

sage: t = BinaryTree()
sage: t.make_node([None, None])
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t1:
....:     t1.make_node([None, None])
sage: t, t1
(., [., .])
sage: with t.clone() as t:
....:     t.make_node([BinaryTree(), BinaryTree(), BinaryTree([])])
Traceback (most recent call last):
...
ValueError: the list must have length 2
sage: with t1.clone() as t2:
....:     t2.make_node([t1, t1])
sage: with t2.clone() as t3:
....:     t3.make_node([t1, t2])
sage: t1, t2, t3
([., .], [[., .], [., .]], [[., .], [[., .], [., .]]])

```

over(*bt*)

Return `self` over `bt`, where “over” is the over ($/$) operation.

If T and T' are two binary trees, then T over T' (written T/T') is defined as the tree obtained by grafting T' on the rightmost leaf of T . More precisely, T/T' is defined by identifying the root of the T' with the rightmost leaf of T . See section 4.5 of [HNT2005].

If T is empty, then $T/T' = T'$.

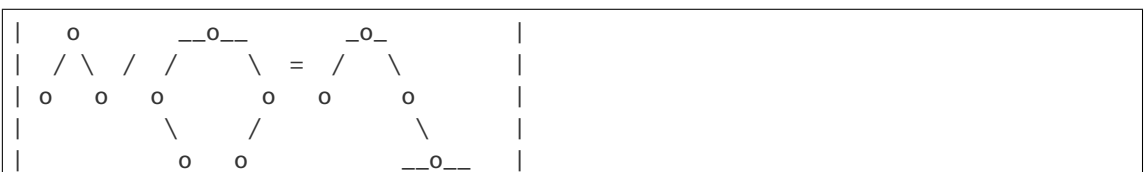

The definition of this “over” operation goes back to Loday-Ronco [LR0102066] (Definition 2.2), but it is denoted by \backslash and called the “under” operation there. In fact, trees in sage have their root at the top, contrary to the trees in [LR0102066] which are growing upwards. For this reason, the names of the over and under operations are swapped, in order to keep a graphical meaning. (Our notation follows that of section 4.5 of [HNT2005].)

See also:

[*under\(\)*](#)

EXAMPLES:

Showing only the nodes of a binary tree, here is an example for the over operation:

(continues on next page)

(continued from previous page)

A Sage example:

```

sage: b1 = BinaryTree([[[]],[[]],[[]]])
sage: b2 = BinaryTree([[None, []],[[]],[[]]])
sage: ascii_art((b1, b2, b1/b2))
(  _o_   ,  _o_   ,  _o_   )
( /   \   /   \   /   \   )
( o     o o     o o     o_ )
(   / \   \   /   \   /   \ )
(   o  o   o     o     o   )
(                               \ )
(                               _o_ )
(                               /   \ )
(                               o     o )
(                               \   / )
(                               o     o )

```

over_decomposition()

Return the unique maximal decomposition as an over product.

This means that the tree is cut along all edges of its rightmost path.

Beware that the factors are ordered starting from the root.

See also:*comb()*, *under_decomposition()*

EXAMPLES:

```

sage: g = BinaryTree([])
sage: r = g.over(g); r
[., [., .]]
sage: l = g.under(g); l
[[., .], .]
sage: r.over_decomposition()
[[., .], [., .]]
sage: l.over_decomposition() == [l]
True

sage: x = g.over(l).over(l).over(g).over(g)
sage: ascii_art(x)
o
      _o_
     /   \
    /     o
   /       \
  /         o   o
 /           \
/             o
sage: x.over_decomposition() == [g,l,l,g,g]
True

```

prune()

Return the binary tree obtained by deleting each leaf of `self`.

The operation of pruning is the left inverse of attaching as many leaves as possible to each node of a binary tree. That is to say, for all binary trees `bt`, we have:

```
bt == bt.to_full().prune()
```

However, it is only a right inverse if and only if `bt` is a full binary tree:

```
bt == bt.prune().to_full()
```

OUTPUT:

A binary tree.

See also:

`to_full()`

EXAMPLES:

```
sage: bt = BinaryTree([[None, []], [[], []], None])
sage: ascii_art(bt)
      o
     /
  --o--
 /   \
o     o
 \   / \
  o  o  o
sage: ascii_art(bt.prune())
      o
     /
      o
     / \
    o  o
```

We check the relationship with `to_full()`:

```
sage: bt = BinaryTree([[], [[None, []], []], [], []])
sage: bt == bt.to_full().prune()
True
sage: bt == bt.prune().to_full()
False

sage: bt = BinaryTree([[], [], [], [[], []], []])
sage: bt.is_full()
True
sage: bt == bt.prune().to_full()
True
```

Pruning the empty tree is again the empty tree:

```
sage: bt = BinaryTree(None)
sage: bt.prune()
.
```

q_hook_length_fraction(*q=None, q_factor=False*)

Compute the *q*-hook length fraction of the binary tree `self`, with an additional “*q*-factor” if desired.

If *T* is a (plane) binary tree and *q* is a polynomial indeterminate over some ring, then the *q*-hook length fraction $h_q(T)$ of *T* is defined by

$$h_q(T) = \frac{[|T|]_q!}{\prod_{t \in T} [|T_t|]_q},$$

where the product ranges over all nodes *t* of *T*, where *T_t* denotes the subtree of *T* consisting of *t* and its all descendants, and where for every tree *S*, we denote by $|S|$ the number of nodes of *S*. While this definition only shows that $h_q(T)$ is a rational function in *T*, it is in fact easy to show that $h_q(T)$ is actually a polynomial in *T*, and thus makes sense when any element of a commutative ring is substituted for *q*. This can also be explicitly seen from the following recursive formula for $h_q(T)$:

$$h_q(T) = \binom{|T| - 1}{|T_1|}_q h_q(T_1)h_q(T_2),$$

where *T* is any nonempty binary tree, and *T₁* and *T₂* are the two child trees of the root of *T*, and where $\binom{a}{b}_q$ denotes a *q*-binomial coefficient.

A variation of the *q*-hook length fraction is the following “*q*-hook length fraction with *q*-factor”:

$$f_q(T) = h_q(T) \cdot \prod_{t \in T} q^{|T_{\text{right}(t)}|},$$

where for every node *t*, we denote by `right(t)` the right child of *t*. This $f_q(T)$ differs from $h_q(T)$ only in a multiplicative factor, which is a power of *q*.

When *q* = 1, both $f_q(T)$ and $h_q(T)$ equal the number of permutations whose binary search tree (see [HNT2005] for the definition) is *T* (after dropping the labels). For example, there are 20 permutations which give a binary tree of the following shape:

by the binary search insertion algorithm, in accordance with the fact that this tree satisfies $f_1(T) = 20$.

When *q* is considered as a polynomial indeterminate, $f_q(T)$ is the generating function for all permutations whose binary search tree is *T* (after dropping the labels) with respect to the number of inversions (i. e., the Coxeter length) of the permutations.

Objects similar to $h_q(T)$ also make sense for general ordered forests (rather than just binary trees), see e. g. [BW1988], Theorem 9.1.

INPUT:

- **q** – a ring element which is to be substituted as *q* into the *q*-hook length fraction (by default, this is set to be the indeterminate *q* in the polynomial ring $\mathbb{Z}[q]$)
- **q_factor** – a Boolean (default: `False`) which determines whether to compute $h_q(T)$ or to compute $f_q(T)$ (namely, $h_q(T)$ is obtained when `q_factor == False`, and $f_q(T)$ is obtained when `q_factor == True`)

EXAMPLES:

Let us start with a simple example. Actually, let us start with the easiest possible example – the binary tree with only one vertex (which is a leaf):

```

sage: b = BinaryTree()
sage: b.q_hook_length_fraction()
1
sage: b.q_hook_length_fraction(q_factor=True)
1

```

Nothing different for a tree with one node and two leaves:

```

sage: b = BinaryTree([]); b
[., .]
sage: b.q_hook_length_fraction()
1
sage: b.q_hook_length_fraction(q_factor=True)
1

```

Let us get to a more interesting tree:

```

sage: b = BinaryTree([[[], []], [[], None]]); b
[[[., .], [., .]], [[., .], .]]
sage: b.q_hook_length_fraction()(q=1)
20
sage: b.q_hook_length_fraction()
q^7 + 2*q^6 + 3*q^5 + 4*q^4 + 4*q^3 + 3*q^2 + 2*q + 1
sage: b.q_hook_length_fraction(q_factor=True)
q^10 + 2*q^9 + 3*q^8 + 4*q^7 + 4*q^6 + 3*q^5 + 2*q^4 + q^3
sage: b.q_hook_length_fraction(q=2)
465
sage: b.q_hook_length_fraction(q=2, q_factor=True)
3720
sage: q = PolynomialRing(ZZ, 'q').gen()
sage: b.q_hook_length_fraction(q=q**2)
q^14 + 2*q^12 + 3*q^10 + 4*q^8 + 4*q^6 + 3*q^4 + 2*q^2 + 1

```

Let us check the fact that $f_q(T)$ is the generating function for all permutations whose binary search tree is T (after dropping the labels) with respect to the number of inversions of the permutations:

```

sage: def q_hook_length_fraction_2(T):
.....:     P = PolynomialRing(ZZ, 'q')
.....:     q = P.gen()
.....:     res = P.zero()
.....:     for w in T.sylvester_class():
.....:         res += q ** Permutation(w).length()
.....:     return res
sage: def test_genfun(i):
.....:     return all( q_hook_length_fraction_2(T)
.....:                 == T.q_hook_length_fraction(q_factor=True)
.....:                 for T in BinaryTrees(i) )
sage: test_genfun(4)
True

```

right_rotate()

Return the result of right rotation applied to the binary tree `self`.

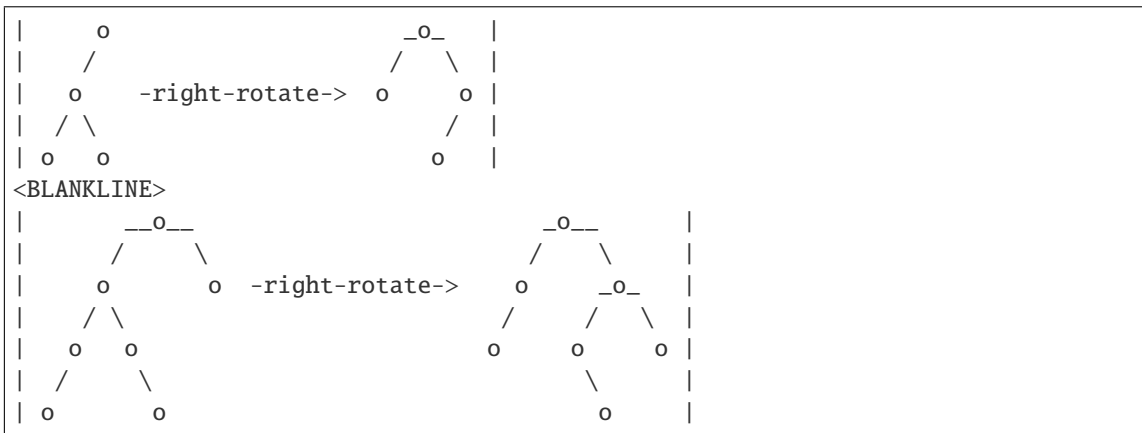

Right rotation on binary trees is defined as follows: Let T be a binary tree such that the left child of the root of T is a node. Let C be the right child of the root of T , and let A and B be the left and right children of

the left child of the root of T . (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Then, the right rotation of T is the binary tree in which the left child of the root is A , whereas the right child of the root is a node whose left and right children are B and C . In pictures:

where asterisks signify a single node each (but A , B and C might be empty).

For example,

Right rotation is the inverse operation to left rotation (*left_rotate()*).

The right rotation operation introduced here is the one defined in Definition 2.1 of [CP2012].

See also:

left_rotate()

EXAMPLES:

```

sage: b = BinaryTree([[[]], []], None); ascii_art([b])
[  o ]
[ /  ]
[ o  ]
[ / \ ]
[ o  o ]
sage: ascii_art([b.right_rotate()])
[  _o_ ]
[ /  \ ]
[ o  o ]
[   /  ]
[   o  ]
sage: b = BinaryTree([[[[]], None], [None, []]], []); ascii_art([b])
[      _o_ ]
[     /  \ ]
[    o    o ]
[   / \   ]
[  o  o   ]
    
```

(continues on next page)

(continued from previous page)

```

[ /   \ ]
[ o     o ]
sage: ascii_art([b.right_rotate()])
[      _o_ ]
[ /       \ ]
[ o       _o_ ]
[ /       / \ ]
[ o     o   o ]
[       \ ]
[        o ]

```

show(with_leaves=False)

Show the binary tree `show`, with or without leaves depending on the Boolean keyword variable `with_leaves`.

Warning: For a labelled binary tree, the labels shown in the picture are not (in general) the ones given by the labelling!

Use `_latex_()`, `view`, `_ascii_art_()` or `pretty_print` for more faithful representations of the data of the tree.

single_edge_cut_shapes()

Return the list of possible single-edge cut shapes for the binary tree.

This is used in `sage.combinat.interval_posets.TamariIntervalPoset.is_new()`.

OUTPUT:

a list of triples (m, i, n) of integers

This is a list running over all inner edges (i.e., edges joining two non-leaf vertices) of the binary tree. The removal of each inner edge defines two binary trees (connected components), the root-tree and the sub-tree. Thus, to every inner edge, we can assign three positive integers: m is the node number of the root-tree R , and n is the node number of the sub-tree S . The integer i is the index of the leaf of R on which S is grafted to obtain the original tree. The leaves of R are numbered starting from 1 (from left to right), hence $1 \leq i \leq m + 1$.

In fact, each of m and n determines the other, as the total node number of R and S is the node number of self.

EXAMPLES:

```

sage: BT = BinaryTrees(3)
sage: [t.single_edge_cut_shapes() for t in BT]
[[ (2, 3, 1), (1, 2, 2) ],
 [ (2, 2, 1), (1, 2, 2) ],
 [ (2, 1, 1), (2, 3, 1) ],
 [ (2, 2, 1), (1, 1, 2) ],
 [ (2, 1, 1), (1, 1, 2) ]]

sage: BT = BinaryTrees(2)
sage: [t.single_edge_cut_shapes() for t in BT]
[[ (1, 2, 1) ], [ (1, 1, 1) ]]

```

(continues on next page)

(continued from previous page)

```
sage: BT = BinaryTrees(1)
sage: [t.single_edge_cut_shapes() for t in BT]
[[]]
```

sylvester_class(*left_to_right=False*)

Iterate over the sylvester class corresponding to the binary tree `self`.

The sylvester class of a tree T is the set of permutations σ whose right-to-left binary search tree (a notion defined in [HNT2005], Definition 7) is T after forgetting the labels. This is an equivalence class of the sylvester congruence (the congruence on words which holds two words $uacvbw$ and $ucavbw$ congruent whenever a, b, c are letters satisfying $a \leq b < c$, and extends by transitivity) on the symmetric group.

For example the following tree's sylvester class consists of the permutations (1, 3, 2) and (3, 1, 2):

```
[  o  ]
[ / \ ]
[ o  o ]
```

(only the nodes are drawn here).

The right-to-left binary search tree of a word is constructed by an RSK-like insertion algorithm which proceeds as follows: Start with an empty labelled binary tree, and read the word from right to left. Each time a letter is read from the word, insert this letter in the existing tree using binary search tree insertion ([binary_search_insert\(\)](#)). This is what the [binary_search_tree\(\)](#) method computes if it is given the keyword `left_to_right=False`.

Here are two more descriptions of the sylvester class of a binary search tree:

- The sylvester class of a binary search tree T is the set of all linear extensions of the poset corresponding to T (that is, of the poset whose Hasse diagram is T , with the root on top), provided that the nodes of T are labelled with $1, 2, \dots, n$ in a binary-search-tree way (i.e., every left descendant of a node has a label smaller than that of the node, and every right descendant of a node has a label higher than that of the node).
- The sylvester class of a binary search tree T (with vertex labels $1, 2, \dots, n$) is the interval $[u, v]$ in the right permutohedron order ([permutohedron_lequal\(\)](#)), where u is the 312-avoiding permutation corresponding to T ([to_312_avoiding_permutation\(\)](#)), and where v is the 132-avoiding permutation corresponding to T ([to_132_avoiding_permutation\(\)](#)).

If the optional keyword variable `left_to_right` is set to `True`, then the *left* sylvester class of `self` is returned instead. This is the set of permutations σ whose left-to-right binary search tree (that is, the result of the [binary_search_tree\(\)](#) with `left_to_right` set to `True`) is `self`. It is an equivalence class of the left sylvester congruence.

Warning: This method yields the elements of the sylvester class as raw lists, not as permutations!

EXAMPLES:

Verifying the claim that the right-to-left binary search trees of the permutations in the sylvester class of a tree t all equal t :

```
sage: def test_bst_of_sc(n, left_to_right):
.....:     for t in BinaryTrees(n):
.....:         for p in t.sylvester_class(left_to_right=left_to_right):
.....:             p_per = Permutation(p)
```

(continues on next page)

(continued from previous page)

```

.....:         tree = p_per.binary_search_tree(left_to_right=left_to_right)
.....:         if not BinaryTree(tree) == t:
.....:             return False
.....:     return True
sage: test_bst_of_sc(4, False)
True
sage: test_bst_of_sc(5, False) # long time
True

```

The same with the left-to-right version of binary search:

```

sage: test_bst_of_sc(4, True)
True
sage: test_bst_of_sc(5, True) # long time
True

```

Checking that the sylvester class is the set of linear extensions of the poset of the tree:

```

sage: all( sorted(t.canonical_labelling().sylvester_class())
.....:      == sorted(list(v for v in t.canonical_labelling().to_poset().linear_
.....:      ↪ extensions())
.....:      for t in BinaryTrees(4) )
True

```

`tamari_greater()`

The list of all trees greater or equal to `self` in the Tamari order.

This is the order filter of the Tamari order generated by `self`.

See `tamari_lequal()` for the definition of the Tamari poset.

See also:

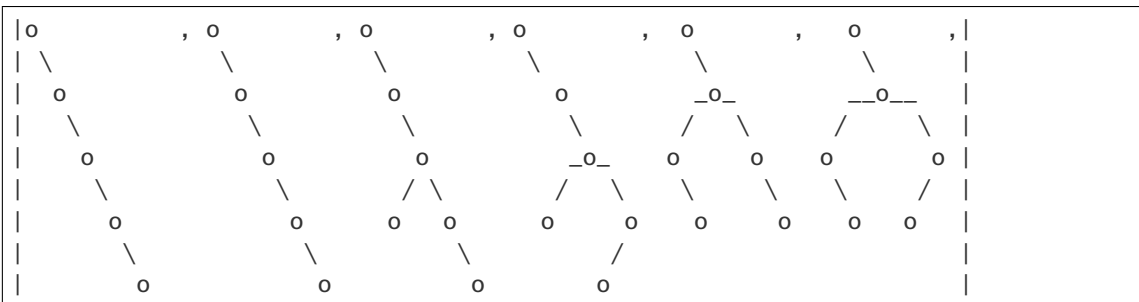

`tamari_smaller()`

EXAMPLES:

For example, the tree:

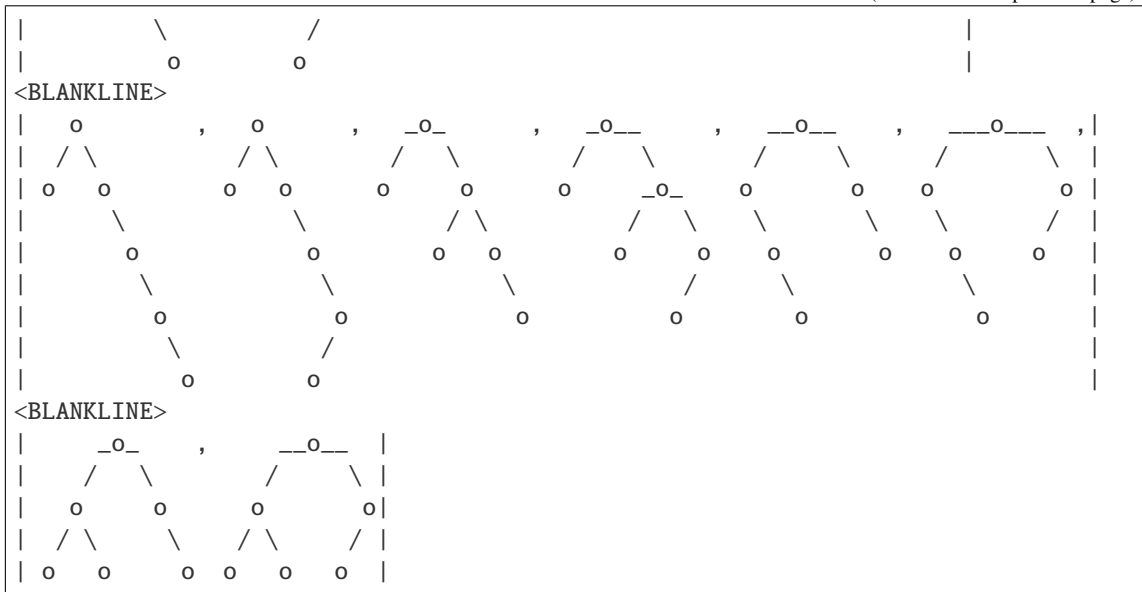

has these trees greater or equal to it:

(continues on next page)

(continued from previous page)

**tamari_interval(*other*)**

Return the Tamari interval between *self* and *other* as a *TamariIntervalPoset*.

A “Tamari interval” is an interval in the Tamari poset. See *tamari_lequal()* for the definition of the Tamari poset.

INPUT:

- *other* – a binary tree greater or equal to *self* in the Tamari order

EXAMPLES:

```
sage: bt = BinaryTree([[None, [], None], None])
sage: ip = bt.tamari_interval(BinaryTree([None, [[None, []], None]])); ip
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)
->1)]
sage: ip.lower_binary_tree()
[[., [[., .], .], .]
sage: ip.upper_binary_tree()
[., [[., [., .]], .]
sage: ip.interval_cardinality()
4
sage: ip.number_of_tamari_inversions()
2
sage: list(ip.binary_trees())
[[., [[., [., .]], .],
 [[., [., [., .]], .],
 [., [[[, .], .], .]],
 [[., [[., .], .]], .]]
sage: bt.tamari_interval(BinaryTree([[None, []], []]))
Traceback (most recent call last):
...
ValueError: the two binary trees are not comparable on the Tamari lattice
```

tamari_join(*other*)

Return the join of the binary trees *self* and *other* (of equal size) in the *n*-th Tamari poset (where *n* is the

size of these trees).

The n -th Tamari poset (defined in `tamari_lequal()`) is known to be a lattice, and the map from the n -th symmetric group S_n to the n -th Tamari poset defined by sending every permutation $p \in S_n$ to the binary search tree of p (more precisely, to `p.binary_search_tree_shape()`) is a lattice homomorphism. (See Theorem 6.2 in [Rea2004].)

See also:

`tamari_lequal()`, `tamari_meet()`.

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014; Frédéric Chapoton, 9 January 2018.

EXAMPLES:

```
sage: a = BinaryTree([None, [None, []]])
sage: b = BinaryTree([None, [], None])
sage: c = BinaryTree([None, [], None])
sage: d = BinaryTree([[], None, None])
sage: e = BinaryTree([], [])
sage: a.tamari_join(c) == a
True
sage: b.tamari_join(c) == b
True
sage: c.tamari_join(e) == a
True
sage: d.tamari_join(e) == e
True
sage: e.tamari_join(b) == a
True
sage: e.tamari_join(a) == a
True
```

```
sage: b1 = BinaryTree([None, [[[], None], None]])
sage: b2 = BinaryTree([[[], None], []])
sage: b1.tamari_join(b2)
[., [[., .], [., .]]]
sage: b3 = BinaryTree([], [[[], None]])
sage: b1.tamari_join(b3)
[., [., [[., .], .]]]
sage: b2.tamari_join(b3)
[[., .], [., [., .]]]
```

The universal property of the meet operation is satisfied:

```
sage: def test_uni_join(p, q):
.....:     j = p.tamari_join(q)
.....:     if not p.tamari_lequal(j):
.....:         return False
.....:     if not q.tamari_lequal(j):
.....:         return False
.....:     for r in p.tamari_greater():
.....:         if q.tamari_lequal(r) and not j.tamari_lequal(r):
.....:             return False
```

(continues on next page)

(continued from previous page)

```

.....:   return True
sage: all( test_uni_join(p, q) for p in BinaryTrees(3) for q in BinaryTrees(3) )
True
sage: p = BinaryTrees(6).random_element(); q = BinaryTrees(6).random_element();
↳ test_uni_join(p, q)
True

```

Border cases:

```

sage: b = BinaryTree(None)
sage: b.tamari_join(b)
.
sage: b = BinaryTree([])
sage: b.tamari_join(b)
[., .]

```

tamari_lequal(t2)

Return True if `self` is less or equal to another binary tree `t2` (of the same size as `self`) in the Tamari order.

The Tamari order on binary trees of size n is the partial order on the set of all binary trees of size n generated by the following requirement: If a binary tree T' is obtained by right rotation (see [right_rotate\(\)](#)) from a binary tree T , then $T < T'$. This not only is a well-defined partial order, but actually is a lattice structure on the set of binary trees of size n , and is a quotient of the weak order on the n -th symmetric group (also known as the right permutohedron order, see [permutohedron_lequal\(\)](#)). See [CP2012]. The set of binary trees of size n equipped with the Tamari order is called the n -th Tamari poset.

The Tamari order can equivalently be defined as follows:

If T and S are two binary trees of size n , then the following four statements are equivalent:

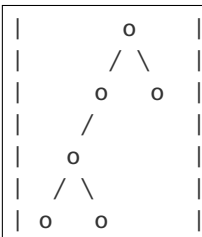

- We have $T \leq S$ in the Tamari order.
- There exist elements t and s of the Sylvester classes ([sylvester_class\(\)](#)) of T and S , respectively, such that $t \leq s$ in the weak order on the symmetric group.
- The 132-avoiding permutation corresponding to T (see [to_132_avoiding_permutation\(\)](#)) is \leq to the 132-avoiding permutation corresponding to S in the weak order on the symmetric group.
- The 312-avoiding permutation corresponding to T (see [to_312_avoiding_permutation\(\)](#)) is \leq to the 312-avoiding permutation corresponding to S in the weak order on the symmetric group.

See also:

[tamari_smaller\(\)](#), [tamari_greater\(\)](#), [tamari_pred\(\)](#), [tamari_succ\(\)](#), [tamari_interval\(\)](#)

EXAMPLES:

This tree:

is Tamari- \leq to the following tree:

Checking this:

```
sage: b = BinaryTree([[[[]], []], None], [])
sage: c = BinaryTree([[[[]], []], [None, []]])
sage: b.tamari_lequal(c)
True
```

tamari_meet(*other*, *side*='right')

Return the meet of the binary trees *self* and *other* (of equal size) in the n -th Tamari poset (where n is the size of these trees).

The n -th Tamari poset (defined in `tamari_lequal()`) is known to be a lattice, and the map from the n -th symmetric group S_n to the n -th Tamari poset defined by sending every permutation $p \in S_n$ to the binary search tree of p (more precisely, to `p.binary_search_tree_shape()`) is a lattice homomorphism. (See Theorem 6.2 in [Rea2004].)

`tamari_lequal()`, `tamari_join()`.

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```
sage: a = BinaryTree([None, [None, []]])
sage: b = BinaryTree([None, [], None])
sage: c = BinaryTree([None, [], None])
sage: d = BinaryTree([[[[]], None], None])
sage: e = BinaryTree([[], []])
sage: a.tamari_meet(c) == c
True
sage: b.tamari_meet(c) == c
True
sage: c.tamari_meet(e) == d
True
sage: d.tamari_meet(e) == d
True
sage: e.tamari_meet(b) == d
True
sage: e.tamari_meet(a) == e
True
```

```
sage: b1 = BinaryTree([None, [[[]], None], None])
sage: b2 = BinaryTree([[[[]], None], [])
sage: b1.tamari_meet(b2)
[[[[], []], []], []]
sage: b3 = BinaryTree([[], [[[]], None])
sage: b1.tamari_meet(b3)
```

(continues on next page)

(continued from previous page)

```
[[[[], .], .], .], .]
sage: b2.tamari_meet(b3)
[[[[], .], .], .], .]
```

The universal property of the meet operation is satisfied:

```
sage: def test_uni_meet(p, q):
.....:     m = p.tamari_meet(q)
.....:     if not m.tamari_lequal(p):
.....:         return False
.....:     if not m.tamari_lequal(q):
.....:         return False
.....:     for r in p.tamari_smaller():
.....:         if r.tamari_lequal(q) and not r.tamari_lequal(m):
.....:             return False
.....:     return True
sage: all( test_uni_meet(p, q) for p in BinaryTrees(3) for q in BinaryTrees(3) )
True
sage: p = BinaryTrees(6).random_element(); q = BinaryTrees(6).random_element();
->test_uni_meet(p, q)
True
```

Border cases:

```
sage: b = BinaryTree(None)
sage: b.tamari_meet(b)
.
sage: b = BinaryTree([])
sage: b.tamari_meet(b)
[., .]
```

tamari_pred()

Compute the list of predecessors of `self` in the Tamari poset.

This list is computed by performing all left rotates possible on its nodes.

See [tamari_lequal\(\)](#) for the definition of the Tamari poset.

EXAMPLES:

For this tree:

the list is:

(continues on next page)

(continued from previous page)

tamari_smaller()

The list of all trees smaller or equal to `self` in the Tamari order.

This is the order ideal of the Tamari order generated by `self`.

See `tamari_lequal()` for the definition of the Tamari poset.

See also:

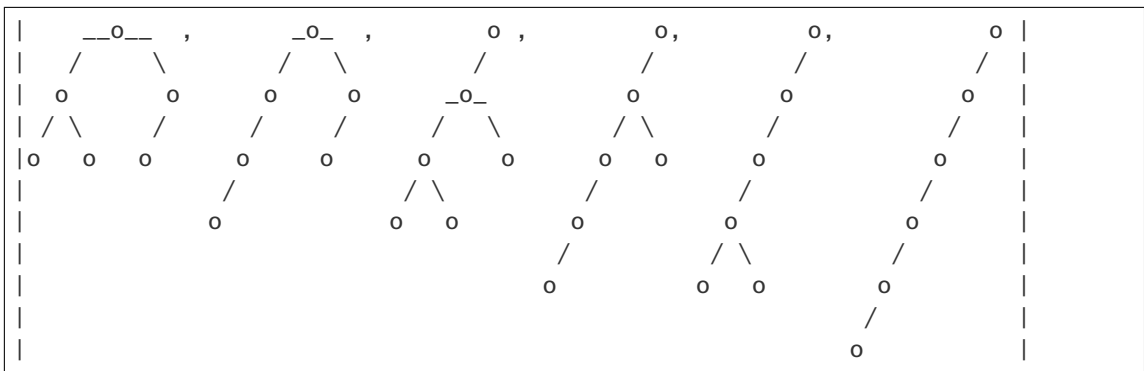

`tamari_greater()`

EXAMPLES:

The tree:

has these trees smaller or equal to it:

tamari_sorting_tuple(reverse=False)

Return the Tamari sorting tuple of `self` and the size of `self`.

This is a pair (w, n) , where n is the number of nodes of `self`, and w is an n -tuple whose i -th entry is the number of all nodes among the descendants of the right child of the i -th node of `self`. Here, the nodes of `self` are numbered from left to right.

INPUT:

- `reverse` – boolean (default `False`) if `True`, return instead the result for the left-right symmetric of the binary tree

OUTPUT:

a pair (w, n) , where w is a tuple of integers, and n the size

Two binary trees of the same size are comparable in the Tamari order if and only if the associated tuples w are componentwise comparable. (This is essentially the Theorem in [HT1972].) This is used in `tamari_lequal()`.

EXAMPLES:

```

sage: [t.tamari_sorting_tuple() for t in BinaryTrees(3)]
[((2, 1, 0), 3),
 ((2, 0, 0), 3),
 ((0, 1, 0), 3),
 ((1, 0, 0), 3),
 ((0, 0, 0), 3)]

sage: t = BinaryTrees(10).random_element()
sage: u = t.left_right_symmetry()
sage: t.tamari_sorting_tuple(True) == u.tamari_sorting_tuple()
True

```

REFERENCES:

- [HT1972]

tamari_succ()

Compute the list of successors of `self` in the Tamari poset.

This is the list of all trees obtained by a right rotate of one of its nodes.

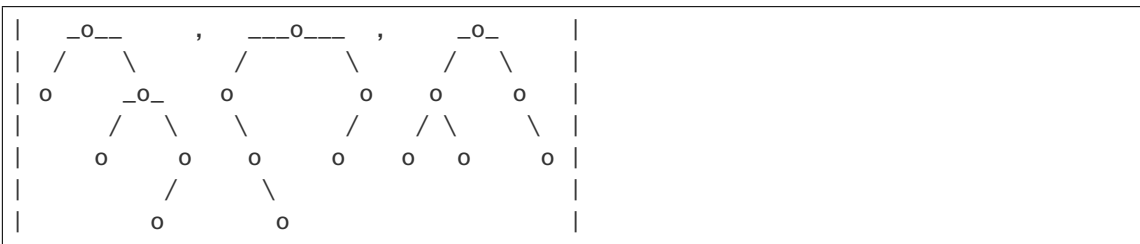

See [tamari_lequal\(\)](#) for the definition of the Tamari poset.

EXAMPLES:

The list of successors of:

is:

**to_132_avoiding_permutation()**

Return a 132-avoiding permutation corresponding to the binary tree.

The linear extensions of a binary tree form an interval of the weak order called the sylvester class of the tree. This permutation is the maximal element of this sylvester class.

EXAMPLES:

```

sage: bt = BinaryTree([], [])
sage: bt.to_132_avoiding_permutation()
[3, 1, 2]
sage: bt = BinaryTree([[[]], [[]], None], [[], []])
sage: bt.to_132_avoiding_permutation()
[8, 6, 7, 3, 4, 1, 2, 5]

```

to_312_avoiding_permutation()

Return a 312-avoiding permutation corresponding to the binary tree.

The linear extensions of a binary tree form an interval of the weak order called the sylvester class of the tree. This permutation is the minimal element of this sylvester class.

EXAMPLES:

```
sage: bt = BinaryTree([], [])
sage: bt.to_312_avoiding_permutation()
[1, 3, 2]
sage: bt = BinaryTree([[[]], [[], None]], [[], []])
sage: bt.to_312_avoiding_permutation()
[1, 3, 4, 2, 6, 8, 7, 5]
```

to_dyck_word(usemap='LOR')

Return the Dyck word associated with `self` using the given map.

INPUT:

- `usemap` – a string, either `1L0R`, `1R0L`, `L1R0`, `R1L0`

The bijection is defined recursively as follows:

- a leaf is associated to the empty Dyck Word
- a tree with children l, r is associated with the Dyck word described by `usemap` where L and R are respectively the Dyck words associated with the trees l and r .

EXAMPLES:

```
sage: BinaryTree().to_dyck_word()
[]
sage: BinaryTree([]).to_dyck_word()
[1, 0]
sage: BinaryTree([[[]], [[], None]], [[], []]).to_dyck_word()
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0, 1, 0]
sage: BinaryTree([[None, []], None]).to_dyck_word()
[1, 1, 0, 1, 0, 0]
sage: BinaryTree([[None, []], None]).to_dyck_word("1R0L")
[1, 0, 1, 1, 0, 0]
sage: BinaryTree([[None, []], None]).to_dyck_word("L1R0")
[1, 1, 0, 0, 1, 0]
sage: BinaryTree([[None, []], None]).to_dyck_word("R1L0")
[1, 1, 0, 1, 0, 0]
sage: BinaryTree([[None, []], None]).to_dyck_word("R10L")
Traceback (most recent call last):
...
ValueError: R10L is not a correct map
```

to_dyck_word_tamari()

Return the Dyck word associated with `self` in consistency with the Tamari order on Dyck words and binary trees.

The bijection is defined recursively as follows:

- a leaf is associated with an empty Dyck word;
- a tree with children l, r is associated with the Dyck word $T(l)1T(r)0$.

EXAMPLES:

```

sage: BinaryTree().to_dyck_word_tamari()
[]
sage: BinaryTree([]).to_dyck_word_tamari()
[1, 0]
sage: BinaryTree([[None, []], None]).to_dyck_word_tamari()
[1, 1, 0, 0, 1, 0]
sage: BinaryTree([[[[]], [[], None]], [[], []]]).to_dyck_word_tamari()
[1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0]

```

to_full()

Return the full binary tree constructed from `self`.

Let T be a binary tree with n nodes. We construct a full binary tree F from T by attaching a leaf to each node of T which does not have 2 children. The resulting tree will have $2n + 1$ nodes.

OUTPUT:

A full binary tree. See `is_full()` for the definition of full.

See also:`prune()`

EXAMPLES:

```

sage: bt = BinaryTree([[None, []], None])
sage: bt.to_full().is_full()
True
sage: ascii_art(bt)
  o
 /
o
 \
  o
sage: ascii_art(bt.to_full())
      --o--
     /    \
    _o_    o
   /  \   /
  o   o  o
   \  /  \
    o o  o
sage: bt = BinaryTree([[], []])
sage: ascii_art(bt)
  o
 / \
o   o
sage: ascii_art(bt.to_full())
      --o--
     /    \
    o      o
   / \   / \
  o  o  o  o

```

(continues on next page)

(continued from previous page)

```
sage: BinaryTree(None).to_full()
[., .]
```

to_ordered_tree_left_branch()

Return an ordered tree of size $n + 1$ by the following recursive rule:

- if x is the left child of y , x becomes the left brother of y
- if x is the right child of y , x becomes the last child of y

EXAMPLES:

```
sage: bt = BinaryTree([], [])
sage: bt.to_ordered_tree_left_branch()
[[], [[]]]
sage: bt = BinaryTree([[[]], [[], None]], [[], [[]]])
sage: bt.to_ordered_tree_left_branch()
[[], [[], [[]], [[], [[]]]]]
```

to_ordered_tree_right_branch()

Return an ordered tree of size $n + 1$ by the following recursive rule:

- if x is the right child of y , x becomes the right brother of y
- if x is the left child of y , x becomes the first child of y

EXAMPLES:

```
sage: bt = BinaryTree([], [])
sage: bt.to_ordered_tree_right_branch()
[[[]], []]
sage: bt = BinaryTree([[[]], [[], None]], [[], [[]]])
sage: bt.to_ordered_tree_right_branch()
[[[[]], [[]]], [[]], [[]], []]
```

to_poset (*with_leaves=False, root_to_leaf=False*)

Return the poset obtained by interpreting the tree as a Hasse diagram.

The default orientation is from leaves to root but you can pass `root_to_leaf=True` to obtain the inverse orientation.

Leaves are ignored by default, but one can set `with_leaves` to `True` to obtain the poset of the complete tree.

INPUT:

- `with_leaves` – (default: `False`) a Boolean, determining whether the resulting poset will be formed from the leaves and the nodes of `self` (if `True`), or only from the nodes of `self` (if `False`)
- `root_to_leaf` – (default: `False`) a Boolean, determining whether the poset orientation should be from root to leaves (if `True`) or from leaves to root (if `False`).

EXAMPLES:

```
sage: bt = BinaryTree([])
sage: bt.to_poset()
Finite poset containing 1 elements
sage: bt.to_poset(with_leaves=True)
```

(continues on next page)

(continued from previous page)

```

Finite poset containing 3 elements
sage: P1 = bt.to_poset(with_leaves=True)
sage: len(P1.maximal_elements())
1
sage: len(P1.minimal_elements())
2
sage: bt = BinaryTree([])
sage: P2 = bt.to_poset(with_leaves=True, root_to_leaf=True)
sage: len(P2.maximal_elements())
2
sage: len(P2.minimal_elements())
1

```

If the tree is labelled, we use its labelling to label the poset. Otherwise, we use the poset canonical labelling:

```

sage: bt = BinaryTree([], [None, []]).canonical_labelling()
sage: bt
2[1[., .], 3[., 4[., .]]]
sage: bt.to_poset().cover_relations()
[[4, 3], [3, 2], [1, 2]]

```

Let us check that the empty binary tree is correctly handled:

```

sage: bt = BinaryTree()
sage: bt.to_poset()
Finite poset containing 0 elements
sage: bt.to_poset(with_leaves=True)
Finite poset containing 1 elements

```

to_tilting()

Transform a binary tree into a tilting object.

Let t be a binary tree with n nodes. There exists a unique depiction of t (above the diagonal) such that all leaves are regularly distributed on the diagonal line from $(0, 0)$ to (n, n) and all edges are either horizontal or vertical. This method provides the coordinates of this depiction, with the root as the top-left vertex.

OUTPUT:

a list of pairs of integers.

Every vertex of the binary tree is mapped to a pair of integers. The conventions are the following. The root has coordinates $(0, n)$ where n is the node number. If a vertex is the left (right) son of another vertex, they share the first (second) coordinate.

EXAMPLES:

```

sage: t = BinaryTrees(1)[0]
sage: t.to_tilting()
[(0, 1)]

sage: for t in BinaryTrees(2):
.....:     print(t.to_tilting())
[(1, 2), (0, 2)]
[(0, 1), (0, 2)]

```

(continues on next page)

(continued from previous page)

```

sage: from sage.combinat.abstract_tree import from_hexacode
sage: t = from_hexacode('2020222002000', BinaryTrees())
sage: print(t.to_tilting())
[(0, 1), (2, 3), (4, 5), (6, 7), (4, 7), (8, 9), (10, 11),
(8, 11), (4, 11), (12, 13), (4, 13), (2, 13), (0, 13)]

sage: t2 = DyckWord([1,1,1,1,0,1,1,0,0,0,1,1,0,1,0,1,1,0,1,1,0,0,0,0,0]).to_
↳binary_tree()
sage: len(t2.to_tilting()) == t2.node_number()
True

```

to_undirected_graph(with_leaves=False)

Return the undirected graph obtained from the tree nodes and edges.

Leaves are ignored by default, but one can set `with_leaves` to `True` to obtain the graph of the complete tree.

INPUT:

- `with_leaves` – (default: `False`) a Boolean, determining whether the resulting graph will be formed from the leaves and the nodes of `self` (if `True`), or only from the nodes of `self` (if `False`)

EXAMPLES:

```

sage: bt = BinaryTree([])
sage: bt.to_undirected_graph()
Graph on 1 vertex
sage: bt.to_undirected_graph(with_leaves=True)
Graph on 3 vertices

sage: bt = BinaryTree()
sage: bt.to_undirected_graph()
Graph on 0 vertices
sage: bt.to_undirected_graph(with_leaves=True)
Graph on 1 vertex

```

If the tree is labelled, we use its labelling to label the graph. Otherwise, we use the graph canonical labelling which means that two different trees can have the same graph.

EXAMPLES:

```

sage: bt = BinaryTree([], [None, []])
sage: bt.canonical_labelling().to_undirected_graph() == bt.to_undirected_graph()
False
sage: BinaryTree([], []).to_undirected_graph() == BinaryTree([[], None], None).
↳to_undirected_graph()
True

```

twisting_number()

Return a pair (number of maximal left branches, number of maximal right branches).

Recalling that a branch of a vertex v is a path from a vertex of the tree to a leaf, a left (resp. right) branch is a branch made only of left (resp. right) edges. The length of a branch is the number of edges composing it. A left (resp. right) branch is maximal if it is not included in a strictly longer left (resp. right) branch.

OUTPUT:

A list of two integers

EXAMPLES:

```

sage: BT = BinaryTree( '.' )
sage: BT.twisting_number()
[0, 0]
sage: BT = BinaryTree( '[.,.]' )
sage: BT.twisting_number()
[0, 0]
sage: BT = BinaryTree( '[[[.,.], .], [.,.]]' ); ascii_art(BT)
      o
     / \
    o   o
   /
  o
sage: BT.twisting_number()
[1, 1]
sage: BT = BinaryTree( '[[[[[., [., .]], .], [[., .], [[[., .], [., .]], [., .
↔]]]], [., [[[., .], [[[., .], [., .]], .]], [., .]]]]' )
sage: ascii_art(BT)
          o
         / \
        /   \
       /     \
      /       \
     /         \
    /           \
   /             \
  /               \
 /                 \
o                   o
 \                 /
  \               /
   \             /
    \           /
     \         /
      \       /
       \     /
        \   /
         \ /
          o
sage: BT.twisting_number()
[5, 6]
sage: BT = BinaryTree( '[.,[[[.,.],.,.]]' ); ascii_art(BT)
      o
       \
        o
       /
      o
     /
    o
sage: BT.twisting_number()
[1, 1]

```

under(bt)

Return self under bt, where “under” is the under (\backslash) operation.

If T and T' are two binary trees, then T under T' (written $T \backslash T'$) is defined as the tree obtained by grafting T on the leftmost leaf of T' . More precisely, $T \backslash T'$ is defined by identifying the root of T with the leftmost leaf of T' .

If T' is empty, then $T \backslash T' = T$.

The definition of this “under” operation goes back to Loday-Ronco [LR0102066] (Definition 2.2), but it is denoted by / and called the “over” operation there. In fact, trees in sage have their root at the top, contrary to the trees in [LR0102066] which are growing upwards. For this reason, the names of the over and under operations are swapped, in order to keep a graphical meaning. (Our notation follows that of section 4.5 of [HNT2005].)

See also:

[over\(\)](#)

EXAMPLES:

Showing only the nodes of a binary tree, here is an example for the under operation:

```
sage: b1 = BinaryTree([[ ], [ ]])
sage: b2 = BinaryTree([None, [ ]])
sage: ascii_art((b1, b2, b1 \ b2))
(  o  ,  o  ,    _o_  )
( / \    \    / \  )
( o  o  o  o  o  )
(                / \  )
(                o  o  )
```

under_decomposition()

Return the unique maximal decomposition as an under product.

This means that the tree is cut along all edges of its leftmost path.

Beware that the factors are ordered starting from the root.

See also:

[comb\(\)](#), [over_decomposition\(\)](#)

EXAMPLES:

```
sage: g = BinaryTree([ ])
sage: r = g.over(g); r
[., [., .]]
sage: l = g.under(g); l
[[., .], .]
sage: l.under_decomposition()
[[., .], [., .]]
sage: r.under_decomposition() == [r]
True

sage: x = r.under(g).under(r).under(g)
sage: ascii_art(x)
      o
      /
     o
    / \
   o  o
  /
 o
 \
  o
```

(continues on next page)

(continued from previous page)

```
sage: x.under_decomposition() == [g,r,g,r]
True
```

class `sage.combinat.binary_tree.BinaryTrees`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Factory for binary trees.

A binary tree is a tree with at most 2 children. The binary trees considered here are also ordered (a.k.a. planar), that is to say, their children are ordered.

A full binary tree is a binary tree with no nodes with 1 child.

INPUT:

- `size` – (optional) an integer
- `full` – (optional) a boolean

OUTPUT:

The set of all (full if `full=True`) binary trees (of the given `size` if specified).

See also:

[*BinaryTree*](#), [*BinaryTree.is_full\(\)*](#)

EXAMPLES:

```
sage: BinaryTrees()
Binary trees

sage: BinaryTrees(2)
Binary trees of size 2

sage: BinaryTrees(full=True)
Full binary trees

sage: BinaryTrees(3, full=True)
Full binary trees of size 3

sage: BinaryTrees(4, full=True)
Traceback (most recent call last):
...
ValueError: n must be 0 or odd
```

Note: This is a factory class whose constructor returns instances of subclasses.

Note: The fact that `BinaryTrees` is a class instead of a simple callable is an implementation detail. It could be changed in the future and one should not rely on it.

leaf()

Return a leaf tree with `self` as parent.

EXAMPLES:

```
sage: BinaryTrees().leaf()
.
```

class `sage.combinat.binary_tree.BinaryTrees_all`

Bases: `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`, `sage.combinat.binary_tree.BinaryTrees`

Element

alias of `BinaryTree`

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```
sage: BinaryTrees().labelled_trees()
Labelled binary trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to self.

EXAMPLES:

```
sage: BinaryTrees().unlabelled_trees()
Binary trees
```

class `sage.combinat.binary_tree.BinaryTrees_size(size)`

Bases: `sage.combinat.binary_tree.BinaryTrees`

The enumerated sets of binary trees of given size.

cardinality()

The cardinality of self

This is a Catalan number.

random_element()

Return a random `BinaryTree` with uniform probability.

This method generates a random `DyckWord` and then uses a bijection between `Dyck` words and binary trees.

EXAMPLES:

```
sage: BinaryTrees(5).random_element() # random
[., [., [., [., [., .]]]]]
sage: BinaryTrees(0).random_element()
.
sage: BinaryTrees(1).random_element()
[., .]
```

class `sage.combinat.binary_tree.FullBinaryTrees_all`

Bases: `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`, `sage.combinat.binary_tree.BinaryTrees`

All full binary trees.

class `sage.combinat.binary_tree.FullBinaryTrees_size(size)`

Bases: `sage.combinat.binary_tree.BinaryTrees`

Full binary trees of a fixed size (number of nodes).

cardinality()

The cardinality of `self`

This is a Catalan number.

random_element()

Return a random `FullBinaryTree` with uniform probability.

This method generates a random `DyckWord` of size $(s - 1)/2$, where s is the size of `self`, which uses a bijection between Dyck words and binary trees to get a binary tree, and convert it to a full binary tree.

EXAMPLES:

```
sage: BinaryTrees(5, full=True).random_element() # random
[[], [], []]
sage: BinaryTrees(0, full=True).random_element()
.
sage: BinaryTrees(1, full=True).random_element()
[., .]
```

class `sage.combinat.binary_tree.LabellledBinaryTree`(*parent, children, label=None, check=True*)
 Bases: `sage.combinat.abstract_tree.AbstractLabellledClonableTree`, `sage.combinat.binary_tree.BinaryTree`

Labellled binary trees.

A labellled binary tree is a binary tree (see [BinaryTree](#) for the meaning of this) with a label assigned to each node. The labels need not be integers, nor are they required to be distinct. `None` can be used as a label.

Warning: While it is possible to assign values to leaves (not just nodes) using this class, these labels are disregarded by various methods such as `labels()`, `map_labels()`, and (ironically) `leaf_labels()`.

INPUT:

- `children` – `None` (default) or a list, tuple or iterable of length 2 of labellled binary trees or convertible objects. This corresponds to the standard recursive definition of a labellled binary tree as being either a leaf, or a pair of:
 - a pair of labellled binary trees,
 - and a label.

(The label is specified in the keyword variable `label`; see below.)

Syntactic sugar allows leaving out all but the outermost calls of the `LabellledBinaryTree()` constructor, so that, e. g., `LabellledBinaryTree([LabellledBinaryTree(None), LabellledBinaryTree(None)])` can be shortened to `LabellledBinaryTree([None, None])`. However, using this shorthand, it is impossible to label any vertex of the tree other than the root (because there is no way to pass a `label` variable without calling `LabellledBinaryTree` explicitly).

It is also allowed to abbreviate `[None, None]` by `[]` if one does not want to label the leaves (which one should not do anyway!).

- `label` – (default: `None`) the label to be put on the root of this tree.
- `check` – (default: `True`) whether checks should be performed or not.

Todo: It is currently not possible to use `LabelledBinaryTree()` as a shorthand for `LabelledBinaryTree(None)` (in analogy to similar syntax in the `BinaryTree` class).

EXAMPLES:

```

sage: LabelledBinaryTree(None)
.
sage: LabelledBinaryTree(None, label="ae")    # not well supported
'ae'
sage: LabelledBinaryTree([])
None[., .]
sage: LabelledBinaryTree([], label=3)    # not well supported
3[., .]
sage: LabelledBinaryTree([None, None])
None[., .]
sage: LabelledBinaryTree([None, None], label=5)
5[., .]
sage: LabelledBinaryTree([None, []])
None[., None[., .]]
sage: LabelledBinaryTree([None, []], label=4)
4[., None[., .]]
sage: LabelledBinaryTree([], None)
None[None[., .], .]
sage: LabelledBinaryTree("[]", label=False)
False[None[., .], .]
sage: LabelledBinaryTree([None, LabelledBinaryTree([None, None], label=4)], label=3)
3[., 4[., .]]
sage: LabelledBinaryTree([None, BinaryTree([None, None])], label=3)
3[., None[., .]]

sage: LabelledBinaryTree([], None, [])
Traceback (most recent call last):
...
ValueError: this is not a binary tree

sage: LBT = LabelledBinaryTree
sage: t1 = LBT([[LBT([], label=2), None], None], label=4); t1
4[None[2[., .], .], .]

```

`binary_search_insert`(*letter*)

Return the result of inserting a letter `letter` into the right strict binary search tree `self`.

INPUT:

- `letter` – any object comparable with the labels of `self`

OUTPUT:

The right strict binary search tree `self` with `letter` inserted into it according to the binary search insertion algorithm.

Note: `self` is supposed to be a binary search tree. This is not being checked!

A right strict binary search tree is defined to be a labelled binary tree such that for each node n with label

x , every descendant of the left child of n has a label $\leq x$, and every descendant of the right child of n has a label $> x$. (Here, only nodes count as descendants, and every node counts as its own descendant too.) Leaves are assumed to have no labels.

Given a right strict binary search tree t and a letter i , the result of inserting i into t (denoted $Ins(i, t)$ in the following) is defined recursively as follows:

- If t is empty, then $Ins(i, t)$ is the tree with one node only, and this node is labelled with i .
- Otherwise, let j be the label of the root of t . If $i > j$, then $Ins(i, t)$ is obtained by replacing the right child of t by $Ins(i, r)$ in t , where r denotes the right child of t . If $i \leq j$, then $Ins(i, t)$ is obtained by replacing the left child of t by $Ins(i, l)$ in t , where l denotes the left child of t .

See, for example, [HNT2005] for properties of this algorithm.

Warning: If t is nonempty, then inserting i into t does not change the root label of t . Hence, as opposed to algorithms like Robinson-Schensted-Knuth, binary search tree insertion involves no bumping.

EXAMPLES:

The example from Fig. 2 of [HNT2005]:

```
sage: LBT = LabelledBinaryTree
sage: x = LBT(None)
sage: x
.
sage: x = x.binary_search_insert("b"); x
b[., .]
sage: x = x.binary_search_insert("d"); x
b[., d[., .]]
sage: x = x.binary_search_insert("e"); x
b[., d[., e[., .]]]
sage: x = x.binary_search_insert("a"); x
b[a[., .], d[., e[., .]]]
sage: x = x.binary_search_insert("b"); x
b[a[., b[., .]], d[., e[., .]]]
sage: x = x.binary_search_insert("d"); x
b[a[., b[., .]], d[d[., .], e[., .]]]
sage: x = x.binary_search_insert("a"); x
b[a[a[., .], b[., .]], d[d[., .], e[., .]]]
sage: x = x.binary_search_insert("c"); x
b[a[a[., .], b[., .]], d[d[c[., .], .], e[., .]]]
```

Other examples:

```
sage: LBT = LabelledBinaryTree
sage: LBT(None).binary_search_insert(3)
3[., .]
sage: LBT([], label = 1).binary_search_insert(3)
1[., 3[., .]]
sage: LBT([], label = 3).binary_search_insert(1)
3[1[., .], .]
sage: res = LBT(None)
sage: for i in [3,1,5,2,4,6]:
.....:     res = res.binary_search_insert(i)
```

(continues on next page)

(continued from previous page)

```
sage: res
3[1[., 2[., .]], 5[4[., .], 6[., .]]]
```

heap_insert()

Return the result of inserting a letter `l` into the binary heap (tree) `self`.

A binary heap is a labelled complete binary tree such that for each node, the label at the node is greater or equal to the label of each of its child nodes. (More precisely, this is called a max-heap.)

For example:

is a binary heap.

See [Wikipedia article Binary_heap#Insert](#) for a description of how to insert a letter into a binary heap. The result is another binary heap.

INPUT:

- `letter` – any object comparable with the labels of `self`

Note: `self` is assumed to be a binary heap (tree). No check is performed.

left_rotate()

Return the result of left rotation applied to the labelled binary tree `self`.

Left rotation on labelled binary trees is defined as follows: Let T be a labelled binary tree such that the right child of the root of T is a node. Let A be the left child of the root of T , and let B and C be the left and right children of the right child of the root of T . (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Furthermore, let x be the label at the root of T , and y be the label at the right child of the root of T . Then, the left rotation of T is the labelled binary tree in which the root is labelled y , the right child of the root is C , whereas the left child of the root is a node labelled x whose left and right children are A and B . In pictures:

Left rotation is the inverse operation to right rotation (*right_rotate()*).

right_rotate()

Return the result of right rotation applied to the labelled binary tree `self`.

Right rotation on labelled binary trees is defined as follows: Let T be a labelled binary tree such that the left child of the root of T is a node. Let C be the right child of the root of T , and let A and B be the left and right children of the left child of the root of T . (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Furthermore, let y be the label at the root of T , and x be the label at the left child of the root of T . Then, the right rotation of T is the labelled binary tree in which the root

is labelled x , the left child of the root is A , whereas the right child of the root is a node labelled y whose left and right children are B and C . In pictures:

Right rotation is the inverse operation to left rotation (`left_rotate()`).

semistandard_insert(*letter*)

Return the result of inserting a letter `letter` into the semistandard tree `self` using the bumping algorithm.

INPUT:

- `letter` – any object comparable with the labels of `self`

OUTPUT:

The semistandard tree `self` with `letter` inserted into it according to the bumping algorithm.

Note: `self` is supposed to be a semistandard tree. This is not being checked!

A semistandard tree is defined to be a labelled binary tree such that for each node n with label x , every descendant of the left child of n has a label $> x$, and every descendant of the right child of n has a label $\geq x$. (Here, only nodes count as descendants, and every node counts as its own descendant too.) Leaves are assumed to have no labels.

Given a semistandard tree t and a letter i , the result of inserting i into t (denoted $Ins(i, t)$ in the following) is defined recursively as follows:

- If t is empty, then $Ins(i, t)$ is the tree with one node only, and this node is labelled with i .
- Otherwise, let j be the label of the root of t . If $i \geq j$, then $Ins(i, t)$ is obtained by replacing the right child of t by $Ins(i, r)$ in t , where r denotes the right child of t . If $i < j$, then $Ins(i, t)$ is obtained by replacing the label at the root of t by i , and replacing the left child of t by $Ins(j, l)$ in t , where l denotes the left child of t .

This algorithm is similar to the Robinson-Schensted-Knuth insertion algorithm for semistandard Young tableaux.

AUTHORS:

- Darij Grinberg (10 Nov 2013).

EXAMPLES:

```

sage: LBT = LabelledBinaryTree
sage: x = LBT(None)
sage: x
.
sage: x = x.semistandard_insert("b"); x
b[., .]
sage: x = x.semistandard_insert("d"); x
b[., d[., .]]
sage: x = x.semistandard_insert("e"); x
b[., d[., e[., .]]
```

(continues on next page)

(continued from previous page)

```

sage: x = x.semistandard_insert("a"); x
a[b[., .], d[., e[., .]]]
sage: x = x.semistandard_insert("b"); x
a[b[., .], b[d[., .], e[., .]]]
sage: x = x.semistandard_insert("d"); x
a[b[., .], b[d[., .], d[e[., .], .]]]
sage: x = x.semistandard_insert("a"); x
a[b[., .], a[b[d[., .], .], d[e[., .], .]]]
sage: x = x.semistandard_insert("c"); x
a[b[., .], a[b[d[., .], .], c[d[e[., .], .], .]]]

```

Other examples:

```

sage: LBT = LabelledBinaryTree
sage: LBT(None).semistandard_insert(3)
3[., .]
sage: LBT([], label = 1).semistandard_insert(3)
1[., 3[., .]]
sage: LBT([], label = 3).semistandard_insert(1)
1[3[., .], .]
sage: res = LBT(None)
sage: for i in [3,1,5,2,4,6]:
.....:     res = res.semistandard_insert(i)
sage: res
1[3[., .], 2[5[., .], 4[., 6[., .]]]]

```

class `sage.combinat.binary_tree.LabelledBinaryTrees`(*category=None*)

Bases: `sage.combinat.ordered_tree.LabelledOrderedTrees`

This is a parent stub to serve as a factory class for trees with various labels constraints.

Element

alias of `LabelledBinaryTree`

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```

sage: LabelledBinaryTrees().labelled_trees()
Labelled binary trees

```

unlabelled_trees()

Return the set of unlabelled trees associated to self.

EXAMPLES:

```

sage: LabelledBinaryTrees().unlabelled_trees()
Binary trees

```

This is used to compute the shape:

```

sage: t = LabelledBinaryTrees().an_element().shape(); t
[[[., .], [., .]], [[., .], [., .]]]
sage: t.parent()
Binary trees

```

`sage.combinat.binary_tree.binary_search_tree_shape(w, left_to_right=True)`
 Direct computation of the binary search tree shape of a list of integers.

INPUT:

- `w` – a list of integers
- `left_to_right` – boolean (default True)

OUTPUT: a non labelled binary tree

This is used under the same name as a method for permutations.

EXAMPLES:

```
sage: from sage.combinat.binary_tree import binary_search_tree_shape
sage: binary_search_tree_shape([1,4,3,2])
[., [[., .], .], .]]
sage: binary_search_tree_shape([5,1,3,2])
[., [[., .], .]], .]
```

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```
sage: binary_search_tree_shape([1,6,4,2], False)
[., .], [., [., .]]]
```

`sage.combinat.binary_tree.from_tamari_sorting_tuple(key)`
 Return a binary tree from its Tamari-sorting tuple.

See `tamari_sorting_tuple()`

INPUT:

- `key` – a tuple of integers

EXAMPLES:

```
sage: from sage.combinat.binary_tree import from_tamari_sorting_tuple
sage: t = BinaryTrees(60).random_element()
sage: from_tamari_sorting_tuple(t.tamari_sorting_tuple()[0]) == t
True
```

5.1.10 Blob Algebras

AUTHORS:

- Travis Scrimshaw (2020-05-16): Initial version

class `sage.combinat.blob_algebra.BlobAlgebra(k, q1, q2, q3, base_ring, prefix)`

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

The blob algebra.

The *blob algebra* (also known as the Temperley-Lieb algebra of type B in [ILZ2018], but is a quotient of the Temperley-Lieb algebra of type B defined in [Graham1985]) is a diagram-type algebra introduced in [MS1994] whose basis consists of *Temperley-Lieb diagrams*, noncrossing perfect matchings, that may contain blobs on strands that can be deformed so that the blob touches the left side (which we can think of as a frozen pole).

The form we give here has 3 parameters, the natural one from the *Temperley-Lieb algebra*, one for the idempotent relation, and one for a loop with a blob.

INPUT:

- k – the order
- q_1 – the loop parameter
- q_2 – the idempotent parameter
- q_3 – the blob loop parameter

EXAMPLES:

```
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B = sorted(B4.basis())
sage: B[14]
B({{-4, -3}}, {{-2, -1}}, {1, 2}, {3, 4})
sage: B[40]
B({{3, 4}}, {{-4, -3}}, {-2, -1}, {1, 2})
sage: B[14] * B[40]
q*r*s*B({}, {{-4, -3}}, {-2, -1}, {1, 2}, {3, 4})
```

REFERENCES:

- [MS1994]
- [ILZ2018]

one_basis()

Return the index of the basis element l .

EXAMPLES:

```
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B4.one_basis()
({}, {{-4, 4}}, {-3, 3}, {-2, 2}, {-1, 1})
```

order()

Return the order of `self`.

The order of a partition algebra is defined as half of the number of nodes in the diagrams.

EXAMPLES:

```
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B4.order()
4
```

product_on_basis(*top*, *bot*)

Return the product of the basis elements indexed by `top` and `bot`.

EXAMPLES:

```
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B = B4.basis()
sage: BD = sorted(B.keys())
sage: BD[14]
```

(continues on next page)

(continued from previous page)

```

({{-4, -3}}, {{-2, -1}}, {1, 2}, {3, 4}})
sage: BD[40]
({{3, 4}}, {{-4, -3}}, {-2, -1}, {1, 2}})
sage: B4.product_on_basis(BD[14], BD[40])
q*r*s*B({}, {{-4, -3}}, {-2, -1}, {1, 2}, {3, 4}})
sage: all(len((x*y).support()) == 1 for x in B for y in B)
True

```

class sage.combinat.blob_algebra.BlobDiagram(*parent, marked, unmarked*)
 Bases: sage.structure.element.Element

A blob diagram.

A blob diagram consists of a perfect matching of the set $\{1, \dots, n\} \sqcup \{-1, \dots, -n\}$ such that the result is a noncrossing matching (a *Temperley-Lieb diagram*), divided into two sets of pairs: one for the pairs with blobs and one for those without. The blobbed pairs must either be either the leftmost propagating strand or to the left of it and not nested.

temperley_lieb_diagram()

Return the Temperley-Lieb diagram corresponding to *self*.

EXAMPLES:

```

sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: B = BD4([[1,-3]], [[2,-4], [3,4]], [-1,-2]])
sage: B.temperley_lieb_diagram()
{{-4, 2}, {-3, 1}, {-2, -1}, {3, 4}}

```

class sage.combinat.blob_algebra.BlobDiagrams(*n*)
 Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresentation

The set of all blob diagrams.

Element

alias of *BlobDiagram*

base_set()

Return the base set of *self*.

EXAMPLES:

```

sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: sorted(BD4.base_set())
[-4, -3, -2, -1, 1, 2, 3, 4]

```

cardinality()

Return the cardinality of *self*.

EXAMPLES:

```

sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: BD4.cardinality()
70

```

order()

Return the order of self.

EXAMPLES:

```
sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: BD4.order()
4
```

5.1.11 Cartesian Products

class `sage.combinat.cartesian_product.CartesianProduct_iters(*iters)`

Bases: `sage.sets.set_from_iterator.EnumeratedSetFromIterator`

Cartesian product of finite sets.

This class will soon be deprecated (see [trac ticket #18411](#) and [trac ticket #19195](#)). One should instead use the functorial construction `cartesian_product`. The main differences in behavior are:

- construction: `CartesianProduct` takes as many argument as there are factors whereas `cartesian_product` takes a single list (or iterable) of factors;
- representation of elements: elements are represented by plain Python list for `CartesianProduct` versus a custom element class for `cartesian_product`;
- membership testing: because of the above, plain Python lists are not considered as elements of a `cartesian_product`.

All of these is illustrated in the examples below.

EXAMPLES:

```
sage: F1 = ['a', 'b']
sage: F2 = [1, 2, 3, 4]
sage: F3 = Permutations(3)
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: C = CartesianProduct_iters(F1, F2, F3)
sage: c = cartesian_product([F1, F2, F3])

sage: type(C.an_element())
<class 'list'>
sage: type(c.an_element())
<class 'sage.sets.cartesian_product.CartesianProduct_with_category.element_class'>

sage: l = ['a', 1, Permutation([3,2,1])]
sage: l in C
True
sage: l in c
False
sage: elt = c(1)
sage: elt
('a', 1, [3, 2, 1])
sage: elt in c
True
```

(continues on next page)

(continued from previous page)

```
sage: elt.parent() is c
True
```

cardinality()

Returns the number of elements in the Cartesian product of everything in *iters.

EXAMPLES:

```
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(range(2), range(3)).cardinality()
6
sage: CartesianProduct_iters(range(2), range(3)).cardinality()
6
sage: CartesianProduct_iters(range(2), range(3), range(4)).cardinality()
24
```

This works correctly for infinite objects:

```
sage: CartesianProduct_iters(ZZ, QQ).cardinality()
+Infinity
sage: CartesianProduct_iters(ZZ, []).cardinality()
0
```

is_finite()

The Cartesian product is finite if all of its inputs are finite, or if any input is empty.

EXAMPLES:

```
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(ZZ, []).is_finite()
True
sage: CartesianProduct_iters(4,4).is_finite()
Traceback (most recent call last):
...
ValueError: Unable to determine whether this product is finite
```

list()

Returns

EXAMPLES:

```
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(range(3), range(3)).list()
[[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], [2, 0], [2, 1], [2, 2]]
sage: CartesianProduct_iters('dog', 'cat').list()
[['d', 'c'],
 ['d', 'a'],
 ['d', 't'],
 ['o', 'c'],
 ['o', 'a'],
 ['o', 't'],
 ['g', 'c'],
 ['g', 'a'],
 ['g', 't']]
```

random_element()

Return a random element from the Cartesian product of *iters.

EXAMPLES:

```
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: c = CartesianProduct_iters('dog', 'cat').random_element()
sage: c in CartesianProduct_iters('dog', 'cat')
True
```

unrank(x)

For finite Cartesian products, we can reduce unrank to the constituent iterators.

EXAMPLES:

```
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: C = CartesianProduct_iters(range(1000), range(1000), range(1000))
sage: C[238792368]
[238, 792, 368]
```

Check for trac ticket #15919:

```
sage: FF = IntegerModRing(29)
sage: C = CartesianProduct_iters(FF, FF, FF)
sage: C.unrank(0)
[0, 0, 0]
```

5.1.12 Enumerated sets of partitions, tableaux, ...

Partitions

- *Integer partitions*
- *Skew Partitions*
- *Partition tuples*
- *Super Partitions*
- *TableauTuples*
- *Skew Tableaux*
- *Ribbons*
- *Ribbon Tableaux*
- *Strong and weak tableaux*
- *Shifted primed tableaux*
- *Residue sequences of tableaux*

RSK

- *Robinson-Schensted-Knuth correspondence*
- *Growth diagrams and dual graded graphs*

5.1.13 Combinatorial Hopf algebras

- *Symmetric Functions*
- *Non-commutative symmetric functions and quasi-symmetric functions*
- *Symmetric functions in non-commuting variables*
- *Schubert Polynomials*
- *Poirier-Reutenauer Hopf algebra of standard tableaux*
- *Free Quasi-symmetric functions*
- *Grossman-Larson Hopf Algebras*
- *Word Quasi-symmetric functions*

5.1.14 Poirier-Reutenauer Hopf algebra of standard tableaux

AUTHORS:

- Franco Saliola (2012): initial implementation
- Travis Scrimshaw (2018-04-11): added missing doctests and reorganization

class sage.combinat.chas.fsym.FSymBases(*parent_with_realization*)
 Bases: sage.categories.realizations.Category_realization_of_parent

The category of graded bases of $FSym$ and $FSym^*$ indexed by standard tableaux.

class ElementMethods

Bases: object

duality_pairing(*other*)

Compute the pairing between self and an element other of the dual.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: F = G.dual_basis()
sage: elt = G[[1,3],[2]] - 3*G[[1,2],[3]]
sage: elt.duality_pairing(F[[1,3],[2]])
1
sage: elt.duality_pairing(F[[1,2],[3]])
-3
sage: elt.duality_pairing(F[[1,2]])
0
```

class ParentMethods

Bases: object

basis(*degree=None*)

The basis elements (optionally: of the specified degree).

OUTPUT: Family

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: TG = FSym.G()
sage: TG.basis()
Lazy family (Term map from Standard tableaux to Hopf algebra of standard_
↪tableaux
over the Rational Field in the Fundamental basis(i))_{i in Standard_
↪tableaux}
sage: TG.basis().keys()
Standard tableaux
sage: TG.basis(degree=3).keys()
Standard tableaux of size 3
sage: TG.basis(degree=3).list()
[G[123], G[13|2], G[12|3], G[1|2|3]]
```

degree_on_basis(*t*)

Return the degree of a standard tableau in the algebra of free symmetric functions.

This is the size of the tableau *t*.

EXAMPLES:

```
sage: G = algebras.FSym(QQ).G()
sage: t = StandardTableau([[1,3],[2]])
sage: G.degree_on_basis(t)
3
sage: u = StandardTableau([[1,3,4,5],[2]])
sage: G.degree_on_basis(u)
5
```

duality_pairing(*x, y*)

The canonical pairing between $FSym$ and $FSym^*$.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: F = G.dual_basis()
sage: t1 = StandardTableau([[1,3,5],[2,4]])
sage: t2 = StandardTableau([[1,3],[2,5],[4]])
sage: G.duality_pairing(G[t1], F[t2])
0
sage: G.duality_pairing(G[t1], F[t1])
1
sage: G.duality_pairing(G[t2], F[t2])
1
sage: F.duality_pairing(F[t2], G[t2])
1

sage: z = G[[1,3,5],[2,4]]
```

(continues on next page)

(continued from previous page)

```
sage: all(F.duality_pairing(F[p1] * F[p2], z) == c
.....:      for ((p1, p2), c) in z.coproduct())
True
```

duality_pairing_matrix(basis, degree)

The matrix of scalar products between elements of $FSym$ and elements of $FSym^*$.

INPUT:

- **basis** – a basis of the dual Hopf algebra
- **degree** – a non-negative integer

OUTPUT:

- the matrix of scalar products between the basis **self** and the basis **basis** in the dual Hopf algebra of degree **degree**

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: G.duality_pairing_matrix(G.dual_basis(), 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

one_basis()

Return the basis index corresponding to 1.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: TG = FSym.G()
sage: TG.one_basis()
[]
```

super_categories()

The super categories of **self**.

EXAMPLES:

```
sage: from sage.combinat.chas.fsym import FSymBases
sage: FSym = algebras.FSym(ZZ)
sage: bases = FSymBases(FSym)
sage: bases.super_categories()
[Category of realizations of Hopf algebra of standard tableaux over the Integer_
↪Ring,
Join of Category of realizations of hopf algebras over Integer Ring
and Category of graded algebras over Integer Ring
and Category of graded coalgebras over Integer Ring,
Category of graded connected hopf algebras with basis over Integer Ring]
```

class sage.combinat.chas.fsym.FSymBasis_abstract(*alg, graded=True*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`

Abstract base class for graded bases of $FSym$ and of $FSym^*$ indexed by standard tableaux.

This must define the following attributes:

- `_prefix` – the basis prefix

`some_elements()`

Return some elements of `self`.

EXAMPLES:

```
sage: G = algebras.FSym(QQ).G()
sage: G.some_elements()
[G[], G[1], G[12], G[1] + G[1|2], G[] + 1/2*G[1]]
```

class `sage.combinat.chas.fsym.FreeSymmetricFunctions`(*base_ring*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The free symmetric functions.

The *free symmetric functions* is a combinatorial Hopf algebra defined using tableaux and denoted $FSym$.

Consider the Hopf algebra $FQSym$ (*FreeQuasisymmetricFunctions*) over a commutative ring R , and its bases (F_w) and (G_w) (where w , in both cases, ranges over all permutations in all symmetric groups S_0, S_1, S_2, \dots). For each word w , let $P(w)$ be the P-tableau of w (that is, the first of the two tableaux obtained by applying the RSK algorithm to w ; see `RSK()`). If t is a standard tableau of size n , then we define $\mathcal{G}_t \in FQSym$ to be the sum of the F_w with w ranging over all permutations of $\{1, 2, \dots, n\}$ satisfying $P(w) = t$. Equivalently, \mathcal{G}_t is the sum of the G_w with w ranging over all permutations of $\{1, 2, \dots, n\}$ satisfying $Q(w) = t$ (where $Q(w)$ denotes the Q-tableau of w).

The R -linear span of the \mathcal{G}_t (for t ranging over all standard tableaux) is a Hopf subalgebra of $FQSym$, denoted by $FSym$ and known as the *free symmetric functions* or the *Poirier-Reutenauer Hopf algebra of tableaux*. It has been introduced in [PoiReu95], where it was denoted by $(ZT, *, \delta)$. (What we call \mathcal{G}_t has just been called t in [PoiReu95].) The family (\mathcal{G}_t) (with t ranging over all standard tableaux) is a basis of $FSym$, called the *Fundamental basis*.

EXAMPLES:

As explained above, $FSym$ is constructed as a Hopf subalgebra of $FQSym$:

```
sage: G = algebras.FSym(QQ).G()
sage: F = algebras.FQSym(QQ).F()
sage: G[[1, 3], [2]]
G[13|2]
sage: G[[1, 3], [2]].to_fqsym()
G[2, 1, 3] + G[3, 1, 2]
sage: F(G[[1, 3], [2]])
F[2, 1, 3] + F[2, 3, 1]
```

This embedding is a Hopf algebra morphism:

```
sage: all(F(G[t1] * G[t2]) == F(G[t1]) * F(G[t2])
.....:     for t1 in StandardTableaux(2)
.....:     for t2 in StandardTableaux(3))
True

sage: FF = F.tensor_square()
sage: all(FF(G[t].coproduct()) == F(G[t]).coproduct()
.....:     for t in StandardTableaux(4))
True
```

There is a Hopf algebra map from $FSym$ onto the Hopf algebra of symmetric functions, which maps a tableau t to the Schur function indexed by the shape of t :

```
sage: TG = algebras.FSym(QQ).G()
sage: t = StandardTableau([[1,3],[2,4],[5]])
sage: TG[t]
G[13|24|5]
sage: TG[t].to_symmetric_function()
s[2, 2, 1]
```

class Fundamental(*alg, graded=True*)

Bases: `sage.combinat.chas.fsym.FSymBasis_abstract`

The Hopf algebra of tableaux on the Fundamental basis.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: TG = FSym.G()
sage: TG
Hopf algebra of standard tableaux over the Rational Field
in the Fundamental basis
```

Elements of the algebra look like:

```
sage: TG.an_element()
2*G[] + 2*G[1] + 3*G[12]
```

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

to_fqsym()

Return the image of `self` under the natural inclusion map to $FQSym$.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[1,3],[2,4],[5]])
sage: G[t].to_fqsym()
G[2, 1, 5, 4, 3] + G[3, 1, 5, 4, 2] + G[3, 2, 5, 4, 1]
+ G[4, 1, 5, 3, 2] + G[4, 2, 5, 3, 1]
```

to_symmetric_function()

Return the image of `self` under the natural projection map to Sym .

The natural projection map $FSym \rightarrow Sym$ sends each standard tableau t to the Schur function s_λ , where λ is the shape of t . This map is a surjective Hopf algebra homomorphism.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[1,3],[2,4],[5]])
sage: G[t].to_symmetric_function()
s[2, 2, 1]
```

coproduct_on_basis(*t*)

Return the coproduct of the basis element indexed by *t*.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[1,2,5], [3,4]])
sage: G.coproduct_on_basis(t)
G[] # G[125|34] + G[1] # G[12|34] + G[1] # G[124|3]
+ G[1|2] # G[13|2] + G[12] # G[12|3] + G[12] # G[123]
+ G[12|34] # G[1] + G[123] # G[12] + G[125|34] # G[]
+ G[13|2] # G[1|2] + G[13|2] # G[12] + G[134|2] # G[1]
```

dual_basis()

Return the dual basis to self.

EXAMPLES:

```
sage: G = algebras.FSym(QQ).G()
sage: G.dual_basis()
Dual Hopf algebra of standard tableaux over the Rational Field
in the FundamentalDual basis
```

product_on_basis(*t1*, *t2*)

Return the product of basis elements indexed by *t1* and *t2*.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t1 = StandardTableau([[1,2], [3]])
sage: t2 = StandardTableau([[1,2,3]])
sage: G.product_on_basis(t1, t2)
G[12456|3] + G[1256|3|4] + G[1256|34] + G[126|35|4]

sage: t1 = StandardTableau([[1],[2]])
sage: t2 = StandardTableau([[1,2]])
sage: G.product_on_basis(t1, t2)
G[134|2] + G[14|2|3]

sage: t1 = StandardTableau([[1,2],[3]])
sage: t2 = StandardTableau([[1],[2]])
sage: G.product_on_basis(t1, t2)
G[12|3|4|5] + G[12|34|5] + G[124|3|5] + G[124|35]
```

G

alias of *FreeSymmetricFunctions.Fundamental*

a_realization()

Return a particular realization of self (the Fundamental basis).

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: FSym.a_realization()
```

(continues on next page)

(continued from previous page)

```
Hopf algebra of standard tableaux over the Rational Field
in the Fundamental basis
```

dual()Return the dual Hopf algebra of $FSym$.

EXAMPLES:

```
sage: algebras.FSym(QQ).dual()
Dual Hopf algebra of standard tableaux over the Rational Field
```

class `sage.combinat.chas.fsym.FreeSymmetricFunctions_Dual`(*base_ring*)Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`The Hopf dual $FSym^*$ of the free symmetric functions $FSym$.See `FreeSymmetricFunctions` for the definition of the latter.

Recall that the fundamental basis of $FSym$ consists of the elements \mathcal{G}_t for t ranging over all standard tableaux. The dual basis of this is called the *dual fundamental basis* of $FSym^*$, and is denoted by (\mathcal{G}_t^*) . The Hopf dual $FSym^*$ is isomorphic to the Hopf algebra $(\mathbf{ZT}, *, \delta')$ from [PoiReu95]; the isomorphism sends a basis element \mathcal{G}_t^* to t .

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: TF[1, 2] * TF[[1], [2]]
F[12|3|4] + F[123|4] + F[124|3] + F[13|2|4] + F[134|2] + F[14|2|3]
sage: TF[[1, 2], [3]].coproduct()
F[] # F[12|3] + F[1] # F[1|2] + F[12] # F[1] + F[12|3] # F[]
```

The Hopf algebra $FSym^*$ is a Hopf quotient of $FQSym$; the canonical projection sends F_w (for a permutation w) to $\mathcal{G}_{Q(w)}^*$, where $Q(w)$ is the Q -tableau of w . This projection is implemented as a coercion:

```
sage: FQSym = algebras.FQSym(QQ)
sage: F = FQSym.F()
sage: TF(F[[1, 3, 2]])
F[12|3]
sage: TF(F[[5, 1, 4, 2, 3]])
F[135|2|4]
```

Falias of `FreeSymmetricFunctions_Dual.FundamentalDual`**class** `FundamentalDual`(*alg*, *graded=True*)Bases: `sage.combinat.chas.fsym.FSymBasis_abstract`

The dual to the Hopf algebra of tableaux, on the fundamental dual basis.

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: TF
```

(continues on next page)

(continued from previous page)

```
Dual Hopf algebra of standard tableaux over the Rational Field
in the FundamentalDual basis
```

Elements of the algebra look like:

```
sage: TF.an_element()
2*F[] + 2*F[1] + 3*F[12]
```

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

to_quasisymmetric_function()

Return the image of `self` under the canonical projection $FSym^* \rightarrow QSym$ to the ring of quasi-symmetric functions.

This projection is the adjoint of the canonical injection $NSym \rightarrow FSym$ (see `to_fsym()`). It sends each tableau t to the fundamental quasi-symmetric function F_α , where α is the descent composition of t .

EXAMPLES:

```
sage: F = algebras.FSym(QQ).dual().F()
sage: F[[1,3,5],[2,4]].to_quasisymmetric_function()
F[1, 2, 2]
```

coproduct_on_basis(t)

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: t = StandardTableau([[1,2,5], [3,4]])
sage: TF.coproduct_on_basis(t)
F[] # F[125|34] + F[1] # F[134|2] + F[12] # F[123]
+ F[12|3] # F[12] + F[12|34] # F[1] + F[125|34] # F[]
```

dual_basis()

Return the dual basis to `self`.

EXAMPLES:

```
sage: F = algebras.FSym(QQ).dual().F()
sage: F.dual_basis()
Hopf algebra of standard tableaux over the Rational Field
in the Fundamental basis
```

product_on_basis(t1, t2)

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: t1 = StandardTableau([[1,2]])
sage: TF.product_on_basis(t1, t1)
F[12|34] + F[123|4] + F[1234] + F[124|3] + F[13|24] + F[134|2]
sage: t0 = StandardTableau([])
```

(continues on next page)

(continued from previous page)

```
sage: TF.product_on_basis(t1, t0) == TF[t1] == TF.product_on_basis(t0, t1)
True
```

a_realization()

Return a particular realization of `self` (the Fundamental dual basis).

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ).dual()
sage: FSym.a_realization()
Dual Hopf algebra of standard tableaux over the Rational Field
in the FundamentalDual basis
```

dual()

Return the dual Hopf algebra of `self`, which is $FSym$.

EXAMPLES:

```
sage: D = algebras.FSym(QQ).dual()
sage: D.dual()
Hopf algebra of standard tableaux over the Rational Field
```

sage.combinat.chas.fsym.ascent_set(*t*)

Return the ascent set of a standard tableau `t` (encoded as a sorted list).

The *ascent set* of a standard tableau `t` is defined as the set of all entries `i` of `t` such that the number `i + 1` either appears to the right of `i` or appears in a row above `i` or does not appear in `t` at all.

EXAMPLES:

```
sage: from sage.combinat.chas.fsym import ascent_set
sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])
sage: ascent_set(t)
[2, 3, 5, 6, 8]
sage: ascent_set(StandardTableau([]))
[]
sage: ascent_set(StandardTableau([[1, 2, 3]]))
[1, 2, 3]
sage: ascent_set(StandardTableau([[1, 2, 4], [3]]))
[1, 3, 4]
sage: ascent_set([[1, 3, 5], [2, 4]])
[2, 4, 5]
```

sage.combinat.chas.fsym.descent_composition(*t*)

Return the descent composition of a standard tableau `t`.

This is the composition of the size of `t` whose partial sums are the elements of the descent set of `t` (see `descent_set()`).

EXAMPLES:

```
sage: from sage.combinat.chas.fsym import descent_composition
sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])
sage: descent_composition(t)
[1, 3, 3, 1]
```

(continues on next page)

(continued from previous page)

```
sage: descent_composition([[1, 3, 5], [2, 4]])
[1, 2, 2]
```

`sage.combinat.chas.fsym.descent_set(t)`

Return the descent set of a standard tableau *t* (encoded as a sorted list).

The *descent set* of a standard tableau *t* is defined as the set of all entries *i* of *t* such that the number *i* + 1 appears in a row below *i* in *t*.

EXAMPLES:

```
sage: from sage.combinat.chas.fsym import descent_set
sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])
sage: descent_set(t)
[1, 4, 7]
sage: descent_set(StandardTableau([]))
[]
sage: descent_set(StandardTableau([[1, 2, 3]]))
[]
sage: descent_set(StandardTableau([[1, 2, 4], [3]]))
[2]
sage: descent_set([[1, 3, 5], [2, 4]])
[1, 3]
```

`sage.combinat.chas.fsym.standardize(t)`

Return the standard tableau corresponding to a given semistandard tableau *t* with no repeated entries.

Note: This is an optimized version of `Tableau.standardization()` for computations in *FSym* by using the assumption of no repeated entries in *t*.

EXAMPLES:

```
sage: from sage.combinat.chas.fsym import standardize
sage: t = Tableau([[1,3,5,7],[2,4,8],[9]])
sage: standardize(t)
[[1, 3, 5, 6], [2, 4, 7], [8]]
sage: t = Tableau([[3,8,9,15],[5,10,12],[133]])
sage: standardize(t)
[[1, 3, 4, 7], [2, 5, 6], [8]]
```

5.1.15 Word Quasi-symmetric functions

AUTHORS:

- Travis Scrimshaw (2018-04-09): initial implementation
- Darij Grinberg and Amy Pang (2018-04-12): further bases and methods

class `sage.combinat.chas.wqsym.WQSymBases(base, graded)`

Bases: `sage.categories.realizations.Category_realization_of_parent`

The category of bases of *WQSym*.

class ElementMethods

Bases: object

algebraic_complement()

Return the image of the element `self` of $WQSym$ under the algebraic complement involution.

If $u = (u_1, u_2, \dots, u_n)$ is a packed word that contains the letters $1, 2, \dots, k$ and no others, then the *complement* of u is defined to be the packed word $\bar{u} := (k + 1 - u_1, k + 1 - u_2, \dots, k + 1 - u_n)$.

The algebraic complement involution is defined as the linear map $WQSym \rightarrow WQSym$ that sends each basis element M_u of the monomial basis of $WQSym$ to the basis element $M_{\bar{u}}$. This is a graded algebra automorphism and a coalgebra anti-automorphism of $WQSym$. Denoting by \bar{f} the image of an element $f \in WQSym$ under the algebraic complement involution, it can be shown that every packed word u satisfies

$$\overline{M_u} = M_{\bar{u}}, \quad \overline{X_u} = X_{\bar{u}},$$

where standard notations for classical bases of $WQSym$ are being used (that is, M for the monomial basis, and X for the characteristic basis).

This can be restated in terms of ordered set partitions: For any ordered set partition $R = (R_1, R_2, \dots, R_k)$, let R^r denote the ordered set partition $(R_k, R_{k-1}, \dots, R_1)$; this is known as the *reversal* of R . Then,

$$\overline{M_A} = M_{A^r}, \quad \overline{X_A} = X_{A^r}$$

for any ordered set partition A .

The formula describing algebraic complements on the Q basis ([WordQuasiSymmetricFunctions.StronglyCoarser](#)) is more complicated, and requires some definitions. We define a partial order \leq on the set of all ordered set partitions as follows: $A \leq B$ if and only if A is strongly finer than B (see [is_strongly_finer\(\)](#) for a definition of this). The *length* $\ell(R)$ of an ordered set partition R shall be defined as the number of parts of R . Use the notation Q for the Q basis. For any ordered set partition A of $[n]$, we have

$$\overline{Q_A} = \sum_P c_{A,P} Q_P,$$

where the sum is over all ordered set partitions P of $[n]$, and where the coefficient $c_{A,P}$ is defined as follows:

- If there exists an ordered set partition R satisfying $R \leq P$ and $A \leq R^r$, then this R is unique, and $c_{A,P} = (-1)^{\ell(R) - \ell(P)}$.
- If there exists no such R , then $c_{A,P} = 0$.

The formula describing algebraic complements on the Φ basis ([WordQuasiSymmetricFunctions.StronglyFiner](#)) is identical to the above formula for the Q basis, except that the \leq sign has to be replaced by \geq in the definition of the coefficients $c_{A,P}$. In fact, both formulas are particular cases of a general formula for involutions: Assume that V is an (additive) abelian group, and that I is a poset. For each $i \in I$, let M_i be an element of V . Also, let ω be an involution of the set I (not necessarily order-preserving or order-reversing), and let ω' be an involutive group endomorphism of V such that each $i \in I$ satisfies $\omega'(M_i) = M_{\omega(i)}$. For each $i \in I$, let $F_i = \sum_{j \geq i} M_j$, where we assume that the sum is finite. Then, each $i \in I$ satisfies

$$\omega'(F_i) = \sum_j \sum_{\substack{k \leq j; \\ \omega(k) \geq i}} \mu(k, j) F_j,$$

where μ denotes the Möbius function. This formula becomes particularly useful when the k satisfying $k \leq j$ and $\omega(k) \geq i$ is unique (if it exists). In our situation, V is $WQSym$, and I is the set of ordered

set partitions equipped either with the \leq partial order defined above or with its opposite order. The M_i is the M_A , whereas the F_i is either Q_i or Φ_i .

If we denote the star involution (`star_involution()`) of the quasisymmetric functions by $f \mapsto f^*$, and if we let π be the canonical projection $WQSym \rightarrow QSym$, then each $f \in WQSym$ satisfies $\pi(\bar{f}) = (\pi(f))^*$.

See also:

`coalgebraic_complement()`, `star_involution()`

EXAMPLES:

Recall that the index set for the bases of $WQSym$ is given by ordered set partitions, not packed words. Translated into the language of ordered set partitions, the algebraic complement involution acts on the Monomial basis by reversing the ordered set partition. In other words, we have

$$\overline{M_{(P_1, P_2, \dots, P_k)}} = M_{(P_k, P_{k-1}, \dots, P_1)}$$

for any standard ordered set partition (P_1, P_2, \dots, P_k) . Let us check this in practice:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: M = WQSym.M()
sage: M[[1,3],[2]].algebraic_complement()
M[{2}, {1, 3}]
sage: M[[1,4],[2,5],[3,6]].algebraic_complement()
M[{3, 6}, {2, 5}, {1, 4}]
sage: (3*M[[1]] - 4*M[[ ]] + 5*M[[1],[2]]).algebraic_complement()
-4*M[ ] + 3*M[{1}] + 5*M[{2}, {1}]
sage: X = WQSym.X()
sage: X[[1,3],[2]].algebraic_complement()
X[{2}, {1, 3}]
sage: C = WQSym.C()
sage: C[[1,3],[2]].algebraic_complement()
-C[{1, 2, 3}] - C[{1, 3}, {2}] + C[{2}, {1, 3}]
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].algebraic_complement()
Q[{3, 4}, {1, 2, 5, 6}] + Q[{3, 4}, {5, 6}, {1, 2}] - Q[{3, 4, 5, 6}, {1, 2}]
↩]
sage: Phi = WQSym.Phi()
sage: Phi[[2], [1,3]].algebraic_complement()
-Phi[{1}, {3}, {2}] + Phi[{1, 3}, {2}] + Phi[{3}, {1}, {2}]
```

The algebraic complement involution intertwines the antipode and the inverse of the antipode:

```
sage: all( M(I).antipode().algebraic_complement().antipode() # long time
.....:      == M(I).algebraic_complement()
.....:      for I in OrderedSetPartitions(4) )
True
```

Testing the $\pi(\bar{f}) = (\pi(f))^*$ relation:

```
sage: all( M[I].algebraic_complement().to_quasisymmetric_function()
.....:      == M[I].to_quasisymmetric_function().star_involution()
.....:      for I in OrderedSetPartitions(4) )
True
```

Todo: Check further commutative squares.

`coalgebraic_complement()`

Return the image of the element `self` of $WQSym$ under the coalgebraic complement involution.

If $u = (u_1, u_2, \dots, u_n)$ is a packed word, then the *reversal* of u is defined to be the packed word $(u_n, u_{n-1}, \dots, u_1)$. This reversal is denoted by u^r .

The coalgebraic complement involution is defined as the linear map $WQSym \rightarrow WQSym$ that sends each basis element M_u of the monomial basis of $WQSym$ to the basis element M_{u^r} . This is a graded coalgebra automorphism and an algebra anti-automorphism of $WQSym$. Denoting by f^r the image of an element $f \in WQSym$ under the coalgebraic complement involution, it can be shown that every packed word u satisfies

$$(M_u)^r = M_{u^r}, \quad (X_u)^r = X_{u^r},$$

where standard notations for classical bases of $WQSym$ are being used (that is, M for the monomial basis, and X for the characteristic basis).

This can be restated in terms of ordered set partitions: For any ordered set partition R of $[n]$, let \overline{R} denote the complement of R (defined in `complement()`). Then,

$$(M_A)^r = M_{\overline{A}}, \quad (X_A)^r = X_{\overline{A}}$$

for any ordered set partition A .

Recall that $WQSym$ is a subring of the ring of all bounded-degree noncommutative power series in countably many indeterminates. The latter ring has an obvious continuous algebra anti-automorphism which sends each letter x_i to x_i (and thus sends each monomial $x_{i_1}x_{i_2}\cdots x_{i_n}$ to $x_{i_n}x_{i_{n-1}}\cdots x_{i_1}$). This anti-automorphism is actually an involution. The coalgebraic complement involution is simply the restriction of this involution to the subring $WQSym$.

The formula describing coalgebraic complements on the Q basis ([WordQuasiSymmetricFunctions.StronglyCoarser](#)) is more complicated, and requires some definitions. We define a partial order \leq on the set of all ordered set partitions as follows: $A \leq B$ if and only if A is strongly finer than B (see `is_strongly_finer()` for a definition of this). The *length* $\ell(R)$ of an ordered set partition R shall be defined as the number of parts of R . Use the notation Q for the Q basis. For any ordered set partition A of $[n]$, we have

$$(Q_A)^r = \sum_P c_{A,P} Q_P,$$

where the sum is over all ordered set partitions P of $[n]$, and where the coefficient $c_{A,P}$ is defined as follows:

- If there exists an ordered set partition R satisfying $R \leq P$ and $A \leq \overline{R}$, then this R is unique, and $c_{A,P} = (-1)^{\ell(R)-\ell(P)}$.
- If there exists no such R , then $c_{A,P} = 0$.

The formula describing coalgebraic complements on the Φ basis ([WordQuasiSymmetricFunctions.StronglyFiner](#)) is identical to the above formula for the Q basis, except that the \leq sign has to be replaced by \geq in the definition of the coefficients $c_{A,P}$. In fact, both formulas are particular cases of the general formula for involutions described in the documentation of `algebraic_complement()`.

If we let π be the canonical projection $WQSym \rightarrow QSym$, then each $f \in WQSym$ satisfies $\pi(f^r) = \pi(f)$.

See also:

`algebraic_complement()`, `star_involution()`

EXAMPLES:

Recall that the index set for the bases of $WQSym$ is given by ordered set partitions, not packed words. Translated into the language of ordered set partitions, the coalgebraic complement involution acts on the Monomial basis by complementing the ordered set partition. In other words, we have

$$(M_A)^r = M_{\bar{A}}$$

for any standard ordered set partition P . Let us check this in practice:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: M = WQSym.M()
sage: M[[1,3],[2]].coalgebraic_complement()
M[{1, 3}, {2}]
sage: M[[1,2],[3]].coalgebraic_complement()
M[{2, 3}, {1}]
sage: M[[1],[4],[2,3]].coalgebraic_complement()
M[{4}, {1}, {2, 3}]
sage: M[[1,4],[2,5],[3,6]].coalgebraic_complement()
M[{3, 6}, {2, 5}, {1, 4}]
sage: (3*M[[1]] - 4*M[[1]] + 5*M[[1],[2]]).coalgebraic_complement()
-4*M[] + 3*M[{1}] + 5*M[{2}, {1}]
sage: X = WQSym.X()
sage: X[[1,3],[2]].coalgebraic_complement()
X[{1, 3}, {2}]
sage: C = WQSym.C()
sage: C[[1,3],[2]].coalgebraic_complement()
C[{1, 3}, {2}]
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].coalgebraic_complement()
Q[{1, 2, 5, 6}, {3, 4}] + Q[{5, 6}, {1, 2}, {3, 4}] - Q[{5, 6}, {1, 2, 3, 4}]
↔
sage: Phi = WQSym.Phi()
sage: Phi[[2],[1,3]].coalgebraic_complement()
-Phi[{2}, {1}, {3}] + Phi[{2}, {1, 3}] + Phi[{2}, {3}, {1}]
```

The coalgebraic complement involution intertwines the antipode and the inverse of the antipode:

```
sage: all( M(I).antipode().coalgebraic_complement().antipode() # long time
.....:      == M(I).coalgebraic_complement()
.....:      for I in OrderedSetPartitions(4) )
True
```

Testing the $\pi(f^r) = \pi(f)$ relation above:

```
sage: all( M[I].coalgebraic_complement().to_quasisymmetric_function()
.....:      == M[I].to_quasisymmetric_function()
.....:      for I in OrderedSetPartitions(4) )
True
```

Todo: Check further commutative squares.

star_involution()

Return the image of the element `self` of $WQSym$ under the star involution.

The star involution is the composition of the algebraic complement involution (`algebraic_complement()`) with the coalgebraic complement involution (`coalgebraic_complement()`). The composition can be performed in either order, as the involutions commute.

The star involution is a graded Hopf algebra anti-automorphism of $WQSym$. Let f^* denote the image of an element $f \in WQSym$ under the star involution. Let \mathbf{M} , X , Q and Φ stand for the monomial, characteristic, Q and Φ bases of $WQSym$. For any ordered set partition A of $[n]$, we let A^* denote the complement (`complement()`) of the reversal (`reversed()`) of A . Then, for any ordered set partition A of $[n]$, we have

$$(\mathbf{M}_A)^* = \mathbf{M}_{A^*}, \quad (X_A)^* = X_{A^*}, \quad (Q_A)^* = Q_{A^*}, \quad (\Phi_A)^* = \Phi_{A^*}.$$

The star involution (`star_involution()`) on the ring of noncommutative symmetric functions is a restriction of the star involution on $WQSym$.

If we denote the star involution (`star_involution()`) of the quasisymmetric functions by $f \mapsto f^*$, and if we let π be the canonical projection $WQSym \rightarrow QSym$, then each $f \in WQSym$ satisfies $\pi(f^*) = (\pi(f))^*$.

Todo: More commutative diagrams? `FQSym` and `FSym` need their own `star_involution` methods defined first.

See also:

`algebraic_complement()`, `coalgebraic_complement()`

EXAMPLES:

Keep in mind that the default input method for basis keys of $WQSym$ is by entering an ordered set partition, not a packed word. Let us check the basis formulas for the star involution:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: M = WQSym.M()
sage: M[[1,3], [2,4,5]].star_involution()
M[{1, 2, 4}, {3, 5}]
sage: M[[1,3],[2]].star_involution()
M[{2}, {1, 3}]
sage: M[[1,4],[2,5],[3,6]].star_involution()
M[{1, 4}, {2, 5}, {3, 6}]
sage: (3*M[[1]] - 4*M[[]] + 5*M[[1],[2]]).star_involution()
-4*M[] + 3*M[{1}] + 5*M[{1}, {2}]
sage: X = WQSym.X()
sage: X[[1,3],[2]].star_involution()
X[{2}, {1, 3}]
sage: C = WQSym.C()
sage: C[[1,3],[2]].star_involution()
-C[{1, 2, 3}] - C[{1, 3}, {2}] + C[{2}, {1, 3}]
sage: Q = WQSym.Q()
sage: Q[[1,3], [2,4,5]].star_involution()
Q[{1, 2, 4}, {3, 5}]
sage: Phi = WQSym.Phi()
sage: Phi[[1,3], [2,4,5]].star_involution()
Phi[{1, 2, 4}, {3, 5}]
```

Testing the formulas for $(Q_A)^*$ and $(\Phi_A)^*$:

```

sage: all(Q[A].star_involution() == Q[A.complement().reversed()] for A in
↳ OrderedSetPartitions(4))
True
sage: all(Phi[A].star_involution() == Phi[A.complement().reversed()] for A
↳ in OrderedSetPartitions(4))
True

```

The star involution commutes with the antipode:

```

sage: all( M(I).antipode().star_involution() # long time
.....:      == M(I).star_involution().antipode()
.....:      for I in OrderedSetPartitions(4) )
True

```

Testing the $\pi(f^*) = (\pi(f))^*$ relation:

```

sage: all( M[I].star_involution().to_quasisymmetric_function()
.....:      == M[I].to_quasisymmetric_function().star_involution()
.....:      for I in OrderedSetPartitions(4) )
True

```

Testing the fact that the star involution on the noncommutative symmetric functions is a restriction of the star involution on $WQSym$:

```

sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: R = NCSF.R()
sage: all(R[I].star_involution().to_fqsym().to_wqsym()
.....:      == R[I].to_fqsym().to_wqsym().star_involution()
.....:      for I in Compositions(4))
True

```

Todo: Check further commutative squares.

`to_quasisymmetric_function()`

The projection of `self` to the ring $QSym$ of quasisymmetric functions.

There is a canonical projection $\pi : WQSym \rightarrow QSym$ that sends every element M_P of the monomial basis of $WQSym$ to the monomial quasisymmetric function M_c , where c is the composition whose parts are the sizes of the blocks of P . This π is a ring homomorphism.

OUTPUT:

- an element of the quasisymmetric functions in the monomial basis

EXAMPLES:

```

sage: M = algebras.WQSym(QQ).M()
sage: M[[1,3],[2]].to_quasisymmetric_function()
M[2, 1]
sage: (M[[1,3],[2]] + 3*M[[2,3],[1]] - M[[1,2,3],]).to_quasisymmetric_
↳ function()
4*M[2, 1] - M[3]
sage: X, Y = M[[1,3],[2]], M[[1,2,3],]
sage: X.to_quasisymmetric_function() * Y.to_quasisymmetric_function() ==
↳ (X*Y).to_quasisymmetric_function()

```

(continues on next page)

(continued from previous page)

```

True

sage: C = algebras.WQSym(QQ).C()

```

class ParentMethods

Bases: object

degree_on_basis(*t*)

Return the degree of an ordered set partition in the algebra of word quasi-symmetric functions.

This is the sum of the sizes of the blocks of the ordered set partition.

EXAMPLES:

```

sage: A = algebras.WQSym(QQ).M()
sage: u = OrderedSetPartition([[2,1],])
sage: A.degree_on_basis(u)
2
sage: u = OrderedSetPartition([[2], [1]])
sage: A.degree_on_basis(u)
2

```

is_commutative()Return whether `self` is commutative.

EXAMPLES:

```

sage: M = algebras.WQSym(ZZ).M()
sage: M.is_commutative()
False

```

is_field(*proof=True*)Return whether `self` is a field.

EXAMPLES:

```

sage: M = algebras.WQSym(QQ).M()
sage: M.is_field()
False

```

one_basis()

Return the index of the unit.

EXAMPLES:

```
sage: A = algebras.WQSym(QQ).M()
sage: A.one_basis()
[]
```

super_categories()

The super categories of self.

EXAMPLES:

```
sage: from sage.combinat.chas.wqsym import WQSymBases
sage: WQSym = algebras.WQSym(ZZ)
sage: bases = WQSymBases(WQSym, True)
sage: bases.super_categories()
[Category of realizations of Word Quasi-symmetric functions over Integer Ring,
Join of Category of realizations of hopf algebras over Integer Ring
and Category of graded algebras over Integer Ring
and Category of graded coalgebras over Integer Ring,
Category of graded connected hopf algebras with basis over Integer Ring]

sage: bases = WQSymBases(WQSym, False)
sage: bases.super_categories()
[Category of realizations of Word Quasi-symmetric functions over Integer Ring,
Join of Category of realizations of hopf algebras over Integer Ring
and Category of graded algebras over Integer Ring
and Category of graded coalgebras over Integer Ring,
Join of Category of filtered connected hopf algebras with basis over Integer
Ring
and Category of graded algebras over Integer Ring
and Category of graded coalgebras over Integer Ring]
```

class `sage.combinat.chas.wqsym.WQSymBasis_abstract`(*alg*, *graded=True*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`

Abstract base class for bases of *WQSym*.

This must define two attributes:

- `_prefix` – the basis prefix
- `_basis_name` – the name of the basis (must match one of the names that the basis can be constructed from *WQSym*)

an_element()

Return an element of self.

EXAMPLES:

```
sage: M = algebras.WQSym(QQ).M()
sage: M.an_element()
M[{{1}}] + 2*M[{{1}}, {2}]
```

options(**get_value*, ***set_value*)

Set and display the global options for bases of `WordQuasiSymmetricFunctions`. If no parameters are set, then the function returns a copy of the options dictionary.

The options can be accessed as the method `WordQuasiSymmetricFunctions.options` of `WordQuasiSymmetricFunctions` or of any associated basis.

OPTIONS:

- `display` – (default: `normal`) Specifies how basis elements of `WordQuasiSymmetricFunctions` should be printed
 - `compact` – Using a severely compacted representation
 - `normal` – Using the normal representation
 - `tight` – Dropping spaces after commas
- `objects` – (default: `compositions`) Specifies how basis elements of `WordQuasiSymmetricFunctions` should be indexed
 - `compositions` – Indexing the basis by ordered set partitions
 - `words` – Indexing the basis by packed words

The 'words' representation of a basis element of `WordQuasiSymmetricFunctions`, indexed by an ordered set partition A , is the packed word associated to A . See `OrderedSetPartition.to_packed_word()` for details.)

EXAMPLES:

```
sage: WQ = WordQuasiSymmetricFunctions(QQ)
sage: M = WQ.M()
sage: elt = M[[[1,2]]]*M[[[1]]]; elt
M[{1, 2}, {3}] + M[{1, 2, 3}] + M[{3}, {1, 2}]
sage: M.options.display = "tight"
sage: elt
M[{1,2},{3}] + M[{1,2,3}] + M[{3},{1,2}]
sage: M.options.display = "compact"
sage: elt
M[12.3] + M[123] + M[3.12]
sage: WQ.options._reset()
sage: M.options.objects = "words"
sage: elt
M[1, 1, 2] + M[1, 1, 1] + M[2, 2, 1]
sage: M.options.display = "tight"
sage: elt
M[1,1,2] + M[1,1,1] + M[2,2,1]
sage: WQ.options.display = "compact"
sage: elt
M[112] + M[111] + M[221]
sage: M.options._reset()
sage: elt
M[{1, 2}, {3}] + M[{1, 2, 3}] + M[{3}, {1, 2}]
```

See `GlobalOptions` for more features of these options.

some_elements()

Return some elements of the word quasi-symmetric functions.

EXAMPLES:

```
sage: M = algebras.WQSym(QQ).M()
sage: M.some_elements()
[M[], M[{1}], M[{1, 2}],
```

(continues on next page)

$$\begin{aligned} &M[\{1\}] + M[\{1\}, \{2\}], \\ &M[] + 1/2 * M[\{1\}] \end{aligned}$$

class sage.combinat.chas.wqsym.**WordQuasiSymmetricFunctions**(*R*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The word quasi-symmetric functions.

The ring of word quasi-symmetric functions can be defined as a subring of the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in $R\langle\langle x_1, x_2, x_3, \dots \rangle\rangle$ of bounded degree). Namely, consider words over the alphabet $\{1, 2, 3, \dots\}$; every noncommutative power series is an infinite R -linear combination of these words. For each such word w , we define the *packing* of w to be the word $\text{pack}(w)$ that is obtained from w by replacing the smallest letter that appears in w by 1, the second-smallest letter that appears in w by 2, etc. (for example, $\text{pack}(4112774) = 3112443$). A word w is said to be *packed* if $\text{pack}(w) = w$. For each packed word u , we define the noncommutative power series $\mathbf{M}_u = \sum w$, where the sum ranges over all words w satisfying $\text{pack}(w) = u$. The span of these power series \mathbf{M}_u is a subring of the ring of all noncommutative power series; it is called the ring of word quasi-symmetric functions, and is denoted by *WQSym*.

For each nonnegative integer n , there is a bijection between packed words of length n and ordered set partitions of $\{1, 2, \dots, n\}$. Under this bijection, a packed word $u = (u_1, u_2, \dots, u_n)$ of length n corresponds to the ordered set partition $P = (P_1, P_2, \dots, P_k)$ of $\{1, 2, \dots, n\}$ whose i -th part P_i (for each i) is the set of all $j \in \{1, 2, \dots, n\}$ such that $u_j = i$.

The basis element \mathbf{M}_u is also denoted as \mathbf{M}_P in this situation. The basis $(\mathbf{M}_P)_P$ is called the *Monomial basis* and is implemented as *Monomial*.

Other bases are the cone basis (aka C basis), the characteristic basis (aka X basis), the Q basis and the Phi basis.

Bases of *WQSym* are implemented (internally) using ordered set partitions. However, the user may access specific basis vectors using either packed words or ordered set partitions. See the examples below, noting especially the section on ambiguities.

WQSym is endowed with a connected graded Hopf algebra structure (see Section 2.2 of [NoThWi08], Section 1.1 of [FoiMal14] and Section 4.3.2 of [MeNoTh11]) given by

$$\Delta(\mathbf{M}_{(P_1, \dots, P_\ell)}) = \sum_{i=0}^{\ell} \mathbf{M}_{\text{st}(P_1, \dots, P_i)} \otimes \mathbf{M}_{\text{st}(P_{i+1}, \dots, P_\ell)}.$$

Here, for any ordered set partition (Q_1, \dots, Q_k) of a finite set Z of integers, we let $\text{st}(Q_1, \dots, Q_k)$ denote the set partition obtained from Z by replacing the smallest element appearing in it by 1, the second-smallest element by 2, and so on.

A rule for multiplying elements of the monomial basis relies on the *quasi-shuffle product* of two ordered set partitions. The quasi-shuffle product \square is given by *ShuffleProduct_overlapping* with the $+$ operation in the overlapping of the shuffles being the union of the sets. The product $\mathbf{M}_P \mathbf{M}_Q$ for two ordered set partitions P and Q of $[n]$ and $[m]$ is then given by

$$\mathbf{M}_P \mathbf{M}_Q = \sum_{R \in P \square Q^+} \mathbf{M}_R,$$

where Q^+ means Q with all numbers shifted upwards by n .

Sometimes, *WQSym* is also denoted as *NCQSym*.

REFERENCES:

- [FoiMal14]

- [MeNoTh11]
- [NoThWi08]
- [BerZab05]

EXAMPLES:

Constructing the algebra and its Monomial basis:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: WQSym
Word Quasi-symmetric functions over Integer Ring
sage: M = WQSym.M()
sage: M
Word Quasi-symmetric functions over Integer Ring in the Monomial basis
sage: M[[]]
M[]
```

Calling basis elements using packed words:

```
sage: x = M[1,2,1]; x
M[{1, 3}, {2}]
sage: x == M[[1,2,1]] == M[Word([1,2,1])]
True
sage: y = M[1,1,2] - M[1,2,2]; y
-M[{1}, {2, 3}] + M[{1, 2}, {3}]
```

Calling basis elements using ordered set partitions:

```
sage: z = M[[1,2,3],,]; z
M[{1, 2, 3}]
sage: z == M[[[1,2,3]]] == M[OrderedSetPartition([[1,2,3]])]
True
sage: M[[1,2],[3]]
M[{1, 2}, {3}]
```

Note that expressions above are output in terms of ordered set partitions, even when input as packed words. Output as packed words can be achieved by modifying the global options. (See `OrderedSetPartitions.options()` for further details.):

```
sage: M.options.objects = "words"
sage: y
-M[1, 2, 2] + M[1, 1, 2]
sage: M.options.display = "compact"
sage: y
-M[122] + M[112]
sage: z
M[111]
```

The options should be reset to display as ordered set partitions:

```
sage: M.options._reset()
sage: z
M[{1, 2, 3}]
```

Illustration of the Hopf algebra structure:

```

sage: M[[2, 3], [5], [6], [4], [1]].coproduct()
M[] # M[{2, 3}, {5}, {6}, {4}, {1}] + M[{1, 2}] # M[{3}, {4}, {2}, {1}]
+ M[{1, 2}, {3}] # M[{3}, {2}, {1}] + M[{1, 2}, {3}, {4}] # M[{2}, {1}]
+ M[{1, 2}, {4}, {5}, {3}] # M[{1}] + M[{2, 3}, {5}, {6}, {4}, {1}] # M[]
sage: _ == M[5,1,1,4,2,3].coproduct()
True
sage: M[[1,1,1]] * M[[1,1,2]] # packed words
M[{1, 2, 3}, {4, 5}, {6}] + M[{1, 2, 3, 4, 5}, {6}]
+ M[{4, 5}, {1, 2, 3}, {6}] + M[{4, 5}, {1, 2, 3, 6}]
+ M[{4, 5}, {6}, {1, 2, 3}]
sage: M[[1,2,3],].antipode() # ordered set partition
-M[{1, 2, 3}]
sage: M[[1], [2], [3]].antipode()
-M[{1, 2, 3}] - M[{2, 3}, {1}] - M[{3}, {1, 2}] - M[{3}, {2}, {1}]
sage: x = M[[1],[2],[3]] + 3*M[[2],[1]]
sage: x.counit()
0
sage: x.antipode()
3*M[{1}, {2}] + 3*M[{1, 2}] - M[{1, 2, 3}] - M[{2, 3}, {1}]
- M[{3}, {1, 2}] - M[{3}, {2}, {1}]

```

Ambiguities

Some ambiguity arises when accessing basis vectors with the dictionary syntax, i.e., $M[\dots]$. A common example is when referencing an ordered set partition with one part. For example, in the expression $M[[1,2]]$, does $[[1,2]]$ refer to an ordered set partition or does $[1,2]$ refer to a packed word? We choose the latter: if the received arguments do not behave like a tuple of iterables, then view them as describing a packed word. (In the running example, one argument is received, which behaves as a tuple of integers.) Here are a variety of ways to get the same basis vector:

```

sage: x = M[1,1]; x
M[{1, 2}]
sage: x == M[[1,1]] # treated as word
True
sage: x == M[[1,2],] == M[[[1,2]]] # treated as ordered set partitions
True

sage: M[[1,3],[2]] # treat as ordered set partition
M[{1, 3}, {2}]
sage: M[[1,3],[2]] == M[1,2,1] # treat as word
True

```

Todo:

- Dendriform structure.

C

alias of `WordQuasiSymmetricFunctions.Cone`

class `Characteristic`(*alg*)

Bases: `sage.combinat.chas.wqsym.WQSymBasis_abstract`

The Characteristic basis of $WQSym$.

The *Characteristic basis* is a graded basis (X_P) of $WQSym$, indexed by ordered set partitions P . It is defined by

$$X_P = (-1)^{\ell(P)} \mathbf{M}_P,$$

where $(\mathbf{M}_P)_P$ denotes the Monomial basis, and where $\ell(P)$ denotes the number of blocks in an ordered set partition P .

EXAMPLES:

```
sage: WQSym = algebras.WQSym(QQ)
sage: X = WQSym.X(); X
Word Quasi-symmetric functions over Rational Field in the Characteristic basis

sage: X[[[1,2,3]]] * X[[1,2],[3]]
X[{1, 2, 3}, {4, 5}, {6}] - X[{1, 2, 3, 4, 5}, {6}]
+ X[{4, 5}, {1, 2, 3}, {6}] - X[{4, 5}, {1, 2, 3, 6}]
+ X[{4, 5}, {6}, {1, 2, 3}]

sage: X[[1, 4], [3], [2]].coproduct()
X[] # X[{1, 4}, {3}, {2}] + X[{1, 2}] # X[{2}, {1}]
+ X[{1, 3}, {2}] # X[{1}] + X[{1, 4}, {3}, {2}] # X[]

sage: M = WQSym.M()
sage: M(X[[1, 2, 3],])
-M[{1, 2, 3}]
sage: M(X[[1, 3], [2]])
M[{1, 3}, {2}]
sage: X(M[[1, 2, 3],])
-X[{1, 2, 3}]
sage: X(M[[1, 3], [2]])
X[{1, 3}, {2}]
```

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

algebraic_complement()

Return the image of the element `self` of $WQSym$ under the algebraic complement involution.

See `WQSymBases.ElementMethods.algebraic_complement()` for a definition of the involution and for examples.

See also:

`coalgebraic_complement()`, `star_involution()`

EXAMPLES:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: X = WQSym.X()
sage: X[[1,2],[5,6],[3,4]].algebraic_complement()
X[{3, 4}, {5, 6}, {1, 2}]
sage: X[[3], [1, 2], [4]].algebraic_complement()
X[{4}, {1, 2}, {3}]
```

coalgebraic_complement()

Return the image of the element `self` of $WQSym$ under the coalgebraic complement involution.

See `WQSymBases.ElementMethods.coalgebraic_complement()` for a definition of the involution and for examples.

See also:

`algebraic_complement()`, `star_involution()`

EXAMPLES:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: X = WQSym.X()
sage: X[[1,2],[5,6],[3,4]].coalgebraic_complement()
X[{5, 6}, {1, 2}, {3, 4}]
sage: X[[3], [1, 2], [4]].coalgebraic_complement()
X[{2}, {3, 4}, {1}]
```

star_involution()

Return the image of the element `self` of `WQSym` under the star involution.

See `WQSymBases.ElementMethods.star_involution()` for a definition of the involution and for examples.

See also:

`algebraic_complement()`, `coalgebraic_complement()`

EXAMPLES:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: X = WQSym.X()
sage: X[[1,2],[5,6],[3,4]].star_involution()
X[{3, 4}, {1, 2}, {5, 6}]
sage: X[[3], [1, 2], [4]].star_involution()
X[{1}, {3, 4}, {2}]
```

class Cone(*alg*)

Bases: `sage.combinat.chas.wqsym.WQSymBasis_abstract`

The Cone basis of `WQSym`.

Let $(X_P)_P$ denote the Characteristic basis of `WQSym`. Denote the quasi-shuffle of two ordered set partitions A and B by $A \square B$. For an ordered set partition $P = (P_1, \dots, P_\ell)$, we form a list of ordered set partitions $[P] := (P'_1, \dots, P'_k)$ as follows. Define a strictly decreasing sequence of integers $\ell + 1 = i_0 > i_1 > \dots > i_k = 1$ recursively by requiring that $\min P_{i_j} \leq \min P_a$ for all $a < i_{j-1}$. Set $P'_j = (P_{i_j}, \dots, P_{i_{j-1}-1})$.

The *Cone basis* $(C_P)_P$ is defined by

$$C_P = \sum_Q X_Q,$$

where the sum is over all elements Q of the quasi-shuffle product $P'_1 \square P'_2 \square \dots \square P'_k$ with $[P] = (P'_1, \dots, P'_k)$.

EXAMPLES:

```
sage: WQSym = algebras.WQSym(QQ)
sage: C = WQSym.C()
sage: C
Word Quasi-symmetric functions over Rational Field in the Cone basis
```

(continues on next page)

(continued from previous page)

```

sage: X = WQSym.X()
sage: X(C[[2,3],[1,4]])
X[{1, 2, 3, 4}] + X[{1, 4}, {2, 3}] + X[{2, 3}, {1, 4}]
sage: X(C[[1,4],[2,3]])
X[{1, 4}, {2, 3}]
sage: X(C[[2,3],[1],[4]])
X[{1}, {2, 3}, {4}] + X[{1}, {2, 3, 4}] + X[{1}, {4}, {2, 3}]
+ X[{1, 2, 3}, {4}] + X[{2, 3}, {1}, {4}]
sage: X(C[[3],[2,5],[1,4]])
X[{1, 2, 3, 4, 5}] + X[{1, 2, 4, 5}, {3}] + X[{1, 3, 4}, {2, 5}]
+ X[{1, 4}, {2, 3, 5}] + X[{1, 4}, {2, 5}, {3}]
+ X[{1, 4}, {3}, {2, 5}] + X[{2, 3, 5}, {1, 4}]
+ X[{2, 5}, {1, 3, 4}] + X[{2, 5}, {1, 4}, {3}]
+ X[{2, 5}, {3}, {1, 4}] + X[{3}, {1, 2, 4, 5}]
+ X[{3}, {1, 4}, {2, 5}] + X[{3}, {2, 5}, {1, 4}]
sage: C(X[[2,3],[1,4]])
-C[{1, 2, 3, 4}] - C[{1, 4}, {2, 3}] + C[{2, 3}, {1, 4}]

```

REFERENCES:

- Section 4 of [Early2017]

Todo: Experiments suggest that `algebraic_complement()`, `coalgebraic_complement()`, and `star_involution()` should have reasonable formulas on the C basis; at least the coefficients of the outputs on any element of the C basis seem to be always 0, 1, -1 . Is this true? What is the formula?

some_elements()

Return some elements of the word quasi-symmetric functions in the Cone basis.

EXAMPLES:

```

sage: C = algebras.WQSym(QQ).C()
sage: C.some_elements()
[C[], C[{1}], C[{1, 2}], C[] + 1/2*C[{1}]]

```

M

alias of `WordQuasiSymmetricFunctions.Monomial`

class Monomial(*alg*, *graded=True*)

Bases: `sage.combinat.chas.wqsym.WQSymBasis_abstract`

The Monomial basis of `WQSym`.

The family (M_u) , as defined in `WordQuasiSymmetricFunctions` with u ranging over all packed words, is a basis for the free R -module `WQSym` and called the *Monomial basis*. Here it is labelled using ordered set partitions.

EXAMPLES:

```

sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); M
Word Quasi-symmetric functions over Rational Field in the Monomial basis
sage: sorted(M.basis(2))
[M[{1, 2}], M[{2}, {1}], M[{1}, {2}]]

```

coproduct_on_basis(*x*)

Return the coproduct of `self` on the basis element indexed by the ordered set partition `x`.

EXAMPLES:

```
sage: M = algebras.WQSym(QQ).M()

sage: M.coproduct(M.one()) # indirect doctest
M[] # M[]
sage: M.coproduct( M([[1]]) ) # indirect doctest
M[] # M[{1}] + M[{1}] # M[]
sage: M.coproduct( M([[1,2]]) )
M[] # M[{1, 2}] + M[{1, 2}] # M[]
sage: M.coproduct( M([[1], [2]]) )
M[] # M[{1}, {2}] + M[{1}] # M[{1}] + M[{1}, {2}] # M[]
```

product_on_basis(*x*, *y*)

Return the (associative) $*$ product of the basis elements of `self` indexed by the ordered set partitions `x` and `y`.

This is the shifted quasi-shuffle product of `x` and `y`.

EXAMPLES:

```
sage: A = algebras.WQSym(QQ).M()
sage: x = OrderedSetPartition([[1],[2,3]])
sage: y = OrderedSetPartition([[1,2]])
sage: z = OrderedSetPartition([[1,2],[3]])
sage: A.product_on_basis(x, y)
M[{1}, {2, 3}, {4, 5}] + M[{1}, {2, 3, 4, 5}]
+ M[{1}, {4, 5}, {2, 3}] + M[{1, 4, 5}, {2, 3}]
+ M[{4, 5}, {1}, {2, 3}]
sage: A.product_on_basis(x, z)
M[{1}, {2, 3}, {4, 5}, {6}] + M[{1}, {2, 3, 4, 5}, {6}]
+ M[{1}, {4, 5}, {2, 3}, {6}] + M[{1}, {4, 5}, {2, 3, 6}]
+ M[{1}, {4, 5}, {6}, {2, 3}] + M[{1, 4, 5}, {2, 3}, {6}]
+ M[{1, 4, 5}, {2, 3, 6}] + M[{1, 4, 5}, {6}, {2, 3}]
+ M[{4, 5}, {1}, {2, 3}, {6}] + M[{4, 5}, {1}, {2, 3, 6}]
+ M[{4, 5}, {1}, {6}, {2, 3}] + M[{4, 5}, {1, 6}, {2, 3}]
+ M[{4, 5}, {6}, {1}, {2, 3}]
sage: A.product_on_basis(y, y)
M[{1, 2}, {3, 4}] + M[{1, 2, 3, 4}] + M[{3, 4}, {1, 2}]
```

Phi

alias of `WordQuasiSymmetricFunctions.StronglyFiner`

Q

alias of `WordQuasiSymmetricFunctions.StronglyCoarser`

class StronglyCoarser(*alg*)

Bases: `sage.combinat.chas.wqsym.WQSymBasis_abstract`

The Q basis of `WQSym`.

We define a partial order \leq on the set of all ordered set partitions as follows: $A \leq B$ if and only if A is strongly finer than B (see `is_strongly_finer()` for a definition of this).

The Q basis $(Q_P)_P$ is a basis of $WQSym$ indexed by ordered set partitions, and is defined by

$$Q_P = \sum M_W,$$

where the sum is over ordered set partitions W satisfying $P \leq W$.

EXAMPLES:

```

sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); Q = WQSym.Q()
sage: Q
Word Quasi-symmetric functions over Rational Field in the Q basis

sage: Q(M[[2,3],[1,4]])
Q[{2, 3}, {1, 4}]
sage: Q(M[[1,2],[3,4]])
Q[{1, 2}, {3, 4}] - Q[{1, 2, 3, 4}]
sage: M(Q[[1,2],[3,4]])
M[{1, 2}, {3, 4}] + M[{1, 2, 3, 4}]
sage: M(Q[[2,3],[1],[4]])
M[{2, 3}, {1}, {4}] + M[{2, 3}, {1, 4}]
sage: M(Q[[3],[2,5],[1,4]])
M[{3}, {2, 5}, {1, 4}]
sage: M(Q[[1,4],[2,3],[5],[6]])
M[{1, 4}, {2, 3}, {5}, {6}] + M[{1, 4}, {2, 3}, {5, 6}]
+ M[{1, 4}, {2, 3, 5}, {6}] + M[{1, 4}, {2, 3, 5, 6}]

sage: Q[[1,3],[2]] * Q[[1],[2]]
Q[{1, 3}, {2}, {4}, {5}] + Q[{1, 3}, {4}, {2}, {5}]
+ Q[{1, 3}, {4}, {5}, {2}] + Q[{4}, {1, 3}, {2}, {5}]
+ Q[{4}, {1, 3}, {5}, {2}] + Q[{4}, {5}, {1, 3}, {2}]

sage: Q[[1,3],[2]].coproduct()
Q[] # Q[{1, 3}, {2}] + Q[{1, 2}] # Q[{1}] + Q[{1, 3}, {2}] # Q[]

```

REFERENCES:

- Section 6 of [BerZab05]

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

algebraic_complement()

Return the image of the element `self` of $WQSym$ under the algebraic complement involution.

See `WQSymBases.ElementMethods.algebraic_complement()` for a definition of the involution and for examples.

See also:

`coalgebraic_complement()`, `star_involution()`

EXAMPLES:

```

sage: WQSym = algebras.WQSym(ZZ)
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].algebraic_complement()
Q[{3, 4}, {1, 2, 5, 6}] + Q[{3, 4}, {5, 6}, {1, 2}]

```

(continues on next page)

(continued from previous page)

```

- Q[{3, 4, 5, 6}, {1, 2}]
sage: Q[[3], [1, 2], [4]].algebraic_complement()
Q[{1, 2, 4}, {3}] + Q[{4}, {1, 2}, {3}] - Q[{4}, {1, 2, 3}]

```

coalgebraic_complement()

Return the image of the element `self` of $WQSym$ under the coalgebraic complement involution.

See `WQSymBases.ElementMethods.coalgebraic_complement()` for a definition of the involution and for examples.

See also:

`algebraic_complement()`, `star_involution()`

EXAMPLES:

```

sage: WQSym = algebras.WQSym(ZZ)
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].coalgebraic_complement()
Q[{1, 2, 5, 6}, {3, 4}] + Q[{5, 6}, {1, 2}, {3, 4}] - Q[{5, 6}, {1, 2, 3,
↪ 4}]
sage: Q[[3], [1, 2], [4]].coalgebraic_complement()
Q[{2}, {1, 3, 4}] + Q[{2}, {3, 4}, {1}] - Q[{2, 3, 4}, {1}]

```

star_involution()

Return the image of the element `self` of $WQSym$ under the star involution.

See `WQSymBases.ElementMethods.star_involution()` for a definition of the involution and for examples.

See also:

`algebraic_complement()`, `coalgebraic_complement()`

EXAMPLES:

```

sage: WQSym = algebras.WQSym(ZZ)
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].star_involution()
Q[{3, 4}, {1, 2}, {5, 6}]
sage: Q[[3], [1, 2], [4]].star_involution()
Q[{1}, {3, 4}, {2}]

```

coproduct_on_basis(x)

Return the coproduct of `self` on the basis element indexed by the ordered set partition `x`.

EXAMPLES:

```

sage: Q = algebras.WQSym(QQ).Q()

sage: Q.coproduct(Q.one()) # indirect doctest
Q[] # Q[]
sage: Q.coproduct(Q([[1]])) # indirect doctest
Q[] # Q[{1}] + Q[{1}] # Q[]
sage: Q.coproduct(Q([[1,2]]))
Q[] # Q[{1, 2}] + Q[{1, 2}] # Q[]
sage: Q.coproduct(Q([[1], [2]]))

```

(continues on next page)

(continued from previous page)

```

Q[] # Q[{1}, {2}] + Q[{1}] # Q[{1}] + Q[{1}, {2}] # Q[]
sage: Q[[1,2],[3],[4]].coproduct()
Q[] # Q[{1, 2}, {3}, {4}] + Q[{1, 2}] # Q[{1}, {2}]
+ Q[{1, 2}, {3}] # Q[{1}] + Q[{1, 2}, {3}, {4}] # Q[]

```

product_on_basis(*x*, *y*)

Return the (associative) * product of the basis elements of the Q basis `self` indexed by the ordered set partitions *x* and *y*.

This is the shifted shuffle product of *x* and *y*.

EXAMPLES:

```

sage: A = algebras.WQSym(QQ).Q()
sage: x = OrderedSetPartition([[1],[2,3]])
sage: y = OrderedSetPartition([[1,2]])
sage: z = OrderedSetPartition([[1,2],[3]])
sage: A.product_on_basis(x, y)
Q[{1}, {2, 3}, {4, 5}] + Q[{1}, {4, 5}, {2, 3}]
+ Q[{4, 5}, {1}, {2, 3}]
sage: A.product_on_basis(x, z)
Q[{1}, {2, 3}, {4, 5}, {6}] + Q[{1}, {4, 5}, {2, 3}, {6}]
+ Q[{1}, {4, 5}, {6}, {2, 3}] + Q[{4, 5}, {1}, {2, 3}, {6}]
+ Q[{4, 5}, {1}, {6}, {2, 3}] + Q[{4, 5}, {6}, {1}, {2, 3}]
sage: A.product_on_basis(y, y)
Q[{1, 2}, {3, 4}] + Q[{3, 4}, {1, 2}]

```

some_elements()

Return some elements of the word quasi-symmetric functions in the Q basis.

EXAMPLES:

```

sage: Q = algebras.WQSym(QQ).Q()
sage: Q.some_elements()
[Q[], Q[{1}], Q[{1, 2}], Q[] + 1/2*Q[{1}]]

```

class StronglyFiner(*alg*)

Bases: `sage.combinat.chas.wqsym.WQSymBasis_abstract`

The Phi basis of $WQSym$.

We define a partial order \leq on the set of all ordered set partitions as follows: $A \leq B$ if and only if A is strongly finer than B (see `is_strongly_finer()` for a definition of this).

The *Phi basis* $(\Phi_P)_P$ is a basis of $WQSym$ indexed by ordered set partitions, and is defined by

$$\Phi_P = \sum M_W,$$

where the sum is over ordered set partitions W satisfying $W \leq P$.

Novelli and Thibon introduced this basis in [NovThi06] Section 2.7.2, and called it the quasi-ribbon basis. It later reappeared in [MeNoTh11] Section 4.3.2.

EXAMPLES:

```

sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); Phi = WQSym.Phi()

```

(continues on next page)

(continued from previous page)

```

sage: Phi
Word Quasi-symmetric functions over Rational Field in the Phi basis

sage: Phi(M[[2,3],[1,4]])

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

algebraic_complement()

Return the image of the element `self` of $WQSym$ under the algebraic complement involution.

See `WQSymBases.ElementMethods.algebraic_complement()` for a definition of the involution and for examples.

See also:

`coalgebraic_complement()`, `star_involution()`

EXAMPLES:

```

sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1],[2,4],[3]].algebraic_complement()
-Phi[{3}, {2}, {4}, {1}] + Phi[{3}, {2, 4}, {1}] + Phi[{3}, {4}, {2}, {1}]
↩

```

(continues on next page)

(continued from previous page)

```
sage: Phi[[1],[2,3],[4]].algebraic_complement()
-Phi[{4}, {2}, {3}, {1}] + Phi[{4}, {2, 3}, {1}] + Phi[{4}, {3}, {2}, {1}]
↩]
```

coalgebraic_complement()

Return the image of the element `self` of $WQSym$ under the coalgebraic complement involution.

See `WQSymBases.ElementMethods.coalgebraic_complement()` for a definition of the involution and for examples.

See also:

`algebraic_complement()`, `star_involution()`

EXAMPLES:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1],[2],[3,4]].coalgebraic_complement()
-Phi[{4}, {3}, {1}, {2}] + Phi[{4}, {3}, {1, 2}] + Phi[{4}, {3}, {2}, {1}]
↩]
sage: Phi[[2],[1,4],[3]].coalgebraic_complement()
-Phi[{3}, {1}, {4}, {2}] + Phi[{3}, {1, 4}, {2}] + Phi[{3}, {4}, {1}, {2}]
↩]
```

star_involution()

Return the image of the element `self` of $WQSym$ under the star involution.

See `WQSymBases.ElementMethods.star_involution()` for a definition of the involution and for examples.

See also:

`algebraic_complement()`, `coalgebraic_complement()`

EXAMPLES:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1,2],[5,6],[3,4]].star_involution()
Phi[{3, 4}, {1, 2}, {5, 6}]
sage: Phi[[3],[1,2],[4]].star_involution()
Phi[{1}, {3, 4}, {2}]
```

coproduct_on_basis(x)

Return the coproduct of `self` on the basis element indexed by the ordered set partition `x`.

The coproduct of the basis element Φ_x indexed by an ordered set partition x of $[n]$ can be computed by the following formula ([NovThi06]):

$$\Delta\Phi_x = \sum \Phi_y \otimes \Phi_z,$$

where the sum ranges over all pairs (y, z) of ordered set partitions y and z such that:

- y and z are ordered set partitions of two complementary subsets of $[n]$;
- x is obtained either by concatenating y and z , or by first concatenating y and z and then merging the two “middle blocks” (i.e., the last block of y and the first block of z); in the latter case, the maximum of the last block of y has to be smaller than the minimum of the first block of z (so that when merging these blocks, their entries don’t need to be sorted).

EXAMPLES:

```

sage: Phi = algebras.WQSym(QQ).Phi()

sage: Phi.coproduct(Phi.one()) # indirect doctest
Phi[] # Phi[]
sage: Phi.coproduct( Phi([[1]]) ) # indirect doctest
Phi[] # Phi[{1}] + Phi[{1}] # Phi[]
sage: Phi.coproduct( Phi([[1,2]]) )
Phi[] # Phi[{1, 2}] + Phi[{1}] # Phi[{1}] + Phi[{1, 2}] # Phi[]
sage: Phi.coproduct( Phi([[1], [2]]) )
Phi[] # Phi[{1}, {2}] + Phi[{1}] # Phi[{1}] + Phi[{1}, {2}] # Phi[]
sage: Phi[[1,2],[3],[4]].coproduct()
Phi[] # Phi[{1, 2}, {3}, {4}] + Phi[{1}] # Phi[{1}, {2}, {3}]
+ Phi[{1, 2}] # Phi[{1}, {2}] + Phi[{1, 2}, {3}] # Phi[{1}]
+ Phi[{1, 2}, {3}, {4}] # Phi[]

```

product_on_basis(x, y)

Return the (associative) $*$ product of the basis elements of the Phi basis `self` indexed by the ordered set partitions x and y .

This is obtained by the following algorithm (going back to [NovThi06]):

Let x be an ordered set partition of $[m]$, and y an ordered set partition of $[n]$. Transform x into a list u of all the m elements of $[m]$ by writing out each block of x (in increasing order) and putting bars between each two consecutive blocks; this is called a barred permutation. Do the same for y , but also shift each entry of the resulting barred permutation by m . Let v be the barred permutation of $[m+n] \setminus [m]$ thus obtained. Now, shuffle the two barred permutations u and v (ignoring the bars) in all the $\binom{n+m}{n}$ possible ways. For each shuffle obtained, place bars between some entries of the shuffle, according to the following rule:

- If two consecutive entries of the shuffle both come from u , then place a bar between them if the corresponding entries of u had a bar between them.
- If the first of two consecutive entries of the shuffle comes from v and the second from u , then place a bar between them.

This results in a barred permutation of $[m+n]$. Transform it into an ordered set partition of $[m+n]$, by treating the bars as dividers separating consecutive blocks.

The product $\Phi_x \Phi_y$ is the sum of Φ_p with p ranging over all ordered set partitions obtained this way.

EXAMPLES:

```

sage: A = algebras.WQSym(QQ).Phi()
sage: x = OrderedSetPartition([[1],[2,3]])
sage: y = OrderedSetPartition([[1,2]])
sage: z = OrderedSetPartition([[1,2],[3]])
sage: A.product_on_basis(x, y)
Phi[{1}, {2, 3, 4, 5}] + Phi[{1}, {2, 4}, {3, 5}]
+ Phi[{1}, {2, 4, 5}, {3}] + Phi[{1, 4}, {2, 3, 5}]
+ Phi[{1, 4}, {2, 5}, {3}] + Phi[{1, 4, 5}, {2, 3}]
+ Phi[{4}, {1}, {2, 3, 5}] + Phi[{4}, {1}, {2, 5}, {3}]
+ Phi[{4}, {1, 5}, {2, 3}] + Phi[{4, 5}, {1}, {2, 3}]
sage: A.product_on_basis(x, z)
Phi[{1}, {2, 3, 4, 5}, {6}] + Phi[{1}, {2, 4}, {3, 5}, {6}]
+ Phi[{1}, {2, 4, 5}, {3, 6}] + Phi[{1}, {2, 4, 5}, {6}, {3}]
+ Phi[{1, 4}, {2, 3, 5}, {6}] + Phi[{1, 4}, {2, 5}, {3, 6}]
+ Phi[{1, 4}, {2, 5}, {6}, {3}] + Phi[{1, 4, 5}, {2, 3, 6}]

```

(continues on next page)

(continued from previous page)

```

+ Phi[{1, 4, 5}, {2, 6}, {3}] + Phi[{1, 4, 5}, {6}, {2, 3}]
+ Phi[{4}, {1}, {2, 3, 5}, {6}]
+ Phi[{4}, {1}, {2, 5}, {3, 6}]
+ Phi[{4}, {1}, {2, 5}, {6}, {3}]
+ Phi[{4}, {1, 5}, {2, 3, 6}] + Phi[{4}, {1, 5}, {2, 6}, {3}]
+ Phi[{4}, {1, 5}, {6}, {2, 3}] + Phi[{4, 5}, {1}, {2, 3, 6}]
+ Phi[{4, 5}, {1}, {2, 6}, {3}] + Phi[{4, 5}, {1, 6}, {2, 3}]
+ Phi[{4, 5}, {6}, {1}, {2, 3}]
sage: A.product_on_basis(y, y)
Phi[{1, 2, 3, 4}] + Phi[{1, 3}, {2, 4}] + Phi[{1, 3, 4}, {2}]
+ Phi[{3}, {1, 2, 4}] + Phi[{3}, {1, 4}, {2}]
+ Phi[{3, 4}, {1, 2}]

```

some_elements()

Return some elements of the word quasi-symmetric functions in the Phi basis.

EXAMPLES:

```

sage: Phi = algebras.WQSym(QQ).Phi()
sage: Phi.some_elements()
[Phi[], Phi[{1}], Phi[{1, 2}], Phi[] + 1/2*Phi[{1}]]

```

X

alias of *WordQuasiSymmetricFunctions.Characteristic*

a_realization()

Return a particular realization of *self* (the *M*-basis).

EXAMPLES:

```

sage: WQSym = algebras.WQSym(QQ)
sage: WQSym.a_realization()
Word Quasi-symmetric functions over Rational Field in the Monomial basis

```

options(*get_value, **set_value)

Set and display the global options for bases of *WordQuasiSymmetricFunctions*. If no parameters are set, then the function returns a copy of the options dictionary.

The options can be accessed as the method *WordQuasiSymmetricFunctions.options* of *WordQuasiSymmetricFunctions* or of any associated basis.

OPTIONS:

- **display** – (default: `normal`) Specifies how basis elements of *WordQuasiSymmetricFunctions* should be printed
 - `compact` – Using a severely compacted representation
 - `normal` – Using the normal representation
 - `tight` – Dropping spaces after commas
- **objects** – (default: `compositions`) Specifies how basis elements of *WordQuasiSymmetricFunctions* should be indexed
 - `compositions` – Indexing the basis by ordered set partitions
 - `words` – Indexing the basis by packed words

The 'words' representation of a basis element of *WordQuasiSymmetricFunctions*, indexed by an ordered set partition A , is the packed word associated to A . See *OrderedSetPartition.to_packed_word()* for details.)

EXAMPLES:

```
sage: WQ = WordQuasiSymmetricFunctions(QQ)
sage: M = WQ.M()
sage: elt = M[[[1,2]]]*M[[[1]]]; elt
M[{1, 2}, {3}] + M[{1, 2, 3}] + M[{3}, {1, 2}]
sage: M.options.display = "tight"
sage: elt
M[{1,2},{3}] + M[{1,2,3}] + M[{3},{1,2}]
sage: M.options.display = "compact"
sage: elt
M[12.3] + M[123] + M[3.12]
sage: WQ.options._reset()
sage: M.options.objects = "words"
sage: elt
M[1, 1, 2] + M[1, 1, 1] + M[2, 2, 1]
sage: M.options.display = "tight"
sage: elt
M[1,1,2] + M[1,1,1] + M[2,2,1]
sage: WQ.options.display = "compact"
sage: elt
M[112] + M[111] + M[221]
sage: M.options._reset()
sage: elt
M[{1, 2}, {3}] + M[{1, 2, 3}] + M[{3}, {1, 2}]
```

See *GlobalOptions* for more features of these options.

5.1.16 Cluster algebras and quivers

- A compendium on the cluster algebra and quiver package in Sage [MS2011]
- *Quiver mutation types*
- *Quiver*
- *ClusterSeed*

5.1.17 ClusterSeed

A *cluster seed* is a pair (B, \mathbf{x}) with B being a *skew-symmetrizable* $(n + m \times n)$ -matrix and with \mathbf{x} being an n -tuple of *independent elements* in the field of rational functions in n variables.

For the compendium on the cluster algebra and quiver package see [MS2011].

See also:

For mutation types of cluster seeds, see `sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType()`. Cluster seeds are closely related to `sage.combinat.cluster_algebra_quiver.quiver.ClusterQuiver()`.

```
class sage.combinat.cluster_algebra_quiver.cluster_seed.ClusterSeed(data, frozen=None,
                                                                    is_principal=False,
                                                                    user_labels=None,
                                                                    user_labels_prefix='x')
```

Bases: `sage.structure.sage_object.SageObject`

The *cluster seed* associated to an *exchange matrix*.

INPUT:

- `data` – can be any of the following:

```
* QuiverMutationType
* str - a string representing a QuiverMutationType or a common quiver type (see ↪
↪Examples)
* ClusterQuiver
* Matrix - a skew-symmetrizable matrix
* DiGraph - must be the input data for a quiver
* List of edges - must be the edge list of a digraph for a quiver
```

EXAMPLES:

```
sage: S = ClusterSeed(['A',5]); S
A seed for a cluster algebra of rank 5 of type ['A', 5]

sage: S = ClusterSeed(['A',[2,5],1]); S
A seed for a cluster algebra of rank 7 of type ['A', [2, 5], 1]

sage: T = ClusterSeed( S ); T
A seed for a cluster algebra of rank 7 of type ['A', [2, 5], 1]

sage: T = ClusterSeed( S._M ); T
A seed for a cluster algebra of rank 7

sage: T = ClusterSeed( S.quiver()._digraph ); T
A seed for a cluster algebra of rank 7

sage: T = ClusterSeed( S.quiver()._digraph.edges(sort=True) ); T
A seed for a cluster algebra of rank 7

sage: S = ClusterSeed(['B',2]); S
A seed for a cluster algebra of rank 2 of type ['B', 2]

sage: S = ClusterSeed(['C',2]); S
```

(continues on next page)

(continued from previous page)

```

A seed for a cluster algebra of rank 2 of type ['B', 2]
sage: S = ClusterSeed(['A', [5,0],1]); S
A seed for a cluster algebra of rank 5 of type ['D', 5]
sage: S = ClusterSeed(['GR',[3,7]]); S
A seed for a cluster algebra of rank 6 of type ['E', 6]
sage: S = ClusterSeed(['F', 4, [2,1]]); S
A seed for a cluster algebra of rank 6 of type ['F', 4, [1, 2]]
sage: S = ClusterSeed(['A',4]); S._use_fpolys
True
sage: S._use_d_vec
True
sage: S._use_g_vec
True
sage: S._use_c_vec
True
sage: S = ClusterSeed(['A', 4]); S.use_fpolys(False); S._use_fpolys
False
sage: S = ClusterSeed(DiGraph([[['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']]],
↪frozen =
.....:    ['c'])); S
A seed for a cluster algebra of rank 4 with 1 frozen variable
sage: S = ClusterSeed(['D', 4],user_labels = [-1, 0, 1, 2]);S
A seed for a cluster algebra of rank 4 of type ['D', 4]

```

LLM_gen_set(*size_limit=-1*)

Produce a list of upper cluster algebra elements corresponding to all vectors in $\{0, 1\}^n$.

INPUT:

- B – a skew-symmetric matrix.
- *size_limit* – a limit on how many vectors you want the function to return.

OUTPUT:

An array of elements in the upper cluster algebra.

EXAMPLES:

```

sage: B = matrix([[0,1,0],[-1,0,1],[0,-1,0],[1,0,0],[0,1,0],[0,0,1]])
sage: C = ClusterSeed(B)
sage: C.LLM_gen_set()
[1,
 (x1 + x3)/x0,
 (x0*x4 + x2)/x1,

```

(continues on next page)

(continued from previous page)

```
(x0*x3*x4 + x1*x2 + x2*x3)/(x0*x1),
(x1*x5 + 1)/x2,
(x1^2*x5 + x1*x3*x5 + x1 + x3)/(x0*x2),
(x0*x1*x4*x5 + x0*x4 + x2)/(x1*x2),
(x0*x1*x3*x4*x5 + x0*x3*x4 + x1*x2 + x2*x3)/(x0*x1*x2)]
```

b_matrix()Returns the B -matrix of `self`.

EXAMPLES:

```
sage: ClusterSeed(['A',4]).b_matrix()
[ 0  1  0  0]
[-1  0 -1  0]
[ 0  1  0  1]
[ 0  0 -1  0]

sage: ClusterSeed(['B',4]).b_matrix()
[ 0  1  0  0]
[-1  0 -1  0]
[ 0  1  0  1]
[ 0  0 -2  0]

sage: ClusterSeed(['D',4]).b_matrix()
[ 0  1  0  0]
[-1  0 -1 -1]
[ 0  1  0  0]
[ 0  1  0  0]

sage: ClusterSeed(QuiverMutationType(['A',2],['B',2])).b_matrix()
[ 0  1  0  0]
[-1  0  0  0]
[ 0  0  0  1]
[ 0  0 -2  0]
```

b_matrix_class(depth=+Infinity, up_to_equivalence=True)Returns all B -matrices in the mutation class of `self`.

INPUT:

- `depth` – (default:infinity) integer or infinity, only seeds with distance at most `depth` from `self` are returned
- `up_to_equivalence` – (default: True) if True, only 'B'-matrices up to equivalence are considered.

EXAMPLES:

- for examples see `b_matrix_class_iter()`

b_matrix_class_iter(depth=+Infinity, up_to_equivalence=True)Returns an iterator through all B -matrices in the mutation class of `self`.

INPUT:

- `depth` – (default:infinity) integer or infinity, only seeds with distance at most `depth` from `self` are returned
- `up_to_equivalence` – (default: True) if True, only 'B'-matrices up to equivalence are considered.

EXAMPLES:

A standard finite type example:

```
sage: S = ClusterSeed(['A',4])
sage: it = S.b_matrix_class_iter()
sage: for T in it: print(T)
[ 0  0  0  1]
[ 0  0  1  1]
[ 0 -1  0  0]

[ 0  1  0 -1]
[-1  0  1  0]
[ 0  0  0 -1]
[ 0  0 -1  1]
[ 0  1  0 -1]
[ 1 -1  1  0]
```

A finite type example with given depth:

```
sage: it = S.b_matrix_class_iter(depth=1)
sage: for T in it: print(T)
[ 0  0  0  1]
[ 0  0  1  1]
[ 0 -1  0  0]
[-1 -1  0  0]
[ 0  0  0  1]
[ 0  0  1  0]
[ 0 -1  0  1]
[-1  0 -1  0]
[ 0  0  1  1]
[ 0  0  0 -1]
[-1  0  0  0]
[-1  1  0  0]
```

Finite type example not considered up to equivalence:

```
sage: S = ClusterSeed(['A',3])
sage: it = S.b_matrix_class_iter(up_to_equivalence=False)
sage: b_matrix_class = list(it)
```

(continues on next page)

(continued from previous page)

```
sage: len(b_matrix_class)
14
sage: b_matrix_class[0]
[ 0  1  0]
[-1  0 -1]
[ 0  1  0]
```

Infinite (but finite mutation) type example:

```
sage: S = ClusterSeed(['A', [1,2], 1])
sage: it = S.b_matrix_class_iter()
sage: for T in it: print(T)
[ 0  1  1]
[-1  0  1]
[-1 -1  0]
[ 0 -2  1]
[ 2  0 -1]
[-1  1  0]
```

Infinite mutation type example:

```
sage: S = ClusterSeed(['E', 10])
sage: it = S.b_matrix_class_iter(depth=3)
sage: len ( [T for T in it] )
266
```

For a cluster seed from an arbitrarily labelled digraph:

```
sage: dg = DiGraph([[ 'a', 'b'], [ 'b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['b'])
sage: S.b_matrix_class()
[
[ 0  0] [ 0  0] [0  0]
[ 0  0] [ 0  0] [0  0]
[-1  1], [-1 -1], [1  1]
]
```

c_matrix(*show_warnings=True*)

Return all *c*-vectors of self.

Warning: this method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:

```
sage: S = ClusterSeed(['A', 3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.c_matrix()
[ 1  0  0]
[ 0  0 -1]
[ 0 -1  0]

sage: S = ClusterSeed(['A', 4])
sage: S.use_g_vectors(False); S.use_fpolys(False); S.use_c_vectors(False); S.
↪ use_d_vectors(False); S.track_mutations(False);
```

(continues on next page)

(continued from previous page)

```

sage: S.c_matrix()
Traceback (most recent call last):
...
ValueError: Unable to calculate c-vectors. Need to use c vectors.

```

c_vector(k)

Return the k -th *c-vector* of `self`. It is obtained as the k -th column vector of the bottom part of the B-matrix of `self`.

Warning: this method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:

```

sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [ S.c_vector(k) for k in range(3) ]
[(1, 0, 0), (0, 0, -1), (0, -1, 0)]

sage: S = ClusterSeed(Matrix([[0,1],[-1,0],[1,0],[-1,1]])); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
sage: S.c_vector(0)
(1, 0)

sage: S = ClusterSeed(Matrix([[0,1],[-1,0],[1,0],[-1,1]])); S.use_c_vectors(bot_
↪is_c=True); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
sage: S.c_vector(0)
(1, -1)

```

cluster()

Returns a copy of the *cluster* of `self`.

EXAMPLES:

```

sage: S = ClusterSeed(['A',3])
sage: S.cluster()
[x0, x1, x2]

sage: S.mutate(1)
sage: S.cluster()
[x0, (x0*x2 + 1)/x1, x2]

sage: S.mutate(2)
sage: S.cluster()
[x0, (x0*x2 + 1)/x1, (x0*x2 + x1 + 1)/(x1*x2)]

sage: S.mutate([2,1])
sage: S.cluster()
[x0, x1, x2]

```

cluster_class(depth=+ Infinity, show_depth=False, up_to_equivalence=True)

Return the cluster class of `self` with respect to certain constraints.

INPUT:

- `depth` – (default: infinity) integer, only seeds with distance at most depth from self are returned
- `return_depth` – (default False) - if True, ignored if depth is set; returns the depth of the mutation class, i.e., the maximal distance from self of an element in the mutation class
- `up_to_equivalence` – (default: True) if True, only clusters up to equivalence are considered.

EXAMPLES:

- for examples see `cluster_class_iter()`

cluster_class_iter(*depth*=+ Infinity, *show_depth*=False, *up_to_equivalence*=True)

Returns an iterator through all clusters in the mutation class of `self`.

INPUT:

- `depth` – (default: infinity) integer or infinity, only seeds with distance at most depth from self are returned
- `show_depth` – (default False) - if True, ignored if depth is set; returns the depth of the mutation class, i.e., the maximal distance from self of an element in the mutation class
- `up_to_equivalence` – (default: True) if True, only clusters up to equivalence are considered.

EXAMPLES:

A standard finite type example:

```
sage: S = ClusterSeed(['A',3])
sage: it = S.cluster_class_iter()
sage: cluster_class = list(it)
sage: len(cluster_class)
14
sage: cluster_class[0]
[x0, x1, x2]
```

A finite type example with given depth:

```
sage: it = S.cluster_class_iter(depth=1)
sage: for T in it: print(T)
[x0, x1, x2]
[x0, x1, (x1 + 1)/x2]
[x0, (x0*x2 + 1)/x1, x2]
[(x1 + 1)/x0, x1, x2]
```

A finite type example where the depth is returned while computing:

```
sage: it = S.cluster_class_iter(show_depth=True)
sage: _ = list(it)
Depth: 0      found: 1      Time: ... s
Depth: 1      found: 4      Time: ... s
Depth: 2      found: 9      Time: ... s
Depth: 3      found: 13     Time: ... s
Depth: 4      found: 14     Time: ... s
```

Finite type examples not considered up to equivalence:

```
sage: it = S.cluster_class_iter(up_to_equivalence=False)
sage: len( [ T for T in it ] )
```

(continues on next page)

```

84
sage: it = ClusterSeed(['A',2]).cluster_class_iter(up_to_equivalence=False)
sage: cluster_class = list(it)
sage: len(cluster_class)
10
sage: cluster_class[0]
[x0, x1]
sage: cluster_class[-1]
[x1, x0]

```

Infinite type examples:

```

sage: S = ClusterSeed(['A',[1,1],1])
sage: it = S.cluster_class_iter()
sage: next(it)
[x0, x1]
sage: next(it)
[x0, (x0^2 + 1)/x1]
sage: next(it)
[(x1^2 + 1)/x0, x1]
sage: next(it)
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^2 + 1)/x1]
sage: next(it)
[(x1^2 + 1)/x0, (x1^4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)]

sage: it = S.cluster_class_iter(depth=3)
sage: for T in it: print(T)
[x0, x1]
[x0, (x0^2 + 1)/x1]
[(x1^2 + 1)/x0, x1]
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^2 + 1)/x1]
[(x1^2 + 1)/x0, (x1^4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)]
[(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2), (x0^6 + 3*x0^4 + 2*x0^2*x1^2 + x1^4 +
↪ 3*x0^2 + 2*x1^2 + 1)/(x0^2*x1^3)]
[(x1^6 + x0^4 + 2*x0^2*x1^2 + 3*x1^4 + 2*x0^2 + 3*x1^2 + 1)/(x0^3*x1^2), (x1^4
↪ x0^2 + 2*x1^2 + 1)/(x0^2*x1)]

```

For a cluster seed from an arbitrarily labelled digraph:

```

sage: dg = DiGraph(['a', 'b'], ['b', 'c'], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen = ['b'])
sage: S.cluster_class()
[[a, c], [a, (b + 1)/c], [(b + 1)/a, c], [(b + 1)/a, (b + 1)/c]]

sage: S2 = ClusterSeed(dg, frozen=[])
sage: S2.cluster_class()[0]
[a, b, c]

```

`cluster_index`(*cluster_str*)

Return the index of a cluster if `use_fpolys` is on.

INPUT:

- `cluster_str` – the string to look for in the cluster

OUTPUT:

An integer or None if the string is not a cluster variable

EXAMPLES:

```
sage: S = ClusterSeed(['A', 4], user_labels=['x', 'y', 'z', 'w']); S.mutate('x')
sage: S.cluster_index('x')
sage: S.cluster_index('(y+1)/x')
0
```

`cluster_variable(k)`

Generates a cluster variable using F-polynomials

EXAMPLES:

```
sage: S = ClusterSeed(['A', 3])
sage: S.mutate([0, 1])
sage: S.cluster_variable(0)
(x1 + 1)/x0
sage: S.cluster_variable(1)
(x0*x2 + x1 + 1)/(x0*x1)
```

`coefficient(k)`

Return the *coefficient* of `self` at index `k`, or vertex `k` if `k` is not an index.

EXAMPLES:

```
sage: S = ClusterSeed(['A', 3]).principal_extension()
sage: S.mutate([2, 1, 2])
sage: [ S.coefficient(k) for k in range(3) ]
[y0, 1/y2, 1/y1]
```

`coefficients()`

Return all *coefficients* of `self`.

EXAMPLES:

```
sage: S = ClusterSeed(['A', 3]).principal_extension()
sage: S.mutate([2, 1, 2])
sage: S.coefficients()
[y0, 1/y2, 1/y1]
```

`d_matrix(show_warnings=True)`

Return the matrix of *d-vectors* of `self`.

EXAMPLES:

```
sage: S = ClusterSeed(['A', 4]); S.d_matrix()
[-1  0  0  0]
[ 0 -1  0  0]
[ 0  0 -1  0]
[ 0  0  0 -1]
sage: S.mutate([1, 2, 1, 0, 1, 3]); S.d_matrix()
[1 1 0 1]
[1 1 1 1]
```

(continues on next page)

(continued from previous page)

```
[1 0 1 1]
[0 0 0 1]
```

d_vector(k)

Return the k -th d -vector of `self`. This is the exponent vector of the denominator of the k -th cluster variable.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3])
sage: S.mutate([2,1,2])
sage: [ S.d_vector(k) for k in range(3) ]
[(-1, 0, 0), (0, 1, 1), (0, 1, 0)]
```

exchangeable_part()

Return the restriction to the principal part (i.e. the exchangeable variables) of `self`.

EXAMPLES:

```
sage: S = ClusterSeed(['A',4])
sage: T = ClusterSeed( S.quiver().digraph().edges(sort=True), frozen=[3] )
sage: T.quiver().digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: T.exchangeable_part().quiver().digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1))]
```

f_polynomial(k)

Return the k -th F -polynomial of `self`. It is obtained from the k -th cluster variable by setting all x_i to 1.

Warning: this method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.f_polynomial(k) for k in range(3)]
[1, y1*y2 + y2 + 1, y1 + 1]

sage: S = ClusterSeed(Matrix([[0,1],[-1,0],[1,0],[-1,1]])); S.use_c_vectors(bot_
↪ is_c=True); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
sage: T = ClusterSeed(Matrix([[0,1],[-1,0]])).principal_extension(); T
A seed for a cluster algebra of rank 2 with principal coefficients
sage: S.mutate(0)
sage: T.mutate(0)
sage: S.f_polynomials()
[y0 + y1, 1]
sage: T.f_polynomials()
[y0 + 1, 1]
```

f_polynomials()

Return all F -polynomials of `self`. These are obtained from the cluster variables by setting all x_i 's to 1.

Warning: this method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.f_polynomials()
[1, y1*y2 + y2 + 1, y1 + 1]
```

find_upper_bound(*verbose=False*)

Return the upper bound of the given cluster algebra as a `quotient_ring`.

The upper bound is the intersection of the Laurent polynomial rings of the initial cluster and its neighboring clusters. As such, it always contains both the cluster algebra and the upper cluster algebra. This function uses the algorithm from [MM2015].

When the initial seed is totally coprime (for example, when the unfrozen part of the exchange matrix has full rank), the upper bound is equal to the upper cluster algebra by [BFZ2005].

Warning: The computation time grows rapidly with the size of the seed and the number of steps. For most seeds larger than four vertices, the algorithm may take an infeasible amount of time. Additionally, it will run forever without terminating whenever the upper bound is infinitely-generated (such as the example in [Spe2013]).

INPUT:

- `verbose` – (default: `False`) if `True`, prints output during the computation.

EXAMPLES:

- finite type:

```
sage: S = ClusterSeed(['A',3])
sage: S.find_upper_bound()
Quotient of Multivariate Polynomial Ring in x0, x1, x2, x0p, x1p, x2p, z0
over Rational Field by the ideal (x0*x0p - x1 - 1, x1*x1p - x0*x2 - 1,
x2*x2p - x1 - 1, x0*z0 - x2p, x1*z0 + z0 - x0p*x2p, x2*z0 - x0p, x1p*z0 +
z0 - x0p*x1p*x2p + x1 + 1)
```

- Markov:

```
sage: B = matrix([[0,2,-2],[-2,0,2],[2,-2,0]])
sage: S = ClusterSeed(B)
sage: S.find_upper_bound()
Quotient of Multivariate Polynomial Ring in x0, x1, x2, x0p, x1p, x2p, z0
over Rational Field by the ideal (x0*x0p - x2^2 - x1^2, x1*x1p - x2^2 -
x0^2, x2*x2p - x1^2 - x0^2, x0p*x1p*x2p - x0*x1*x2p - x0*x2*x1p -
x1*x2*x0p - 2*x0*x1*x2, x0^3*z0 - x1p*x2p + x1*x2, x0*x1*z0 - x2p - x2,
x1^3*z0 - x0p*x2p + x0*x2, x0*x2*z0 - x1p - x1, x1*x2*z0 - x0p - x0, x2^
3*z0 - x0p*x1p + x0*x1)
```

first_green_vertex()

Return the first green vertex of `self`.

A vertex is defined to be green if its `c`-vector has all non-positive entries. More information on green vertices can be found at [BDP2013]

EXAMPLES:

```
sage: ClusterSeed(['A', 3]).principal_extension().first_green_vertex()
0

sage: ClusterSeed(['A', [3, 3], 1]).principal_extension().first_green_vertex()
0
```

first_red_vertex()

Return the first red vertex of *self*.

A vertex is defined to be red if its *c*-vector has all non-negative entries. More information on red vertices can be found at [BDP2013].

EXAMPLES:

```
sage: ClusterSeed(['A', 3]).principal_extension().first_red_vertex()

sage: ClusterSeed(['A', [3, 3], 1]).principal_extension().first_red_vertex()

sage: Q = ClusterSeed(['A', [3, 3], 1]).principal_extension()
sage: Q.mutate(1)
sage: Q.first_red_vertex()
1
```

first_urban_renewal()

Return the first urban renewal vertex.

An urban renewal vertex is one in which there are two arrows pointing toward the vertex and two arrows pointing away.

EXAMPLES:

```
sage: G = ClusterSeed(['GR', [4, 9]]); G.first_urban_renewal()
5
```

free_vertices()

Return the list of *exchangeable vertices* of *self*.

EXAMPLES:

```
sage: S = ClusterSeed(DiGraph(['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']),
.....:                 frozen = ['b', 'd'])
sage: S.free_vertices()
['a', 'c', 'e']

sage: S = ClusterSeed(DiGraph([5, 'b']))
sage: S.free_vertices()
[5, 'b']
```

frozen_vertices()

Return the list of *frozen vertices* of *self*.

EXAMPLES:

```
sage: S = ClusterSeed(DiGraph(['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']),
.....:                 frozen = ['b', 'd'])
sage: sorted(S.frozen_vertices())
['b', 'd']
```

g_matrix(*show_warnings=True*)

Return the matrix of all *g*-vectors of `self`. These are the degree vectors of the cluster variables after setting all y_i 's to 0.

Warning: this method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.g_matrix()
[ 1  0  0]
[ 0  0 -1]
[ 0 -1  0]

sage: S = ClusterSeed(['A',3])
sage: S.mutate([0,1])
sage: S.g_matrix()
[-1 -1  0]
[ 1  0  0]
[ 0  0  1]

sage: S = ClusterSeed(['A',4]); S.use_g_vectors(False); S.use_fpolys(False); S.
↳g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_c_vectors(False); S.use_fpolys(False); S.
↳track_mutations(False); S.g_matrix()
Traceback (most recent call last):
...
ValueError: Unable to calculate g-vectors. Need to use g vectors.
```

g_vector(*k*)

Return the *k*-th *g*-vector of `self`. This is the degree vector of the *k*-th cluster variable after setting all y_i 's to 0.

Warning: this method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [ S.g_vector(k) for k in range(3) ]
[(1, 0, 0), (0, 0, -1), (0, -1, 0)]
```

get_upper_cluster_algebra_element(*a*)

Computes an element in the upper cluster algebra of B corresponding to the vector $a \in \mathbf{Z}^n$.

See [LLM2014] for more details.

INPUT:

- B – a skew-symmetric matrix. Must have the same number of columns as the length of the vectors in vd .
- a – a vector in \mathbf{Z}^n where n is the number of columns in B .

OUTPUT:

Returns an element in the upper cluster algebra. Depending on the input it may or may not be irreducible.

EXAMPLES:

```
sage: B = matrix([[0,3,-3],[-3,0,3],[3,-3,0],[1,0,0],[0,1,0],[0,0,1]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,0])
(x0^3*x2^3*x3*x4 + x2^6*x3 + x1^3*x2^3)/(x0*x1)
sage: C.get_upper_cluster_algebra_element([1,1,1])
x0^2*x1^2*x2^2*x3*x4*x5 + x0^2*x1^2*x2^2

sage: B = matrix([[0,3,0],[-3,0,3],[0,-3,0]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,0])
(x1^3*x2^3 + x0^3 + x2^3)/(x0*x1)
sage: C.get_upper_cluster_algebra_element([1,1,1])
(x0^3*x1^3 + x1^3*x2^3 + x0^3 + x2^3)/(x0*x1*x2)

sage: B = matrix([[0,2],[-3,0],[4,-5]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1])
(x2^9 + x1^3*x2^5 + x0^2*x2^4)/(x0*x1)

sage: B = matrix([[0,3,-5],[-3,0,4],[5,-4,0]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,1])
x0^4*x1^2*x2^3 + x0^2*x1^3*x2^4
```

greedy($a1, a2, algorithm='by_recursion'$)

Returns the greedy element $x[a_1, a_2]$ assuming that self is rank two.

The third input can be ‘by_recursion’, ‘by_combinatorics’, or ‘just_numbers’ to specify if the user wants the element computed by the recurrence, combinatorial formula, or wants to set x_1 and x_2 to be one.

See [LLZ2014] for more details.

EXAMPLES:

```
sage: S = ClusterSeed(['R2', [3, 3]])
sage: S.greedy(4, 4)
(x0^12 + x1^12 + 4*x0^9 + 4*x1^9 + 6*x0^6 + 4*x0^3*x1^3 + 6*x1^6 + 4*x0^3 +
↪4*x1^3 + 1)/(x0^4*x1^4)
sage: S.greedy(4, 4, 'by_combinatorics')
(x0^12 + x1^12 + 4*x0^9 + 4*x1^9 + 6*x0^6 + 4*x0^3*x1^3 + 6*x1^6 + 4*x0^3 +
↪4*x1^3 + 1)/(x0^4*x1^4)
sage: S.greedy(4, 4, 'just_numbers')
35
sage: S = ClusterSeed(['R2', [2, 2]])
sage: S.greedy(1, 2)
(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2)
```

(continues on next page)

(continued from previous page)

```
sage: S.greedy(1, 2, 'by_combinatorics')
(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2)
```

green_vertices()

Return the list of green vertices of `self`.

A vertex is defined to be green if its *c*-vector has all non-positive entries. More information on green vertices can be found at [BDP2013]

OUTPUT:

The green vertices as a list of integers.

EXAMPLES:

```
sage: ClusterSeed(['A', 3]).principal_extension().green_vertices()
[0, 1, 2]

sage: ClusterSeed(['A', [3, 3], 1]).principal_extension().green_vertices()
[0, 1, 2, 3, 4, 5]
```

ground_field()

Returns the *ground field* of the cluster of `self`.

EXAMPLES:

```
sage: S = ClusterSeed(['A', 3])
sage: S.ground_field()
Multivariate Polynomial Ring in x0, x1, x2, y0, y1, y2 over Rational Field
```

highest_degree_denominator (*filter=None*)

Return the vertex of the cluster polynomial with highest degree in the denominator.

INPUT:

- `filter` - Filter should be a list or iterable

OUTPUT:

An integer.

EXAMPLES:

```
sage: B = matrix([[0, -1, 0, -1, 1, 1], [1, 0, 1, 0, -1, -1], [0, -1, 0, -1, 1, 1], [1, 0, 1, 0, -1, -1], [-1, 1, -1, 1, 0, 0], [-1, 1, -1, 1, 0, 0]])
sage: C = ClusterSeed(B).principal_extension(); C.mutate([0, 1, 2, 4, 3, 2, 5, 4, 3])
sage: C.highest_degree_denominator()
5
```

interact (*fig_size=1, circular=True*)

Start an interactive window for cluster seed mutations.

Only in *Jupyter notebook mode*.

INPUT:

- `fig_size` – (default: 1) factor by which the size of the plot is multiplied.
- `circular` – (default: True) if True, the circular plot is chosen, otherwise `>>spring<<` is used.

is_acyclic()

Return True iff self is acyclic (i.e., if the underlying quiver is acyclic).

EXAMPLES:

```
sage: ClusterSeed(['A', 4]).is_acyclic()
True

sage: ClusterSeed(['A', [2, 1], 1]).is_acyclic()
True

sage: ClusterSeed([[0, 1], [1, 2], [2, 0]]).is_acyclic()
False
```

is_bipartite(*return_bipartition=False*)

Return True iff self is bipartite (i.e., if the underlying quiver is bipartite).

INPUT:

- *return_bipartition* – (default: False) if True, the bipartition is returned in the case of *self* being bipartite.

EXAMPLES:

```
sage: ClusterSeed(['A', [3, 3], 1]).is_bipartite()
True

sage: ClusterSeed(['A', [4, 3], 1]).is_bipartite()
False
```

is_finite()

Return True if self is of finite type.

EXAMPLES:

```
sage: S = ClusterSeed(['A', 3])
sage: S.is_finite()
True

sage: S = ClusterSeed(['A', [2, 2], 1])
sage: S.is_finite()
False
```

is_mutation_finite(*nr_of_checks=None, return_path=False*)

Returns True if self is of finite mutation type.

INPUT:

- *nr_of_checks* – (default: None) number of mutations applied. Standard is 500*(number of vertices of self).
- *return_path* – (default: False) if True, in case of self not being mutation finite, a path from self to a quiver with an edge label (a,-b) and $a*b > 4$ is returned.

ALGORITHM:

- A cluster seed is mutation infinite if and only if every $b_{ij} * b_{ji} > -4$. Thus, we apply random mutations in random directions

WARNING:

- Uses a non-deterministic method by random mutations in various directions.
- In theory, it can return a wrong True.

EXAMPLES:

```
sage: S = ClusterSeed(['A',10])
sage: S._mutation_type = None
sage: S.is_mutation_finite()
True

sage: S = ClusterSeed([(0,1),(1,2),(2,3),(3,4),(4,5),(5,6),(6,7),(7,8),(2,9)])
sage: S.is_mutation_finite()
False
```

m()

Returns the number of *frozen variables* of *self*.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3])
sage: S.n()
3

sage: S.m()
0

sage: S = S.principal_extension()
sage: S.m()
3
```

most_decreased_denominator_after_mutation()

Return the vertex that will produce the most decrease in denominator degrees after mutation

EXAMPLES:

```
sage: S = ClusterSeed(['A',5])
sage: S.mutate([0,2,3,1,2,3,1,2,0,2,3])
sage: S.most_decreased_denominator_after_mutation()
2
```

most_decreased_edge_after_mutation()

Return the vertex that will produce the least degrees after mutation

EXAMPLES:

```
sage: S = ClusterSeed(['A',5])
sage: S.mutate([0,2,3,1,2,3,1,2,0,2,3])
sage: S.most_decreased_edge_after_mutation()
2
```

mutate(sequence, inplace=True, input_type=None)

Mutate *self* at a vertex or a sequence of vertices.

INPUT:

- *sequence* – a vertex of *self*, an iterator of vertices of *self*, a function which takes in the

ClusterSeed and returns a vertex or an iterator of vertices, or a string representing a type of vertices to mutate

- `inplace` – (default: `True`) if `False`, the result is returned, otherwise `self` is modified
- `input_type` – (default: `None`) indicates the type of data contained in the sequence

Possible values for vertex types in `sequence` are:

- `"first_source"`: mutates at first found source vertex,
- `"sources"`: mutates at all sources,
- `"first_sink"`: mutates at first sink,
- `"sinks"`: mutates at all sink vertices,
- `"green"`: mutates at the first green vertex,
- `"red"`: mutates at the first red vertex,
- `"urban_renewal"` or `"urban"`: mutates at first urban renewal vertex,
- `"all_urban_renewals"` or `"all_urban"`: mutates at all urban renewal vertices.

For `input_type`, if no value is given, preference will be given to vertex names, then indices, then cluster variables. If all input is not of the same type, an error is given. Possible values for `input_type` are:

- `"vertices"`: interprets the input sequence as vertices
- `"indices"`: interprets the input sequence as indices
- `"cluster_vars"`: interprets the input sequence as cluster variables this must be selected if inputting a sequence of cluster variables.

EXAMPLES:

```
sage: S = ClusterSeed(['A',4]); S.b_matrix()
[ 0  1  0  0]
[-1  0 -1  0]
[ 0  1  0  1]
[ 0  0 -1  0]

sage: S.mutate(0); S.b_matrix()
[ 0 -1  0  0]
[ 1  0 -1  0]
[ 0  1  0  1]
[ 0  0 -1  0]

sage: T = S.mutate(0, inplace=False); T
A seed for a cluster algebra of rank 4 of type ['A', 4]

sage: S.mutate(0)
sage: S == T
True

[(x0 + 1)/xneg1, (x0*x1 + xneg1 + x1)/(xneg1*x0), x1]

```

mutation_analysis(options=['all'], filter=None)

Runs an analysis of all potential mutation options. Note that this might take a long time on large seeds.

Notes: Edges are only returned if we have a non-valued quiver. Green and red vertices are only returned if

the cluster is principal.

INPUT:

- `options` – (default: ['all']) a list of mutation options.
- `filter` – (default: None) A vertex or interval of vertices to limit our search to

Possible options are:

- "all" - All options below
- "edges" - Number of edges (works with skew-symmetric quivers)
- "edge_diff" - Edges added/deleted (works with skew-symmetric quivers)
- "green_vertices" - List of green vertices (works with principals)
- "green_vertices_diff" - Green vertices added/removed (works with principals)
- "red_vertices" - List of red vertices (works with principals)
- "red_vertices_diff" - Red vertices added/removed (works with principals)
- "urban_renewals" - List of urban renewal vertices
- "urban_renewals_diff" - Urban renewal vertices added/removed
- "sources" - List of source vertices
- "sources_diff" - Source vertices added/removed
- "sinks" - List of sink vertices
- "sinks_diff" - Sink vertices added/removed
- "denominators" - List of all denominators of the cluster variables

OUTPUT:

Outputs a dictionary indexed by the vertex numbers. Each vertex will itself also be a dictionary with each desired option included as a key in the dictionary. As an example you would get something similar to: {0: {'edges': 1}, 1: {'edges': 2}}. This represents that if you were to do a mutation at the current seed then mutating at vertex 0 would result in a quiver with 1 edge and mutating at vertex 0 would result in a quiver with 2 edges.

EXAMPLES:

```
sage: B = [[0, 4, 0, -1],[-4,0, 3, 0],[0, -3, 0, 1],[1, 0, -1, 0]]
sage: S = ClusterSeed(matrix(B)); S.mutate([2,3,1,2,1,3,0,2])

```

mutation_class(depth=*+ Infinity*, show_depth=*False*, return_paths=*False*, up_to_equivalence=*True*, only_sink_source=*False*)

Return the mutation class of *self* with respect to certain constraints.

Note: Vertex labels are not tracked in this method.

See also:

[`mutation_class_iter\(\)`](#)

INPUT:

- `depth` – (default: `infinity`) integer, only seeds with distance at most `depth` from `self` are returned
- `show_depth` – (default: `False`) if `True`, the actual depth of the mutation is shown
- `return_paths` – (default: `False`) if `True`, a shortest path of mutation sequences from `self` to the given quiver is returned as well
- `up_to_equivalence` – (default: `True`) if `True`, only seeds up to equivalence are considered
- `sink_source` – (default: `False`) if `True`, only mutations at sinks and sources are applied

EXAMPLES:

- for examples see [`mutation_class_iter\(\)`](#)

`mutation_class_iter`(*depth*=+ *Infinity*, *show_depth*=*False*, *return_paths*=*False*, *up_to_equivalence*=*True*, *only_sink_source*=*False*)

Return an iterator for the mutation class of `self` with respect to certain constraints.

INPUT:

- `depth` – (default: `infinity`) integer or `infinity`, only seeds with distance at most `depth` from `self` are returned.
- `show_depth` – (default: `False`) if `True`, the current depth of the mutation is shown while computing.
- `return_paths` – (default: `False`) if `True`, a shortest path of mutations from `self` to the given quiver is returned as well.
- `up_to_equivalence` – (default: `True`) if `True`, only one seed up to simultaneous permutation of rows and columns of the exchange matrix is recorded.
- `sink_source` – (default: `False`) if `True`, only mutations at sinks and sources are applied.

EXAMPLES:

A standard finite type example:

```
sage: S = ClusterSeed(['A', 3])
sage: it = S.mutation_class_iter()
sage: for T in it: print(T)
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
```

(continues on next page)

(continued from previous page)

```
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
```

A finite type example with given depth:

```
sage: it = S.mutation_class_iter(depth=1)
sage: for T in it: print(T)
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
```

A finite type example where the depth is shown while computing:

```
sage: it = S.mutation_class_iter(show_depth=True)
sage: for T in it: pass
Depth: 0      found: 1      Time: ... s
Depth: 1      found: 4      Time: ... s
Depth: 2      found: 9      Time: ... s
Depth: 3      found: 13     Time: ... s
Depth: 4      found: 14     Time: ... s
```

A finite type example with shortest paths returned:

```
sage: it = S.mutation_class_iter(return_paths=True)
sage: mutation_class = list(it)
sage: len(mutation_class)
14
sage: mutation_class[0]
(A seed for a cluster algebra of rank 3 of type ['A', 3], [])
```

Finite type examples not considered up to equivalence:

```
sage: it = S.mutation_class_iter(up_to_equivalence=False)
sage: len( [ T for T in it ] )
84

sage: it = ClusterSeed(['A', 2]).mutation_class_iter(return_paths=True, up_to_
↪equivalence=False)
sage: mutation_class = list(it)
sage: len(mutation_class)
10
sage: mutation_class[0]
(A seed for a cluster algebra of rank 2 of type ['A', 2], [])
```

Check that [trac ticket #14638](#) is fixed:

```
sage: S = ClusterSeed(['E', 6])
sage: MC = S.mutation_class(depth=7); len(MC) # long time
534
```

Infinite type examples:

```

sage: S = ClusterSeed(['A',[1,1],1])
sage: it = S.mutation_class_iter()
sage: next(it)
A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1]
sage: next(it)
A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1]
sage: next(it)
A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1]
sage: next(it)
A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1]

sage: it = S.mutation_class_iter(depth=3, return_paths=True)
sage: for T in it: print(T)
(A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1], [])
(A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1], [1])
(A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1], [0])
(A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1], [1, 0])
(A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1], [0, 1])
(A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1], [1, 0, 1])
(A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1], [0, 1, 0])

```

mutation_sequence(*sequence*, *show_sequence=False*, *fig_size=1.2*, *return_output='seed'*)

Return the seeds obtained by mutating *self* at all vertices in *sequence*.

INPUT:

- *sequence* – an iterable of vertices of *self*.
- *show_sequence* – (default: False) if True, a png containing the associated quivers is shown.
- *fig_size* – (default: 1.2) factor by which the size of the plot is multiplied.
- *return_output* – (default: 'seed') determines what output is to be returned:

```

* if 'seed', outputs all the cluster seeds obtained by the ``sequence`` of
↳ mutations.
* if 'matrix', outputs a list of exchange matrices.
* if 'var', outputs a list of new cluster variables obtained at each step.

```

EXAMPLES:

```

sage: S = ClusterSeed(['A',2])
sage: for T in S.mutation_sequence([0,1,0]):
.....:     print(T.b_matrix())
[ 0 -1]
[ 1  0]
[ 0  1]
[-1  0]
[ 0 -1]
[ 1  0]

sage: S = ClusterSeed(['A',2])
sage: S.mutation_sequence([0,1,0,1], return_output='var')
[(x1 + 1)/x0, (x0 + x1 + 1)/(x0*x1), (x0 + 1)/x1, x0]

```

mutation_type()

Returns the `mutation_type` of each connected component of `self`, if it can be determined. Otherwise, the mutation type of this component is set to be unknown.

The mutation types of the components are ordered by vertex labels.

WARNING:

- All finite types can be detected,
- All affine types can be detected, EXCEPT affine type D (the algorithm is not yet implemented)
- All exceptional types can be detected.
- Might fail to work if it is used within different Sage processes simultaneously (that happened in the doctesting).

EXAMPLES:

- finite types:

```
sage: S = ClusterSeed(['A',5])
sage: S._mutation_type = S._quiver._mutation_type = None
sage: S.mutation_type()
['A', 5]

sage: S = ClusterSeed([(0,1),(1,2),(2,3),(3,4)])
sage: S.mutation_type()
['A', 5]

sage: S = ClusterSeed(DiGraph([['a','b'],['c','b'],['c','d'],['e','d']],
↪ frozen = ['c']))
sage: S.mutation_type()
[ ['A', 2], ['A', 2] ]
```

- affine types:

```
sage: S = ClusterSeed(['E',8,[1,1]]); S
A seed for a cluster algebra of rank 10 of type ['E', 8, [1, 1]]
sage: S._mutation_type = S._quiver._mutation_type = None; S
A seed for a cluster algebra of rank 10
sage: S.mutation_type() # long time
['E', 8, [1, 1]]
```

- the not yet working affine type D:

```
sage: S = ClusterSeed(['D',4,1])
sage: S._mutation_type = S._quiver._mutation_type = None
sage: S.mutation_type() # todo: not implemented
['D', 4, 1]
```

- the exceptional types:

```
sage: S = ClusterSeed(['X',6])
sage: S._mutation_type = S._quiver._mutation_type = None
sage: S.mutation_type() # long time
['X', 6]
```

- infinite types:

```

sage: S = ClusterSeed(['GR',[4,9]])
sage: S._mutation_type = S._quiver._mutation_type = None
sage: S.mutation_type()
'undetermined infinite mutation type'

```

mutations()

Return the list of mutations `self` has undergone if they are being tracked.

EXAMPLES:

```

sage: S = ClusterSeed(['A',3])
sage: S.mutations()
[]

sage: S.mutate([0,1,0,2])
sage: S.mutations()
[0, 1, 0, 2]

sage: S.track_mutations(False)
sage: S.mutations()
Traceback (most recent call last):
...
ValueError: Not recording mutation sequence.  Need to track mutations.

```

n()

Return the number of *exchangeable variables* of `self`.

EXAMPLES:

```

sage: S = ClusterSeed(['A', 3])
sage: S.n()
3

```

oriented_exchange_graph()

Return the oriented exchange graph of `self` as a directed graph.

The seed must be a cluster seed for a cluster algebra of finite type with principal coefficients (the corresponding quiver must have mutable vertices $0, 1, \dots, n-1$).

EXAMPLES:

```

sage: S = ClusterSeed(['A', 2]).principal_extension()
sage: G = S.oriented_exchange_graph(); G
Digraph on 5 vertices
sage: G.out_degree_sequence()
[2, 1, 1, 1, 0]

sage: S = ClusterSeed(['B', 2]).principal_extension()
sage: G = S.oriented_exchange_graph(); G
Digraph on 6 vertices
sage: G.out_degree_sequence()
[2, 1, 1, 1, 1, 0]

```

plot(circular=False, mark=None, save_pos=False, force_c=False, with_greens=False, add_labels=False)

Returns the plot of the quiver of `self`.

INPUT:

- `circular` – (default:False) if True, the circular plot is chosen, otherwise `>>spring<<` is used.
- `mark` – (default: None) if set to `i`, the vertex `i` is highlighted.
- `save_pos` – (default:False) if True, the positions of the vertices are saved.
- `force_c` – (default:False) if True, will show the frozen vertices even if they were never initialized
- `with_greens` – (default:False) if True, will display the green vertices in green
- `add_labels` – (default:False) if True, will use the initial variables as labels

EXAMPLES:

```
sage: S = ClusterSeed(['A',5])
sage: S.plot()
Graphics object consisting of 15 graphics primitives
sage: S.plot(circular=True)
Graphics object consisting of 15 graphics primitives
sage: S.plot(circular=True, mark=1)
Graphics object consisting of 15 graphics primitives
```

`principal_extension()`

Return the principal extension of `self`, yielding a $2n \times n$ matrix.

Raises an error if the input seed has a non-square exchange matrix. In this case, the method instead adds n frozen variables to any previously frozen variables. I.e., the seed obtained by adding a frozen variable to every exchangeable variable of `self`.

EXAMPLES:

```
sage: S = ClusterSeed([[0,1],[1,2],[2,3],[2,4]]); S
A seed for a cluster algebra of rank 5

sage: T = S.principal_extension(); T
A seed for a cluster algebra of rank 5 with principal coefficients

sage: T.b_matrix()
[ 0  1  0  0  0]
[-1  0  1  0  0]
[ 0 -1  0  1  1]
[ 0  0 -1  0  0]
[ 0  0 -1  0  0]
[ 1  0  0  0  0]
[ 0  1  0  0  0]
[ 0  0  1  0  0]
[ 0  0  0  1  0]
[ 0  0  0  0  1]

sage: S = ClusterSeed(['A', 4], user_labels=['a', 'b', 'c', 'd'])
sage: T = S.principal_extension()
sage: T.cluster()
[a, b, c, d]
sage: T.coefficients()
[y0, y1, y2, y3]
sage: S2 = ClusterSeed(['A', 4], user_labels={0:'a', 1:'b', 2:'c', 3:'d'})
sage: S2 == S
True
```

(continues on next page)

(continued from previous page)

```
sage: T2 = S2.principal_extension()
sage: T2 == T
True
```

quiver()

Return the *quiver* associated to *self*.

EXAMPLES:

```
sage: S = ClusterSeed(['A', 3])
sage: S.quiver()
Quiver on 3 vertices of type ['A', 3]
```

red_vertices()

Return the list of red vertices of *self*.

A vertex is defined to be red if its *c*-vector has all non-negative entries. More information on red vertices can be found at [BDP2013].

OUTPUT:

The red vertices as a list of integers.

EXAMPLES:

```
sage: ClusterSeed(['A', 3]).principal_extension().red_vertices()
[]

sage: ClusterSeed(['A', [3, 3], 1]).principal_extension().red_vertices()
[]

sage: Q = ClusterSeed(['A', [3, 3], 1]).principal_extension()
sage: Q.mutate(1)
sage: Q.red_vertices()
[1]
```

reorient(*data*)

Reorients *self* with respect to the given total order, or with respect to an iterator of ordered pairs.

WARNING:

- This operation might change the mutation type of *self*.
- Ignores ordered pairs (i, j) for which neither (i, j) nor (j, i) is an edge of *self*.

INPUT:

- *data* – an iterator defining a total order on *self.vertices()*, or an iterator of ordered pairs in *self* defining the new orientation of these edges.

EXAMPLES:

```
sage: S = ClusterSeed(['A', [2, 3], 1])
sage: S.mutation_type()
['A', [2, 3], 1]

sage: S.reorient([(0, 1), (2, 3)])
sage: S.mutation_type()
```

(continues on next page)

(continued from previous page)

```

['D', 5]
sage: S.reorient([(1,0),(2,3)])
sage: S.mutation_type()
['A', [1, 4], 1]
sage: S.reorient([0,1,2,3,4])
sage: S.mutation_type()
['A', [1, 4], 1]

```

reset_cluster()

Reset the cluster of `self` to the initial cluster.

EXAMPLES:

```

sage: S = ClusterSeed(['A',3])
sage: S.mutate([1,2,1])
sage: S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]

sage: S.reset_cluster()
sage: S.cluster()
[x0, x1, x2]

sage: T = S.principal_extension()
sage: T.cluster()
[x0, x1, x2]
sage: T.mutate([1,2,1])
sage: T.cluster()
[x0, (x1*y2 + x0)/x2, (x1*y1*y2 + x0*y1 + x2)/(x1*x2)]

sage: T.reset_cluster()
sage: T.cluster()
[x0, x1, x2]

sage: S = ClusterSeed(['B',3],user_labels=[[1,2],[2,3],[3,4]],user_labels_
→prefix='p')
sage: S.mutate([0,1])
sage: S.cluster()
[(p_2_3 + 1)/p_1_2, (p_1_2*p_3_4^2 + p_2_3 + 1)/(p_1_2*p_2_3), p_3_4]

sage: S.reset_cluster()
sage: S.cluster()
[p_1_2, p_2_3, p_3_4]
sage: S.g_matrix()
[1 0 0]
[0 1 0]
[0 0 1]
sage: S.f_polynomials()
[1, 1, 1]

```

reset_coefficients()

Resets the coefficients of `self` to the frozen variables but keeps the current cluster. Raises an error if the

number of frozen variables is different than the number of exchangeable variables.

WARNING: This command to be phased out since 'use_c_vectors()' does this more effectively.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.b_matrix()
[ 0  1  0]
[-1  0 -1]
[ 0  1  0]
[ 1  0  0]
[ 0  1  0]
[ 0  0  1]
sage: S.mutate([1,2,1])
sage: S.b_matrix()
[ 0  1 -1]
[-1  0  1]
[ 1 -1  0]
[ 1  0  0]
[ 0  1 -1]
[ 0  0 -1]
sage: S.reset_coefficients()
sage: S.b_matrix()
[ 0  1 -1]
[-1  0  1]
[ 1 -1  0]
[ 1  0  0]
[ 0  1  0]
[ 0  0  1]
```

save_image(*filename*, *circular=False*, *mark=None*, *save_pos=False*)

Saves the plot of the underlying digraph of the quiver of *self*.

INPUT:

- *filename* – the filename the image is saved to.
- *circular* – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
- *mark* – (default: None) if set to *i*, the vertex *i* is highlighted.
- *save_pos* – (default:False) if True, the positions of the vertices are saved.

EXAMPLES:

```
sage: S = ClusterSeed(['F',4,[1,2]])
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix=".png") as f:
.....:     S.save_image(f.name)
```

set_c_matrix(*data*)

Will force set the c matrix according to a matrix, a quiver, or a seed.

INPUT:

- *data* – The matrix to set the c matrix to. Also allowed to be a quiver or cluster seed, in which case the *b_matrix* is used.

EXAMPLES:

```

sage: S = ClusterSeed(['A',3])
sage: X = matrix([[0,0,1],[0,1,0],[1,0,0]])
sage: S.set_c_matrix(X)
sage: S.c_matrix()
[0 0 1]
[0 1 0]
[1 0 0]

sage: Y = matrix([[-1,0,1],[0,1,0],[1,0,0]])
sage: S.set_c_matrix(Y)
C matrix does not look to be valid - there exists a column containing positive_
↪and negative entries.
Continuing...

sage: Z = matrix([[1,0,1],[0,1,0],[2,0,2]])
sage: S.set_c_matrix(Z)
C matrix does not look to be valid - not a linearly independent set.
Continuing...

```

set_cluster(*cluster*, *force=False*)

Sets the cluster for *self* to *cluster*.

Warning: Initialization may lead to inconsistent data.

INPUT:

- *cluster* – an iterable defining a cluster for *self*.

EXAMPLES:

```

sage: S = ClusterSeed(['A',3])
sage: cluster = S.cluster()
sage: S.mutate([1,2,1])
sage: S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]
sage: cluster2 = S.cluster()

sage: S.set_cluster(cluster)
Warning: using set_cluster at this point could lead to inconsistent seed data.

sage: S.set_cluster(cluster, force=True)
sage: S.cluster()
[x0, x1, x2]
sage: S.set_cluster(cluster2, force=True)
sage: S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]

sage: S = ClusterSeed(['A',3]); S.use_fpolys(False)
sage: S.set_cluster([1,1,1])
Warning: clusters not being tracked so this command is ignored.

```

show(*fig_size=1*, *circular=False*, *mark=None*, *save_pos=False*, *force_c=False*, *with_greens=False*, *add_labels=False*)

Shows the plot of the quiver of *self*.

INPUT:

- `fig_size` – (default: 1) factor by which the size of the plot is multiplied.
- `circular` – (default: False) if True, the circular plot is chosen, otherwise `>>spring<<` is used.
- `mark` – (default: None) if set to `i`, the vertex `i` is highlighted.
- `save_pos` – (default: False) if True, the positions of the vertices are saved.
- `force_c` – (default: False) if True, will show the frozen vertices even if they were never initialized
- `with_greens` – (default: False) if True, will display the green vertices in green
- `add_labels` – (default: False) if True, will use the initial variables as labels

smallest_c_vector()

Return the vertex with the smallest `c` vector.

OUTPUT:

An integer.

EXAMPLES:

```
sage: B = matrix([[0,2],[-2,0]])
sage: C = ClusterSeed(B).principal_extension()
sage: C.mutate(0)
sage: C.smallest_c_vector()
0
```

track_mutations(*use=True*)

Begins tracking the mutation path.

Warning: May initialize all other data to ensure that all `c`, `d`, and `g` vectors agree on the start of mutations.

INPUT:

- `use` – (default: True) If True, will begin filling the mutation path

EXAMPLES:

```
sage: S = ClusterSeed(['A',4]); S.track_mutations(False)
sage: S.mutate(0)
sage: S.mutations()
Traceback (most recent call last):
...
ValueError: Not recording mutation sequence.  Need to track mutations.
sage: S.track_mutations(True)
sage: S.g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

sage: S.mutate([0,1])
sage: S.mutations()
[0, 1]
```

universal_extension()

Return the universal extension of `self`.

This is the initial seed of the associated cluster algebra with universal coefficients, as defined in section 12 of [FZ2007].

This method works only if `self` is a bipartite, finite-type seed.

Due to some limitations in the current implementation of `CartanType`, we need to construct the set of almost positive coroots by hand. As a consequence their ordering is not the standard one (the rows of the bottom part of the exchange matrix might be a shuffling of those you would expect).

EXAMPLES:

```

sage: S = ClusterSeed(['A',2])
sage: T = S.universal_extension()
sage: T.b_matrix()
[ 0  1]
[-1  0]
[-1  0]
[ 1  0]
[ 1 -1]
[ 0  1]
[ 0 -1]

sage: S = ClusterSeed(['A',3])
sage: T = S.universal_extension()
sage: T.b_matrix()
[ 0  1  0]
[-1  0 -1]
[ 0  1  0]
[-1  0  0]
[ 1  0  0]
[ 1 -1  0]
[ 1 -1  1]
[ 0  1  0]
[ 0 -1  0]
[ 0 -1  1]
[ 0  0 -1]
[ 0  0  1]

sage: S = ClusterSeed(['B',2])
sage: T = S.universal_extension()
sage: T.b_matrix()
[ 0  1]
[-2  0]
[-1  0]
[ 1  0]
[ 1 -1]
[ 2 -1]
[ 0  1]
[ 0 -1]

sage: S = ClusterSeed(['A', 5], user_labels = [-2, -1, 0, 1 ,2])
sage: U = S.universal_extension()
sage: U.b_matrix() == ClusterSeed(['A', 5]).universal_extension().b_matrix()
True

```

urban_renewals(*return_first=False*)

Return the list of the urban renewal vertices of `self`.

An urban renewal vertex is one in which there are two arrows pointing toward the vertex and two arrows

pointing away.

INPUT:

- `return_first` – (default:False) if True, will return the first urban renewal

OUTPUT:

A list of vertices (as integers)

EXAMPLES:

```
sage: G = ClusterSeed(['GR', [4, 9]]); G.urban_renewals()
[5, 6]
```

use_c_vectors(*use=True, bot_is_c=False, force=False*)

Reconstruct c vectors from other data or initialize if no usable data exists.

Warning: Initialization may lead to inconsistent data.

INPUT:

- `use` – (default:True) If True, will use c vectors
- `bot_is_c` – (default:False) If True and ClusterSeed self has `self_m == self_n`, then will assume bottom half of the extended exchange matrix is the c-matrix. If true, lets the ClusterSeed know c-vectors can be calculated.

EXAMPLES:

```
sage: S = ClusterSeed(['A', 4])
sage: S.use_c_vectors(False); S.use_g_vectors(False); S.use_fpolys(False); S.
↳track_mutations(False)
sage: S.use_c_vectors(True)
Warning: Initializing c-vectors at this point could lead to inconsistent seed_
↳data.

sage: S.use_c_vectors(True, force=True)
sage: S.c_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

sage: S = ClusterSeed(['A', 4])
sage: S.use_c_vectors(False); S.use_g_vectors(False); S.use_fpolys(False); S.
↳track_mutations(False)
sage: S.mutate(1)
sage: S.use_c_vectors(True, force=True)
sage: S.c_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

use_d_vectors(*use=True, force=False*)

Reconstruct d vectors from other data or initialize if no usable data exists.

Warning: Initialization may lead to inconsistent data.

INPUT:

- use – (default:True) If True, will use d vectors

EXAMPLES:

```

sage: S = ClusterSeed(['A',4])
sage: S.use_d_vectors(True)
sage: S.d_matrix()
[-1  0  0  0]
[ 0 -1  0  0]
[ 0  0 -1  0]
[ 0  0  0 -1]

sage: S = ClusterSeed(['A',4]); S.use_d_vectors(False); S.track_
↳mutations(False); S.mutate(1); S.d_matrix()
[-1  0  0  0]
[ 0  1  0  0]
[ 0  0 -1  0]
[ 0  0  0 -1]
sage: S.use_fpolys(False)
sage: S.d_matrix()
Traceback (most recent call last):
...
ValueError: Unable to calculate d-vectors. Need to use d vectors.

sage: S = ClusterSeed(['A',4]); S.use_d_vectors(False); S.track_
↳mutations(False); S.mutate(1); S.d_matrix()
[-1  0  0  0]
[ 0  1  0  0]
[ 0  0 -1  0]
[ 0  0  0 -1]
sage: S.use_fpolys(False)
sage: S.use_d_vectors(True)
Warning: Initializing d-vectors at this point could lead to inconsistent seed_
↳data.

sage: S.use_d_vectors(True, force=True)
sage: S.d_matrix()
[-1  0  0  0]
[ 0 -1  0  0]
[ 0  0 -1  0]
[ 0  0  0 -1]

sage: S = ClusterSeed(['A',4]); S.mutate(1); S.d_matrix()
[-1  0  0  0]
[ 0  1  0  0]
[ 0  0 -1  0]
[ 0  0  0 -1]
sage: S = ClusterSeed(['A',4]); S.use_d_vectors(True); S.mutate(1); S.d_matrix()
[-1  0  0  0]
[ 0  1  0  0]
[ 0  0 -1  0]
[ 0  0  0 -1]

```

use_fpolys(*use=True, user_labels=None, user_labels_prefix=None*)

Use F-polynomials in our Cluster Seed

Note: This will automatically try to recompute the cluster variables if possible

INPUT:

- **use** – (default:True) If True, will use F-polynomials
- **user_labels** – (default:None) If set will overwrite the default cluster variable labels
- **user_labels_prefix** – (default:None) If set will overwrite the default

EXAMPLES:

```
sage: S = ClusterSeed(['A',4]); S.use_fpolys(False); S._cluster
sage: S.use_fpolys(True)
sage: S.cluster()
[x0, x1, x2, x3]

sage: S = ClusterSeed(['A',4]); S.use_fpolys(False); S.track_mutations(False);
↳S.mutate(1)
sage: S.use_fpolys(True)
Traceback (most recent call last):
...
ValueError: F-polynomials and Cluster Variables cannot be reconstructed from
↳given data.
sage: S.cluster()
Traceback (most recent call last):
...
ValueError: Clusters not being tracked
```

use_g_vectors(*use=True, force=False*)

Reconstruct g vectors from other data or initialize if no usable data exists.

Warning: Initialization may lead to inconsistent data.

INPUT:

- **use** – (default:True) If True, will use g vectors

EXAMPLES:

```
sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False)
sage: S.use_g_vectors(True)
sage: S.g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False)
sage: S.mutate(1)
sage: S.use_g_vectors(True)
sage: S.g_matrix()
[ 1  0  0  0]
[ 0 -1  0  0]
```

(continues on next page)

(continued from previous page)

```

[ 0 0 1 0]
[ 0 0 0 1]

sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False); S.track_mutations(False)
sage: S.mutate(1)
sage: S.use_c_vectors(False)
sage: S.g_matrix()
Traceback (most recent call last):
...
ValueError: Unable to calculate g-vectors. Need to use g vectors.

sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False); S.track_mutations(False)
sage: S.mutate(1)
sage: S.use_c_vectors(False)
sage: S.use_g_vectors(True)
Warning: Initializing g-vectors at this point could lead to inconsistent seed_
↪data.

sage: S.use_g_vectors(True, force=True)
sage: S.g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

```

variable_class(*depth*=+ Infinity, *ignore_bipartite_belt*=False)

Returns all cluster variables in the mutation class of *self*.

INPUT:

- *depth* – (default:infinity) integer, only seeds with distance at most *depth* from *self* are returned
- *ignore_bipartite_belt* – (default:False) if True, the algorithms does not use the bipartite belt

EXAMPLES:

- for examples see [variable_class_iter\(\)](#)

variable_class_iter(*depth*=+ Infinity, *ignore_bipartite_belt*=False)

Returns an iterator for all cluster variables in the mutation class of *self*.

INPUT:

- *depth* – (default:infinity) integer, only seeds with distance at most *depth* from *self* are returned
- *ignore_bipartite_belt* – (default:False) if True, the algorithms does not use the bipartite belt

EXAMPLES:

A standard finite type example:

```

sage: S = ClusterSeed(['A',3])
sage: it = S.variable_class_iter()
sage: for T in it: print(T)
x0
x1

```

(continues on next page)

(continued from previous page)

```
x2
(x1 + 1)/x0
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2)
(x1 + 1)/x2
(x0*x2 + x1 + 1)/(x0*x1)
(x0*x2 + 1)/x1
(x0*x2 + x1 + 1)/(x1*x2)
```

Finite type examples with given depth:

```
sage: it = S.variable_class_iter(depth=1)
sage: for T in it: print(T)
Found a bipartite seed - restarting the depth counter at zero and constructing
↳ the variable class using its bipartite belt.
x0
x1
x2
(x1 + 1)/x0
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2)
(x1 + 1)/x2
(x0*x2 + x1 + 1)/(x0*x1)
(x0*x2 + 1)/x1
(x0*x2 + x1 + 1)/(x1*x2)
```

Note that the notion of *depth* depends on whether a bipartite seed is found or not, or if it is manually ignored:

```
sage: it = S.variable_class_iter(depth=1, ignore_bipartite_belt=True)
sage: for T in it: print(T)
x0
x1
x2
(x1 + 1)/x2
(x0*x2 + 1)/x1
(x1 + 1)/x0

sage: S.mutate([0,1])
sage: it2 = S.variable_class_iter(depth=1)
sage: for T in it2: print(T)
(x1 + 1)/x0
(x0*x2 + x1 + 1)/(x0*x1)
x2
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2)
x1
(x0*x2 + 1)/x1
```

Infinite type examples:

```
sage: S = ClusterSeed(['A', [1,1], 1])
sage: it = S.variable_class_iter(depth=2)
sage: for T in it: print(T)
Found a bipartite seed - restarting the depth counter at zero and constructing
↳ the variable class using its bipartite belt.
x0
```

(continues on next page)

(continued from previous page)

```

x1
(x1^2 + 1)/x0
(x1^4 + x0^2 + 2*x1^2 + 1)/(x0^2*x1)
(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2)
(x0^2 + 1)/x1
(x1^6 + x0^4 + 2*x0^2*x1^2 + 3*x1^4 + 2*x0^2 + 3*x1^2 + 1)/(x0^3*x1^2)
(x1^8 + x0^6 + 2*x0^4*x1^2 + 3*x0^2*x1^4 + 4*x1^6 + 3*x0^4 + 6*x0^2*x1^2 + 6*x1^
↪ 4 + 3*x0^2 + 4*x1^2 + 1)/(x0^4*x1^3)
(x0^8 + 4*x0^6 + 3*x0^4*x1^2 + 2*x0^2*x1^4 + x1^6 + 6*x0^4 + 6*x0^2*x1^2 + 3*x1^
↪ 4 + 4*x0^2 + 3*x1^2 + 1)/(x0^3*x1^4)
(x0^6 + 3*x0^4 + 2*x0^2*x1^2 + x1^4 + 3*x0^2 + 2*x1^2 + 1)/(x0^2*x1^3)

```

x(k)

Return the k -th initial cluster variable for the associated cluster seed, or the cluster variable of the corresponding vertex in `self.quiver`.

EXAMPLES:

```

sage: S = ClusterSeed(['A', 3])
sage: S.mutate([2, 1])
sage: S.x(0)
x0

sage: S.x(1)
x1

sage: S.x(2)
x2

sage: dg = DiGraph(['a', 'b'], ['b', 'c'], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen = ['c'])
sage: S.x(0)
a
sage: S.x('a')
a

```

y(k)

Return the k -th initial coefficient (frozen variable) for the associated cluster seed, or the cluster variable of the corresponding vertex in `self.quiver`.

EXAMPLES:

```

sage: S = ClusterSeed(['A', 3]).principal_extension()
sage: S.mutate([2, 1])
sage: S.y(0)
y0

sage: S.y(1)
y1

sage: S.y(2)
y2

```

(continues on next page)

(continued from previous page)

```

sage: dg = DiGraph([[ 'a', 'b'], [ 'b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen = [ 'c'])
sage: S.y(0)
c
sage: S.y('c')
c

```

```

class sage.combinat.cluster_algebra_quiver.cluster_seed.ClusterVariable(parent, numerator,
                                                                    denominator,
                                                                    coerce=True,
                                                                    reduce=True,
                                                                    mutation_type=None,
                                                                    variable_type=None,
                                                                    xdim=0)

```

Bases: `sage.rings.fraction_field_element.FractionFieldElement`

This class is a thin wrapper for cluster variables in cluster seeds.

It provides the extra feature to store if a variable is frozen or not.

- the associated positive root:

```

sage: S = ClusterSeed([ 'A', 3])
sage: for T in S.variable_class_iter():
.....:     print("{} {}".format(T, T.almost_positive_root()))
x0 -alpha[1]
x1 -alpha[2]
x2 -alpha[3]
(x1 + 1)/x0 alpha[1]
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2) alpha[1] + alpha[2] + alpha[3]
(x1 + 1)/x2 alpha[3]
(x0*x2 + x1 + 1)/(x0*x1) alpha[1] + alpha[2]
(x0*x2 + 1)/x1 alpha[2]
(x0*x2 + x1 + 1)/(x1*x2) alpha[2] + alpha[3]

```

almost_positive_root()

Return the *almost positive root* associated to `self` if `self` is of finite type.

EXAMPLES:

```

sage: S = ClusterSeed([ 'A', 3])
sage: for T in S.variable_class_iter():
.....:     print("{} {}".format(T, T.almost_positive_root()))
x0 -alpha[1]
x1 -alpha[2]
x2 -alpha[3]
(x1 + 1)/x0 alpha[1]
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2) alpha[1] + alpha[2] + alpha[3]
(x1 + 1)/x2 alpha[3]
(x0*x2 + x1 + 1)/(x0*x1) alpha[1] + alpha[2]
(x0*x2 + 1)/x1 alpha[2]
(x0*x2 + x1 + 1)/(x1*x2) alpha[2] + alpha[3]

```

`sage.combinat.cluster_algebra_quiver.cluster_seed.PathSubset(n, m)`

Encodes a *maximal* Dyck path from $(0,0)$ to (n,m) (for $n \geq m \geq 0$) as a subset of $\{0,1,2,\dots,2n-1\}$. The encoding

is given by indexing horizontal edges by odd numbers and vertical edges by evens.

The horizontal between (i,j) and $(i+1,j)$ is indexed by the odd number $2*i+1$. The vertical between (i,j) and $(i,j+1)$ is indexed by the even number $2*j$.

EXAMPLES:

```
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import PathSubset
sage: PathSubset(4,0)
{1, 3, 5, 7}
sage: PathSubset(4,1)
{1, 3, 5, 6, 7}
sage: PathSubset(4,2)
{1, 2, 3, 5, 6, 7}
sage: PathSubset(4,3)
{1, 2, 3, 4, 5, 6, 7}
sage: PathSubset(4,4)
{0, 1, 2, 3, 4, 5, 6, 7}
```

`sage.combinat.cluster_algebra_quiver.cluster_seed.SetToPath(T)`

Rearranges the encoding for a *maximal* Dyck path (as a set) so that it is a list in the proper order of the edges.

EXAMPLES:

```
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import PathSubset
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import SetToPath
sage: SetToPath(PathSubset(4,0))
[1, 3, 5, 7]
sage: SetToPath(PathSubset(4,1))
[1, 3, 5, 7, 6]
sage: SetToPath(PathSubset(4,2))
[1, 3, 2, 5, 7, 6]
sage: SetToPath(PathSubset(4,3))
[1, 3, 2, 5, 4, 7, 6]
sage: SetToPath(PathSubset(4,4))
[1, 0, 3, 2, 5, 4, 7, 6]
```

`sage.combinat.cluster_algebra_quiver.cluster_seed.coeff_recurs($p, q, a1, a2, b, c$)`

Coefficients in Laurent expansion of greedy element, as defined by recursion.

EXAMPLES:

```
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import coeff_recurs
sage: coeff_recurs(1, 1, 5, 5, 3, 3)
10
```

`sage.combinat.cluster_algebra_quiver.cluster_seed.get_green_vertices(C)`

Get the green vertices from a matrix. Will go through each column and return the ones where no entry is greater than 0.

INPUT:

- C – The C matrix to check

EXAMPLES:

```

sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import get_green_
      ↪vertices
sage: S = ClusterSeed(['A',4]); S.mutate([1,2,3,2,0,1,2,0,3])
sage: get_green_vertices(S.c_matrix())
[0, 3]

```

`sage.combinat.cluster_algebra_quiver.cluster_seed.get_red_vertices(C)`

Get the red vertices from a matrix.

Will go through each column and return the ones where no entry is less than 0.

INPUT:

- C – The C matrix to check

EXAMPLES:

```

sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import get_red_vertices
sage: S = ClusterSeed(['A',4]); S.mutate([1,2,3,2,0,1,2,0,3])
sage: get_red_vertices(S.c_matrix())
[1, 2]

```

`sage.combinat.cluster_algebra_quiver.cluster_seed.is_LeLiZel_allowable(T, n, m, b, c)`

Check if the subset T contributes to the computation of the greedy element $x[m,n]$ in the rank two (b,c)-cluster algebra.

This uses the conditions of Lee-Li-Zelevinsky's paper [LLZ2014].

EXAMPLES:

```

sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import is_LeLiZel_
      ↪allowable
sage: is_LeLiZel_allowable({1,3,2,5,7,6},4,2,6,6)
False
sage: is_LeLiZel_allowable({1,2,5},3,3,1,1)
True

```

5.1.18 mutation_class

This file contains helper functions for compute the mutation class of a cluster algebra or quiver.

For the compendium on the cluster algebra and quiver package see [MS2011]

AUTHORS:

- Gregg Musiker
- Christian Stump

5.1.19 Helper functions for mutation types of quivers

This file contains helper functions for detecting the mutation type of a cluster algebra or quiver.

For the compendium on the cluster algebra and quiver package see [MS2011]

AUTHORS:

- Gregg Musiker
- Christian Stump

`sage.combinat.cluster_algebra_quiver.mutation_type.is_mutation_finite`(*M*, *nr_of_checks=None*)
Use a non-deterministic method by random mutations in various directions. Can result in a wrong answer.

Warning: This method modifies the input matrix *M*!

INPUT:

- `nr_of_checks` – (default: `None`) number of mutations applied. Standard is $500 \times (\text{number of vertices of self})$.

ALGORITHM:

A quiver is mutation infinite if and only if every edge label (a,b) satisfy $a \cdot b > 4$. Thus, we apply random mutations in random directions

EXAMPLES:

```
sage: from sage.combinat.cluster_algebra_quiver.mutation_type import is_mutation_
↪finite

sage: Q = ClusterQuiver(['A',10])
sage: M = Q.b_matrix()
sage: is_mutation_finite(M)
(True, None)

sage: Q = ClusterQuiver([(0,1),(1,2),(2,3),(3,4),(4,5),(5,6),(6,7),(7,8),(2,9)])
sage: M = Q.b_matrix()
sage: is_mutation_finite(M) # random
(False, [9, 6, 9, 8, 9, 4, 0, 4, 5, 2, 1, 0, 1, 0, 7, 1, 9, 2, 5, 7, 8, 6, 3, 0, 2, ↪
↪5, 4, 2, 6, 9, 2, 7, 3, 5, 3, 7, 9, 5, 9, 0, 2, 7, 9, 2, 4, 2, 1, 6, 9, 4, 3, 5, ↪
↪0, 8, 2, 9, 5, 3, 7, 0, 1, 8, 3, 7, 2, 7, 3, 4, 8, 0, 4, 9, 5, 2, 8, 4, 8, 1, 7, ↪
↪8, 9, 1, 5, 0, 8, 7, 4, 8, 9, 8, 0, 7, 4, 7, 1, 2, 8, 6, 1, 3, 9, 3, 9, 1, 3, 2, ↪
↪4, 9, 5, 1, 2, 9, 4, 8, 5, 3, 4, 6, 8, 9, 2, 5, 9, 4, 6, 2, 1, 4, 9, 6, 0, 9, 8, ↪
↪0, 4, 7, 9, 2, 1, 6])
```

Check that [trac ticket #19495](#) is fixed:

```
sage: dg = DiGraph(); dg.add_vertex(0); S = ClusterSeed(dg); S
A seed for a cluster algebra of rank 1
sage: S.is_mutation_finite()
True
```

`sage.combinat.cluster_algebra_quiver.mutation_type.load_data`(*n*, *user=True*)

Load a dict with keys being tuples representing exceptional QuiverMutationTypes, and with values being lists or sets containing all mutation equivalent quivers as dig6 data.

We check

- the data stored by the user (unless `user=False` was given)
- and the data installed by the optional package `database_mutation_class`.

INPUT:

- `user` – boolean (default: `True`) whether to look at user data. If not, only consider the optional package.

EXAMPLES:

```
sage: from sage.combinat.cluster_algebra_quiver.mutation_type import load_data
sage: load_data(2) # random - depends on the data the user has stored
{'G': 2): [('AO', ((0, 1), (1, -3))), ('AO', ((0, 1), (3, -1)))]}
```

5.1.20 Quiver

A *quiver* is an oriented graph without loops, two-cycles, or multiple edges. The edges are labelled by pairs $(i, -j)$ (with i and j being positive integers) such that the matrix $M = (m_{ab})$ with $m_{ab} = i, m_{ba} = -j$ for an edge $(i, -j)$ between vertices a and b is skew-symmetrizable.

Warning: This is not the standard definition of a quiver. Normally, in cluster algebra theory, a quiver is defined as an oriented graph without loops and two-cycles but with multiple edges allowed; the edges are unlabelled. This notion of quivers, however, can be seen as a particular case of our notion of quivers. Namely, if we have a quiver (in the regular sense of this word) with (precisely) i edges from a to b , then we represent it by a quiver (in our sense of this word) with an edge from a to b labelled by the pair $(i, -i)$.

For the compendium on the cluster algebra and quiver package see [MS2011]

AUTHORS:

- Gregg Musiker
- Christian Stump

See also:

For mutation types of combinatorial quivers, see `QuiverMutationType()`. Cluster seeds are closely related to `ClusterSeed()`.

class `sage.combinat.cluster_algebra_quiver.quiver.ClusterQuiver`(*data*, *frozen=None*, *user_labels=None*)

Bases: `sage.structure.sage_object.SageObject`

The *quiver* associated to an *exchange matrix*.

INPUT:

- `data` – can be any of the following:

```
* QuiverMutationType
* str - a string representing a QuiverMutationType or a common quiver type (see
↳ Examples)
* ClusterQuiver
* Matrix - a skew-symmetrizable matrix
* DiGraph - must be the input data for a quiver
* List of edges - must be the edge list of a digraph for a quiver
```

- `frozen` – (default:None) sets the list of frozen variables if the input type is a `DiGraph`, it is ignored otherwise
- `user_labels` – (default:None) sets the names of the labels for the vertices of the quiver if the input type is not a `DiGraph`; otherwise it is ignored

EXAMPLES:

From a `QuiverMutationType`:

```

sage: Q = ClusterQuiver(['A',5]); Q
Quiver on 5 vertices of type ['A', 5]

sage: Q = ClusterQuiver(['B',2]); Q
Quiver on 2 vertices of type ['B', 2]
sage: Q2 = ClusterQuiver(['C',2]); Q2
Quiver on 2 vertices of type ['B', 2]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
True
sage: MT = Q2.mutation_type(); MT.standard_quiver() == Q2
False

sage: Q = ClusterQuiver(['A',[2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]

sage: Q = ClusterQuiver(['A', [5,0],1]); Q
Quiver on 5 vertices of type ['D', 5]
sage: Q.is_finite()
True
sage: Q.is_acyclic()
False

sage: Q = ClusterQuiver(['F', 4, [2,1]]); Q
Quiver on 6 vertices of type ['F', 4, [1, 2]]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False
sage: dg = Q.digraph(); Q.mutate([2,1,4,0,5,3])
sage: dg2 = Q.digraph(); dg2.is_isomorphic(dg,edge_labels=True)
False
sage: dg2.is_isomorphic(MT.standard_quiver().digraph(),edge_labels=True)
True

sage: Q = ClusterQuiver(['G',2, (3,1)]); Q
Quiver on 4 vertices of type ['G', 2, [1, 3]]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False

sage: Q = ClusterQuiver(['GR',[3,6]]); Q
Quiver on 4 vertices of type ['D', 4]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False

sage: Q = ClusterQuiver(['GR',[3,7]]); Q
Quiver on 6 vertices of type ['E', 6]

```

(continues on next page)

(continued from previous page)

```

sage: Q = ClusterQuiver(['TR',2]); Q
Quiver on 3 vertices of type ['A', 3]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False
sage: Q.mutate([1,0]); MT.standard_quiver() == Q
True

sage: Q = ClusterQuiver(['TR',3]); Q
Quiver on 6 vertices of type ['D', 6]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False

```

From a *ClusterQuiver*:

```

sage: Q = ClusterQuiver(['A',[2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q ); T
Quiver on 7 vertices of type ['A', [2, 5], 1]

```

From a Matrix:

```

sage: Q = ClusterQuiver(['A',[2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q._M ); T
Quiver on 7 vertices

sage: Q = ClusterQuiver( matrix([[0,1,-1],[-1,0,1],[1,-1,0],[1,2,3]]) ); Q
Quiver on 4 vertices with 1 frozen vertex

sage: Q = ClusterQuiver( matrix([]) ); Q
Quiver without vertices

```

From a DiGraph:

```

sage: Q = ClusterQuiver(['A',[2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q._digraph ); T
Quiver on 7 vertices

sage: Q = ClusterQuiver( DiGraph([[1,2],[2,3],[3,4],[4,1]]) ); Q
Quiver on 4 vertices

sage: Q = ClusterQuiver(DiGraph([[ 'a', 'b'], [ 'b', 'c'], [ 'c', 'd'], [ 'd', 'e' ]]),
.....:                    frozen=[ 'c' ]); Q
Quiver on 5 vertices with 1 frozen vertex
sage: Q.mutation_type()
[ ['A', 2], ['A', 2] ]
sage: Q
Quiver on 5 vertices of type [ ['A', 2], ['A', 2] ] with 1 frozen vertex

```

From a List of edges:

```

sage: Q = ClusterQuiver(['A', [2,5], 1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q._digraph.edges(sort=True) ); T
Quiver on 7 vertices

sage: Q = ClusterQuiver([[1, 2], [2, 3], [3, 4], [4, 1]]); Q
Quiver on 4 vertices

```

b_matrix()

Return the b-matrix of self.

EXAMPLES:

```

sage: ClusterQuiver(['A', 4]).b_matrix()
[ 0  1  0  0]
[-1  0 -1  0]
[ 0  1  0  1]
[ 0  0 -1  0]

sage: ClusterQuiver(['B', 4]).b_matrix()
[ 0  1  0  0]
[-1  0 -1  0]
[ 0  1  0  1]
[ 0  0 -2  0]

sage: ClusterQuiver(['D', 4]).b_matrix()
[ 0  1  0  0]
[-1  0 -1 -1]
[ 0  1  0  0]
[ 0  1  0  0]

sage: ClusterQuiver(QuiverMutationType(['A', 2], ['B', 2])).b_matrix()
[ 0  1  0  0]
[-1  0  0  0]
[ 0  0  0  1]
[ 0  0 -2  0]

```

canonical_label(certificate=False)

Return the canonical labelling of self.

See `sage.graphs.generic_graph.GenericGraph.canonical_label()`.

INPUT:

- `certificate` – boolean (default: `False`) if `True`, the dictionary from `self.vertices()` to the vertices of the returned quiver is returned as well.

EXAMPLES:

```

sage: Q = ClusterQuiver(['A', 4]); Q.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: T = Q.canonical_label(); T.digraph().edges(sort=True)
[(0, 3, (1, -1)), (1, 2, (1, -1)), (1, 3, (1, -1))]

```

(continues on next page)

(continued from previous page)

```

sage: T, iso = Q.canonical_label(certificate=True)
sage: T.digraph().edges(sort=True); iso
[(0, 3, (1, -1)), (1, 2, (1, -1)), (1, 3, (1, -1))]
{0: 0, 1: 3, 2: 1, 3: 2}

sage: Q = ClusterQuiver(QuiverMutationType([[ 'B', 2 ], [ 'A', 1 ] ])); Q
Quiver on 3 vertices of type [ [ 'B', 2 ], [ 'A', 1 ] ]

sage: Q.canonical_label()
Quiver on 3 vertices of type [ [ 'A', 1 ], [ 'B', 2 ] ]

sage: Q.canonical_label(certificate=True)
(Quiver on 3 vertices of type [ [ 'A', 1 ], [ 'B', 2 ] ], {0: 1, 1: 2, 2: 0})

```

d_vector_fan()

Return the d-vector fan associated with the quiver.

It is the fan whose maximal cones are generated by the d-matrices of the clusters.

This is a complete simplicial fan (and even smooth when the initial quiver is acyclic). It only makes sense for quivers of finite type.

EXAMPLES:

```

sage: Fd = ClusterQuiver([[1,2]]).d_vector_fan(); Fd
Rational polyhedral fan in 2-d lattice N
sage: Fd.ngenerating_cones()
5

sage: Fd = ClusterQuiver([[1,2],[2,3]]).d_vector_fan(); Fd
Rational polyhedral fan in 3-d lattice N
sage: Fd.ngenerating_cones()
14
sage: Fd.is_smooth()
True

sage: Fd = ClusterQuiver([[1,2],[2,3],[3,1]]).d_vector_fan(); Fd
Rational polyhedral fan in 3-d lattice N
sage: Fd.ngenerating_cones()
14
sage: Fd.is_smooth()
False

```

digraph()

Return the underlying digraph of self.

EXAMPLES:

```

sage: ClusterQuiver([ 'A', 1 ]).digraph()
Digraph on 1 vertex
sage: list(ClusterQuiver([ 'A', 1 ]).digraph())
[0]
sage: ClusterQuiver([ 'A', 1 ]).digraph().edges(sort=True)
[]

```

(continues on next page)

(continued from previous page)

```

sage: ClusterQuiver(['A',4]).digraph()
Digraph on 4 vertices
sage: ClusterQuiver(['A',4]).digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: ClusterQuiver(['B',4]).digraph()
Digraph on 4 vertices
sage: ClusterQuiver(['A',4]).digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: ClusterQuiver(QuiverMutationType(['A',2],['B',2])).digraph()
Digraph on 4 vertices

sage: ClusterQuiver(QuiverMutationType(['A',2],['B',2])).digraph().
↳edges(sort=True)
[(0, 1, (1, -1)), (2, 3, (1, -2))]

sage: ClusterQuiver(['C', 4], user_labels = ['x', 'y', 'z', 'w']).digraph().
↳edges(sort=True)
[('x', 'y', (1, -1)), ('z', 'w', (2, -1)), ('z', 'y', (1, -1))]

```

exchangeable_part()

Return the restriction to the principal part (i.e. exchangeable part) of `self`, the subquiver obtained by deleting the frozen vertices of `self`.

EXAMPLES:

```

sage: Q = ClusterQuiver(['A',4])
sage: T = ClusterQuiver(Q.digraph().edges(sort=True), frozen=[3])
sage: T.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: T.exchangeable_part().digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1))]

sage: Q2 = Q.principal_extension()
sage: Q3 = Q2.principal_extension()
sage: Q2.exchangeable_part() == Q3.exchangeable_part()
True

```

first_sink()

Return the first vertex of `self` that is a sink.

EXAMPLES:

```

sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([1,2,4,3,2])
sage: Q.first_sink()
0

```

first_source()

Return the first vertex of `self` that is a source

EXAMPLES:

```
sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([2,1,3,4,2])
sage: Q.first_source()
1
```

free_vertices()

Return the list of free vertices of self.

EXAMPLES:

```
sage: Q = ClusterQuiver(DiGraph([[ 'a', 'b'], [ 'c', 'b'], [ 'c', 'd'], [ 'e', 'd'
↔ ']]),
.....:                      frozen=['b', 'd'])
sage: Q.free_vertices()
['a', 'c', 'e']
```

frozen_vertices()

Return the list of frozen vertices of self.

EXAMPLES:

```
sage: Q = ClusterQuiver(DiGraph([[ 'a', 'b'], [ 'c', 'b'], [ 'c', 'd'], [ 'e', 'd'
↔ ']]),
.....:                      frozen=['b', 'd'])
sage: sorted(Q.frozen_vertices())
['b', 'd']
```

g_vector_fan()

Return the g-vector fan associated with the quiver.

It is the fan whose maximal cones are generated by the g-matrices of the clusters.

This is a complete simplicial fan. It is only supported for quivers of finite type.

EXAMPLES:

```
sage: Fg = ClusterQuiver([[1,2]]).g_vector_fan(); Fg
Rational polyhedral fan in 2-d lattice N
sage: Fg.ngenerating_cones()
5

sage: Fg = ClusterQuiver([[1,2],[2,3]]).g_vector_fan(); Fg
Rational polyhedral fan in 3-d lattice N
sage: Fg.ngenerating_cones()
14
sage: Fg.is_smooth()
True

sage: Fg = ClusterQuiver([[1,2],[2,3],[3,1]]).g_vector_fan(); Fg
Rational polyhedral fan in 3-d lattice N
sage: Fg.ngenerating_cones()
14
sage: Fg.is_smooth()
True
```

interact(*fig_size=1, circular=True*)

Start an interactive window for cluster quiver mutations.

Only in *Jupyter notebook mode*.

INPUT:

- `fig_size` – (default: 1) factor by which the size of the plot is multiplied.
- `circular` – (default: True) if True, the circular plot is chosen, otherwise `>>spring<<` is used.

`is_acyclic()`

Return true if self is acyclic.

EXAMPLES:

```
sage: ClusterQuiver(['A',4]).is_acyclic()
True
sage: ClusterQuiver(['A',[2,1],1]).is_acyclic()
True
sage: ClusterQuiver([[0,1],[1,2],[2,0]]).is_acyclic()
False
```

`is_bipartite(return_bipartition=False)`

Return True if self is bipartite.

EXAMPLES:

```
sage: ClusterQuiver(['A',[3,3],1]).is_bipartite()
True
sage: ClusterQuiver(['A',[4,3],1]).is_bipartite()
False
```

`is_finite()`

Return True if self is of finite type.

EXAMPLES:

```
sage: Q = ClusterQuiver(['A',3])
sage: Q.is_finite()
True
sage: Q = ClusterQuiver(['A',[2,2],1])
sage: Q.is_finite()
False
sage: Q = ClusterQuiver([[ 'A',3],['B',3]])
sage: Q.is_finite()
True
sage: Q = ClusterQuiver(['T',[4,4,4]])
sage: Q.is_finite()
False
sage: Q = ClusterQuiver([[ 'A',3],['T',[4,4,4]])]
sage: Q.is_finite()
False
sage: Q = ClusterQuiver([[ 'A',3],['T',[2,2,3]])]
sage: Q.is_finite()
True
sage: Q = ClusterQuiver([[ 'A',3],['D',5]])
```

(continues on next page)

(continued from previous page)

```

sage: Q.is_finite()
True
sage: Q = ClusterQuiver([[ 'A', 3], [ 'D', 5, 1]])
sage: Q.is_finite()
False

sage: Q = ClusterQuiver([[0, 1, 2], [1, 2, 2], [2, 0, 2]])
sage: Q.is_finite()
False

sage: Q = ClusterQuiver([[0, 1, 2], [1, 2, 2], [2, 0, 2], [3, 4, 1], [4, 5, 1]])
sage: Q.is_finite()
False

```

is_mutation_finite(*nr_of_checks=None, return_path=False*)

Uses a non-deterministic method by random mutations in various directions. Can result in a wrong answer.

INPUT:

- **nr_of_checks** – (default: None) number of mutations applied. Standard is 500*(number of vertices of self).
- **return_path** – (default: False) if True, in case of self not being mutation finite, a path from self to a quiver with an edge label (a,-b) and $a*b > 4$ is returned.

ALGORITHM:

A quiver is mutation infinite if and only if every edge label (a,-b) satisfy $a*b > 4$. Thus, we apply random mutations in random directions

EXAMPLES:

```

sage: Q = ClusterQuiver([ 'A', 10])
sage: Q._mutation_type = None
sage: Q.is_mutation_finite()
True

sage: Q = ClusterQuiver([(0, 1), (1, 2), (2, 3), (3, 4), (4, 5), (5, 6), (6, 7), (7, 8), (2, 9)])
sage: Q.is_mutation_finite()
False

```

m()

Return the number of frozen vertices of self.

EXAMPLES:

```

sage: Q = ClusterQuiver([ 'A', 4])
sage: Q.m()
0

sage: T = ClusterQuiver(Q.digraph().edges(sort=True), frozen=[3])
sage: T.n()
3
sage: T.m()
1

```

mutate(*data*, *inplace=True*)

Mutates *self* at a sequence of vertices.

INPUT:

- *sequence* – a vertex of *self*, an iterator of vertices of *self*, a function which takes in the ClusterQuiver and returns a vertex or an iterator of vertices, or a string of the parameter wanting to be called on ClusterQuiver that will return a vertex or an iterator of vertices.
- *inplace* – (default: True) if False, the result is returned, otherwise *self* is modified.

EXAMPLES:

```

sage: Q = ClusterQuiver(['A',4]); Q.b_matrix()
[ 0  1  0  0]
[-1  0 -1  0]
[ 0  1  0  1]
[ 0  0 -1  0]

sage: Q.mutate(0); Q.b_matrix()
[ 0 -1  0  0]
[ 1  0 -1  0]
[ 0  1  0  1]
[ 0  0 -1  0]

sage: T = Q.mutate(0, inplace=False); T
Quiver on 4 vertices of type ['A', 4]

sage: Q.mutate(0)
sage: Q == T
True

sage: Q.mutate([0,1,0])
sage: Q.b_matrix()
[ 0 -1  1  0]
[ 1  0  0  0]
[-1  0  0  1]
[ 0  0 -1  0]

sage: Q = ClusterQuiver(QuiverMutationType(['A',1],['A',3]))
sage: Q.b_matrix()
[ 0  0  0  0]
[ 0  0  1  0]
[ 0 -1  0 -1]
[ 0  0  1  0]

sage: T = Q.mutate(0,inplace=False)
sage: Q == T
True

sage: Q = ClusterQuiver(['A',3]); Q.b_matrix()
[ 0  1  0]
[-1  0 -1]
[ 0  1  0]
sage: Q.mutate('first_sink'); Q.b_matrix()

```

(continues on next page)

(continued from previous page)

```

[ 0 -1  0]
[ 1  0  1]
[ 0 -1  0]
sage: Q.mutate('first_source'); Q.b_matrix()
[ 0  1  0]
[-1  0 -1]
[ 0  1  0]

sage: dg = DiGraph()
sage: dg.add_vertices(['a','b','c','d','e'])
sage: dg.add_edges([[ 'a','b'], [ 'b','c'], [ 'c','d'], [ 'd','e']])
sage: Q2 = ClusterQuiver(dg, frozen=['c']); Q2.b_matrix()
[ 0  1  0  0]
[-1  0  0  0]
[ 0  0  0  1]
[ 0  0 -1  0]
[ 0 -1  1  0]

sage: Q2.mutate('a'); Q2.b_matrix()
[ 0 -1  0  0]
[ 1  0  0  0]
[ 0  0  0  1]
[ 0  0 -1  0]
[ 0 -1  1  0]

sage: dg = DiGraph([[ 'a', 'b'], [ 'b', 'c']], format='list_of_edges')
sage: Q = ClusterQuiver(dg);Q
Quiver on 3 vertices
sage: Q.mutate(['a','b'],inplace=False).digraph().edges(sort=True)
[( 'a', 'b', (1, -1)), ( 'c', 'b', (1, -1))]

```

mutation_class(depth=*+ Infinity*, show_depth=*False*, return_paths=*False*, data_type=*'quiver'*, up_to_equivalence=*True*, sink_source=*False*)

Return the mutation class of *self* together with certain constraints.

INPUT:

- *depth* – (default: *infinity*) integer, only seeds with distance at most *depth* from *self* are returned
- *show_depth* – (default: *False*) if *True*, the actual depth of the mutation is shown
- *return_paths* – (default: *False*) if *True*, a shortest path of mutation sequences from *self* to the given quiver is returned as well
- *data_type* – (default: *"quiver"*) can be one of the following:
 - *"quiver"* – the quiver is returned
 - *"dig6"* – the dig6-data is returned
 - *"path"* – shortest paths of mutation sequences from *self* are returned
- *sink_source* – (default: *False*) if *True*, only mutations at sinks and sources are applied

EXAMPLES:

```

sage: Q = ClusterQuiver(['A', 3])
sage: Ts = Q.mutation_class()
sage: for T in Ts: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: Ts = Q.mutation_class(depth=1)
sage: for T in Ts: print(T)

```

mutation_class_iter(*depth*=+ Infinity, *show_depth*=False, *return_paths*=False, *data_type*='quiver', *up_to_equivalence*=True, *sink_source*=False)

Return an iterator for the mutation class of `self` together with certain constraints.

INPUT:

- `depth` – (default: infinity) integer, only quivers with distance at most `depth` from `self` are returned.
- `show_depth` – (default: False) if True, the actual depth of the mutation is shown.
- `return_paths` – (default: False) if True, a shortest path of mutation sequences from `self` to the given quiver is returned as well.
- `data_type` – (default: “quiver”) can be one of the following:

```

* "quiver"
* "matrix"
* "digraph"
* "dig6"
* "path"

```

- `up_to_equivalence` – (default: True) if True, only one quiver for each graph-isomorphism class is recorded.
- `sink_source` – (default: False) if True, only mutations at sinks and sources are applied.

EXAMPLES:

```

sage: Q = ClusterQuiver(['A', 3])
sage: it = Q.mutation_class_iter()
sage: for T in it: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: it = Q.mutation_class_iter(depth=1)
sage: for T in it: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: it = Q.mutation_class_iter(show_depth=True)
sage: for T in it: pass
Depth: 0    found: 1      Time: ... s
Depth: 1    found: 3      Time: ... s
Depth: 2    found: 4      Time: ... s

```

(continues on next page)

(continued from previous page)

```

sage: it = Q.mutation_class_iter(return_paths=True)

sage: S = ClusterQuiver(dg, frozen=['b'])
sage: S.mutation_class()
[Quiver on 3 vertices with 1 frozen vertex,

```

(continues on next page)

(continued from previous page)

```
Quiver on 3 vertices with 1 frozen vertex,
Quiver on 3 vertices with 1 frozen vertex]
```

mutation_sequence(*sequence*, *show_sequence=False*, *fig_size=1.2*)

Return a list containing the sequence of quivers obtained from `self` by a sequence of mutations on vertices.

INPUT:

- `sequence` – a list or tuple of vertices of `self`.
- `show_sequence` – (default: False) if True, a png containing the mutation sequence is shown.
- `fig_size` – (default: 1.2) factor by which the size of the sequence is expanded.

EXAMPLES:

```
sage: Q = ClusterQuiver(['A',4])
sage: seq = Q.mutation_sequence([0,1]); seq
[Quiver on 4 vertices of type ['A', 4], Quiver on 4 vertices of type ['A', 4],
 ←Quiver on 4 vertices of type ['A', 4]]
sage: [T.b_matrix() for T in seq]
[
 [ 0  1  0  0] [ 0 -1  0  0] [ 0  1 -1  0]
 [-1  0 -1  0] [ 1  0 -1  0] [-1  0  1  0]
 [ 0  1  0  1] [ 0  1  0  1] [ 1 -1  0  1]
 [ 0  0 -1  0], [ 0  0 -1  0], [ 0  0 -1  0]
]
```

mutation_type()

Return the mutation type of `self`.

Return the `mutation_type` of each connected component of `self` if it can be determined, otherwise, the mutation type of this component is set to be unknown.

The mutation types of the components are ordered by vertex labels.

If you do many type recognitions, you should consider to save exceptional mutation types using [`save_quiver_data\(\)`](#)

WARNING:

- All finite types can be detected,
- All affine types can be detected, EXCEPT affine type D (the algorithm is not yet implemented)
- All exceptional types can be detected.

EXAMPLES:

```
sage: ClusterQuiver(['A',4]).mutation_type()
['A', 4]
sage: ClusterQuiver(['A',(3,1),1]).mutation_type()
['A', [1, 3], 1]
sage: ClusterQuiver(['C',2]).mutation_type()
['B', 2]
sage: ClusterQuiver(['B',4,1]).mutation_type()
['BD', 4, 1]
```

finite types:

```

sage: Q = ClusterQuiver(['A',5])
sage: Q._mutation_type = None
sage: Q.mutation_type()
['A', 5]

sage: Q = ClusterQuiver([(0,1),(1,2),(2,3),(3,4)])
sage: Q.mutation_type()
['A', 5]

sage: Q = ClusterQuiver(DiGraph([[ 'a', 'b'], [ 'c', 'b'], [ 'c', 'd'], [ 'e', 'd'
↔ ']]),
.....:                               frozen=[ 'c' ])
sage: Q.mutation_type()
[ ['A', 2], ['A', 2] ]

```

affine types:

```

sage: Q = ClusterQuiver(['E',8,[1,1]]); Q
Quiver on 10 vertices of type ['E', 8, [1, 1]]
sage: Q._mutation_type = None; Q
Quiver on 10 vertices
sage: Q.mutation_type() # long time
['E', 8, [1, 1]]

```

the not yet working affine type D (unless user has saved small classical quiver data):

```

sage: Q = ClusterQuiver(['D',4,1])
sage: Q._mutation_type = None
sage: Q.mutation_type() # todo: not implemented
['D', 4, 1]

```

the exceptional types:

```

sage: Q = ClusterQuiver(['X',6])
sage: Q._mutation_type = None
sage: Q.mutation_type() # long time
['X', 6]

```

examples from page 8 of [Ke2008]:

```

sage: dg = DiGraph(); dg.add_edges([(9,0),(9,4),(4,6),(6,7),(7,8),(8,3),(3,5),
↔(5,6),(8,1),(2,3)])
sage: ClusterQuiver( dg ).mutation_type() # long time
['E', 8, [1, 1]]

sage: dg = DiGraph( { 0:[3], 1:[0,4], 2:[0,6], 3:[1,2,7], 4:[3,8], 5:[2], 6:[3,
↔5], 7:[4,6], 8:[7] } )
sage: ClusterQuiver( dg ).mutation_type() # long time
['E', 8, 1]

sage: dg = DiGraph( { 0:[3,9], 1:[0,4], 2:[0,6], 3:[1,2,7], 4:[3,8], 5:[2],↔
↔6:[3,5], 7:[4,6], 8:[7], 9:[1] } )
sage: ClusterQuiver( dg ).mutation_type() # long time
['E', 8, [1, 1]]

```

infinite types:

```
sage: Q = ClusterQuiver(['GR',[4,9]])
sage: Q._mutation_type = None
sage: Q.mutation_type()
'undetermined infinite mutation type'
```

reducible types:

```
sage: Q = ClusterQuiver(['A', 3], ['B', 3])
sage: Q._mutation_type = None
sage: Q.mutation_type()
[ ['A', 3], ['B', 3] ]

sage: Q = ClusterQuiver(['A', 3], ['T', [4,4,4]])
sage: Q._mutation_type = None
sage: Q.mutation_type()
[['A', 3], 'undetermined infinite mutation type']

sage: Q = ClusterQuiver(['A', 3], ['B', 3], ['T', [4,4,4]])
sage: Q._mutation_type = None
sage: Q.mutation_type()
[['A', 3], ['B', 3], 'undetermined infinite mutation type']

sage: Q = ClusterQuiver([0,1,2],[1,2,2],[2,0,2],[3,4,1],[4,5,1])
sage: Q.mutation_type()
['undetermined finite mutation type', ['A', 3]]
```

n()

Return the number of free vertices of self.

EXAMPLES:

```
sage: ClusterQuiver(['A',4]).n()
4
sage: ClusterQuiver(['A',(3,1),1]).n()
4
sage: ClusterQuiver(['B',4]).n()
4
sage: ClusterQuiver(['B',4,1]).n()
5
```

number_of_edges()

Return the total number of edges on the quiver

Note: This only works with non-valued quivers. If used on a non-valued quiver then the positive value is taken to be the number of edges added

OUTPUT:

An integer of the number of edges.

EXAMPLES:

```
sage: S = ClusterQuiver(['A',4]); S.number_of_edges()
3
```

(continues on next page)

(continued from previous page)

```
sage: S = ClusterQuiver(['B',4]); S.number_of_edges()
3
```

plot(*circular=True, center=(0, 0), directed=True, mark=None, save_pos=False, greens=[]*)
Return the plot of the underlying digraph of *self*.

INPUT:

- *circular* – (default: True) if True, the circular plot is chosen, otherwise `>>spring<<` is used.
- *center* – (default:(0,0)) sets the center of the circular plot, otherwise it is ignored.
- *directed* – (default: True) if True, the directed version is shown, otherwise the undirected.
- *mark* – (default: None) if set to *i*, the vertex *i* is highlighted.
- *save_pos* – (default: False) if True, the positions of the vertices are saved.
- *greens* – (default: []) if set to a list, will display the green vertices as green

EXAMPLES:

```
sage: Q = ClusterQuiver(['A',5])
sage: Q.plot()
Graphics object consisting of 15 graphics primitives
sage: Q.plot(circular=True)
Graphics object consisting of 15 graphics primitives
sage: Q.plot(circular=True, mark=1)
Graphics object consisting of 15 graphics primitives
```

poincare_semistable(*theta, d*)

Return the Poincaré polynomial of the moduli space of semi-stable representations of dimension vector *d*.

INPUT:

- *theta* – stability weight, as list or vector of rationals
- *d* – dimension vector, as list or vector of coprime integers

The semi-stability is taken with respect to the slope function

$$\mu(d) = \theta(d) / \dim(d)$$

where *d* is a dimension vector.

This uses the matrix-inversion algorithm from [Rei2002].

EXAMPLES:

```
sage: Q = ClusterQuiver(['A',2])
sage: Q.poincare_semistable([1,0],[1,0])
1
sage: Q.poincare_semistable([1,0],[1,1])
1

sage: K2 = ClusterQuiver(matrix([[0,2],[-2,0]]))
sage: theta = (1, 0)
sage: K2.poincare_semistable(theta, [1,0])
```

(continues on next page)

(continued from previous page)

```

1
sage: K2.poincare_semistable(theta, [1,1])
v^2 + 1
sage: K2.poincare_semistable(theta, [1,2])
1
sage: K2.poincare_semistable(theta, [1,3])
0

sage: K3 = ClusterQuiver(matrix([[0,3],[-3,0]]))
sage: theta = (1, 0)
sage: K3.poincare_semistable(theta, (2,3))
v^12 + v^10 + 3*v^8 + 3*v^6 + 3*v^4 + v^2 + 1
sage: K3.poincare_semistable(theta, (3,4))(1)
68

```

REFERENCES:

principal_extension(*inplace=False*)

Return the principal extension of `self`, adding `n` frozen vertices to any previously frozen vertices. I.e., the quiver obtained by adding an outgoing edge to every mutable vertex of `self`.

EXAMPLES:

```

sage: Q = ClusterQuiver(['A',2]); Q
Quiver on 2 vertices of type ['A', 2]
sage: T = Q.principal_extension(); T
Quiver on 4 vertices of type ['A', 2] with 2 frozen vertices
sage: T2 = T.principal_extension(); T2
Quiver on 6 vertices of type ['A', 2] with 4 frozen vertices
sage: Q.digraph().edges(sort=True)
[(0, 1, (1, -1))]
sage: T.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 0, (1, -1)), (3, 1, (1, -1))]
sage: T2.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 0, (1, -1)), (3, 1, (1, -1)), (4, 0, (1, -1)), (5, 1, (1, -1))]

```

qmu_save(*filename=None*)

Save `self` in a `.qmu` file.

This file can then be opened in Bernhard Keller's Quiver Applet.

See <https://webusers.imj-prg.fr/~bernhard.keller/quivermutation/>

INPUT:

- `filename` – the filename the image is saved to.

If a filename is not specified, the default name is `from_sage.qmu` in the current sage directory.

EXAMPLES:

```

sage: Q = ClusterQuiver(['F',4,[1,2]])
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix=".qmu") as f:
.....:     Q.qmu_save(f.name)

```

Make sure we can save quivers with $m! = n$ frozen variables, see [trac ticket #14851](#):

```
sage: S = ClusterSeed(['A',3])
sage: T1 = S.principal_extension()
sage: Q = T1.quiver()
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix=".qmu") as f:
.....:     Q.qmu_save(f.name)
```

relabel(*relabelling*, *inplace=True*)

Return the quiver after doing a relabelling

Will relabel the vertices of the quiver

INPUT:

- *relabelling* – Dictionary of labels to move around
- *inplace* – (default: True) if True, will return a duplicate of the quiver

EXAMPLES:

```
sage: S = ClusterQuiver(['A',4]).relabel({1:'5',2:'go'})
```

reorient(*data*)

Reorient self with respect to the given total order, or with respect to an iterator of edges in self to be reverted.

Warning: This operation might change the mutation type of self.

INPUT:

- *data* – an iterator defining a total order on `self.vertices()`, or an iterator of edges in self to be reoriented.

EXAMPLES:

```
sage: Q = ClusterQuiver(['A',(2,3)],1])
sage: Q.mutation_type()
['A', [2, 3], 1]

sage: Q.reorient([(0,1),(1,2),(2,3),(3,4)])
sage: Q.mutation_type()
['D', 5]

sage: Q.reorient([0,1,2,3,4])
sage: Q.mutation_type()
['A', [1, 4], 1]
```

save_image(*filename*, *circular=False*)

Save the plot of the underlying digraph of self.

INPUT:

- *filename* – the filename the image is saved to.
- *circular* – (default: False) if True, the circular plot is chosen, otherwise `>>spring<<` is used.

EXAMPLES:

```

sage: Q = ClusterQuiver(['F',4,[1,2]])
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix=".png") as f:
.....:     Q.save_image(f.name)

```

show(*fig_size=1, circular=False, directed=True, mark=None, save_pos=False, greens=[]*)

Show the plot of the underlying digraph of `self`.

INPUT:

- `fig_size` – (default: 1) factor by which the size of the plot is multiplied.
- `circular` – (default: False) if True, the circular plot is chosen, otherwise `>>spring<<` is used.
- `directed` – (default: True) if True, the directed version is shown, otherwise the undirected.
- `mark` – (default: None) if set to `i`, the vertex `i` is highlighted.
- `save_pos` – (default: False) if True, the positions of the vertices are saved.
- `greens` – (default: []) if set to a list, will display the green vertices as green

sinks()

Return all vertices of `self` that are sinks.

EXAMPLES:

```

sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([1,2,4,3,2])
sage: Q.sinks()
[0, 2]

sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([2,1,3,4,2])
sage: Q.sinks()
[3]

```

sources()

Return all vertices of `self` that are sources.

EXAMPLES:

```

sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([1,2,4,3,2])
sage: Q.sources()
[]

sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([2,1,3,4,2])
sage: Q.sources()
[1]

```

5.1.21 Quiver mutation types

AUTHORS:

- Gregg Musiker (2012, initial version)
- Christian Stump (2012, initial version)
- Hugh Thomas (2012, initial version)

`sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType(*args)`

Quiver mutation types can be seen as a slight generalization of generalized Cartan types.

Background on generalized Cartan types can be found at

[Wikipedia article Generalized_Cartan_matrix](#)

For the compendium on the cluster algebra and quiver package in Sage see [MS2011]

A B -matrix is a skew-symmetrizable $(n \times n)$ -matrix M . I.e., there exists an invertible diagonal matrix D such that DM is skew-symmetric. M can be encoded as a *quiver* by having a directed edge from vertex i to vertex j with label (a, b) if $a = M_{i,j} > 0$ and $b = M_{j,i} < 0$. We consider quivers up to *mutation equivalence*.

To a quiver mutation type we can associate a *generalized Cartan type* by sending M to the generalized Cartan matrix $C(M)$ obtained by replacing all positive entries by their negatives and adding 2's on the main diagonal.

`QuiverMutationType` constructs a quiver mutation type object. For more detail on the possible different types, please see the compendium.

INPUT:

The input consists either of a quiver mutation type, or of a `letter` (a string), a `rank` (one integer or a list/tuple of integers), and an optional `twist` (an integer or a list of integers). There are several different naming conventions for quiver mutation types.

- Finite type – `letter` is a Dynkin type (A-G), and `rank` is the rank.
- Affine type – there is more than one convention for naming affine types.
 - Kac's notation: `letter` is a Dynkin type, `rank` is the rank of the associated finite Dynkin diagram, and `twist` is the twist, which could be 1, 2, or 3. In the special case of affine type A, there is more than one quiver mutation type associated to the Cartan type. In this case only, `rank` is a pair of integers (i, j) , giving the number of edges pointing clockwise and the number of edges pointing counter-clockwise. The total number of vertices is given by $i+j$ in this case.
 - Naive notation: `letter` is one of 'BB', 'BC', 'BD', 'CC', 'CD'. The name specifies the two ends of the diagram, which are joined by a path. The total number of vertices is given by `rank + 1` (to match the indexing people expect because these are affine types). In general, `rank` must be large enough for the picture to make sense, but we accept `letter` is BC and `rank=1`.
 - Macdonald notation: for the dual of an untwisted affine type (such as ['C', 6, 1]), we accept a twist of -1 (i.e., ['C', 6, -1]).
- Elliptic type – `letter` is a Dynkin type, `rank` is the rank of the finite Dynkin diagram, and `twist` is a tuple of two integers. We follow Saito's notation.
- Other shapes:
 - Rank 2: `letter` is 'R2', and `rank` is a pair of integers specifying the label on the unique edge.
 - Triangle: `letter` is TR, and `rank` is the number of vertices along a side.

- T: This defines a quiver shaped like a T. letter is ‘T’, and the rank is a triple, whose entries specify the number of vertices along each path from the branch point (counting the branch point).
- Grassmannian: This defines the cluster algebra (without coefficients) corresponding to the cluster algebra with coefficients which is the coordinate ring of a Grassmannian. letter is ‘GR’. rank is a pair of integers (k, n) with ‘k’ < ‘n’ specifying the Grassmannian of k -planes in n -space. This defines a quiver given by a $(k-1) \times (n-k-1)$ grid where each square is cyclically oriented.
- Exceptional mutation finite quivers: The two exceptional mutation finite quivers, found by Derksen-Owen, have letter as ‘X’ and rank 6 or 7, equal to the number of vertices.
- AE, BE, CE, DE: Quivers are built of one end which looks like type (affine A), B, C, or D, and the other end which looks like type E (i.e., it consists of two antennae, one of length one, and one of length two). letter is ‘AE’, ‘BE’, ‘CE’, or ‘DE’, and rank is the total number of vertices. Note that ‘AE’ is of a slightly different form and requires rank to be a pair of integers (i,j) just as in the case of affine type A. See Exercise 4.3 in Kac’s book Infinite Dimensional Lie Algebras for more details.
- Infinite type E: It is also possible to obtain infinite-type E quivers by specifying letter as ‘E’ and rank as the number of vertices.

REFERENCES:

- A good reference for finite and affine Dynkin diagrams, including Kac’s notation, is the [Wikipedia article Dynkin diagram](#).
- A good reference for the skew-symmetrizable elliptic diagrams is “Cluster algebras of finite mutation type via unfolding” by A. Felikson, M. Shapiro, and P. Tumarkin, [FST2012].

EXAMPLES:

Finite types:

```

sage: QuiverMutationType('A', 1)
['A', 1]
sage: QuiverMutationType('A', 5)
['A', 5]

sage: QuiverMutationType('B', 2)
['B', 2]
sage: QuiverMutationType('B', 5)
['B', 5]

sage: QuiverMutationType('C', 2)
['B', 2]
sage: QuiverMutationType('C', 5)
['C', 5]

sage: QuiverMutationType('D', 2)
[ ['A', 1], ['A', 1] ]
sage: QuiverMutationType('D', 3)
['A', 3]
sage: QuiverMutationType('D', 4)
['D', 4]

sage: QuiverMutationType('E', 6)
['E', 6]

sage: QuiverMutationType('G', 2)

```

(continues on next page)

(continued from previous page)

```

['G', 2]

['CC', 4, 1]

sage: QuiverMutationType('BC', 1, 1)
['BC', 1, 1]
sage: QuiverMutationType('BC',5, 1)
['BC', 5, 1]

sage: QuiverMutationType('BD',3, 1)
['BD', 3, 1]
sage: QuiverMutationType('BD',5, 1)
['BD', 5, 1]

sage: QuiverMutationType('CD',3, 1)
['CD', 3, 1]
sage: QuiverMutationType('CD',5, 1)
['CD', 5, 1]

sage: QuiverMutationType('D',4, 1)
['D', 4, 1]
sage: QuiverMutationType('D',6, 1)
['D', 6, 1]

sage: QuiverMutationType('E',6, 1)
['E', 6, 1]
sage: QuiverMutationType('E',7, 1)
['E', 7, 1]

```

(continues on next page)

(continued from previous page)

```

sage: QuiverMutationType('E',8, 1)
['E', 8, 1]

sage: QuiverMutationType('F',4, 1)
['F', 4, 1]
sage: QuiverMutationType('F',4,-1)
['F', 4, -1]

sage: QuiverMutationType('G', 2, 1)
['G', 2, 1]
sage: QuiverMutationType('G', 2,-1)
['G', 2, -1]
sage: QuiverMutationType('A',3, 2) == QuiverMutationType('D',3, 2)
True

```

Affine types using Kac's Notation:

```

sage: QuiverMutationType('A', 1, 1)
['A', [1, 1], 1]
sage: QuiverMutationType('B',5, 1)
['BD', 5, 1]
sage: QuiverMutationType('C',5, 1)
['CC', 5, 1]
sage: QuiverMutationType('A', 2, 2)
['BC', 1, 1]
sage: QuiverMutationType('A',7, 2)
['CD', 4, 1]
sage: QuiverMutationType('A',8, 2)
['BC', 4, 1]
sage: QuiverMutationType('D',6, 2)
['BB', 5, 1]
sage: QuiverMutationType('E',6, 2)
['F', 4, -1]
sage: QuiverMutationType('D',4,3)
['G', 2, -1]

```

Elliptic types:

```

sage: QuiverMutationType('E',6,[1, 1])
['E', 6, [1, 1]]
sage: QuiverMutationType('F',4,[2, 1])
['F', 4, [1, 2]]
sage: QuiverMutationType('G', 2,[3,3])
['G', 2, [3, 3]]

```

Mutation finite types:

Rank 2 cases:

```

sage: QuiverMutationType('R2',(1, 1))
['A', 2]
sage: QuiverMutationType('R2',(1, 2))
['B', 2]

```

(continues on next page)

(continued from previous page)

```

sage: QuiverMutationType('R2', (1, 3))
['G', 2]
sage: QuiverMutationType('R2', (1, 4))
['BC', 1, 1]
sage: QuiverMutationType('R2', (1, 5))
['R2', [1, 5]]
sage: QuiverMutationType('R2', (2, 2))
['A', [1, 1], 1]
sage: QuiverMutationType('R2', (3, 5))
['R2', [3, 5]]

```

Exceptional Derksen-Owen quivers:

```

sage: QuiverMutationType('X', 6)
['X', 6]

```

(Mainly) mutation infinite types:

Infinite type E:

```

sage: QuiverMutationType('E', 9)
['E', 8, 1]
sage: QuiverMutationType('E', 10)
['E', 10]
sage: QuiverMutationType('E', 12)
['E', 12]

sage: QuiverMutationType('AE', (2, 3))
['AE', [2, 3]]
sage: QuiverMutationType('BE', 5)
['BE', 5]
sage: QuiverMutationType('CE', 5)
['CE', 5]
sage: QuiverMutationType('DE', 6)
['DE', 6]

```

Grassmannian types:

```

sage: QuiverMutationType('GR', (2, 4))
['A', 1]
sage: QuiverMutationType('GR', (2, 6))
['A', 3]
sage: QuiverMutationType('GR', (3, 6))
['D', 4]
sage: QuiverMutationType('GR', (3, 7))
['E', 6]
sage: QuiverMutationType('GR', (3, 8))
['E', 8]
sage: QuiverMutationType('GR', (3, 10))
['GR', [3, 10]]

```

Triangular types:

```

sage: QuiverMutationType('TR', 2)
['A', 3]
sage: QuiverMutationType('TR', 3)
['D', 6]
sage: QuiverMutationType('TR', 4)
['E', 8, [1, 1]]
sage: QuiverMutationType('TR', 5)
['TR', 5]

```

T types:

```

sage: QuiverMutationType('T', (1, 1, 1))
['A', 1]
sage: QuiverMutationType('T', (1, 1, 4))
['A', 4]
sage: QuiverMutationType('T', (1, 4, 4))
['A', 7]
sage: QuiverMutationType('T', (2, 2, 2))
['D', 4]
sage: QuiverMutationType('T', (2, 2, 4))
['D', 6]
sage: QuiverMutationType('T', (2, 3, 3))
['E', 6]
sage: QuiverMutationType('T', (2, 3, 4))
['E', 7]
sage: QuiverMutationType('T', (2, 3, 5))
['E', 8]
sage: QuiverMutationType('T', (2, 3, 6))
['E', 8, 1]
sage: QuiverMutationType('T', (2, 3, 7))
['E', 10]
sage: QuiverMutationType('T', (3, 3, 3))
['E', 6, 1]
sage: QuiverMutationType('T', (3, 3, 4))
['T', [3, 3, 4]]

```

Reducible types:

```

sage: QuiverMutationType(['A', 3], ['B', 4])
[ ['A', 3], ['B', 4] ]

```

```

class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationTypeFactory
Bases: sage.structure.sage_object.SageObject

```

```

samples(finite=None, affine=None, elliptic=None, mutation_finite=None)

```

Return a sample of the available quiver mutations types.

INPUT:

- `finite`
- `affine`
- `elliptic`
- `mutation_finite`

All four input keywords default values are None. If set to True or False, only these samples are returned.

EXAMPLES:

```

sage: QuiverMutationType.samples()
[['A', 1], ['A', 5], ['B', 2], ['B', 5], ['C', 3],
 ['C', 5], [ ['A', 1], ['A', 1] ], ['D', 5], ['E', 6],
 ['E', 7], ['E', 8], ['F', 4], ['G', 2],
 ['A', [1, 1], 1], ['A', [4, 5], 1], ['D', 4, 1],
 ['BB', 5, 1], ['E', 6, [1, 1]], ['E', 7, [1, 1]],
 ['R2', [1, 5]], ['R2', [3, 5]], ['E', 10], ['BE', 5],
 ['GR', [3, 10]], ['T', [3, 3, 4]]]

sage: QuiverMutationType.samples(finite=True)
[['A', 1], ['A', 5], ['B', 2], ['B', 5], ['C', 3],
 ['C', 5], [ ['A', 1], ['A', 1] ], ['D', 5], ['E', 6],
 ['E', 7], ['E', 8], ['F', 4], ['G', 2]]

sage: QuiverMutationType.samples(affine=True)
[['A', [1, 1], 1], ['A', [4, 5], 1], ['D', 4, 1], ['BB', 5, 1]]

sage: QuiverMutationType.samples(elliptic=True)
[['E', 6, [1, 1]], ['E', 7, [1, 1]]]

sage: QuiverMutationType.samples(mutation_finite=False)
[['R2', [1, 5]], ['R2', [3, 5]], ['E', 10], ['BE', 5],
 ['GR', [3, 10]], ['T', [3, 3, 4]]]

```

class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType_Irreducible(*letter*, *rank*, *twist=None*)

Bases: [sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType_abstract](#)

The mutation type for a cluster algebra or a quiver. Should not be called directly, but through QuiverMutationType.

class_size()

If it is known, the size of the mutation class of all quivers which are mutation equivalent to the standard quiver of *self* (up to isomorphism) is returned.

Otherwise, `NotImplemented` is returned.

Formula for finite type A is taken from Torildsen - Counting cluster-tilted algebras of type A_n . Formulas for affine type A and finite type D are taken from Bastian, Prellberg, Rubey, Stump - Counting the number of elements in the mutation classes of \tilde{A}_n quivers. Formulas for finite and affine types B and C are proven but not yet published. Conjectural formulas for several other non-simply-laced affine types are implemented. Exceptional Types (finite, affine, and elliptic) E, F, G, and X are hardcoded.

EXAMPLES:

```

sage: mut_type = QuiverMutationType( ['A',5] ); mut_type
['A', 5]
sage: mut_type.class_size()
19

sage: mut_type = QuiverMutationType( ['A',[10,3], 1] ); mut_type

```

(continues on next page)

(continued from previous page)

```

['A', [3, 10], 1]
sage: mut_type.class_size()
142120

sage: mut_type = QuiverMutationType( ['B',6] ); mut_type
['B', 6]
sage: mut_type.class_size()
132

sage: mut_type = QuiverMutationType( ['BD',6, 1] ); mut_type
['BD', 6, 1]
sage: mut_type.class_size()
Warning: This method uses a formula which has not been proved correct.
504

```

Check that [trac ticket #14048](#) is fixed:

```

sage: mut_type = QuiverMutationType( ['F',4,(2, 1)] )
sage: mut_type.class_size()
90

```

dual()

Return the `QuiverMutationType` which is dual to self.

EXAMPLES:

```

sage: mut_type = QuiverMutationType('A',5); mut_type
['A', 5]
sage: mut_type.dual()
['A', 5]

sage: mut_type = QuiverMutationType('B',5); mut_type
['B', 5]
sage: mut_type.dual()
['C', 5]
sage: mut_type.dual().dual()
['B', 5]
sage: mut_type.dual().dual() == mut_type
True

```

irreducible_components()

Return a list of all irreducible components of self.

EXAMPLES:

```

sage: mut_type = QuiverMutationType('A',3); mut_type
['A', 3]
sage: mut_type.irreducible_components()
(['A', 3],)

```

```

class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType_Reducible(*args)
    Bases:
        sage.combinat.cluster_algebra_quiver.quiver_mutation_type.
        QuiverMutationType_abstract

```

The mutation type for a cluster algebra or a quiver. Should not be called directly, but through `QuiverMutationType`. Inherits from `QuiverMutationType_abstract`.

`class_size()`

If it is known, the size of the mutation class of all quivers which are mutation equivalent to the standard quiver of `self` (up to isomorphism) is returned.

Otherwise, `NotImplemented` is returned.

EXAMPLES:

```
sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.class_size()
20

sage: mut_type = QuiverMutationType(['A',3],['B',3],['X',6])
sage: mut_type
[ ['A', 3], ['B', 3], ['X', 6] ]
sage: mut_type.class_size()
100
```

`dual()`

Return the `QuiverMutationType` which is dual to `self`.

EXAMPLES:

```
sage: mut_type = QuiverMutationType(['A',5],['B',6],['C',5],['D',4]); mut_type
[ ['A', 5], ['B', 6], ['C', 5], ['D', 4] ]
sage: mut_type.dual()
[ ['A', 5], ['C', 6], ['B', 5], ['D', 4] ]
```

`irreducible_components()`

Return a list of all irreducible components of `self`.

EXAMPLES:

```
sage: mut_type = QuiverMutationType('A',3); mut_type
['A', 3]
sage: mut_type.irreducible_components()
(['A', 3],)

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.irreducible_components()
(['A', 3], ['B', 3])

sage: mut_type = QuiverMutationType(['A',3],['B',3],['X',6])
sage: mut_type
[ ['A', 3], ['B', 3], ['X', 6] ]
sage: mut_type.irreducible_components()
(['A', 3], ['B', 3], ['X', 6])
```

`class`

`sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType_abstract`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.sage_object.SageObject`

EXAMPLES:

```
sage: mut_type1 = QuiverMutationType('A',5)
sage: mut_type2 = QuiverMutationType('A',5)
sage: mut_type3 = QuiverMutationType('A',6)
sage: mut_type1 == mut_type2
True
sage: mut_type1 == mut_type3
False
```

b_matrix()

Return the B-matrix of the standard quiver of self.

The conventions for B-matrices agree with Fomin-Zelevinsky (up to a reordering of the simple roots).

EXAMPLES:

```
sage: mut_type = QuiverMutationType( ['A',5] ); mut_type
['A', 5]
sage: mut_type.b_matrix()
[ 0  1  0  0  0]
[-1  0 -1  0  0]
[ 0  1  0  1  0]
[ 0  0 -1  0 -1]
[ 0  0  0  1  0]

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.b_matrix()
[ 0  1  0  0  0  0]
[-1  0 -1  0  0  0]
[ 0  1  0  0  0  0]
[ 0  0  0  0  1  0]
[ 0  0  0 -1  0 -1]
[ 0  0  0  0  2  0]
```

cartan_matrix()

Return the Cartan matrix of self.

Note that (up to a reordering of the simple roots) the convention for the definition of Cartan matrix, used here and elsewhere in Sage, agrees with the conventions of Kac, Fulton-Harris, and Fomin-Zelevinsky, but disagrees with the convention of Bourbaki. The (i, j) entry is $2(\alpha_i, \alpha_j)/(\alpha_i, \alpha_i)$.

EXAMPLES:

```
sage: mut_type = QuiverMutationType(['A',5]); mut_type
['A', 5]
sage: mut_type.cartan_matrix()
[ 2 -1  0  0  0]
[-1  2 -1  0  0]
[ 0 -1  2 -1  0]
[ 0  0 -1  2 -1]
[ 0  0  0 -1  2]

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[ ['A', 3], ['B', 3] ]
```

(continues on next page)

(continued from previous page)

```

sage: mut_type.cartan_matrix()
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2  0  0  0]
[ 0  0  0  2 -1  0]
[ 0  0  0 -1  2 -1]
[ 0  0  0  0 -2  2]

```

is_affine()

Return True if self is of affine type.

EXAMPLES:

```

sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_affine()
False

sage: mt = QuiverMutationType(['A', [4, 2], 1])
sage: mt.is_affine()
True

```

is_elliptic()

Return True if self is of elliptic type.

EXAMPLES:

```

sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_elliptic()
False

sage: mt = QuiverMutationType(['E', 6, [1, 1]])
sage: mt.is_elliptic()
True

```

is_finite()

Return True if self is of finite type.

This means that the cluster algebra associated to self has only a finite number of cluster variables.

EXAMPLES:

```

sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_finite()
True

sage: mt = QuiverMutationType(['A', [4, 2], 1])
sage: mt.is_finite()
False

```

is_irreducible()

Return True if self is irreducible.

EXAMPLES:

```
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_irreducible()
True
```

is_mutation_finite()

Return True if `self` is of finite mutation type.

This means that its mutation class has only finitely many different B-matrices.

EXAMPLES:

```
sage: mt = QuiverMutationType(['D', 5, 1])
sage: mt.is_mutation_finite()
True
```

is_simply_laced()

Return True if `self` is simply laced.

This means that the only arrows that appear in the quiver of `self` are single unlabelled arrows.

EXAMPLES:

```
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_simply_laced()
True

sage: mt = QuiverMutationType(['B', 2])
sage: mt.is_simply_laced()
False

sage: mt = QuiverMutationType(['A', (1, 1), 1])
sage: mt.is_simply_laced()
False
```

is_skew_symmetric()

Return True if the B-matrix of `self` is skew-symmetric.

EXAMPLES:

```
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_skew_symmetric()
True

sage: mt = QuiverMutationType(['B', 2])
sage: mt.is_skew_symmetric()
False

sage: mt = QuiverMutationType(['A', (1, 1), 1])
sage: mt.is_skew_symmetric()
True
```

letter()

Return the classification letter of `self`.

EXAMPLES:

```

sage: mut_type = QuiverMutationType( ['A',5] ); mut_type
['A', 5]
sage: mut_type.letter()
'A'

sage: mut_type = QuiverMutationType( ['BC',5, 1] ); mut_type
['BC', 5, 1]
sage: mut_type.letter()
'BC'

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.letter()
'A x B'

sage: mut_type = QuiverMutationType(['A',3],['B',3],['X',6]); mut_type
[ ['A', 3], ['B', 3], ['X', 6] ]
sage: mut_type.letter()
'A x B x X'

```

plot(*circular=False, directed=True*)

Return the plot of the underlying graph or digraph of self.

INPUT:

- *circular* – (default:False) if True, the circular plot is chosen, otherwise `>>spring<<` is used.
- *directed* – (default: True) if True, the directed version is shown, otherwise the undirected.

EXAMPLES:

```

sage: QMT = QuiverMutationType(['A',5])
sage: pl = QMT.plot()
sage: pl = QMT.plot(circular=True)

```

properties()

Print a scheme of all properties of self.

Most properties have natural definitions for either irreducible or reducible types. *affine* and *elliptic* are only defined for irreducible types.

EXAMPLES:

```

sage: mut_type = QuiverMutationType(['A',3]); mut_type
['A', 3]
sage: mut_type.properties()
['A', 3] has rank 3 and the following properties:
- irreducible:      True
- mutation finite:  True
- simply-laced:     True
- skew-symmetric:  True
- finite:           True
- affine:           False
- elliptic:         False

sage: mut_type = QuiverMutationType(['B',3]); mut_type

```

(continues on next page)

(continued from previous page)

```

['B', 3]
sage: mut_type.properties()
['B', 3] has rank 3 and the following properties:
- irreducible:      True
- mutation finite:  True
- simply-laced:     False
- skew-symmetric:  False
- finite:           True
- affine:           False
- elliptic:         False

sage: mut_type = QuiverMutationType(['B',3, 1]); mut_type
['BD', 3, 1]
sage: mut_type.properties()
['BD', 3, 1] has rank 4 and the following properties:
- irreducible:      True
- mutation finite:  True
- simply-laced:     False
- skew-symmetric:  False
- finite:           False
- affine:           True
- elliptic:         False

sage: mut_type = QuiverMutationType(['E',6,[1, 1]]); mut_type
['E', 6, [1, 1]]
sage: mut_type.properties()
['E', 6, [1, 1]] has rank 8 and the following properties:
- irreducible:      True
- mutation finite:  True
- simply-laced:     False
- skew-symmetric:  True
- finite:           False
- affine:           False
- elliptic:         True

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.properties()
[ ['A', 3], ['B', 3] ] has rank 6 and the following properties:
- irreducible:      False
- mutation finite:  True
- simply-laced:     False
- skew-symmetric:  False
- finite:           True

sage: mut_type = QuiverMutationType('GR',[4,9]); mut_type
['GR', [4, 9]]
sage: mut_type.properties()
['GR', [4, 9]] has rank 12 and the following properties:
- irreducible:      True
- mutation finite:  False
- simply-laced:     True

```

(continues on next page)

(continued from previous page)

```
- skew-symmetric:  True
- finite:          False
- affine:         False
- elliptic:       False
```

rank()

Return the rank in the standard quiver of `self`.

The rank is the number of vertices.

EXAMPLES:

```
sage: mut_type = QuiverMutationType( ['A',5] ); mut_type
['A', 5]
sage: mut_type.rank()
5

sage: mut_type = QuiverMutationType( ['A',[4,5], 1] ); mut_type
['A', [4, 5], 1]
sage: mut_type.rank()
9

sage: mut_type = QuiverMutationType( ['BC',5, 1] ); mut_type
['BC', 5, 1]
sage: mut_type.rank()
6

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.rank()
6

sage: mut_type = QuiverMutationType(['A',3],['B',3],['X',6]); mut_type
[ ['A', 3], ['B', 3], ['X', 6] ]
sage: mut_type.rank()
12
```

show(*circular=False, directed=True*)

Show the plot of the underlying digraph of `self`.

INPUT:

- `circular` – (default:False) if True, the circular plot is chosen, otherwise `>>spring<<` is used.
- `directed` – (default: True) if True, the directed version is shown, otherwise the undirected.

standard_quiver()

Return the standard quiver of `self`.

EXAMPLES:

```
sage: mut_type = QuiverMutationType( ['A',5] ); mut_type
['A', 5]
sage: mut_type.standard_quiver()
Quiver on 5 vertices of type ['A', 5]
```

(continues on next page)

(continued from previous page)

```

sage: mut_type = QuiverMutationType( ['A',[5,3], 1 ] ); mut_type
['A', [3, 5], 1]
sage: mut_type.standard_quiver()
Quiver on 8 vertices of type ['A', [3, 5], 1]

sage: mut_type = QuiverMutationType(['A',3],[ 'B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.standard_quiver()
Quiver on 6 vertices of type [ ['A', 3], ['B', 3] ]

sage: mut_type = QuiverMutationType(['A',3],[ 'B',3],[ 'X',6]); mut_type
[ ['A', 3], ['B', 3], ['X', 6] ]
sage: mut_type.standard_quiver()
Quiver on 12 vertices of type [ ['A', 3], ['B', 3], ['X', 6] ]

```

```

sage.combinat.cluster_algebra_quiver.quiver_mutation_type.save_quiver_data(n, up_to=True,
                                                                    types='ClassicalExceptional',
                                                                    verbose=True)

```

Save mutation classes of certain quivers of ranks up to and equal to n or equal to n to DOT_SAGE/cluster_algebra_quiver/mutation_classes_n.dig6.

This data will then be used to determine quiver mutation types.

INPUT:

- n : the rank (or the upper limit on the rank) of the mutation classes that are being saved.
- `up_to` – (default:True) if True, saves data for ranks smaller than or equal to n . If False, saves data for rank exactly n .
- `types` – (default:'ClassicalExceptional') if all, saves data for both exceptional mutation-finite quivers and for classical quiver. The input 'Exceptional' or 'Classical' is also allowed to save only part of this data.

5.1.22 Cluster complex (or generalized dual associahedron)

EXAMPLES:

A first example of a cluster complex:

```

sage: C = ClusterComplex(['A', 2]); C
Cluster complex of type ['A', 2] with 5 vertices and 5 facets

```

Its vertices, facets, and minimal non-faces:

```

sage: C.vertices()
(0, 1, 2, 3, 4)

sage: C.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

sage: for F in C.facets(): F.cluster()
[(-1, 0), (0, -1)]
[(-1, 0), (0, 1)]
[(0, -1), (1, 0)]

```

(continues on next page)

(continued from previous page)

```
[(1, 0), (1, 1)]
[(1, 1), (0, 1)]
```

```
sage: C.minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

We can do everything we can do on simplicial complexes, e.g. computing its homology:

```
sage: C.homology()
{0: 0, 1: Z}
```

AUTHORS:

- Christian Stump (2011) Initial version

class `sage.combinat.cluster_complex.ClusterComplex`($W, k, \text{coxeter_element}, \text{algorithm}$)

Bases: `sage.combinat.subword_complex.SubwordComplex`

A cluster complex (or generalized dual associahedron).

The cluster complex (or generalized dual associahedron) is a simplicial complex constructed from a cluster algebra. Its vertices are the cluster variables and its facets are the clusters, i.e., maximal subsets of compatible cluster variables.

The cluster complex of type A_n is the simplicial complex with vertices being (proper) diagonals in a convex $(n + 3)$ -gon and with facets being triangulations.

The implementation of the cluster complex depends on its connection to subword complexes, see [CLS2014]. Let c be a Coxeter element with reduced word c in a finite Coxeter group W , and let w_\circ be the c -sorting word for the longest element $w_\circ \in W$.

The multi-cluster complex $\Delta(W, k)$ has vertices in one-to-one correspondence with letters in the word $Q = c^k w_\circ$ and with facets being complements in Q of reduced expressions for w_\circ .

For $k = 1$, the multi-cluster complex is isomorphic to the cluster complex as defined above.

EXAMPLES:

A first example of a cluster complex:

```
sage: C = ClusterComplex(['A', 2]); C
Cluster complex of type ['A', 2] with 5 vertices and 5 facets
```

Its vertices, facets, and minimal non-faces:

```
sage: C.vertices()
(0, 1, 2, 3, 4)

sage: C.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

sage: C.minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

We can do everything we can do on simplicial complexes, e.g. computing its homology:

```
sage: C.homology()
{0: 0, 1: Z}
```

We can also create a multi-cluster complex:

```
sage: ClusterComplex(['A', 2], k=2)
Multi-cluster complex of type ['A', 2] with 7 vertices and 14 facets
```

REFERENCES:

- [CLS2014]

Element

alias of *ClusterComplexFacet*

cyclic_rotation()

Return the operation on the facets of *self* obtained by the cyclic rotation as defined in [CLS2014].

EXAMPLES:

```
sage: ClusterComplex(['A', 2]).cyclic_rotation()
<function ...act at ...>
```

k()

Return the index *k* of *self*.

EXAMPLES:

```
sage: ClusterComplex(['A', 2]).k()
1
```

minimal_nonfaces()

Return the minimal non-faces of *self*.

EXAMPLES:

```
sage: ClusterComplex(['A', 2]).minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

class `sage.combinat.cluster_complex.ClusterComplexFacet`(*parent, positions, facet_test=True*)

Bases: *sage.combinat.subword_complex.SubwordComplexFacet*

A cluster (i.e., a facet) of a cluster complex.

cluster()

Return this cluster as a set of almost positive roots.

EXAMPLES:

```
sage: C = ClusterComplex(['A', 2])
sage: F = C((0, 1))
sage: F.cluster()
[(-1, 0), (0, -1)]
```

product_of_upper_cluster()

Return the product of the upper cluster in reversed order.

EXAMPLES:

```
sage: C = ClusterComplex(['A', 2])
sage: for F in C: F.product_of_upper_cluster().reduced_word()
[]
```

(continues on next page)

(continued from previous page)

```
[2]
[1]
[1, 2]
[1, 2]
```

upper_cluster()

Return the part of the cluster that contains positive roots

EXAMPLES:

```
sage: C = ClusterComplex(['A', 2])
sage: F = C((0, 1))
sage: F.upper_cluster()
[]
```

5.1.23 Colored Permutations

Todo: Much of the colored permutations (and element) class can be generalized to $G \wr S_n$ **class** sage.combinat.colored_permutations.**ColoredPermutation**(parent, colors, perm)

Bases: sage.structure.element.MultiplicativeGroupElement

A colored permutation.

colors()

Return the colors of self.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: s1,s2,t = C.gens()
sage: x = s1*s2*t
sage: x.colors()
[1, 0, 0]
```

has_left_descent(i)

Return True if i is a left descent of self.

Let $p = ((s_1, \dots, s_n), \sigma)$ be a colored permutation. We say p has a left n -descent if $s_n > 0$. If $i < n$, then we say p has a left i -descent if either

- $s_i \neq 0, s_{i+1} = 0$ and $\sigma_i < \sigma_{i+1}$ or
- $s_i = s_{i+1}$ and $\sigma_i > \sigma_{i+1}$.

This notion of a left i -descent is done in order to recursively construct $w(p) = \sigma_i w(\sigma_i^{-1} p)$, where $w(p)$ denotes a reduced word of p .

EXAMPLES:

```
sage: C = ColoredPermutations(2, 4)
sage: s1,s2,s3,s4 = C.gens()
sage: x = s4*s1*s2*s3*s4
sage: [x.has_left_descent(i) for i in C.index_set()]
```

(continues on next page)

(continued from previous page)

```
[True, False, False, True]

sage: C = ColoredPermutations(1, 5)
sage: s1,s2,s3,s4 = C.gens()
sage: x = s4*s1*s2*s3*s4
sage: [x.has_left_descent(i) for i in C.index_set()]
[True, False, False, True]

sage: C = ColoredPermutations(3, 3)
sage: x = C([[2,1,0],[3,1,2]])
sage: [x.has_left_descent(i) for i in C.index_set()]
[False, True, False]

sage: C = ColoredPermutations(4, 4)
sage: x = C([[2,1,0,1],[3,2,4,1]])
sage: [x.has_left_descent(i) for i in C.index_set()]
[False, True, False, True]
```

inverse()

Return the inverse of self.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: s1,s2,t = C.gens()
sage: ~t
[[0, 0, 3], [1, 2, 3]]
sage: all(x * ~x == C.one() for x in C.gens())
True
```

length()

Return the length of self in generating reflections.

This is the minimal numbers of generating reflections needed to obtain self.

EXAMPLES:

```
sage: C = ColoredPermutations(3, 3)
sage: x = C([[2,1,0],[3,1,2]])
sage: x.length()
7

sage: C = ColoredPermutations(4, 4)
sage: x = C([[2,1,0,1],[3,2,4,1]])
sage: x.length()
12
```

one_line_form()

Return the one line form of self.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: s1,s2,t = C.gens()
sage: x = s1*s2*t
```

(continues on next page)

(continued from previous page)

```
sage: x
[[1, 0, 0], [3, 1, 2]]
sage: x.one_line_form()
[(1, 3), (0, 1), (0, 2)]
```

permutation()

Return the permutation of `self`.

This is obtained by forgetting the colors.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: s1,s2,t = C.gens()
sage: x = s1*s2*t
sage: x.permutation()
[3, 1, 2]
```

reduced_word()

Return a word in the simple reflections to obtain `self`.

EXAMPLES:

```
sage: C = ColoredPermutations(3, 3)
sage: x = C([[2,1,0],[3,1,2]])
sage: x.reduced_word()
[2, 1, 3, 2, 1, 3, 3]

sage: C = ColoredPermutations(4, 4)
sage: x = C([[2,1,0,1],[3,2,4,1]])
sage: x.reduced_word()
[2, 1, 4, 3, 2, 1, 4, 3, 2, 4, 4, 3]
```

to_matrix()

Return a matrix of `self`.

The colors are mapped to roots of unity.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: s1,s2,t = C.gens()
sage: x = s1*s2*t*s2; x.one_line_form()
[(1, 2), (0, 1), (0, 3)]
sage: M = x.to_matrix(); M
[  0  1  0]
[zeta4  0  0]
[  0  0  1]
```

The matrix multiplication is in the *opposite* order:

```
sage: M == s2.to_matrix()*t.to_matrix()*s2.to_matrix()*s1.to_matrix()
True
```

class `sage.combinat.colored_permutations.ColoredPermutations`(m, n)

Bases: `sage.structure.parent.Parent`, `sage.structure.unique_representation.UniqueRepresentation`

The group of m -colored permutations on $\{1, 2, \dots, n\}$.

Let S_n be the symmetric group on n letters and C_m be the cyclic group of order m . The m -colored permutation group on n letters is given by $P_n^m = C_m \wr S_n$. This is also the complex reflection group $G(m, 1, n)$.

We define our multiplication by

$$((s_1, \dots, s_n), \sigma) \cdot ((t_1, \dots, t_n), \tau) = ((s_1 t_{\sigma(1)}, \dots, s_n t_{\sigma(n)}), \tau \sigma).$$

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3); C
4-colored permutations of size 3
sage: s1,s2,t = C.gens()
sage: (s1, s2, t)
([[0, 0, 0], [2, 1, 3]], [[0, 0, 0], [1, 3, 2]], [[0, 0, 1], [1, 2, 3]])
sage: s1*s2
[[0, 0, 0], [3, 1, 2]]
sage: s1*s2*s1 == s2*s1*s2
True
sage: t^4 == C.one()
True
sage: s2*t*s2
[[0, 1, 0], [1, 2, 3]]
```

We can also create a colored permutation by passing either a list of tuples consisting of (color, element):

```
sage: x = C([(2,1), (3,3), (3,2)]); x
[[2, 3, 3], [1, 3, 2]]
```

or a list of colors and a permutation:

```
sage: C([[3,3,1], [1,3,2]])
[[3, 3, 1], [1, 3, 2]]
```

There is also the natural lift from permutations:

```
sage: P = Permutations(3)
sage: C(P.an_element())
[[0, 0, 0], [3, 1, 2]]
```

REFERENCES:

- [Wikipedia article Generalized_symmetric_group](#)
- [Wikipedia article Complex_reflection_group](#)

Element

alias of `ColoredPermutation`

as_permutation_group()

Return the permutation group corresponding to self.

EXAMPLES:

```

sage: C = ColoredPermutations(4, 3)
sage: C.as_permutation_group()
Complex reflection group G(4, 1, 3) as a permutation group

```

cardinality()

Return the cardinality of self.

EXAMPLES:

```

sage: C = ColoredPermutations(4, 3)
sage: C.cardinality()
384
sage: C.cardinality() == 4**3 * factorial(3)
True

```

codegrees()

Return the codegrees of self.

Let G be a complex reflection group. The codegrees $d_1^* \leq d_2^* \leq \dots \leq d_\ell^*$ of G can be defined by:

$$\prod_{i=1}^{\ell} (q - d_i^* - 1) = \sum_{g \in G} \det(g) q^{\dim(V^g)},$$

where V is the natural complex vector space that G acts on and ℓ is the `rank()`.

If $m = 1$, then we are in the special case of the symmetric group and the codegrees are $(n-2, n-3, \dots, 1, 0)$. Otherwise the degrees are $((n-1)m, (n-2)m, \dots, m, 0)$.

EXAMPLES:

```

sage: C = ColoredPermutations(4, 3)
sage: C.codegrees()
(8, 4, 0)
sage: S = ColoredPermutations(1, 3)
sage: S.codegrees()
(1, 0)

```

coxeter_matrix()

Return the Coxeter matrix of self.

EXAMPLES:

```

sage: C = ColoredPermutations(3, 4)
sage: C.coxeter_matrix()
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]

sage: C = ColoredPermutations(1, 4)
sage: C.coxeter_matrix()
[1 3 2]
[3 1 3]
[2 3 1]

```

degrees()

Return the degrees of self.

The degrees of a complex reflection group are the degrees of the fundamental invariants of the ring of polynomial invariants.

If $m = 1$, then we are in the special case of the symmetric group and the degrees are $(2, 3, \dots, n, n + 1)$. Otherwise the degrees are $(m, 2m, \dots, nm)$.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: C.degrees()
(4, 8, 12)
sage: S = ColoredPermutations(1, 3)
sage: S.degrees()
(2, 3)
```

We now check that the product of the degrees is equal to the cardinality of `self`:

```
sage: prod(C.degrees()) == C.cardinality()
True
sage: prod(S.degrees()) == S.cardinality()
True
```

`fixed_point_polynomial` ($q=None$)

The fixed point polynomial of `self`.

The fixed point polynomial f_G of a complex reflection group G is counting the dimensions of fixed points subspaces:

$$f_G(q) = \sum_{w \in W} q^{\dim V^w}.$$

Furthermore, let d_1, d_2, \dots, d_ℓ be the degrees of G , where ℓ is the `rank`. Then the fixed point polynomial is given by

$$f_G(q) = \prod_{i=1}^{\ell} (q + d_i - 1).$$

INPUT:

- q – (default: the generator of `ZZ['q']`) the parameter q

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: C.fixed_point_polynomial()
q^3 + 21*q^2 + 131*q + 231

sage: S = ColoredPermutations(1, 3)
sage: S.fixed_point_polynomial()
q^2 + 3*q + 2
```

`gens`

Return the generators of `self`.

EXAMPLES:

```

sage: C = ColoredPermutations(4, 3)
sage: C.gens()
([[0, 0, 0], [2, 1, 3]],
 [[0, 0, 0], [1, 3, 2]],
 [[0, 0, 1], [1, 2, 3]])

sage: S = SignedPermutations(4)
sage: S.gens()
([2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3], [1, 2, 3, -4])

```

index_set()

Return the index set of self.

EXAMPLES:

```

sage: C = ColoredPermutations(3, 4)
sage: C.index_set()
(1, 2, 3, 4)

sage: C = ColoredPermutations(1, 4)
sage: C.index_set()
(1, 2, 3)

```

is_well_generated()

Return if self is a well-generated complex reflection group.

A complex reflection group G is well-generated if it is generated by ℓ reflections. Equivalently, G is well-generated if $d_i + d_i^* = d_\ell$ for all $1 \leq i \leq \ell$.

EXAMPLES:

```

sage: C = ColoredPermutations(4, 3)
sage: C.is_well_generated()
True
sage: C = ColoredPermutations(2, 8)
sage: C.is_well_generated()
True
sage: C = ColoredPermutations(1, 4)
sage: C.is_well_generated()
True

```

matrix_group()

Return the matrix group corresponding to self.

EXAMPLES:

```

sage: C = ColoredPermutations(4, 3)
sage: C.matrix_group()
Matrix group over Cyclotomic Field of order 4 and degree 2 with 3 generators (
[0 1 0] [1 0 0] [ 1 0 0]
[1 0 0] [0 0 1] [ 0 1 0]
[0 0 1], [0 1 0], [ 0 0 zeta4]
)

```

number_of_reflection_hyperplanes()

Return the number of reflection hyperplanes of self.

The number of reflection hyperplanes of a complex reflection group is equal to the sum of the codegrees plus the rank.

EXAMPLES:

```
sage: C = ColoredPermutations(1, 2)
sage: C.number_of_reflection_hyperplanes()
1
sage: C = ColoredPermutations(1, 3)
sage: C.number_of_reflection_hyperplanes()
3
sage: C = ColoredPermutations(4, 12)
sage: C.number_of_reflection_hyperplanes()
276
```

one()

Return the identity element of `self`.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: C.one()
[[0, 0, 0], [1, 2, 3]]
```

order()

Return the cardinality of `self`.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: C.cardinality()
384
sage: C.cardinality() == 4**3 * factorial(3)
True
```

rank()

Return the rank of `self`.

The rank of a complex reflection group is equal to the dimension of the complex vector space the group acts on.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 12)
sage: C.rank()
12
sage: C = ColoredPermutations(7, 4)
sage: C.rank()
4
sage: C = ColoredPermutations(1, 4)
sage: C.rank()
3
```

simple_reflection(*i*)

Return the *i*-th simple reflection of `self`.

EXAMPLES:

```

sage: C = ColoredPermutations(4, 3)
sage: C.gens()
([[0, 0, 0], [2, 1, 3]], [[0, 0, 0], [1, 3, 2]], [[0, 0, 1], [1, 2, 3]])
sage: C.simple_reflection(2)
[[0, 0, 0], [1, 3, 2]]
sage: C.simple_reflection(3)
[[0, 0, 1], [1, 2, 3]]

sage: S = SignedPermutations(4)
sage: S.simple_reflection(1)
[2, 1, 3, 4]
sage: S.simple_reflection(4)
[1, 2, 3, -4]

```

class sage.combinat.colored_permutations.**SignedPermutation**(parent, colors, perm)
 Bases: *sage.combinat.colored_permutations.ColoredPermutation*

A signed permutation.

has_left_descent(i)

Return True if i is a left descent of self.

EXAMPLES:

```

sage: S = SignedPermutations(4)
sage: s1,s2,s3,s4 = S.gens()
sage: x = s4*s1*s2*s3*s4
sage: [x.has_left_descent(i) for i in S.index_set()]
[True, False, False, True]

```

inverse()

Return the inverse of self.

EXAMPLES:

```

sage: S = SignedPermutations(4)
sage: s1,s2,s3,s4 = S.gens()
sage: x = s4*s1*s2*s3*s4
sage: ~x
[2, 3, -4, -1]
sage: x * ~x == S.one()
True

```

order()

Return the multiplicative order of the signed permutation.

EXAMPLES:

```

sage: pi = SignedPermutations(7)([2,-1,4,-6,-5,-3,7])
sage: pi.to_cycles(singletons=False)
[(1, 2, -1, -2), (3, 4, -6), (5, -5)]
sage: pi.order()
12

```

to_cycles(singletons=True, use_min=True, negative_singletons=True)

Return the signed permutation self as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest positive element. We do not include the corresponding negative cycles.

INPUT:

- `singletons` – (default: `True`) whether to include singleton cycles or not
- `use_min` – (default: `True`) if `False`, the cycles are returned in the order of increasing *largest* (not smallest) elements, and each cycle starts with its largest element

EXAMPLES:

```
sage: pi = SignedPermutations(7)([2,-1,4,-6,-5,-3,7])
sage: pi.to_cycles()
[(1, 2, -1, -2), (3, 4, -6), (5, -5), (7,)]
sage: pi.to_cycles(singletons=False)
[(1, 2, -1, -2), (3, 4, -6), (5, -5)]
sage: pi.to_cycles(use_min=False)
[(7,), (6, -3, -4), (5, -5), (2, -1, -2, 1)]
sage: pi.to_cycles(singletons=False, use_min=False)
[(6, -3, -4), (5, -5), (2, -1, -2, 1)]
```

to_matrix()

Return a matrix of `self`.

EXAMPLES:

```
sage: S = SignedPermutations(4)
sage: s1,s2,s3,s4 = S.gens()
sage: x = s4*s1*s2*s3*s4
sage: M = x.to_matrix(); M
[ 0  1  0  0]
[ 0  0  1  0]
[ 0  0  0 -1]
[-1  0  0  0]
```

The matrix multiplication is in the *opposite* order:

```
sage: m1,m2,m3,m4 = [g.to_matrix() for g in S.gens()]
sage: M == m4 * m3 * m2 * m1 * m4
True
```

class `sage.combinat.colored_permutations.SignedPermutations(n)`

Bases: `sage.combinat.colored_permutations.ColoredPermutations`

Group of signed permutations.

The group of signed permutations is also known as the hyperoctahedral group, the Coxeter group of type B_n , and the 2-colored permutation group. Thus it can be constructed as the wreath product $S_2 \wr S_n$.

EXAMPLES:

```
sage: S = SignedPermutations(4)
sage: s1,s2,s3,s4 = S.group_generators()
sage: x = s4*s1*s2*s3*s4; x
[-4, 1, 2, -3]
sage: x^4 == S.one()
True
```

This is a finite Coxeter group of type B_n :

```
sage: S.canonical_representation()
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 2 with a.
↪= 1.414213562373095? with Coxeter matrix:
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: S.long_element()
[-1, -2, -3, -4]
sage: S.long_element().reduced_word()
[1, 2, 1, 3, 2, 1, 4, 3, 2, 1, 4, 3, 2, 4, 3, 4]
```

We can also go between the 2-colored permutation group:

```
sage: C = ColoredPermutations(2, 3)
sage: S = SignedPermutations(3)
sage: S.an_element()
[-3, 1, 2]
sage: C(S.an_element())
[[1, 0, 0], [3, 1, 2]]
sage: S(C(S.an_element())) == S.an_element()
True
sage: S(C.an_element())
[-3, 1, 2]
```

There is also the natural lift from permutations:

```
sage: P = Permutations(3)
sage: x = S(P.an_element()); x
[3, 1, 2]
sage: x.parent()
Signed permutations of 3
```

REFERENCES:

- [Wikipedia article Hyperoctahedral_group](#)

Element

alias of *SignedPermutation*

long_element(*index_set=None*)

Return the longest element of *self*, or of the parabolic subgroup corresponding to the given *index_set*.

INPUT:

- *index_set* – (optional) a subset (as a list or iterable) of the nodes of the indexing set

EXAMPLES:

```
sage: S = SignedPermutations(4)
sage: S.long_element()
[-1, -2, -3, -4]
```

one()

Return the identity element of *self*.

EXAMPLES:

```
sage: S = SignedPermutations(4)
sage: S.one()
[1, 2, 3, 4]
```

simple_reflection(*i*)

Return the *i*-th simple reflection of self.

EXAMPLES:

```
sage: S = SignedPermutations(4)
sage: S.simple_reflection(1)
[2, 1, 3, 4]
sage: S.simple_reflection(4)
[1, 2, 3, -4]
```

5.1.24 Combinatorial Functions

This module implements some combinatorial functions, as listed below. For a more detailed description, see the relevant docstrings.

Sequences:

- Bell numbers, `bell_number()`
- Catalan numbers, `catalan_number()` (not to be confused with the Catalan constant)
- Narayana numbers, `narayana_number()`
- Euler numbers, `euler_number()` (Maxima)
- Eulerian numbers, `eulerian_number()`
- Eulerian polynomial, `eulerian_polynomial()`
- Fibonacci numbers, `fibonacci()` (PARI) and `fibonacci_number()` (GAP) The PARI version is better.
- Lucas numbers, `lucas_number1()`, `lucas_number2()`.
- Stirling numbers, `stirling_number1()`, `stirling_number2()`.
- Polygonal numbers, `polygonal_number()`

Set-theoretic constructions:

- Derangements of a multiset, `derangements()` and `number_of_derangements()`.
- Tuples of a multiset, `tuples()` and `number_of_tuples()`. An ordered tuple of length *k* of set *S* is a ordered selection with repetitions of *S* and is represented by a sorted list of length *k* containing elements from *S*.
- Unordered tuples of a set, `unordered_tuples()` and `number_of_unordered_tuples()`. An unordered tuple of length *k* of set *S* is an unordered selection with repetitions of *S* and is represented by a sorted list of length *k* containing elements from *S*.

Warning: The following function is deprecated and will soon be removed.

- Permutations of a multiset, `permutations()`, `permutations_iterator()`, `number_of_permutations()`. A permutation is a list that contains exactly the same elements but possibly in different order.

Related functions:

- Bernoulli polynomials, `bernoulli_polynomial()`

Implemented in other modules (listed for completeness):

The `sage.arith.all` module contains the following combinatorial functions:

- `binomial` the binomial coefficient (wrapped from PARI)
- `factorial` (wrapped from PARI)
- `partition` (from the Python Cookbook) Generator of the list of all the partitions of the integer n .
- `number_of_partitions()` (wrapped from PARI) the *number* of partitions:
- `falling_factorial()` Definition: for integer $a \geq 0$ we have $x(x-1)\cdots(x-a+1)$. In all other cases we use the GAMMA-function: $\frac{\Gamma(x+1)}{\Gamma(x-a+1)}$.
- `rising_factorial()` Definition: for integer $a \geq 0$ we have $x(x+1)\cdots(x+a-1)$. In all other cases we use the GAMMA-function: $\frac{\Gamma(x+a)}{\Gamma(x)}$.
- `gaussian_binomial` the gaussian binomial

$$\binom{n}{k}_q = \frac{(1-q^n)(1-q^{n-1})\cdots(1-q^{n-r+1})}{(1-q)(1-q^2)\cdots(1-q^r)}.$$

The `sage.groups.perm_gps.permgroup_elements` contains the following combinatorial functions:

- `matrix` method of `PermutationGroupElement` yielding the permutation matrix of the group element.

Todo:**GUAVA commands:**

- `VandermondeMat`
- `GrayMat` returns a list of all different vectors of length n over the field F , using Gray ordering.

Not in GAP:

- `Rencontres numbers` ([Wikipedia article Rencontres_number](#))
-

Functions and classes

class `sage.combinat.combinat.CombinatorialClass`(*category=None*)

Bases: `sage.structure.parent.Parent`

This class is deprecated, and will disappear as soon as all derived classes in Sage's library will have been fixed. Please derive directly from `Parent` and use the category `EnumeratedSets`, `FiniteEnumeratedSets`, or `InfiniteEnumeratedSets`, as appropriate.

For examples, see:

```
sage: FiniteEnumeratedSets().example()
An example of a finite enumerated set: {1,2,3}
sage: InfiniteEnumeratedSets().example()
An example of an infinite enumerated set: the non negative integers
```

Element

alias of `CombinatorialObject`

cardinality()

Default implementation of cardinality which just goes through the iterator of the combinatorial class to count the number of objects.

EXAMPLES:

```
sage: class C(CombinatorialClass):
.....:     def __iter__(self):
.....:         return iter([1,2,3])
sage: C().cardinality() #indirect doctest
3
```

element_class()

This function is a temporary helper so that a `CombinatorialClass` behaves as a parent for creating elements. This will disappear when combinatorial classes will be turned into actual parents (in the category `EnumeratedSets`).

filter(*f*, *name=None*)

Return the combinatorial subclass of `f` which consists of the elements `x` of `self` such that `f(x)` is `True`.

EXAMPLES:

```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).filter(lambda x: x.avoids([1,2]))
sage: P.list()
[[3, 2, 1]]
```

first()

Default implementation for `first` which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.first() # indirect doctest
1
```

is_finite()

Return whether `self` is finite or not.

EXAMPLES:

```
sage: Partitions(5).is_finite()
True
sage: Permutations().is_finite()
False
```

last()

Default implementation for first which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.last() # indirect doctest
3
```

list()

The default implementation of list which builds the list from the iterator.

EXAMPLES:

```
sage: class C(CombinatorialClass):
.....:     def __iter__(self):
.....:         return iter([1,2,3])
sage: C().list() #indirect doctest
[1, 2, 3]
```

map(*f*, *name*, *is_injective*=None)

Return the image $\{f(x)|x \in \text{self}\}$ of this combinatorial class by *f*, as a combinatorial class.

INPUT:

- *is_injective* – boolean (default: True) whether to assume that *f* is injective.

EXAMPLES:

```
sage: R = Permutations(3).map(attrcall('reduced_word')); R
Image of Standard permutations of 3 by The map *.reduced_word() from Standard_
↳permutations of 3
sage: R.cardinality()
6
sage: R.list()
[[], [2], [1], [1, 2], [2, 1], [2, 1, 2]]
sage: [ r for r in R]
[[], [2], [1], [1, 2], [2, 1], [2, 1, 2]]
```

If the function is not injective, then there may be repeated elements:

```
sage: P = Partitions(4)
sage: P.list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: P.map(len).list()
[1, 2, 2, 3, 4]
```

Use *is_injective*=False to get a correct result in this case:

```
sage: P.map(len, is_injective=False).list()
[1, 2, 3, 4]
```

next(*obj*)

Default implementation for next which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.next(2) # indirect doctest
3
```

previous(*obj*)

Default implementation for next which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.previous(2) # indirect doctest
1
```

random_element()

Default implementation of random which uses unrank.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.random_element() # random # indirect doctest
1
```

rank(*obj*)

Default implementation of rank which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.rank(3) # indirect doctest
2
```

union(*right_cc*, *name=None*)

Return the combinatorial class representing the union of *self* and *right_cc*.

EXAMPLES:

```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(2).union(Permutations_CC(1))
sage: P.list()
[[1, 2], [2, 1], [1]]
```

unrank(*r*)

Default implementation of unrank which goes through the iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.unrank(1) # indirect doctest
2
```

```
class sage.combinat.combinat.CombinatorialElement(parent, *args, **kwargs)
```

Bases: `sage.combinat.combinat.CombinatorialObject`, `sage.structure.element.Element`

`CombinatorialElement` is both a `CombinatorialObject` and an `Element`. So it represents a list which is an element of some parent.

A `CombinatorialElement` subclass also automatically supports the `__classcall__` mechanism.

Warning: This class is slowly being deprecated. Use `ClonableList` instead.

INPUT:

- `parent` – the `Parent` class for this element.
- `lst` – a list or any object that can be converted to a list by calling `list()`.

EXAMPLES:

```
sage: from sage.combinat.combinat import CombinatorialElement
sage: e = CombinatorialElement(Partitions(6), [3,2,1])
sage: e == loads(dumps(e))
True
sage: parent(e)
Partitions of the integer 6
sage: list(e)
[3, 2, 1]
```

Check classcalls:

```
sage: class Foo(CombinatorialElement):
.....:     @staticmethod
.....:     def __classcall__(cls, x):
.....:         return x
sage: Foo(17)
17
```

```
class sage.combinat.combinat.CombinatorialObject(l, copy=True)
```

Bases: `sage.structure.sage_object.SageObject`

`CombinatorialObject` provides a thin wrapper around a list. The main differences are that `__setitem__` is disabled so that `CombinatorialObjects` are shallowly immutable, and the intention is that they are semantically immutable.

Because of this, `CombinatorialObjects` provide a `__hash__` function which computes the hash of the string representation of a list and the hash of its parent's class. Thus, each `CombinatorialObject` should have a unique string representation.

See also:

`CombinatorialElement` if you want a combinatorial object which is an element of a parent.

Warning: This class is slowly being deprecated. Use `ClonableList` instead.

INPUT:

- `l` – a list or any object that can be converted to a list by calling `list()`.
- `copy` – (boolean, default `True`) if `False`, then `l` must be a list, which is assigned to `self._list` without copying.

EXAMPLES:

```
sage: c = CombinatorialObject([1,2,3])
sage: c == loads(dumps(c))
True
sage: c._list
[1, 2, 3]
sage: c._hash is None
True
```

For efficiency, you can specify `copy=False` if you know what you are doing:

```
sage: from sage.combinat.combinat import CombinatorialObject
sage: x = [3, 2, 1]
sage: C = CombinatorialObject(x, copy=False)
sage: C
[3, 2, 1]
sage: x[0] = 5
sage: C
[5, 2, 1]
```

index(*key*)

EXAMPLES:

```
sage: c = CombinatorialObject([1,2,3])
sage: c.index(1)
0
sage: c.index(3)
2
```

class `sage.combinat.combinat.FilteredCombinatorialClass`(*combinatorial_class*, *f*, *name=None*)

Bases: `sage.combinat.combinat.CombinatorialClass`

A filtered combinatorial class `F` is a subset of another combinatorial class `C` specified by a function `f` that takes in an element `c` of `C` and returns `True` if and only if `c` is in `F`.

cardinality()

EXAMPLES:

```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).filter(lambda x: x.avoids([1,2]))
sage: P.cardinality()
1
```

class `sage.combinat.combinat.InfiniteAbstractCombinatorialClass`(*category=None*)

Bases: `sage.combinat.combinat.CombinatorialClass`

This is an internal class that should not be used directly. A class which inherits from `InfiniteAbstractCombinatorialClass` inherits the standard methods `list` and `count`.

If `self._infinite_cclass_slice` exists then `self.__iter__` returns an iterator for `self`, otherwise raise `NotImplementedError`. The method `self._infinite_cclass_slice` is supposed to accept any integer as an argument and return something which is iterable.

cardinality()

Count the elements of the combinatorial class.

EXAMPLES:

```
sage: R = InfiniteAbstractCombinatorialClass()
doctest:warning...
DeprecationWarning: this class is deprecated, do not use
See https://trac.sagemath.org/31545 for details.

sage: R.cardinality()
+Infinity
```

list()

Return an error since `self` is an infinite combinatorial class.

EXAMPLES:

```
sage: R = InfiniteAbstractCombinatorialClass()
sage: R.list()
Traceback (most recent call last):
...
NotImplementedError: infinite list
```

class `sage.combinat.combinat.MapCombinatorialClass(cc, f, name, is_injective=None)`

Bases: `sage.sets.image_set.ImageSubobject`, `sage.combinat.combinat.CombinatorialClass`

The image of a combinatorial class through a function.

INPUT:

- `is_injective` – boolean (default: `True`) whether to assume that `f` is injective.

See `CombinatorialClass.map()` for examples

EXAMPLES:

```
sage: R = SymmetricGroup(10).map(attrcall('reduced_word'))
sage: R.an_element()
[9, 8, 7, 6, 5, 4, 3, 2]
sage: R.cardinality()
3628800
sage: i = iter(R)
sage: next(i), next(i), next(i)
([], [1, 2, 3, 4, 5, 6, 7, 8, 9], [1])
```

class `sage.combinat.combinat.Permutations_CC(n)`

Bases: `sage.combinat.combinat.CombinatorialClass`

A testing class for `CombinatorialClass` since `Permutations` no longer inherits from `CombinatorialClass` in trac ticket #14772.

class `sage.combinat.combinat.UnionCombinatorialClass`(*left_cc, right_cc, name=None*)
 Bases: `sage.combinat.combinat.CombinatorialClass`

A UnionCombinatorialClass is a union of two other combinatorial classes.

cardinality()

EXAMPLES:

```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.cardinality()
8
```

first()

EXAMPLES:

```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.first()
[1, 2, 3]
```

last()

EXAMPLES:

```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.last()
[2, 1]
```

list()

EXAMPLES:

```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.list()
[[1, 2, 3],
 [1, 3, 2],
 [2, 1, 3],
 [2, 3, 1],
 [3, 1, 2],
 [3, 2, 1],
 [1, 2],
 [2, 1]]
```

rank(*x*)

EXAMPLES:

```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.rank(Permutation([2,1]))
7
sage: P.rank(Permutation([1,2,3]))
0
```

unrank(*x*)

EXAMPLES:

```

sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.unrank(7)
[2, 1]
sage: P.unrank(0)
[1, 2, 3]

```

`sage.combinat.combinat.bell_number`(n , *algorithm*='flint', ***options*)

Return the n -th Bell number.

This is the number of ways to partition a set of n elements into pairwise disjoint nonempty subsets.

INPUT:

- n – a positive integer
- *algorithm* – (Default: 'flint') any one of the following:
 - 'dobinski' – Use Dobinski's formula implemented in Sage
 - 'flint' – Wrap FLINT's `arith_bell_number`
 - 'gap' – Wrap GAP's Bell
 - 'mpmath' – Wrap `mpmath`'s `bell`

Warning: When using the `mpmath` algorithm to compute Bell numbers and you specify `prec`, it can return incorrect results due to low precision. See the examples section.

Let B_n denote the n -th Bell number. Dobinski's formula is:

$$B_n = e^{-1} \sum_{k=0}^{\infty} \frac{k^n}{k!}.$$

To show our implementation of Dobinski's method works, suppose that $n \geq 5$ and let k_0 be the smallest positive integer such that $\frac{k_0^n}{k_0!} < 1$. Note that $k_0 > n$ and $k_0 \leq 2n$ because we can prove that $\frac{(2n)^n}{(2n)!} < 1$ by Stirling.

If $k > k_0$, then we have $\frac{k^n}{k!} < \frac{1}{2^{k-k_0}}$. We show this by induction: let $c_k = \frac{k^n}{k!}$, if $k > n$ then

$$\frac{c_{k+1}}{c_k} = \frac{(1+k^{-1})^n}{k+1} < \frac{(1+n^{-1})^n}{n} < \frac{1}{2}.$$

The last inequality can easily be checked numerically for $n \geq 5$.

Using this, we can see that $\frac{c_k}{c_{k_0}} < \frac{1}{2^{k-k_0}}$ for $k > k_0 > n$. So summing this it gives that $\sum_{k=k_0+1}^{\infty} \frac{k^n}{k!} < 1$, and hence

$$B_n = e^{-1} \left(\sum_{k=0}^{k_0} \frac{k^n}{k!} + E_1 \right) = e^{-1} \sum_{k=0}^{k_0} \frac{k^n}{k!} + E_2,$$

where $0 < E_1 < 1$ and $0 < E_2 < e^{-1}$. Next we have for any $q > 0$

$$\sum_{k=0}^{k_0} \frac{k^n}{k!} = \frac{1}{q} \sum_{k=0}^{k_0} \left\lfloor \frac{qk^n}{k!} \right\rfloor + \frac{E_3}{q}$$

where $0 \leq E_3 \leq k_0 + 1 \leq 2n + 1$. Let $E_4 = \frac{E_3}{q}$ and let $q = 2n + 1$. We find $0 \leq E_4 \leq 1$. These two bounds give:

$$\begin{aligned} B_n &= \frac{e^{-1}}{q} \sum_{k=0}^{k_0} \left\lfloor \frac{qk^n}{k!} \right\rfloor + e^{-1}E_4 + E_2 \\ &= \frac{e^{-1}}{q} \sum_{k=0}^{k_0} \left\lfloor \frac{qk^n}{k!} \right\rfloor + E_5 \end{aligned}$$

where

$$0 < E_5 = e^{-1}E_4 + E_2 \leq e^{-1} + e^{-1} < \frac{3}{4}.$$

It follows that

$$B_n = \left\lceil \frac{e^{-1}}{q} \sum_{k=0}^{k_0} \left\lfloor \frac{qk^n}{k!} \right\rfloor \right\rceil.$$

Now define

$$b = \sum_{k=0}^{k_0} \left\lfloor \frac{qk^n}{k!} \right\rfloor.$$

This b can be computed exactly using integer arithmetic. To avoid the costly integer division by $k!$, we collect more terms and do only one division, for example with 3 terms:

$$\frac{k^n}{k!} + \frac{(k+1)^n}{(k+1)!} + \frac{(k+2)^n}{(k+2)!} = \frac{k^n(k+1)(k+2) + (k+1)^n(k+2) + (k+2)^n}{(k+2)!}$$

In the implementation, we collect $\sqrt{n}/2$ terms.

To actually compute B_n from b , we let $p = \lceil \log_2(b) \rceil + 1$ such that $b < 2^p$ and we compute with p bits of precision. This implies that b (and $q < b$) can be represented exactly.

We compute $\frac{e^{-1}}{q}b$, rounding down, and we must have an absolute error of at most $1/4$ (given that $E_5 < 3/4$). This means that we need a relative error of at most

$$\frac{eq}{4b} > \frac{(eq)/4}{2^p} > \frac{7}{2^p}$$

(assuming $n \geq 5$). With a precision of p bits and rounding down, every rounding has a relative error of at most $2^{1-p} = 2/2^p$. Since we do 3 roundings (b and q do not require rounding), we get a relative error of at most $6/2^p$. All this implies that the precision of p bits is sufficient.

EXAMPLES:

```
sage: bell_number(10)
115975
sage: bell_number(2)
2
sage: bell_number(-10)
Traceback (most recent call last):
...
ArithmeticError: Bell numbers not defined for negative indices
sage: bell_number(1)
1
sage: bell_number(1/3)
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

When using the `mpmath` algorithm, we are required have `mpmath`'s precision set to at least $\log_2(B_n)$ bits. If upon computing the Bell number the first time, we deem the precision too low, we use our guess to (temporarily) raise `mpmath`'s precision and the Bell number is recomputed.

```
sage: k = bell_number(30, 'mpmath'); k
846749014511809332450147
sage: k == bell_number(30)
True
```

If you knows what precision is necessary before computing the Bell number, you can use the `prec` option:

```
sage: k2 = bell_number(30, 'mpmath', prec=30); k2
846749014511809332450147
sage: k == k2
True
```

Warning: Running `mpmath` with the precision set too low can result in incorrect results:

```
sage: k = bell_number(30, 'mpmath', prec=15); k
846749014511809388871680
sage: k == bell_number(30)
False
```

AUTHORS:

- Robert Gerbicz
- Jeroen Demeyer: improved implementation of Dobinski formula with more accurate error estimates (trac ticket #17157)

- <http://mathworld.wolfram.com/DobinskisFormula.html>

`sage.combinat.combinat.bell_polynomial`(n, k)

Return the Bell Polynomial

$$B_{n,k}(x_0, x_1, \dots, x_{n-k}) = \sum_{\sum j_i=k, \sum (i+1)j_i=n} \frac{n!}{j_0!j_1! \cdots j_{n-k}!} \left(\frac{x_0}{(0+1)!}\right)^{j_0} \left(\frac{x_1}{(1+1)!}\right)^{j_1} \cdots \left(\frac{x_{n-k}}{(n-k+1)!}\right)^{j_{n-k}}.$$

INPUT:

- n – integer
- k – integer

OUTPUT:

- a polynomial in $n - k + 1$ variables over \mathbf{Z}

EXAMPLES:

```
sage: bell_polynomial(6,2)
10*x2^2 + 15*x1*x3 + 6*x0*x4
sage: bell_polynomial(6,3)
15*x1^3 + 60*x0*x1*x2 + 15*x0^2*x3
```

- Thierry Monteil (2015-09-29): the result must always be a polynomial.

sage.combinat.combinat.**bernoulli_polynomial**(x, n)

Return the n -th Bernoulli polynomial evaluated at x .

The generating function for the Bernoulli polynomials is

$$\frac{te^{xt}}{e^t - 1} = \sum_{n=0}^{\infty} B_n(x) \frac{t^n}{n!},$$

and they are given directly by

$$B_n(x) = \sum_{i=0}^n \binom{n}{i} B_{n-i} x^i.$$

One has $B_n(x) = -n\zeta(1-n, x)$, where $\zeta(s, x)$ is the Hurwitz zeta function. Thus, in a certain sense, the Hurwitz zeta function generalizes the Bernoulli polynomials to non-integer values of n .

EXAMPLES:

```
sage: y = QQ['y'].0
sage: bernoulli_polynomial(y, 5)
y^5 - 5/2*y^4 + 5/3*y^3 - 1/6*y
sage: bernoulli_polynomial(y, 5)(12)
199870
sage: bernoulli_polynomial(12, 5)
199870
sage: bernoulli_polynomial(y^2 + 1, 5)
y^10 + 5/2*y^8 + 5/3*y^6 - 1/6*y^2
sage: P.<t> = ZZ[]
sage: p = bernoulli_polynomial(t, 6)
sage: p.parent()
Univariate Polynomial Ring in t over Rational Field
```

We verify an instance of the formula which is the origin of the Bernoulli polynomials (and numbers):

```
sage: power_sum = sum(k^4 for k in range(10))
sage: 5*power_sum == bernoulli_polynomial(10, 5) - bernoulli(5)
True
```

REFERENCES:

- [Wikipedia article Bernoulli_polynomials](#)

`sage.combinat.combinat.catalan_number(n)`

Return the n -th Catalan number.

The n -th Catalan number is given directly in terms of binomial coefficients by

$$C_n = \frac{1}{n+1} \binom{2n}{n} = \frac{(2n)!}{(n+1)!n!} \quad \text{for } n \geq 0.$$

Consider the set $S = \{1, \dots, n\}$. A noncrossing partition of S is a partition in which no two blocks “cross” each other, i.e., if a and b belong to one block and x and y to another, they are not arranged in the order $axyb$. C_n is the number of noncrossing partitions of the set S . There are many other interpretations (see REFERENCES).

When $n = -1$, this function returns the limit value $-1/2$. For other $n < 0$ it returns 0.

INPUT:

- n – integer

OUTPUT:

integer

EXAMPLES:

```
sage: [catalan_number(i) for i in range(7)]
[1, 1, 2, 5, 14, 42, 132]
sage: x = (QQ[['x']]).0(8)
sage: (-1/2)*sqrt(1 - 4*x)
-1/2 + x + x^2 + 2*x^3 + 5*x^4 + 14*x^5 + 42*x^6 + 132*x^7 + 0(x^8)
sage: [catalan_number(i) for i in range(-7,7)]
[0, 0, 0, 0, 0, 0, -1/2, 1, 1, 2, 5, 14, 42, 132]
sage: [catalan_number(n).mod(2) for n in range(16)]
[1, 1, 0, 1, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 1]
```

REFERENCES:

- [Wikipedia article Catalan_number](#)
- <http://www-history.mcs.st-andrews.ac.uk/~history/Miscellaneous/CatalanNumbers/catalan.html>

`sage.combinat.combinat.euler_number(n, algorithm='flint')`

Return the n -th Euler number.

INPUT:

- n – a positive integer
- `algorithm` – (Default: 'flint') any one of the following:
 - 'maxima' – Wraps Maxima's euler.
 - 'flint' – Wrap FLINT's arith_euler_number

EXAMPLES:

```
sage: [euler_number(i) for i in range(10)]
[1, 0, -1, 0, 5, 0, -61, 0, 1385, 0]
sage: x = PowerSeriesRing(QQ, 'x').gen().0(10)
sage: 2/(exp(x)+exp(-x))
1 - 1/2*x^2 + 5/24*x^4 - 61/720*x^6 + 277/8064*x^8 + 0(x^10)
sage: [euler_number(i)/factorial(i) for i in range(11)]
[1, 0, -1/2, 0, 5/24, 0, -61/720, 0, 277/8064, 0, -50521/3628800]
```

(continues on next page)

(continued from previous page)

```
sage: euler_number(-1)
Traceback (most recent call last):
...
ValueError: n (-1) must be a nonnegative integer
```

REFERENCES:

- [Wikipedia article Euler_number](#)

`sage.combinat.combinat.eulerian_number(n, k, algorithm='recursive')`

Return the Eulerian number of index (n, k).

This is the coefficient of t^k in the Eulerian polynomial $A_n(t)$.

INPUT:

- n – integer
- k – integer between 0 and n - 1
- algorithm – "recursive" (default) or "formula"

OUTPUT:

an integer

See also:

[eulerian_polynomial\(\)](#)

EXAMPLES:

```
sage: from sage.combinat.combinat import eulerian_number
sage: [eulerian_number(5,i) for i in range(5)]
[1, 26, 66, 26, 1]
```

`sage.combinat.combinat.eulerian_polynomial(n, algorithm='derivative')`

Return the Eulerian polynomial of index n.

This is the generating polynomial counting permutations in the symmetric group S_n according to their number of descents.

INPUT:

- n – an integer
- algorithm – "derivative" (default) or "coeffs"

OUTPUT:

polynomial in one variable t

See also:

[eulerian_number\(\)](#)

EXAMPLES:

```
sage: from sage.combinat.combinat import eulerian_polynomial
sage: eulerian_polynomial(5)
t^4 + 26*t^3 + 66*t^2 + 26*t + 1
```

REFERENCES:

- [Wikipedia article Eulerian_number](#)

`sage.combinat.combinat.fibonacci(n, algorithm='pari')`

Return the n -th Fibonacci number.

The Fibonacci sequence F_n is defined by the initial conditions $F_1 = F_2 = 1$ and the recurrence relation $F_{n+2} = F_{n+1} + F_n$. For negative n we define $F_n = (-1)^{n+1}F_{-n}$, which is consistent with the recurrence relation.

INPUT:

- `algorithm` – a string:
 - "pari" - (default) use the PARI C library's `pari:fibonacci` function
 - "gap" - use GAP's Fibonacci function

Note: PARI is tens to hundreds of times faster than GAP here. Moreover, PARI works for every large input whereas GAP does not.

EXAMPLES:

```
sage: fibonacci(10)
55
sage: fibonacci(10, algorithm='gap')
55
```

```
sage: fibonacci(-100)
-354224848179261915075
sage: fibonacci(100)
354224848179261915075
```

```
sage: fibonacci(0)
0
sage: fibonacci(1/2)
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

`sage.combinat.combinat.fibonacci_sequence(start, stop=None, algorithm=None)`

Return an iterator over the Fibonacci sequence, for all fibonacci numbers f_n from $n = \text{start}$ up to (but not including) $n = \text{stop}$

INPUT:

- `start` – starting value
- `stop` – stopping value
- `algorithm` – (default: None) passed on to fibonacci function (or not passed on if None, i.e., use the default)

EXAMPLES:

```
sage: fibs = [i for i in fibonacci_sequence(10, 20)]
sage: fibs
[55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181]
```

```
sage: sum([i for i in fibonacci_sequence(100, 110)])
69919376923075308730013
```

See also:[*fibonacci_xrange\(\)*](#)**AUTHORS:**

- Bobby Moretti

sage.combinat.combinat.**fibonacci_xrange**(start, stop=None, algorithm='pari')

Return an iterator over all of the Fibonacci numbers in the given range, including $f_n = \text{start}$ up to, but not including, $f_n = \text{stop}$.

EXAMPLES:

```
sage: fibs_in_some_range = [i for i in fibonacci_xrange(10^7, 10^8)]
sage: len(fibs_in_some_range)
4
sage: fibs_in_some_range
[14930352, 24157817, 39088169, 63245986]
```

```
sage: fibs = [i for i in fibonacci_xrange(10, 100)]
sage: fibs
[13, 21, 34, 55, 89]
```

```
sage: list(fibonacci_xrange(13, 34))
[13, 21]
```

A solution to the second Project Euler problem:

```
sage: sum([i for i in fibonacci_xrange(10^6) if is_even(i)])
1089154
```

See also:[*fibonacci_sequence\(\)*](#)**AUTHORS:**

- Bobby Moretti

sage.combinat.combinat.**lucas_number1**(n, P, Q)

Return the n -th Lucas number “of the first kind” (this is not standard terminology). The Lucas sequence $L_n^{(1)}$ is defined by the initial conditions $L_1^{(1)} = 0$, $L_2^{(1)} = 1$ and the recurrence relation $L_{n+2}^{(1)} = P \cdot L_{n+1}^{(1)} - Q \cdot L_n^{(1)}$.

Wraps GAP’s `Lucas(...)` [1].

$P = 1$, $Q = -1$ gives the Fibonacci sequence.

INPUT:

- n – integer
- P , Q – integer or rational numbers

OUTPUT: integer or rational number

EXAMPLES:

```
sage: lucas_number1(5, 1, -1)
5
sage: lucas_number1(6, 1, -1)
```

(continues on next page)

(continued from previous page)

```

8
sage: lucas_number1(7,1,-1)
13
sage: lucas_number1(7,1,-2)
43
sage: lucas_number1(5,2,3/5)
229/25
sage: lucas_number1(5,2,1.5)
1/4

```

There was a conjecture that the sequence L_n defined by $L_{n+2} = L_{n+1} + L_n$, $L_1 = 1$, $L_2 = 3$, has the property that n prime implies that L_n is prime.

```

sage: lucas = lambda n : Integer((5/2)*lucas_number1(n,1,-1)+(1/2)*lucas_number2(n,
↪1,-1))
sage: [[lucas(n),is_prime(lucas(n)),n+1,is_prime(n+1)] for n in range(15)]
[[1, False, 1, False],
 [3, True, 2, True],
 [4, False, 3, True],
 [7, True, 4, False],
 [11, True, 5, True],
 [18, False, 6, False],
 [29, True, 7, True],
 [47, True, 8, False],
 [76, False, 9, False],
 [123, False, 10, False],
 [199, True, 11, True],
 [322, False, 12, False],
 [521, True, 13, True],
 [843, False, 14, False],
 [1364, False, 15, False]]

```

Can you use Sage to find a counterexample to the conjecture?

sage.combinat.combinat.lucas_number2(n, P, Q)

Return the n -th Lucas number “of the second kind” (this is not standard terminology). The Lucas sequence $L_n^{(2)}$ is defined by the initial conditions $L_1^{(2)} = 2$, $L_2^{(2)} = P$ and the recurrence relation $L_{n+2}^{(2)} = P \cdot L_{n+1}^{(2)} - Q \cdot L_n^{(2)}$.

Wraps GAP’s Lucas(...)[2].

INPUT:

- n - integer
- P, Q - integer or rational numbers

OUTPUT: integer or rational number

EXAMPLES:

```

sage: [lucas_number2(i,1,-1) for i in range(10)]
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
sage: [fibonacci(i-1)+fibonacci(i+1) for i in range(10)]
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]

```

```

sage: n = lucas_number2(5,2,3); n
2
sage: type(n)
<class 'sage.rings.integer.Integer'>
sage: n = lucas_number2(5,2,-3/9); n
418/9
sage: type(n)
<class 'sage.rings.rational.Rational'>

```

The case $P = 1, Q = -1$ is the Lucas sequence in Brualdi's Introductory Combinatorics, 4th ed., Prentice-Hall, 2004:

```

sage: [lucas_number2(n,1,-1) for n in range(10)]
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]

```

`sage.combinat.combinat.narayana_number(n, k)`

Return the Narayana number of index (n, k).

For every integer $n \geq 1$, the sum of Narayana numbers $\sum_k N_{n,k}$ is the Catalan number C_n .

INPUT:

- n – an integer
- k – an integer between 0 and $n - 1$

OUTPUT:

an integer

EXAMPLES:

```

sage: from sage.combinat.combinat import narayana_number
sage: [narayana_number(3, i) for i in range(3)]
[1, 3, 1]
sage: sum(narayana_number(7,i) for i in range(7)) == catalan_number(7)
True

```

REFERENCES:

- [Wikipedia article Narayana_number](#)

`sage.combinat.combinat.number_of_tuples($S, k, algorithm='naive'$)`

Return the size of `tuples(S, k)` when S is a set. More generally, return the size of `tuples(set(S), k)`. (So, unlike `tuples()`, this method removes redundant entries from S .)

INPUT:

- S – the base set
- k – the length of the tuples
- `algorithm` – can be one of the following:
 - 'naive' - (default) use the naive counting $|S|^k$
 - 'gap' - wraps GAP's `NrTuples`

Warning: When using `algorithm='gap'`, `S` must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If `S` consists of all complicated Sage objects, this function might *not* do what you expect.

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: number_of_tuples(S,2)
25
sage: number_of_tuples(S,2, algorithm="gap")
25
sage: S = [1,1,2,3,4,5]
sage: number_of_tuples(S,2)
25
sage: number_of_tuples(S,2, algorithm="gap")
25
sage: number_of_tuples(S,0)
1
sage: number_of_tuples(S,0, algorithm="gap")
1
```

`sage.combinat.combinat.number_of_unordered_tuples(S, k, algorithm='naive')`

Return the size of `unordered_tuples(S, k)` when `S` is a set.

INPUT:

- `S` – the base set
- `k` – the length of the tuples
- `algorithm` – can be one of the following:
 - 'naive' - (default) use the naive counting $\binom{|S|+k-1}{k}$
 - 'gap' - wraps GAP's `NrUnorderedTuples`

Warning: When using `algorithm='gap'`, `S` must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If `S` consists of all complicated Sage objects, this function might *not* do what you expect.

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: number_of_unordered_tuples(S,2)
15
sage: number_of_unordered_tuples(S,2, algorithm="gap")
15
sage: S = [1,1,2,3,4,5]
sage: number_of_unordered_tuples(S,2)
15
sage: number_of_unordered_tuples(S,2, algorithm="gap")
15
sage: number_of_unordered_tuples(S,0)
1
```

(continues on next page)

(continued from previous page)

```
sage: number_of_unordered_tuples(S,0, algorithm="gap")
1
```

```
sage.combinat.combinat.polygonal_number(s, n)
```

Return the n -th s -gonal number.

Polygonal sequences are represented by dots forming a regular polygon. Two famous sequences are the triangular numbers (3rd column of Pascal's Triangle) and the square numbers. The n -th term in a polygonal sequence is defined by

$$P(s, n) = \frac{n^2(s-2) - n(s-4)}{2},$$

where s is the number of sides of the polygon.

INPUT:

- s – integer greater than 1; the number of sides of the polygon
- n – integer; the index of the returned s -gonal number

OUTPUT: an integer

EXAMPLES:

The triangular numbers:

```
sage: [polygonal_number(3, n) for n in range(10)]
[0, 1, 3, 6, 10, 15, 21, 28, 36, 45]

sage: [polygonal_number(3, n) for n in range(-10, 0)]
[45, 36, 28, 21, 15, 10, 6, 3, 1, 0]
```

The square numbers:

```
sage: [polygonal_number(4, n) for n in range(10)]
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

The pentagonal numbers:

```
sage: [polygonal_number(5, n) for n in range(10)]
[0, 1, 5, 12, 22, 35, 51, 70, 92, 117]
```

The hexagonal numbers:

```
sage: [polygonal_number(6, n) for n in range(10)]
[0, 1, 6, 15, 28, 45, 66, 91, 120, 153]
```

The input is converted into an integer:

```
sage: polygonal_number(3.0, 2.0)
3
```

A non-integer input returns an error:

```
sage: polygonal_number(3.5, 1)
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
TypeError: Attempt to coerce non-integral RealNumber to Integer
```

s must be greater than 1:

```
sage: polygonal_number(1, 4)
Traceback (most recent call last):
...
ValueError: s (=1) must be greater than 1
```

REFERENCES:

- [Wikipedia article Polygonal_number](#)

`sage.combinat.combinat.stirling_number1($n, k, algorithm='gap'$)`
Return the n -th Stirling number $S_1(n, k)$ of the first kind.

This is the number of permutations of n points with k cycles.

See [Wikipedia article Stirling_numbers_of_the_first_kind](#).

INPUT:

- n – nonnegative machine-size integer
- k – nonnegative machine-size integer
- `algorithm`:
 - "gap" (default) – use GAP's `Stirling1` function
 - "flint" – use flint's `arith_stirling_number_1u` function

EXAMPLES:

```
sage: stirling_number1(3,2)
3
sage: stirling_number1(5,2)
50
sage: 9*stirling_number1(9,5)+stirling_number1(9,4)
269325
sage: stirling_number1(10,5)
269325
```

Indeed, $S_1(n, k) = S_1(n - 1, k - 1) + (n - 1)S_1(n - 1, k)$.

`sage.combinat.combinat.stirling_number2($n, k, algorithm=None$)`
Return the n -th Stirling number $S_2(n, k)$ of the second kind.

This is the number of ways to partition a set of n elements into k pairwise disjoint nonempty subsets. The n -th Bell number is the sum of the $S_2(n, k)$'s, $k = 0, \dots, n$.

See [Wikipedia article Stirling_numbers_of_the_second_kind](#).

INPUT:

- n – nonnegative machine-size integer
- k – nonnegative machine-size integer
- `algorithm`:
 - None (default) – use native implementation

- "flint" – use flint's `arith_stirling_number_2` function
- "gap" – use GAP's `Stirling2` function
- "maxima" – use Maxima's `stirling2` function

EXAMPLES:

Print a table of the first several Stirling numbers of the second kind:

```
sage: for n in range(10):
.....:     for k in range(10):
.....:         print(str(stirling_number2(n,k)).rjust(k and 6))
```

1	0	0	0	0	0	0	0	0	0
0	1	0	0	0	0	0	0	0	0
0	1	1	0	0	0	0	0	0	0
0	1	3	1	0	0	0	0	0	0
0	1	7	6	1	0	0	0	0	0
0	1	15	25	10	1	0	0	0	0
0	1	31	90	65	15	1	0	0	0
0	1	63	301	350	140	21	1	0	0
0	1	127	966	1701	1050	266	28	1	0
0	1	255	3025	7770	6951	2646	462	36	1

Stirling numbers satisfy $S_2(n, k) = S_2(n - 1, k - 1) + kS_2(n - 1, k)$:

```
sage: 5*stirling_number2(9,5) + stirling_number2(9,4)
42525
sage: stirling_number2(10,5)
42525
```

`sage.combinat.combinat.tuples(S, k, algorithm='itertools')`

Return a list of all k -tuples of elements of a given set S .

This function accepts the set S in the form of any iterable (list, tuple or iterator), and returns a list of k -tuples. If S contains duplicate entries, then you should expect the method to return tuples multiple times!

Recall that k -tuples are ordered (in the sense that two k -tuples differing in the order of their entries count as different) and can have repeated entries (even if S is a list with no repetition).

INPUT:

- S – the base set
- k – the length of the tuples
- `algorithm` – can be one of the following:
 - 'itertools' - (default) use python's itertools
 - 'native' - use a native Sage implementation

Note: The ordering of the list of tuples depends on the algorithm.

EXAMPLES:

```
sage: S = [1,2]
sage: tuples(S,3)
[(1, 1, 1), (1, 1, 2), (1, 2, 1), (1, 2, 2),
```

(continues on next page)

(continued from previous page)

```
(2, 1, 1), (2, 1, 2), (2, 2, 1), (2, 2, 2)]
sage: mset = ["s","t","e","i","n"]
sage: tuples(mset, 2)
[('s', 's'), ('s', 't'), ('s', 'e'), ('s', 'i'), ('s', 'n'),
 ('t', 's'), ('t', 't'), ('t', 'e'), ('t', 'i'), ('t', 'n'),
 ('e', 's'), ('e', 't'), ('e', 'e'), ('e', 'i'), ('e', 'n'),
 ('i', 's'), ('i', 't'), ('i', 'e'), ('i', 'i'), ('i', 'n'),
 ('n', 's'), ('n', 't'), ('n', 'e'), ('n', 'i'), ('n', 'n')]
```

```
sage: K.<a> = GF(4, 'a')
sage: mset = [x for x in K if x != 0]
sage: tuples(mset, 2)
[(a, a), (a, a + 1), (a, 1), (a + 1, a), (a + 1, a + 1),
 (a + 1, 1), (1, a), (1, a + 1), (1, 1)]
```

We check that the implementations agree (up to ordering):

```
sage: tuples(S, 3, 'native')
[(1, 1, 1), (2, 1, 1), (1, 2, 1), (2, 2, 1),
 (1, 1, 2), (2, 1, 2), (1, 2, 2), (2, 2, 2)]
```

Lastly we check on a multiset:

```
sage: S = [1,1,2]
sage: sorted(tuples(S, 3)) == sorted(tuples(S, 3, 'native'))
True
```

AUTHORS:

- Jon Hanke (2006-08)

`sage.combinat.combinat.unordered_tuples(S, k, algorithm='itertools')`

Return a list of all unordered tuples of length k of the set S .

An unordered tuple of length k of set S is a unordered selection with repetitions of S and is represented by a sorted list of length k containing elements from S .

Unlike `tuples()`, the result of this method does not depend on how often an element appears in S ; only the *set* S is being used. For example, `unordered_tuples([1, 1, 1], 2)` will return `[(1, 1)]`. If you want it to return `[(1, 1), (1, 1), (1, 1)]`, use Python's `itertools.combinations_with_replacement` instead.

INPUT:

- S – the base set
- k – the length of the tuples
- `algorithm` – can be one of the following:
 - `'itertools'` - (default) use python's `itertools`
 - `'gap'` - wraps GAP's `UnorderedTuples`

Warning: When using `algorithm='gap'`, S must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If S consists of all complicated Sage objects, this function might *not* do what you expect.

EXAMPLES:

```
sage: S = [1,2]
sage: unordered_tuples(S, 3)
[(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)]
```

We check that this agrees with GAP:

```
sage: unordered_tuples(S, 3, algorithm='gap')
[(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)]
```

We check the result on strings:

```
sage: S = ["a","b","c"]
sage: unordered_tuples(S, 2)
[('a', 'a'), ('a', 'b'), ('a', 'c'), ('b', 'b'), ('b', 'c'), ('c', 'c')]
sage: unordered_tuples(S, 2, algorithm='gap')
[('a', 'a'), ('a', 'b'), ('a', 'c'), ('b', 'b'), ('b', 'c'), ('c', 'c')]
```

Lastly we check on a multiset:

```
sage: S = [1,1,2]
sage: unordered_tuples(S, 3) == unordered_tuples(S, 3, 'gap')
True
sage: unordered_tuples(S, 3)
[(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)]
```

`sage.combinat.combinat.unshuffle_iterator(a, one=1)`

Iterate over the unshuffles of a list (or tuple) `a`, also yielding the signs of the respective permutations.

If n and k are integers satisfying $0 \leq k \leq n$, then a $(k, n - k)$ -unshuffle means a permutation $\pi \in S_n$ such that $\pi(1) < \pi(2) < \dots < \pi(k)$ and $\pi(k+1) < \pi(k+2) < \dots < \pi(n)$. This method provides, for a list $a = (a_1, a_2, \dots, a_n)$ of length n , an iterator yielding all pairs:

$$\left((a_{\pi(1)}, a_{\pi(2)}, \dots, a_{\pi(k)}), (a_{\pi(k+1)}, a_{\pi(k+2)}, \dots, a_{\pi(n)}) \right), (-1)^\pi$$

for all $k \in \{0, 1, \dots, n\}$ and all $(k, n - k)$ -unshuffles π . The optional variable `one` can be set to a different value which results in the $(-1)^\pi$ component being multiplied by said value.

The iterator does not yield these in order of increasing k .

EXAMPLES:

```
sage: from sage.combinat.combinat import unshuffle_iterator
sage: list(unshuffle_iterator([1, 3, 4]))
[((((), (1, 3, 4)), 1), (((1,), (3, 4)), 1), (((3,), (1, 4)), -1),
 ((1, 3), (4,)), 1), (((4,), (1, 3)), 1), (((1, 4), (3,)), -1),
 ((3, 4), (1,)), 1), (((1, 3, 4), ()), 1)]
sage: list(unshuffle_iterator([3, 1]))
[((((), (3, 1)), 1), (((3,), (1,)), 1), (((1,), (3,)), -1),
 ((3, 1), ()), 1)]
sage: list(unshuffle_iterator([8]))
[((((), (8,)), 1), (((8,), ()), 1)]
sage: list(unshuffle_iterator([]))
[((((), ()), 1)]
sage: list(unshuffle_iterator([3, 1], 3/2))
```

(continues on next page)

(continued from previous page)

```
[(((), (3, 1)), 3/2), (((), (1,)), 3/2), (((1,), (3,)), -3/2),
(((3, 1), ()), 3/2)]
```

5.1.25 Fast computation of combinatorial functions (Cython + mpz)

Currently implemented:

- Stirling numbers of the second kind
- iterators for set partitions
- iterator for Lyndon words
- iterator for perfect matchings
- conjugate of partitions

AUTHORS:

- Fredrik Johansson (2010-10): Stirling numbers of second kind
- Martin Rubey and Travis Scrimshaw (2018): iterators for set partitions, Lyndon words, and perfect matchings

`sage.combinat.combinat_cython.conjugate(p)`

Return the conjugate partition associated to the partition `p` as a list.

EXAMPLES:

```
sage: from sage.combinat.combinat_cython import conjugate
sage: conjugate([2,2])
[2, 2]
sage: conjugate([6,3,1])
[3, 2, 2, 1, 1, 1]
```

`sage.combinat.combinat_cython.linear_extension_iterator(D)`

Iterate over the linear extensions of the poset.

The list `_le` keeps track of the current linear extensions. The boolean variable `is_plus` keeps track of the “sign”.

INPUT:

- `D`, the Hasse diagram of a poset.

Warning: It is assumed that `D` is not modified while the linear extensions are generated.

EXAMPLES:

```
sage: from sage.combinat.combinat_cython import linear_extension_iterator
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] }).hasse_diagram
sage: list(linear_extension_iterator(D))
[[0, 1, 2, 3, 4],
 [0, 2, 1, 3, 4],
 [0, 2, 1, 4, 3],
 [0, 2, 4, 1, 3],
 [0, 1, 2, 4, 3]]
```

(continues on next page)

(continued from previous page)

```

sage: D = posets.BooleanLattice(3)._hasse_diagram
sage: len(list(linear_extension_iterator(D)))
48

sage: D = posets.AntichainPoset(9)._hasse_diagram
sage: len(list(linear_extension_iterator(D))) == factorial(9)      # long time
True

```

`sage.combinat.combinat_cython.lyndon_word_iterator`(n, k)

Generate the Lyndon words of fixed length k with n letters.

The resulting Lyndon words will be words represented as lists whose alphabet is `range(n)` ($= \{0, 1, \dots, n-1\}$).

ALGORITHM:

The iterative FKM Algorithm 7.2 from [Rus2003].

EXAMPLES:

```

sage: from sage.combinat.combinat_cython import lyndon_word_iterator
sage: list(lyndon_word_iterator(4, 2))
[[0, 1], [0, 2], [0, 3], [1, 2], [1, 3], [2, 3]]
sage: list(lyndon_word_iterator(2, 4))
[[0, 0, 0, 1], [0, 0, 1, 1], [0, 1, 1, 1]]

```

`sage.combinat.combinat_cython.perfect_matchings_iterator`(n)

Iterate over all perfect matchings with n parts.

This iterates over all perfect matchings of $\{0, 1, \dots, 2n-1\}$ using a Gray code for fixed-point-free involutions due to Walsh [Wal2001].

EXAMPLES:

```

sage: from sage.combinat.combinat_cython import perfect_matchings_iterator
sage: list(perfect_matchings_iterator(1))
[[0, 1]]
sage: list(perfect_matchings_iterator(2))
[[0, 1], (2, 3)], [(0, 2), (1, 3)], [(0, 3), (1, 2)]]

sage: list(perfect_matchings_iterator(0))
[[]]

```

REFERENCES:

- [Wal2001]

`sage.combinat.combinat_cython.set_partition_composition`($sp1, sp2$)

Return a tuple consisting of the composition of the set partitions $sp1$ and $sp2$ and the number of components removed from the middle rows of the graph.

EXAMPLES:

```

sage: from sage.combinat.combinat_cython import set_partition_composition
sage: sp1 = ((1,-2), (2,-1))
sage: sp2 = ((1,-2), (2,-1))
sage: p, c = set_partition_composition(sp1, sp2)

```

(continues on next page)

(continued from previous page)

```
sage: (SetPartition(p), c) == (SetPartition([[1,-1],[2,-2]]), 0)
True
```

sage.combinat.combinat_cython.**set_partition_iterator**(*base_set*)

A fast iterator for the set partitions of the base set, which returns lists of lists instead of set partitions types.

EXAMPLES:

```
sage: from sage.combinat.combinat_cython import set_partition_iterator
sage: list(set_partition_iterator([1,-1,x]))
[[[1, -1, x]],
 [[1, -1], [x]],
 [[1, x], [-1]],
 [[1], [-1, x]],
 [[1], [-1], [x]]]
```

sage.combinat.combinat_cython.**set_partition_iterator_blocks**(*base_set, k*)

A fast iterator for the set partitions of the base set into the specified number of blocks, which returns lists of lists instead of set partitions types.

EXAMPLES:

```
sage: from sage.combinat.combinat_cython import set_partition_iterator_blocks
sage: list(set_partition_iterator_blocks([1,-1,x], 2))
[[[1, x], [-1]], [[1], [-1, x]], [[1, -1], [x]]]
```

5.1.26 Combinations

AUTHORS:

- Mike Hansen (2007): initial implementation
- Vincent Delecroix (2011): cleaning, bug corrections, doctests
- Antoine Genitrini (2020) : new implementation of the lexicographic unranking of combinations

class sage.combinat.combination.**ChooseNK**(*mset, k*)

Bases: *sage.combinat.combination.Combinations_setk*

sage.combinat.combination.**Combinations**(*mset, k=None*)

Return the combinatorial class of combinations of the multiset *mset*. If *k* is specified, then it returns the combinatorial class of combinations of *mset* of size *k*.

A *combination* of a multiset *M* is an unordered selection of *k* objects of *M*, where every object can appear at most as many times as it appears in *M*.

The combinatorial classes correctly handle the cases where *mset* has duplicate elements.

EXAMPLES:

```
sage: C = Combinations(range(4)); C
Combinations of [0, 1, 2, 3]
sage: C.list()
[[],
 [0],
 [1],
```

(continues on next page)

(continued from previous page)

```
[2],

[1, 3],
[2, 3],
[0, 1, 2],
[0, 1, 3],
[0, 2, 3],
[1, 2, 3],
[0, 1, 2, 3]]
sage: C.cardinality()
16
```

```
sage: C2 = Combinations(range(4),2); C2
Combinations of [0, 1, 2, 3] of length 2
sage: C2.list()
[[0, 1], [0, 2], [0, 3], [1, 2], [1, 3], [2, 3]]
sage: C2.cardinality()
6
```

```
sage: Combinations([1,2,2,3]).list()
[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 2],
 [2, 3],
 [1, 2, 2],
 [1, 2, 3],
 [2, 2, 3],
 [1, 2, 2, 3]]
```

```
sage: Combinations([1,2,3], 2).list()
[[1, 2], [1, 3], [2, 3]]
```

```
sage: mset = [1,1,2,3,4,4,5]
sage: Combinations(mset,2).list()
[[1, 1],
 [1, 2],
 [1, 3],
 [1, 4],
 [1, 5],
 [2, 3],
 [2, 4],
 [2, 5],
 [3, 4],
```

(continues on next page)

(continued from previous page)

```
[3, 5],
[4, 4],
[4, 5]]
```

```
sage: mset = ["d","a","v","i","d"]
sage: Combinations(mset,3).list()
[['d', 'd', 'a'],
 ['d', 'd', 'v'],
 ['d', 'd', 'i'],
 ['d', 'a', 'v'],
 ['d', 'a', 'i'],
 ['d', 'v', 'i'],
 ['a', 'v', 'i']]
```

```
sage: X = Combinations([1,2,3,4,5],3)
sage: [x for x in X]
[[1, 2, 3],
 [1, 2, 4],
 [1, 2, 5],
 [1, 3, 4],
 [1, 3, 5],
 [1, 4, 5],
 [2, 3, 4],
 [2, 3, 5],
 [2, 4, 5],
 [3, 4, 5]]
```

It is possible to take combinations of Sage objects:

```
sage: Combinations([vector([1,1]), vector([2,2]), vector([3,3])], 2).list()
[[ (1, 1), (2, 2) ], [ (1, 1), (3, 3) ], [ (2, 2), (3, 3) ]]
```

```
class sage.combinat.combination.Combinations_mset(mset)
```

Bases: `sage.structure.parent.Parent`

cardinality()

```
class sage.combinat.combination.Combinations_msetk(mset, k)
```

Bases: `sage.structure.parent.Parent`

cardinality()

Return the size of combinations(mset, k).

IMPLEMENTATION: Wraps GAP's NrCombinations.

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: Combinations(mset,2).cardinality()
12
```

```
class sage.combinat.combination.Combinations_set(mset)
```

Bases: `sage.combinat.combination.Combinations_mset`

cardinality()

Return the size of Combinations(set).

EXAMPLES:

```
sage: Combinations(range(16000)).cardinality() == 2^16000
True
```

rank(*x*)

EXAMPLES:

```
sage: c = Combinations([1,2,3])
sage: list(range(c.cardinality())) == list(map(c.rank, c))
True
```

unrank(*r*)

EXAMPLES:

```
sage: c = Combinations([1,2,3])
sage: c.list() == list(map(c.unrank, range(c.cardinality())))
True
```

class sage.combinat.combination.**Combinations_setk**(*mset*, *k*)

Bases: *sage.combinat.combination.Combinations_msetk*

cardinality()

Return the size of combinations(set, k).

EXAMPLES:

```
sage: Combinations(range(16000), 5).cardinality()
8732673194560003200
```

list()

EXAMPLES:

```
sage: Combinations([1,2,3,4,5],3).list()
[[1, 2, 3],
 [1, 2, 4],
 [1, 2, 5],
 [1, 3, 4],
 [1, 3, 5],
 [1, 4, 5],
 [2, 3, 4],
 [2, 3, 5],
 [2, 4, 5],
 [3, 4, 5]]
```

rank(*x*)

EXAMPLES:

```
sage: c = Combinations([1,2,3], 2)
sage: list(range(c.cardinality())) == list(map(c.rank, c.list()))
True
```

unrank(*r*)

EXAMPLES:

```
sage: c = Combinations([1,2,3], 2)
sage: c.list() == list(map(c.unrank, range(c.cardinality())))
True
```

`sage.combinat.combination.from_rank(r, n, k)`

Return the combination of rank *r* in the subsets of `range(n)` of size *k* when listed in lexicographic order.

The algorithm used is based on factoradics and presented in [DGH2020]. It is there compared to the other from the literature.

EXAMPLES:

```
sage: import sage.combinat.combination as combination
sage: combination.from_rank(0,3,0)
()
sage: combination.from_rank(0,3,1)
(0,)
sage: combination.from_rank(1,3,1)
(1,)
sage: combination.from_rank(2,3,1)
(2,)
sage: combination.from_rank(0,3,2)
(0, 1)
sage: combination.from_rank(1,3,2)
(0, 2)
sage: combination.from_rank(2,3,2)
(1, 2)
sage: combination.from_rank(0,3,3)
(0, 1, 2)
```

`sage.combinat.combination.rank(comb, n, check=True)`

Return the rank of *comb* in the subsets of `range(n)` of size *k* where *k* is the length of *comb*.

The algorithm used is based on combinadics and James McCaffrey's MSDN article. See: [Wikipedia article Combinadic](#).

EXAMPLES:

```
sage: import sage.combinat.combination as combination
sage: combination.rank((), 3)
0
sage: combination.rank((0,), 3)
0
sage: combination.rank((1,), 3)
1
sage: combination.rank((2,), 3)
2
sage: combination.rank((0,1), 3)
0
sage: combination.rank((0,2), 3)
1
sage: combination.rank((1,2), 3)
2
sage: combination.rank((0,1,2), 3)
0
```

(continues on next page)

(continued from previous page)

```

sage: combination.rank((0,1,2,3), 3)
Traceback (most recent call last):
...
ValueError: len(comb) must be <= n
sage: combination.rank((0,0), 2)
Traceback (most recent call last):
...
ValueError: comb must be a subword of (0,1,...,n)

sage: combination.rank([1,2], 3)
2
sage: combination.rank([0,1,2], 3)
0

```

5.1.27 Combinatorial maps

This module provides a decorator that can be used to add semantic to a Python method by marking it as implementing a *combinatorial map*, that is a map between two `enumerated sets`:

```

sage: from sage.combinat.combinatorial_map import combinatorial_map
sage: class MyPermutation():
...:     @combinatorial_map()
...:     def reverse(self):
...:         """
...:         Reverse the permutation
...:         """
...:         # ... code ...

```

By default, this decorator is a no-op: it returns the decorated method as is:

```

sage: MyPermutation.reverse
<function MyPermutation.reverse at ...>

```

See `combinatorial_map_wrapper()` for the various options this decorator can take.

Projects built on top of Sage are welcome to customize locally this hook to instrument the Sage code and exploit this semantic information. Typically, the decorator could be used to populate a database of maps. For a real-life application, see the project *FindStat* < <http://findstat.org/> >. As a basic example, a variant of the decorator is provided as `combinatorial_map_wrapper()`; it wraps the decorated method, so that one can later use `combinatorial_maps_in_class()` to query an object, or class thereof, for all the combinatorial maps that apply to it.

Note: Since decorators are evaluated upon loading Python modules, customizing `combinatorial map` needs to be done before the modules using it are loaded. In the examples below, where we illustrate the customized `combinatorial_map` decorator on the `sage.combinat.permutation` module, we resort to force a reload of this module after dynamically changing `sage.combinat.combinatorial_map.combinatorial_map`. This is good enough for those doctests, but remains fragile.

For real use cases, it is probably best to just edit this source file statically (see below).

`class sage.combinat.combinatorial_map.CombinatorialMap(f, order=None, name=None)`

Bases: object

This is a wrapper class for methods that are *combinatorial maps*.

For further details and doctests, see [Combinatorial maps](#) and [combinatorial_map_wrapper\(\)](#).

name()

Returns the name of a combinatorial map. This is used for the string representation of self.

EXAMPLES:

```
sage: from sage.combinat.combinatorial_map import combinatorial_map
sage: class CombinatorialClass:
.....:     @combinatorial_map(name='map1')
.....:     def to_self_1(): pass
.....:     @combinatorial_map()
.....:     def to_self_2(): pass
sage: CombinatorialClass.to_self_1.name()
'map1'
sage: CombinatorialClass.to_self_2.name()
'to_self_2'
```

order()

Returns the order of self, or None if the order is not known.

EXAMPLES:

```
sage: from sage.combinat.combinatorial_map import combinatorial_map
sage: class CombinatorialClass:
.....:     @combinatorial_map(order=2)
.....:     def to_self_1(): pass
.....:     @combinatorial_map()
.....:     def to_self_2(): pass
sage: CombinatorialClass.to_self_1.order()
2
sage: CombinatorialClass.to_self_2.order() is None
True
```

unbounded_map()

Return the unbounded version of self.

You can use this method to return a function which takes as input an element in the domain of the combinatorial map. See the example below.

EXAMPLES:

```
sage: sage.combinat.combinatorial_map.combinatorial_map = sage.combinat.
↳combinatorial_map.combinatorial_map_wrapper
sage: from importlib import reload
sage: _ = reload(sage.combinat.permutation)
sage: from sage.combinat.permutation import Permutation
sage: pi = Permutation([1,3,2])
sage: f = pi.reverse
sage: F = f.unbounded_map()
sage: F(pi)
[2, 3, 1]
```

`sage.combinat.combinatorial_map.combinatorial_map(f=None, order=None, name=None)`
 Combinatorial map decorator

See *Combinatorial maps* for a description of this decorator and its purpose. This default implementation does nothing.

INPUT:

- `f` – (default: `None`, if `combinatorial_map` is used as a decorator) a function
- `name` – (default: `None`) the name for nicer outputs on combinatorial maps
- `order` – (default: `None`) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

OUTPUT:

- `f` unchanged

EXAMPLES:

```
sage: from sage.combinat.combinatorial_map import combinatorial_map_trivial as combinatorial_map
sage: class MyPermutation():
.....:     @combinatorial_map
.....:     def reverse(self):
.....:         """
.....:         Reverse the permutation
.....:         """
.....:         # ... code ...
.....:     @combinatorial_map(name='descent set of permutation')
.....:     def descent_set(self):
.....:         """
.....:         The descent set of the permutation
.....:         """
.....:         # ... code ...

sage: MyPermutation.reverse
<function MyPermutation.reverse at ...>

sage: MyPermutation.descent_set
<function MyPermutation.descent_set at ...>
```

`sage.combinat.combinatorial_map.combinatorial_map_trivial(f=None, order=None, name=None)`
 Combinatorial map decorator

See *Combinatorial maps* for a description of this decorator and its purpose. This default implementation does nothing.

INPUT:

- `f` – (default: `None`, if `combinatorial_map` is used as a decorator) a function
- `name` – (default: `None`) the name for nicer outputs on combinatorial maps
- `order` – (default: `None`) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

OUTPUT:

- `f` unchanged

EXAMPLES:

```
sage: from sage.combinat.combinatorial_map import combinatorial_map_trivial as combinatorial_map
↪combinatorial_map
sage: class MyPermutation():
.....:     @combinatorial_map
.....:     def reverse(self):
.....:         """
.....:         Reverse the permutation
.....:         """
.....:         # ... code ...
.....:     @combinatorial_map(name='descent set of permutation')
.....:     def descent_set(self):
.....:         """
.....:         The descent set of the permutation
.....:         """
.....:         # ... code ...

sage: MyPermutation.reverse
<function MyPermutation.reverse at ...>

sage: MyPermutation.descent_set
<function MyPermutation.descent_set at ...>
```

sage.combinat.combinatorial_map.**combinatorial_map_wrapper**(*f=None, order=None, name=None*)
Combinatorial map decorator (basic example).

See *Combinatorial maps* for a description of the `combinatorial_map` decorator and its purpose. This implementation, together with `combinatorial_maps_in_class()` illustrates how to use this decorator as a hook to instrument the Sage code.

INPUT:

- *f* – (default: None, if `combinatorial_map` is used as a decorator) a function
- *name* – (default: None) the name for nicer outputs on combinatorial maps
- *order* – (default: None) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

OUTPUT:

- A combinatorial map. This is an instance of the *CombinatorialMap*.

EXAMPLES:

We define a class illustrating the use of this implementation of the `combinatorial_map` decorator with its various arguments:

```
sage: from sage.combinat.combinatorial_map import combinatorial_map_wrapper as combinatorial_map
↪combinatorial_map
sage: class MyPermutation():
.....:     @combinatorial_map()
.....:     def reverse(self):
.....:         """
.....:         Reverse the permutation
.....:         """
.....:     pass
```

(continues on next page)

(continued from previous page)

```

.....: @combinatorial_map(order=2)
.....: def inverse(self):
.....:     """
.....:     The inverse of the permutation
.....:     """
.....:     pass
.....: @combinatorial_map(name='descent set of permutation')
.....: def descent_set(self):
.....:     """
.....:     The descent set of the permutation
.....:     """
.....:     pass
.....: def major_index(self):
.....:     """
.....:     The major index of the permutation
.....:     """
.....:     pass
sage: MyPermutation.reverse
Combinatorial map: reverse
sage: MyPermutation.descent_set
Combinatorial map: descent set of permutation
sage: MyPermutation.inverse
Combinatorial map: inverse

```

One can now determine all the combinatorial maps associated with a given object as follows:

```

sage: from sage.combinat.combinatorial_map import combinatorial_maps_in_class
sage: X = combinatorial_maps_in_class(MyPermutation); X # random
[Combinatorial map: reverse,
Combinatorial map: descent set of permutation,
Combinatorial map: inverse]

```

The method `major_index` defined about is not a combinatorial map:

```

sage: MyPermutation.major_index
<function MyPermutation.major_index at ...>

```

But one can define a function that turns `major_index` into a combinatorial map:

```

sage: def major_index(p):
.....:     return p.major_index()
sage: major_index
<function major_index at ...>
sage: combinatorial_map(major_index)
Combinatorial map: major_index

```

`sage.combinat.combinatorial_map.combinatorial_maps_in_class(cls)`

Return the combinatorial maps of the class as a list of combinatorial maps.

For further details and doctests, see [Combinatorial maps](#) and [combinatorial_map_wrapper\(\)](#).

EXAMPLES:

```

sage: sage.combinat.combinatorial_map.combinatorial_map = sage.combinat.
↳combinatorial_map.combinatorial_map_wrapper
sage: from importlib import reload
sage: _ = reload(sage.combinat.permutation)
sage: from sage.combinat.combinatorial_map import combinatorial_maps_in_class
sage: p = Permutation([1,3,2,4])
sage: cmaps = combinatorial_maps_in_class(p)
sage: cmaps # random
[Combinatorial map: Robinson-Schensted insertion tableau,
Combinatorial map: Robinson-Schensted recording tableau,
Combinatorial map: Robinson-Schensted tableau shape,
Combinatorial map: complement,
Combinatorial map: descent composition,
Combinatorial map: inverse, ...]
sage: p.left_tableau in cmaps
True
sage: p.right_tableau in cmaps
True
sage: p.complement in cmaps
True

```

5.1.28 Integer compositions

A composition c of a nonnegative integer n is a list of positive integers (the *parts* of the composition) with total sum n .

This module provides tools for manipulating compositions and enumerated sets of compositions.

EXAMPLES:

```

sage: Composition([5, 3, 1, 3])
[5, 3, 1, 3]
sage: list(Compositions(4))
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]

```

AUTHORS:

- Mike Hansen, Nicolas M. Thiéry
- MuPAD-Combinat developers (algorithms and design inspiration)
- Travis Scrimshaw (2013-02-03): Removed CombinatorialClass

```

class sage.combinat.composition.Composition(parent, *args, **kwds)
Bases: sage.combinat.combinat.CombinatorialElement

```

Integer compositions

A composition of a nonnegative integer n is a list (i_1, \dots, i_k) of positive integers with total sum n .

EXAMPLES:

The simplest way to create a composition is by specifying its entries as a list, tuple (or other iterable):

```

sage: Composition([3,1,2])
[3, 1, 2]
sage: Composition((3,1,2))
[3, 1, 2]

```

(continues on next page)

(continued from previous page)

```
sage: Composition(i for i in range(2,5))
[2, 3, 4]
```

You can also create a composition from its code. The *code* of a composition (i_1, i_2, \dots, i_k) of n is a list of length n that consists of a 1 followed by $i_1 - 1$ zeros, then a 1 followed by $i_2 - 1$ zeros, and so on.

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Composition(code=_)
[4, 1, 2, 3, 5]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Composition(code=_)
[3, 1, 2, 3, 5]
```

You can also create the composition of n corresponding to a subset of $\{1, 2, \dots, n-1\}$ under the bijection that maps the composition (i_1, i_2, \dots, i_k) of n to the subset $\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \dots, i_1 + \dots + i_{k-1}\}$ (see `to_subset()`):

```
sage: Composition(from_subset={1, 2, 4}, 5)
[1, 1, 2, 1]
sage: Composition([1, 1, 2, 1]).to_subset()
{1, 2, 4}
```

The following notation equivalently specifies the composition from the set $\{i_1 - 1, i_1 + i_2 - 1, i_1 + i_2 + i_3 - 1, \dots, i_1 + \dots + i_{k-1} - 1, n - 1\}$ or $\{i_1 - 1, i_1 + i_2 - 1, i_1 + i_2 + i_3 - 1, \dots, i_1 + \dots + i_{k-1} - 1\}$ and n . This provides compatibility with Python's 0-indexing.

```
sage: Composition(descents=[1,0,4,8,11])
[1, 1, 3, 4, 3]
sage: Composition(descents=[0,1,3,4])
[1, 1, 2, 1]
sage: Composition(descents=([0,1,3],5))
[1, 1, 2, 1]
sage: Composition(descents=({0,1,3},5))
[1, 1, 2, 1]
```

EXAMPLES:

```
sage: C = Composition([3,1,2])
sage: TestSuite(C).run()
```

complement()

Return the complement of the composition `self`.

The complement of a composition I is defined as follows:

If I is the empty composition, then the complement is the empty composition as well. Otherwise, let S be the descent set of I (that is, the subset $\{i_1, i_1 + i_2, \dots, i_1 + i_2 + \dots + i_{k-1}\}$ of $\{1, 2, \dots, |I| - 1\}$, where I is written as (i_1, i_2, \dots, i_k)). Then, the complement of I is defined as the composition of size $|I|$ whose descent set is $\{1, 2, \dots, |I| - 1\} \setminus S$.

The complement of a composition I also is the reverse composition (`reversed()`) of the conjugate (`conjugate()`) of I .

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
sage: Composition([1, 1, 3, 1, 2, 1, 3]).complement()
[3, 1, 3, 3, 1, 1]
```

conjugate()

Return the conjugate of the composition self.

The conjugate of a composition I is defined as the complement (see [complement\(\)](#)) of the reverse composition (see [reversed\(\)](#)) of I .

An equivalent definition of the conjugate goes by saying that the ribbon shape of the conjugate of a composition I is the conjugate of the ribbon shape of I . (The ribbon shape of a composition is returned by [to_skew_partition\(\)](#).)

This implementation uses the algorithm from mupad-combinat.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
```

The ribbon shape of the conjugate of I is the conjugate of the ribbon shape of I :

```
sage: all( I.conjugate().to_skew_partition()
.....:      == I.to_skew_partition().conjugate()
.....:      for I in Compositions(4) )
True
```

descents (*final_descent=False*)

This gives one fewer than the partial sums of the composition.

This is here to maintain some sort of backward compatibility, even through the original implementation was broken (it gave the wrong answer). The same information can be found in [partial_sums\(\)](#).

See also:

[partial_sums\(\)](#)

INPUT:

- `final_descent` – (Default: `False`) a boolean integer

OUTPUT:

- the list of partial sums of `self` with each part decremented by 1. This includes the sum of all entries when `final_descent` is `True`.

EXAMPLES:

```
sage: c = Composition([2,1,3,2])
sage: c.descents()
[1, 2, 5]
sage: c.descents(final_descent=True)
[1, 2, 5, 7]
```

fatten (*grouping*)

Return the composition fatter than `self`, obtained by grouping together consecutive parts according to `grouping`.

INPUT:

- **grouping** – a composition whose sum is the length of `self`

EXAMPLES:

Let us start with the composition:

```
sage: c = Composition([4,5,2,7,1])
```

With grouping equal to $(1, \dots, 1)$, c is left unchanged:

```
sage: c.fatten(Composition([1,1,1,1,1]))
[4, 5, 2, 7, 1]
```

With grouping equal to (ℓ) where ℓ is the length of c , this yields the coarsest composition above c :

```
sage: c.fatten(Composition([5]))
[19]
```

Other values for grouping yield (all the) other compositions coarser than c :

```
sage: c.fatten(Composition([2,1,2]))
[9, 2, 8]
sage: c.fatten(Composition([3,1,1]))
[11, 7, 1]
```

fatter()

Return the set of compositions which are fatter than `self`.

Complexity for generation: $O(|c|)$ memory, $O(|r|)$ time where $|c|$ is the size of `self` and r is the result.

EXAMPLES:

```
sage: C = Composition([4,5,2]).fatter()
sage: C.cardinality()
4
sage: list(C)
[[4, 5, 2], [4, 7], [9, 2], [11]]
```

Some extreme cases:

```
sage: list(Composition([5]).fatter())
[[5]]
sage: list(Composition([]).fatter())
[[]]
sage: list(Composition([1,1,1,1]).fatter()) == list(Compositions(4))
True
```

finer()

Return the set of compositions which are finer than `self`.

EXAMPLES:

```
sage: C = Composition([3,2]).finer()
sage: C.cardinality()
8
sage: C.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 2, 1, 1], [1, 2, 2], [2, 1, 1, 1], [2, 1, 2], [3, 1, 1], [3, 2]]
```

(continues on next page)

(continued from previous page)

```
sage: Composition([]).finer()
{[]}
```

inf(*other*, *check=True*)

Return the meet of *self* with a composition *other* of the same size.

The meet of two compositions I and J of size n is the finest composition of n which is coarser than each of I and J . It can be described as the composition whose descent set is the intersection of the descent sets of I and J .

INPUT:

- *other* – composition of same size as *self*
- *check* – (default: True) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

- the meet of the compositions *self* and *other*

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).meet([4, 3, 2])
[4, 5]
sage: Composition([9, 6]).meet([1, 3, 6, 3, 2])
[15]
sage: Composition([9, 6]).meet([1, 3, 5, 1, 3, 2])
[9, 6]
sage: Composition([1, 1, 1, 1, 1]).meet([3, 2])
[3, 2]
sage: Composition([4, 2]).meet([3, 3])
[6]
sage: Composition([]).meet([])
[]
sage: Composition([1]).meet([1])
[1]
```

Let us verify on small examples that the meet of I and J is coarser than both of I and J :

```
sage: all( all( I.is_finer(I.meet(J)) and
.....:         J.is_finer(I.meet(J))
.....:         for J in Compositions(4) )
.....:     for I in Compositions(4) )
True
```

and is the finest composition to do so:

```
sage: all( all( all( I.meet(J).is_finer(K)
.....:                 for K in I.fatter()
.....:                 if J.is_finer(K) )
.....:         for J in Compositions(3) )
.....:     for I in Compositions(3) )
True
```

The descent set of the meet of I and J is the intersection of the descent sets of I and J :

```

sage: def test_meet(n):
.....:     return all( all( I.to_subset().intersection(J.to_subset())
.....:                     == I.meet(J).to_subset()
.....:                     for J in Compositions(n) )
.....:                 for I in Compositions(n) )
sage: all( test_meet(n) for n in range(1, 5) )
True

```

See also:[join\(\)](#)**AUTHORS:**

- Darij Grinberg (2013-09-05)

is_finer(*co2*)

Return True if the composition *self* is finer than the composition *co2*; otherwise, return False.

EXAMPLES:

```

sage: Composition([4,1,2]).is_finer([3,1,3])
False
sage: Composition([3,1,3]).is_finer([4,1,2])
False
sage: Composition([1,2,2,1,1,2]).is_finer([5,1,3])
True
sage: Composition([2,2,2]).is_finer([4,2])
True

```

join(*other*, *check=True*)

Return the join of *self* with a composition *other* of the same size.

The join of two compositions *I* and *J* of size *n* is the coarsest composition of *n* which refines each of *I* and *J*. It can be described as the composition whose descent set is the union of the descent sets of *I* and *J*. It is also the concatenation of I_1, I_2, \dots, I_m , where $I = I_1 \bullet I_2 \bullet \dots \bullet I_m$ is the ribbon decomposition of *I* with respect to *J* (see [ribbon_decomposition\(\)](#)).

INPUT:

- *other* – composition of same size as *self*
- *check* – (default: True) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

- the join of the compositions *self* and *other*

EXAMPLES:

```

sage: Composition([3, 1, 1, 3, 1]).join([4, 3, 2])
[3, 1, 1, 2, 1, 1]
sage: Composition([9, 6]).join([1, 3, 6, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([9, 6]).join([1, 3, 5, 1, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([1, 1, 1, 1, 1]).join([3, 2])
[1, 1, 1, 1, 1]

```

(continues on next page)

(continued from previous page)

```
sage: Composition([4, 2]).join([3, 3])
[3, 1, 2]
sage: Composition([]).join([])
[]
```

Let us verify on small examples that the join of I and J refines both of I and J :

```
sage: all( all( I.join(J).is_finer(I) and
.....:         I.join(J).is_finer(J)
.....:         for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

and is the coarsest composition to do so:

```
sage: all( all( all( K.is_finer(I.join(J))
.....:         for K in I.finer()
.....:         if K.is_finer(J) )
.....: for J in Compositions(3) )
.....: for I in Compositions(3) )
True
```

Let us check that the join of I and J is indeed the concatenation of I_1, I_2, \dots, I_m , where $I = I_1 \bullet I_2 \bullet \dots \bullet I_m$ is the ribbon decomposition of I with respect to J :

```
sage: all( all( Composition.sum(I.ribbon_decomposition(J)[0])
.....:         == I.join(J) for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

Also, the descent set of the join of I and J is the union of the descent sets of I and J :

```
sage: all( all( I.to_subset().union(J.to_subset())
.....:         == I.join(J).to_subset()
.....:         for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

See also:

[`meet\(\)`](#), [`ribbon_decomposition\(\)`](#)

AUTHORS:

- Darij Grinberg (2013-09-05)

major_index()

Return the major index of `self`. The major index is defined as the sum of the descents.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).major_index()
31
```

meet(*other*, *check=True*)

Return the meet of `self` with a composition `other` of the same size.

The meet of two compositions I and J of size n is the finest composition of n which is coarser than each of I and J . It can be described as the composition whose descent set is the intersection of the descent sets of I and J .

INPUT:

- `other` – composition of same size as `self`
- `check` – (default: `True`) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

- the meet of the compositions `self` and `other`

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).meet([4, 3, 2])
[4, 5]
sage: Composition([9, 6]).meet([1, 3, 6, 3, 2])
[15]
sage: Composition([9, 6]).meet([1, 3, 5, 1, 3, 2])
[9, 6]
sage: Composition([1, 1, 1, 1, 1]).meet([3, 2])
[3, 2]
sage: Composition([4, 2]).meet([3, 3])
[6]
sage: Composition([]).meet([])
[]
sage: Composition([1]).meet([1])
[1]
```

Let us verify on small examples that the meet of I and J is coarser than both of I and J :

```
sage: all( all( I.is_finer(I.meet(J)) and
.....:         J.is_finer(I.meet(J))
.....:         for J in Compositions(4) )
.....:     for I in Compositions(4) )
True
```

and is the finest composition to do so:

```
sage: all( all( all( I.meet(J).is_finer(K)
.....:                 for K in I.fatter()
.....:                 if J.is_finer(K) )
.....:         for J in Compositions(3) )
.....:     for I in Compositions(3) )
True
```

The descent set of the meet of I and J is the intersection of the descent sets of I and J :

```
sage: def test_meet(n):
.....:     return all( all( I.to_subset().intersection(J.to_subset())
.....:                       == I.meet(J).to_subset()
.....:                       for J in Compositions(n) )
.....:                 for I in Compositions(n) )
```

(continues on next page)

(continued from previous page)

```
sage: all( test_meet(n) for n in range(1, 5) )
True
```

See also:[join\(\)](#)

AUTHORS:

- Darij Grinberg (2013-09-05)

near_concatenation(*other*)Return the near-concatenation of two nonempty compositions *self* and *other*.The near-concatenation $I \odot J$ of two nonempty compositions I and J is defined as the composition $(i_1, i_2, \dots, i_{n-1}, i_n + j_1, j_2, j_3, \dots, j_m)$, where $(i_1, i_2, \dots, i_n) = I$ and $(j_1, j_2, \dots, j_m) = J$.

This method returns None if one of the two input compositions is empty.

EXAMPLES:

```
sage: Composition([1, 1, 3]).near_concatenation(Composition([4, 1, 2]))
[1, 1, 7, 1, 2]
sage: Composition([6]).near_concatenation(Composition([1, 5]))
[7, 5]
sage: Composition([1, 5]).near_concatenation(Composition([6]))
[1, 11]
```

partial_sums(*final=True*)

The partial sums of the sequence defined by the entries of the composition.

If $I = (i_1, \dots, i_m)$ is a composition, then the partial sums of the entries of the composition are $[i_1, i_1 + i_2, \dots, i_1 + i_2 + \dots + i_m]$.

INPUT:

- *final* – (default: True) whether or not to include the final partial sum, which is always the size of the composition.

See also:[to_subset\(\)](#)

EXAMPLES:

```
sage: Composition([1,1,3,1,2,1,3]).partial_sums()
[1, 2, 5, 6, 8, 9, 12]
```

With *final* = False, the last partial sum is not included:

```
sage: Composition([1,1,3,1,2,1,3]).partial_sums(final=False)
[1, 2, 5, 6, 8, 9]
```

peaks()Return a list of the peaks of the composition *self*.

The peaks of a composition are the descents which do not immediately follow another descent.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).peaks()
[4, 7]
```

refinement_splitting(*J*)

Return the refinement splitting of `self` according to `J`.

INPUT:

- `J` – A composition such that `self` is finer than `J`

OUTPUT:

- the unique list of compositions $(I^{(p)})_{p=1,\dots,m}$, obtained by splitting I , such that $|I^{(p)}| = J_p$ for all $p = 1, \dots, m$.

See also:

[`refinement_splitting_lengths\(\)`](#)

EXAMPLES:

```
sage: Composition([1,2,2,1,1,2]).refinement_splitting([5,1,3])
[[1, 2, 2], [1], [1, 2]]
sage: Composition([]).refinement_splitting([])
[]
sage: Composition([3]).refinement_splitting([2])
Traceback (most recent call last):
...
ValueError: compositions self (= [3]) and J (= [2]) must be of the same size
sage: Composition([2,1]).refinement_splitting([1,2])
Traceback (most recent call last):
...
ValueError: composition J (= [2, 1]) does not refine self (= [1, 2])
```

refinement_splitting_lengths(*J*)

Return the lengths of the compositions in the refinement splitting of `self` according to `J`.

See also:

[`refinement_splitting\(\)`](#) for the definition of refinement splitting

EXAMPLES:

```
sage: Composition([1,2,2,1,1,2]).refinement_splitting_lengths([5,1,3])
[3, 1, 2]
sage: Composition([]).refinement_splitting_lengths([])
[]
sage: Composition([3]).refinement_splitting_lengths([2])
Traceback (most recent call last):
...
ValueError: compositions self (= [3]) and J (= [2]) must be of the same size
sage: Composition([2,1]).refinement_splitting_lengths([1,2])
Traceback (most recent call last):
...
ValueError: composition J (= [2, 1]) does not refine self (= [1, 2])
```

reversed()

Return the reverse composition of `self`.

The reverse composition of a composition (i_1, i_2, \dots, i_k) is defined as the composition $(i_k, i_{k-1}, \dots, i_1)$.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).reversed()
[3, 1, 2, 1, 3, 1, 1]
```

ribbon_decomposition(*other*, *check=True*)

Return a pair describing the ribbon decomposition of a composition *self* with respect to a composition *other* of the same size.

If I and J are two compositions of the same nonzero size, then the ribbon decomposition of I with respect to J is defined as follows: Write I and J as $I = (i_1, i_2, \dots, i_n)$ and $J = (j_1, j_2, \dots, j_m)$. Then, the equality $I = I_1 \bullet I_2 \bullet \dots \bullet I_m$ holds for a unique m -tuple (I_1, I_2, \dots, I_m) of compositions such that each I_k has size j_k and for a unique choice of $m - 1$ signs \bullet each of which is either the concatenation sign \cdot or the near-concatenation sign \odot (see `__add__()` and `near_concatenation()` for the definitions of these two signs). This m -tuple and this choice of signs together are said to form the ribbon decomposition of I with respect to J . If I and J are empty, then the same definition applies, except that there are 0 rather than $m - 1$ signs.

See Section 4.8 of [NCSF1].

INPUT:

- *other* – composition of same size as *self*
- *check* – (default: True) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

- a pair (u, v) , where u is a tuple of compositions (corresponding to the m -tuple (I_1, I_2, \dots, I_m) in the above definition), and v is a tuple of 0 in the above definition, with a 0 standing for \cdot and a 1 standing for \odot .

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).ribbon_decomposition([4, 3, 2])
((([3, 1], [1, 2], [1, 1]), (0, 1))
sage: Composition([9, 6]).ribbon_decomposition([1, 3, 6, 3, 2])
((([1], [3], [5, 1], [3], [2]), (1, 1, 1, 1))
sage: Composition([9, 6]).ribbon_decomposition([1, 3, 5, 1, 3, 2])
((([1], [3], [5], [1], [3], [2]), (1, 1, 0, 1, 1))
sage: Composition([1, 1, 1, 1, 1]).ribbon_decomposition([3, 2])
((([1, 1, 1], [1, 1]), (0,))
sage: Composition([4, 2]).ribbon_decomposition([6])
((([4, 2],), (,))
sage: Composition([]).ribbon_decomposition([])
((), ())
```

Let us check that the defining property $I = I_1 \bullet I_2 \bullet \dots \bullet I_m$ is satisfied:

```
sage: def compose_back(u, v):
.....:     comp = u[0]
.....:     r = len(v)
.....:     if len(u) != r + 1:
.....:         raise ValueError("something is wrong")
.....:     for i in range(r):
```

(continues on next page)

(continued from previous page)

```

.....:         if v[i] == 0:
.....:             comp += u[i + 1]
.....:         else:
.....:             comp = comp.near_concatenation(u[i + 1])
.....:     return comp
sage: all( all( all( compose_back(*(I.ribbon_decomposition(J))) == I
.....:             for J in Compositions(n) )
.....:         for I in Compositions(n) )
.....:     for n in range(1, 5) )
True

```

AUTHORS:

- Darij Grinberg (2013-08-29)

shuffle_product(*other*, *overlap=False*)The (overlapping) shuffles of *self* and *other*.

Suppose $I = (i_1, \dots, i_k)$ and $J = (j_1, \dots, j_l)$ are two compositions. A *shuffle* of I and J is a composition of length $k + l$ that contains both I and J as subsequences.

More generally, an *overlapping shuffle* of I and J is obtained by distributing the elements of I and J (preserving the relative ordering of these elements) among the positions of an empty list; an element of I and an element of J are permitted to share the same position, in which case they are replaced by their sum. In particular, a shuffle of I and J is an overlapping shuffle of I and J .

INPUT:

- *other* – composition
- *overlap* – boolean (default: `False`); if `True`, the overlapping shuffle product is returned.

OUTPUT:

An enumerated set (allowing for multiplicities)

EXAMPLES:

The shuffle product of $[2, 2]$ and $[1, 1, 3]$:

```

sage: alph = Composition([2,2])
sage: beta = Composition([1,1,3])
sage: S = alph.shuffle_product(beta); S
Shuffle product of [2, 2] and [1, 1, 3]
sage: S.list()
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2], [1, 2, 2, ↵
↵1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3], [1, 1, 2, 3, 2], [1,
↵1, 3, 2, 2]]

```

The *overlapping* shuffle product of $[2, 2]$ and $[1, 1, 3]$:

```

sage: alph = Composition([2,2])
sage: beta = Composition([1,1,3])
sage: O = alph.shuffle_product(beta, overlap=True); O
Overlapping shuffle product of [2, 2] and [1, 1, 3]
sage: O.list()
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2], [1, 2, 2, ↵
↵1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3], [1, 1, 2, 3, 2], [1,
↵1, 3, 2, 2], [3, 2, 1, 3], [2, 3, 1, 3], [3, 1, 2, 3], [2, 1, 3, 2, 3], [2, 1, 3, 2, 2], [2, 1, 1, 5], [1, 3, 2, 3], [1, 2, 3, 3], [1, 3, 3, 2], [1, 2, 1, 5], ↵
↵1, 1, 5, 2], [1, 1, 2, 5], [3, 3, 3], [3, 1, 5], [1, 3, 5]]

```

(continued from previous page)

Note that the shuffle product of two compositions can include the same composition more than once since a composition can be a shuffle of two compositions in several ways. For example:

```
sage: w1 = Composition([1])
sage: S = w1.shuffle_product(w1); S
Shuffle product of [1] and [1]
sage: S.list()
[[1, 1], [1, 1]]
sage: O = w1.shuffle_product(w1, overlap=True); O
Overlapping shuffle product of [1] and [1]
sage: O.list()
[[1, 1], [1, 1], [2]]
```

size()

Return the size of `self`, that is the sum of its parts.

EXAMPLES:

```
sage: Composition([7,1,3]).size()
11
```

static sum(compositions)

Return the concatenation of the given compositions.

INPUT:

- `compositions` – a list (or iterable) of compositions

EXAMPLES:

```
sage: Composition.sum([Composition([1, 1, 3]), Composition([4, 1, 2]),
↳ Composition([3,1])])
[1, 1, 3, 4, 1, 2, 3, 1]
```

Any iterable can be provided as input:

```
sage: Composition.sum([Composition([i,i]) for i in [4,1,3]])
[4, 4, 1, 1, 3, 3]
```

Empty inputs are handled gracefully:

```
sage: Composition.sum([]) == Composition([])
True
```

sup(other, check=True)

Return the join of `self` with a composition `other` of the same size.

The join of two compositions I and J of size n is the coarsest composition of n which refines each of I and J . It can be described as the composition whose descent set is the union of the descent sets of I and J . It is also the concatenation of I_1, I_2, \dots, I_m , where $I = I_1 \bullet I_2 \bullet \dots \bullet I_m$ is the ribbon decomposition of I with respect to J (see `ribbon_decomposition()`).

INPUT:

- `other` – composition of same size as `self`

- `check` – (default: `True`) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

- the join of the compositions `self` and `other`

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).join([4, 3, 2])
[3, 1, 1, 2, 1, 1]
sage: Composition([9, 6]).join([1, 3, 6, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([9, 6]).join([1, 3, 5, 1, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([1, 1, 1, 1, 1]).join([3, 2])
[1, 1, 1, 1, 1]
sage: Composition([4, 2]).join([3, 3])
[3, 1, 2]
sage: Composition([]).join([])
[]
```

Let us verify on small examples that the join of I and J refines both of I and J :

```
sage: all( all( I.join(J).is_finer(I) and
.....:         I.join(J).is_finer(J)
.....:         for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

and is the coarsest composition to do so:

```
sage: all( all( all( K.is_finer(I.join(J))
.....:         for K in I.finer()
.....:         if K.is_finer(J) )
.....: for J in Compositions(3) )
.....: for I in Compositions(3) )
True
```

Let us check that the join of I and J is indeed the concatenation of I_1, I_2, \dots, I_m , where $I = I_1 \bullet I_2 \bullet \dots \bullet I_m$ is the ribbon decomposition of I with respect to J :

```
sage: all( all( Composition.sum(I.ribbon_decomposition(J)[0])
.....:         == I.join(J) for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

Also, the descent set of the join of I and J is the union of the descent sets of I and J :

```
sage: all( all( I.to_subset().union(J.to_subset())
.....:         == I.join(J).to_subset()
.....:         for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

See also:`meet()`, `ribbon_decomposition()`**AUTHORS:**

- Darij Grinberg (2013-09-05)

to_code()Return the code of the composition `self`.

The code of a composition I is a list of length $\text{size}(I)$ of 1s and 0s such that there is a 1 wherever a new part starts. (Exceptional case: When the composition is empty, the code is `[0]`.)

EXAMPLES:

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
```

to_partition()Return the partition obtained by sorting `self` into decreasing order.**EXAMPLES:**

```
sage: Composition([2,1,3]).to_partition()
[3, 2, 1]
sage: Composition([4,2,2]).to_partition()
[4, 2, 2]
sage: Composition([]).to_partition()
[]
```

to_skew_partition(overlap=1)Return the skew partition obtained from `self`.

This is a skew partition whose rows have the entries of `self` as their length, taken in reverse order (so the first entry of `self` is the length of the lowermost row, etc.). The parameter `overlap` indicates the number of cells on each row that are directly below cells of the previous row. When it is set to 1 (its default value), the result is the ribbon shape of `self`.

EXAMPLES:

```
sage: Composition([3,4,1]).to_skew_partition()
[6, 6, 3] / [5, 2]
sage: Composition([3,4,1]).to_skew_partition(overlap=0)
[8, 7, 3] / [7, 3]
sage: Composition([]).to_skew_partition()
[] / []
sage: Composition([1,2]).to_skew_partition()
[2, 1] / []
sage: Composition([2,1]).to_skew_partition()
[2, 2] / [1]
```

to_subset(final=False)

The subset corresponding to `self` under the bijection (see below) between compositions of n and subsets of $\{1, 2, \dots, n-1\}$.

The bijection maps a composition (i_1, \dots, i_k) of n to $\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \dots, i_1 + \dots + i_{k-1}\}$.

INPUT:

- `final` – (default: `False`) whether or not to include the final partial sum, which is always the size of the composition.

See also:

`partial_sums()`

EXAMPLES:

```
sage: Composition([1,1,3,1,2,1,3]).to_subset()
{1, 2, 5, 6, 8, 9}
sage: for I in Compositions(3): print(I.to_subset())
{1, 2}
{1}
{2}
{}
```

With `final=True`, the sum of all the elements of the composition is included in the subset:

```
sage: Composition([1,1,3,1,2,1,3]).to_subset(final=True)
{1, 2, 5, 6, 8, 9, 12}
```

wll_gt(*co2*)

Return `True` if the composition `self` is greater than the composition `co2` with respect to the wll-ordering; otherwise, return `False`.

The wll-ordering is a total order on the set of all compositions defined as follows: A composition I is greater than a composition J if and only if one of the following conditions holds:

- The size of I is greater than the size of J .
- The size of I equals the size of J , but the length of I is greater than the length of J .
- The size of I equals the size of J , and the length of I equals the length of J , but I is lexicographically greater than J .

(“wll-ordering” is short for “weight, length, lexicographic ordering”.)

EXAMPLES:

```
sage: Composition([4,1,2]).wll_gt([3,1,3])
True
sage: Composition([7]).wll_gt([4,1,2])
False
sage: Composition([8]).wll_gt([4,1,2])
True
sage: Composition([3,2,2,2]).wll_gt([5,2])
True
sage: Composition([]).wll_gt([3])
False
sage: Composition([2,1]).wll_gt([2,1])
False
sage: Composition([2,2,2]).wll_gt([4,2])
True
sage: Composition([4,2]).wll_gt([2,2,2])
False
sage: Composition([1,1,2]).wll_gt([2,2])
True
```

(continues on next page)

(continued from previous page)

```
sage: Composition([2,2]).wll_gt([1,3])
True
sage: Composition([2,1,2]).wll_gt([])
True
```

class sage.combinat.composition.**Compositions**(*is_infinite=False*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Set of integer compositions.

A composition c of a nonnegative integer n is a list of positive integers with total sum n .

See also:

- [Composition](#)
- [Partitions](#)
- [IntegerVectors](#)

EXAMPLES:

There are 8 compositions of 4:

```
sage: Compositions(4).cardinality()
8
```

Here is the list of them:

```
sage: Compositions(4).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

You can use the `.first()` method to get the ‘first’ composition of a number:

```
sage: Compositions(4).first()
[1, 1, 1, 1]
```

You can also calculate the ‘next’ composition given the current one:

```
sage: Compositions(4).next([1,1,2])
[1, 2, 1]
```

If n is not specified, this returns the combinatorial class of all (non-negative) integer compositions:

```
sage: Compositions()
Compositions of non-negative integers
sage: [] in Compositions()
True
sage: [2,3,1] in Compositions()
True
sage: [-2,3,1] in Compositions()
False
```

If n is specified, it returns the class of compositions of n :

```
sage: Compositions(3)
Compositions of 3
sage: list(Compositions(3))
[[1, 1, 1], [1, 2], [2, 1], [3]]
sage: Compositions(3).cardinality()
4
```

The following examples show how to test whether or not an object is a composition:

```
sage: [3,4] in Compositions()
True
sage: [3,4] in Compositions(7)
True
sage: [3,4] in Compositions(5)
False
```

Similarly, one can check whether or not an object is a composition which satisfies further constraints:

```
sage: [4,2] in Compositions(6, inner=[2,2])
True
sage: [4,2] in Compositions(6, inner=[2,3])
False
sage: [4,1] in Compositions(5, inner=[2,1], max_slope = 0)
True
```

An example with incompatible constraints:

```
sage: [4,2] in Compositions(6, inner=[2,2], min_part=3)
False
```

The options `length`, `min_length`, and `max_length` can be used to set length constraints on the compositions. For example, the compositions of 4 of length equal to, at least, and at most 2 are given by:

```
sage: Compositions(4, length=2).list()
[[3, 1], [2, 2], [1, 3]]
sage: Compositions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
sage: Compositions(4, max_length=2).list()
[[4], [3, 1], [2, 2], [1, 3]]
```

Setting both `min_length` and `max_length` to the same value is equivalent to setting `length` to this value:

```
sage: Compositions(4, min_length=2, max_length=2).list()
[[3, 1], [2, 2], [1, 3]]
```

The options `inner` and `outer` can be used to set part-by-part containment constraints. The list of compositions of 4 bounded above by `[3, 1, 2]` is given by:

```
sage: list(Compositions(4, outer=[3,1,2]))
[[3, 1], [2, 1, 1], [1, 1, 2]]
```

`outer` sets `max_length` to the length of its argument. Moreover, the parts of `outer` may be infinite to clear the constraint on specific parts. This is the list of compositions of 4 of length at most 3 such that the first and third parts are at most 1:

```
sage: Compositions(4, outer=[1,oo,1]).list()
[[1, 3], [1, 2, 1]]
```

This is the list of compositions of 4 bounded below by [1,1,1]:

```
sage: Compositions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

The options `min_slope` and `max_slope` can be used to set constraints on the slope, that is the difference $p[i+1]-p[i]$ of two consecutive parts. The following is the list of weakly increasing compositions of 4:

```
sage: Compositions(4, min_slope=0).list()
[[4], [2, 2], [1, 3], [1, 1, 2], [1, 1, 1, 1]]
```

Here are the weakly decreasing ones:

```
sage: Compositions(4, max_slope=0).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The following is the list of compositions of 4 such that two consecutive parts differ by at most one:

```
sage: Compositions(4, min_slope=-1, max_slope=1).list()
[[4], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

The constraints can be combined together in all reasonable ways. This is the list of compositions of 5 of length between 2 and 4 such that the difference between consecutive parts is between -2 and 1:

```
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4).list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2], [2, 1, 1, 1], [1, 2, 2], [1, 2, 1,
↪ 1], [1, 1, 2, 1], [1, 1, 1, 2]]
```

We can do the same thing with an outer constraint:

```
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4,
↪ outer=[2,5,2]).list()
[[2, 3], [2, 2, 1], [2, 1, 2], [1, 2, 2]]
```

However, providing incoherent constraints may yield strange results. It is up to the user to ensure that the inner and outer compositions themselves satisfy the parts and slope constraints.

Note that if you specify `min_part=0`, then the objects produced may have parts equal to zero. This violates the internal assumptions that the composition class makes. Use at your own risk, or preferably consider using `IntegerVectors` instead:

```
sage: Compositions(2, length=3, min_part=0).list()
doctest:...: RuntimeWarning: Currently, setting min_part=0 produces Composition_
↪ objects which violate internal assumptions. Calling methods on these objects may_
↪ produce errors or WRONG results!
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]

sage: list(IntegerVectors(2, 3))
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

The generation algorithm is constant amortized time, and handled by the generic tool `IntegerListsLex`.

Elementalias of *Composition***from_code(*code*)**

Return the composition from its code. The code of a composition I is a list of length $\text{size}(I)$ consisting of 1s and 0s such that there is a 1 wherever a new part starts. (Exceptional case: When the composition is empty, the code is $[0]$.)

EXAMPLES:

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Compositions().from_code(_)
[4, 1, 2, 3, 5]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Compositions().from_code(_)
[3, 1, 2, 3, 5]
```

from_descents(*descents*, *nps*=None)

Return a composition from the list of descents.

INPUT:

- *descents* – an iterable
- *nps* – (default: None) an integer or None

OUTPUT:

- The composition of *nps* whose descents are listed in *descents*, assuming that *nps* is not None (otherwise, the last element of *descents* is removed from *descents*, and *nps* is set to be this last element plus 1).

EXAMPLES:

```
sage: [x-1 for x in Composition([1, 1, 3, 4, 3]).to_subset()]
[0, 1, 4, 8]
sage: Compositions().from_descents([1,0,4,8],12)
[1, 1, 3, 4, 3]
sage: Compositions().from_descents([1,0,4,8,11])
[1, 1, 3, 4, 3]
```

from_subset(*S*, *n*)

The composition of n corresponding to the subset S of $\{1, 2, \dots, n-1\}$ under the bijection that maps the composition (i_1, i_2, \dots, i_k) of n to the subset $\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \dots, i_1 + \dots + i_{k-1}\}$ (see *Composition.to_subset()*).

INPUT:

- S – an iterable, a subset of $\{1, 2, \dots, n-1\}$
- n – an integer

EXAMPLES:

```
sage: Compositions().from_subset([2,1,5,9], 12)
[1, 1, 3, 4, 3]
sage: Compositions().from_subset({2,1,5,9}, 12)
[1, 1, 3, 4, 3]
```

(continues on next page)

(continued from previous page)

```
sage: Compositions().from_subset([], 12)
[12]
sage: Compositions().from_subset([], 0)
[]
```

class `sage.combinat.composition.Compositions_all`

Bases: `sage.combinat.composition.Compositions`

Class of all compositions.

subset(*size=None*)

Return the set of compositions of the given size.

EXAMPLES:

```
sage: C = Compositions()
sage: C.subset(4)
Compositions of 4
sage: C.subset(size=3)
Compositions of 3
```

class `sage.combinat.composition.Compositions_constraints(*args, **kws)`

Bases: `sage.combinat.integer_lists.invlex.IntegerListsLex`

class `sage.combinat.composition.Compositions_n(n)`

Bases: `sage.combinat.composition.Compositions`

Class of compositions of a fixed n .

cardinality()

Return the number of compositions of n .

random_element()

Return a random `Composition` with uniform probability.

This method generates a random binary word starting with a 1 and then uses the bijection between compositions and their code.

EXAMPLES:

```
sage: Compositions(5).random_element() # random
[2, 1, 1, 1]
sage: Compositions(0).random_element()
[]
sage: Compositions(1).random_element()
[1]
```

`sage.combinat.composition.composition_iterator_fast(n)`

Iterator over compositions of n yielded as lists.

5.1.29 Signed Compositions

class `sage.combinat.composition_signed.SignedCompositions(n)`

Bases: `sage.combinat.composition.Compositions_n`

The class of signed compositions of *n*.

EXAMPLES:

```
sage: SC3 = SignedCompositions(3); SC3
Signed compositions of 3
sage: SC3.cardinality()
18
sage: len(SC3.list())
18
sage: SC3.first()
[1, 1, 1]
sage: SC3.last()
[-3]
sage: SC3.random_element() # random
[1, -1, 1]
sage: SC3.list()
[[1, 1, 1],
 [1, 1, -1],
 [1, -1, 1],
 [1, -1, -1],
 [-1, 1, 1],
 [-1, 1, -1],
 [-1, -1, 1],
 [-1, -1, -1],
 [1, 2],
 [1, -2],
 [-1, 2],
 [-1, -2],
 [2, 1],
 [2, -1],
 [-2, 1],
 [-2, -1],
 [3],
 [-3]]
```

cardinality()

Return the number of elements in `self`.

The number of signed compositions of *n* is equal to

$$\sum_{i=1}^{n+1} \binom{n-1}{i-1} 2^i$$

EXAMPLES:

```
sage: SC4 = SignedCompositions(4)
sage: SC4.cardinality() == len(SC4.list())
True
sage: SignedCompositions(3).cardinality()
18
```

5.1.30 Composition Tableaux

AUTHORS:

- Chris Berg, Jeff Ferreira (2012-9): Initial version

class sage.combinat.composition_tableau.**CompositionTableau**(parent, t)

Bases: *sage.combinat.combinat.CombinatorialElement*

A composition tableau.

A *composition tableau* t of shape $I = (I_1, \dots, I_\ell)$ is an array of boxes in rows, I_i boxes in row i , filled with positive integers such that:

- 1) the entries in the rows of t weakly decrease from left to right,
- 2) the left-most column of t strictly increase from top to bottom.
- 3) Add zero entries to the rows of t until the resulting array is rectangular of shape $\ell \times m$. For $1 \leq i < j \leq \ell$, $2 \leq k \leq m$ and $(t(j, k) \neq 0$, and also if $t(j, k) \geq t(i, k)$) implies $t(j, k) > t(i, k - 1)$.

INPUT:

- \mathbf{t} – A list of lists

EXAMPLES:

```
sage: CompositionTableau([[1],[2,2]])
[[1], [2, 2]]
sage: CompositionTableau([[1],[3,2],[4,4]])
[[1], [3, 2], [4, 4]]
sage: CompositionTableau([])
[]
```

descent_composition()

Return the composition corresponding to the set of all i that do not have $i + 1$ appearing strictly to the left of i in *self*.

EXAMPLES:

```
sage: CompositionTableau([[1],[3,2],[4,4]]).descent_composition()
[1, 2, 2]
```

descent_set()

Return the set of all i that *do not* have $i + 1$ appearing strictly to the left of i in *self*.

EXAMPLES:

```
sage: CompositionTableau([[1],[3,2],[4,4]]).descent_set()
[1, 3]
```

is_standard()

Return True if *self* is a standard composition tableau and False otherwise.

EXAMPLES:

```
sage: CompositionTableau([[1,1],[3,2],[4,4,3]]).is_standard()
False
sage: CompositionTableau([[2,1],[3],[4]]).is_standard()
True
```

pp()

Return a pretty print string of self.

EXAMPLES:

```
sage: CompositionTableau([[1],[3,2],[4,4]]).pp()
1
3 2
4 4
```

shape_composition()

Return a Composition object which is the shape of self.

EXAMPLES:

```
sage: CompositionTableau([[1,1],[3,2],[4,4,3]]).shape_composition()
[2, 2, 3]
sage: CompositionTableau([[2,1],[3],[4]]).shape_composition()
[2, 1, 1]
```

shape_partition()

Return a partition which is the shape of self sorted into weakly decreasing order.

EXAMPLES:

```
sage: CompositionTableau([[1,1],[3,2],[4,4,3]]).shape_partition()
[3, 2, 2]
sage: CompositionTableau([[2,1],[3],[4]]).shape_partition()
[2, 1, 1]
```

size()

Return the number of boxes in self.

EXAMPLES:

```
sage: CompositionTableau([[1],[3,2],[4,4]]).size()
5
```

weight()

Return a composition where entry i is the number of times that i appears in self.

EXAMPLES:

```
sage: CompositionTableau([[1],[3,2],[4,4]]).weight()
[1, 1, 1, 2, 0]
```

class sage.combinat.composition_tableau.**CompositionTableaux**(**kws)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Composition tableaux.

INPUT:

Keyword arguments:

- size – the size of the composition tableaux
- shape – the shape of the composition tableaux

- `max_entry` – the maximum entry for the composition tableaux

Positional arguments:

- The first argument is interpreted as `size` or `shape` depending on whether it is an integer or a composition.

EXAMPLES:

```

sage: CT = CompositionTableaux(3); CT
Composition Tableaux of size 3 and maximum entry 3
sage: list(CT)
[[[1], [2], [3]],
 [[1], [2, 2]],
 [[1], [3, 2]],
 [[1], [3, 3]],
 [[2], [3, 3]],
 [[1, 1], [2]],
 [[1, 1], [3]],
 [[2, 1], [3]],
 [[2, 2], [3]],
 [[1, 1, 1]],
 [[2, 1, 1]],
 [[2, 2, 1]],
 [[2, 2, 2]],
 [[3, 1, 1]],
 [[3, 2, 1]],
 [[3, 2, 2]],
 [[3, 3, 1]],
 [[3, 3, 2]],
 [[3, 3, 3]]

sage: CT = CompositionTableaux([1,2,1]); CT
Composition tableaux of shape [1, 2, 1] and maximum entry 4
sage: list(CT)
[[[1], [2, 2], [3]],
 [[1], [2, 2], [4]],
 [[1], [3, 2], [4]],
 [[1], [3, 3], [4]],
 [[2], [3, 3], [4]]]

sage: CT = CompositionTableaux(shape=[1,2,1],max_entry=3); CT
Composition tableaux of shape [1, 2, 1] and maximum entry 3
sage: list(CT)
[[[1], [2, 2], [3]]]

sage: CT = CompositionTableaux(2,max_entry=3); CT
Composition Tableaux of size 2 and maximum entry 3
sage: list(CT)
[[[1], [2]],
 [[1], [3]],
 [[2], [3]],
 [[1, 1]],
 [[2, 1]],
 [[2, 2]],
 [[3, 1]],

```

(continues on next page)

(continued from previous page)

```

[[3, 2]],
[[3, 3]]

sage: CT = CompositionTableaux(0); CT
Composition Tableaux of size 0 and maximum entry 0
sage: list(CT)
[[]]

```

Elementalias of *CompositionTableau*

```

class sage.combinat.composition_tableau.CompositionTableauxBacktracker(shape,
                                                                    max_entry=None)

```

Bases: *sage.combinat.backtrack.GenericBacktracker*

A backtracker class for generating sets of composition tableaux.

get_next_pos(*ii, jj*)

EXAMPLES:

```

sage: from sage.combinat.composition_tableau import
↳ CompositionTableauxBacktracker
sage: T = CompositionTableau([[2, 1], [5, 4, 3, 2], [6], [7, 7, 6]])
sage: n = CompositionTableauxBacktracker(T.shape_composition())
sage: n.get_next_pos(1, 1)
(1, 2)

```

```

class sage.combinat.composition_tableau.CompositionTableaux_all(max_entry=None)
Bases: sage.combinat.composition_tableau.CompositionTableaux, sage.sets.
disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets

```

All composition tableaux.

an_element()

Return a particular element of self.

EXAMPLES:

```

sage: CT = CompositionTableaux()
sage: CT.an_element()
[[1, 1], [2]]

```

```

class sage.combinat.composition_tableau.CompositionTableaux_shape(comp, max_entry=None)

```

Bases: *sage.combinat.composition_tableau.CompositionTableaux*Composition tableaux of a fixed shape *comp* with a given max entry.

INPUT:

- *comp* – a composition.
- *max_entry* – a nonnegative integer. This keyword argument defaults to the size of *comp*.

an_element()Return a particular element of *CompositionTableaux_shape*.

EXAMPLES:

```
sage: CT = CompositionTableaux([1,2,1])
sage: CT.an_element()
[[1], [2, 2], [3]]
```

class sage.combinat.composition_tableau.**CompositionTableaux_size**(*n*, *max_entry=None*)

Bases: *sage.combinat.composition_tableau.CompositionTableaux*

Composition tableaux of a fixed size *n*.

INPUT:

- *n* – a nonnegative integer.
- *max_entry* – a nonnegative integer. This keyword argument defaults to *n*.

OUTPUT:

- The class of composition tableaux of size *n*.

5.1.31 Constellations

A constellation is a tuple (g_0, g_1, \dots, g_k) of permutations such that the product $g_0 g_1 \dots g_k$ is the identity. One often assumes that the group generated by g_0, g_1, \dots, g_k acts transitively ([LZ2004] definition 1). Geometrically, it corresponds to a covering of the 2-sphere ramified over k points (the transitivity condition corresponds to the connectivity of the covering).

EXAMPLES:

```
sage: c = Constellation(['(1,2)', '(1,3)', None])
sage: c
Constellation of length 3 and degree 3
g0 (1,2)(3)
g1 (1,3)(2)
g2 (1,3,2)
sage: C = Constellations(3,4); C
Connected constellations of length 3 and degree 4 on {1, 2, 3, 4}
sage: C.cardinality() # long time
426

sage: C = Constellations(3, 4, domain=('a', 'b', 'c', 'd'))
sage: C
Connected constellations of length 3 and degree 4 on {'a', 'b', 'c', 'd'}
sage: c = C(('a', 'c'), ('b', 'c'), ('a', 'd')), None)
sage: c
Constellation of length 3 and degree 4
g0 ('a', 'c')('b')('d')
g1 ('a', 'd')('b', 'c')
g2 ('a', 'd', 'c', 'b')
sage: c.is_connected()
True
sage: c.euler_characteristic()
2
sage: TestSuite(C).run()
```

sage.combinat.constellation.Constellation(*g=None*, *mutable=False*, *connected=True*, *check=True*)

Constellation

INPUT:

- `g` – a list of permutations
- `mutable` – whether the result is mutable or not. Default is `False`.
- `connected` – whether the result should be connected. Default is `True`.
- `check` – whether or not to check. If it is `True`, then the list `g` must contains no `None`.

EXAMPLES:

Simple initialization:

```
sage: Constellation(['(0,1)', '(0,3)(1,2)', '(0,3,1,2)'])
Constellation of length 3 and degree 4
g0 (0,1)(2)(3)
g1 (0,3)(1,2)
g2 (0,3,1,2)
```

One of the permutation can be omitted:

```
sage: Constellation(['(0,1)', None, '(0,4)(1,2,3)'])
Constellation of length 3 and degree 5
g0 (0,1)(2)(3)(4)
g1 (0,3,2,1,4)
g2 (0,4)(1,2,3)
```

One can define mutable constellations:

```
sage: Constellation([(0,2,1), [2,1,0], [1,2,0]], mutable=True)
Constellation of length 3 and degree 3
g0 (0)(1,2)
g1 (0,2)(1)
g2 (0,1,2)
```

class `sage.combinat.constellation.Constellation_class`(*parent, g, connected, mutable, check*)

Bases: `sage.structure.element.Element`

Constellation

A constellation or a tuple of permutations (g_0, g_1, \dots, g_k) such that the product $g_0 g_1 \dots g_k$ is the identity.

braid_group_action(*i*)

Act on `self` as the braid group generator that exchanges position *i* and *i* + 1.

INPUT:

- *i* – integer in $[0, n - 1]$ where *n* is the length of `self`

EXAMPLES:

```
sage: sigma = lambda c, i: c.braid_group_action(i)

sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', None]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: sigma(c, 1)
```

(continues on next page)

(continued from previous page)

```

Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0,1,3,2,4)
g2 (0,3)(1)(2)(4)

```

Check the commutation relation:

```

sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', '(2,5)(0,4)', None])
sage: d = Constellation(['(0,1,3,5)', '(2,3,4)', '(0,3,5)', None])
sage: c13 = sigma(sigma(c, 0), 2)
sage: c31 = sigma(sigma(c, 2), 0)
sage: c13 == c31
True
sage: d13 = sigma(sigma(d, 0), 2)
sage: d31 = sigma(sigma(d, 2), 0)
sage: d13 == d31
True

```

Check the braid relation:

```

sage: c121 = sigma(sigma(sigma(c, 1), 2), 1)
sage: c212 = sigma(sigma(sigma(c, 2), 1), 2)
sage: c121 == c212
True
sage: d121 = sigma(sigma(sigma(d, 1), 2), 1)
sage: d212 = sigma(sigma(sigma(d, 2), 1), 2)
sage: d121 == d212
True

```

braid_group_orbit()

Return the graph of the action of the braid group.

The action is considered up to isomorphism of constellation.

EXAMPLES:

```

sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', None]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: G = c.braid_group_orbit()
sage: G.num_verts()
4
sage: G.num_edges()
12

```

connected_components()

Return the connected components.

OUTPUT:

A list of connected constellations.

EXAMPLES:

```

sage: c = Constellation(['(0,1)(2)', None, '(0,1)(2)'], connected=False)
sage: cc = c.connected_components(); cc
[Constellation of length 3 and degree 2
g0 (0,1)
g1 (0)(1)
g2 (0,1),
Constellation of length 3 and degree 1
g0 (0)
g1 (0)
g2 (0)]
sage: all(c2.is_connected() for c2 in cc)
True

sage: c = Constellation(['(0,1,2)', None], connected=False)
sage: c.connected_components()
[Constellation of length 2 and degree 3
g0 (0,1,2)
g1 (0,2,1)]

```

copy()

Return a copy of self.

degree()

Return the degree of the constellation.

The degree of a constellation is the number n that corresponds to the symmetric group $S(n)$ in which the permutations of the constellation are defined.

EXAMPLES:

```

sage: c = Constellation([])
sage: c.degree()
0
sage: c = Constellation(['(0,1)', None])
sage: c.degree()
2
sage: c = Constellation(['(0,1)', '(0,3,2)(1,5)', None, '(4,3,2,1)'])
sage: c.degree()
6

```

euler_characteristic()

Return the Euler characteristic of the surface.

ALGORITHM:

Hurwitz formula

EXAMPLES:

```

sage: c = Constellation(['(0,1)', '(0,2)', None])
sage: c.euler_characteristic()
2
sage: c = Constellation(['(0,1,2,3)', '(1,3,0,2)', '(0,3,1,2)', None])
sage: c.euler_characteristic()
-4

```

g(*i=None*)

Return the permutation g_i of the constellation.

INPUT:

- *i* – integer or None (default)

If None, return instead the list of all g_i .

EXAMPLES:

```
sage: c = Constellation(['(0,1,2)(3,4)', '(0,3)', None])
sage: c.g(0)
(0,1,2)(3,4)
sage: c.g(1)
(0,3)
sage: c.g(2)
(0,4,3,2,1)
sage: c.g()
[(0,1,2)(3,4), (0,3), (0,4,3,2,1)]
```

genus()

Return the genus of the surface.

EXAMPLES:

```
sage: c = Constellation(['(0,1)', '(0,2)', None])
sage: c.genus()
0

sage: c = Constellation(['(0,1)(2,3,4)', '(1,3,4)(2,0)', None])
sage: c.genus()
1
```

is_connected()

Test of connectedness.

EXAMPLES:

```
sage: c = Constellation(['(0,1)(2)', None, '(0,1)(2)'], connected=False)
sage: c.is_connected()
False
sage: c = Constellation(['(0,1,2)', None], connected=False)
sage: c.is_connected()
True
```

is_isomorphic(*other, return_map=False*)

Test of isomorphism.

Return True if the constellations are isomorphic (*i.e.* related by a common conjugacy) and return the permutation that conjugate the two permutations if *return_map* is True in such a way that `self.relabel(m) == other`.

ALGORITHM:

uses canonical labels obtained from the method `relabel()`.

EXAMPLES:

```

sage: c = Constellation([[1,0,2],[2,1,0],[0,2,1],None])
sage: d = Constellation([[2,1,0],[0,2,1],[1,0,2],None])
sage: answer, mapping = c.is_isomorphic(d,return_map=True)
sage: answer
True
sage: c.relabel(mapping) == d
True

```

is_mutable()

Return False as self is immutable.

EXAMPLES:

```

sage: c = Constellation([[0,2,1],[2,1,0],[1,2,0]], mutable=False)
sage: c.is_mutable()
False

```

length()

Return the number of permutations.

EXAMPLES:

```

sage: c = Constellation(['(0,1)', '(0,2)', '(0,3)', None])
sage: c.length()
4
sage: c = Constellation(['(0,1,3)', None, '(1,2)'])
sage: c.length()
3

```

mutable_copy()

Return a mutable copy of self.

EXAMPLES:

```

sage: c = Constellation([[0,2,1],[2,1,0],[1,2,0]], mutable=False)
sage: d = c.mutable_copy()
sage: d.is_mutable()
True

```

passport (*i=None*)

Return the profile of self.

The profile of a constellation is the tuple of partitions associated to the conjugacy classes of the permutations of the constellation.

This is also called the passport.

EXAMPLES:

```

sage: c = Constellation(['(0,1,2)(3,4)', '(0,3)', None])
sage: c.profile()
([3, 2], [2, 1, 1, 1], [5])

```

profile (*i=None*)

Return the profile of self.

The profile of a constellation is the tuple of partitions associated to the conjugacy classes of the permutations of the constellation.

This is also called the passport.

EXAMPLES:

```
sage: c = Constellation(['(0,1,2)(3,4)', '(0,3)', None])
sage: c.profile()
([3, 2], [2, 1, 1, 1], [5])
```

relabel(*perm=None, return_map=False*)

Relabel self.

If *perm* is provided then relabel with respect to *perm*. Otherwise use canonical labels. In that case, if *return_map* is provided, the return also the map used for canonical labels.

Algorithm:

the cycle for $g(0)$ are adjacent and the cycle are joined with respect to the other permutations. The minimum is taken for all possible renumerations.

EXAMPLES:

```
sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', None]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: c2 = c.relabel(); c2
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,2)(3)(4)
g2 (0,1,4,3,2)
```

The map returned when the option *return_map* is set to `True` can be used to set the relabelling:

```
sage: c3, perm = c.relabel(return_map=True)
sage: c3 == c2 and c3 == c.relabel(perm=perm)
True

sage: S5 = SymmetricGroup(range(5))
sage: d = c.relabel(S5([4,3,1,0,2])); d
Constellation of length 3 and degree 5
g0 (0,2,1)(3,4)
g1 (0)(1)(2,3)(4)
g2 (0,1,2,4,3)
sage: d.is_isomorphic(c)
True
```

We check that after a random relabelling the new constellation is isomorphic to the initial one:

```
sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', None])
sage: p = S5.random_element()
sage: cc = c.relabel(perm=p)
sage: cc.is_isomorphic(c)
True
```

Check that it works for “non standard” labels:

```

sage: c = Constellation([(('a','b'),('c','d','e')),('b','d'), None])
sage: c.relabel()
Constellation of length 3 and degree 5
g0 ('a','b')('c','d','e')
g1 ('a')('b','c')('d')('e')
g2 ('a','b','e','d','c')

```

set_immutable()

Do nothing, as self is already immutable.

EXAMPLES:

```

sage: c = Constellation([[0,2,1],[2,1,0],[1,2,0]], mutable=False)
sage: c.set_immutable()
sage: c.is_mutable()
False

```

switch(*i*, *j0*, *j1*)

Perform the multiplication by the transposition (j_0, j_1) between the permutations g_i and g_{i+1} .

The modification is local in the sense that it modifies g_i and g_{i+1} but does not modify the product $g_i g_{i+1}$. The new constellation is

$$(g_0, \dots, g_{i-1}, g_i(j_0 j_1), (j_0 j_1)g_{i+1}, g_{i+2}, \dots, g_k)$$

EXAMPLES:

```

sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', None], mutable=True); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: c.is_mutable()
True
sage: c.switch(1,2,3); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2,3)
g2 (0,1,3,4)(2)
sage: c._check()
sage: c.switch(2,1,3); c
Constellation of length 3 and degree 5
g0 (0,1,4,2,3)
g1 (0)(1,4)(2,3)
g2 (0,3,4)(1)(2)
sage: c._check()
sage: c.switch(0,0,1); c
Constellation of length 3 and degree 5
g0 (0)(1,4,2,3)
g1 (0,4,1)(2,3)
g2 (0,3,4)(1)(2)
sage: c._check()

```

`sage.combinat.constellation.Constellations(*data, **options)`

Build a set of constellations.

INPUT:

- `profile` – an optional profile
- `length` – an optional length
- `degree` – an optional degree
- `connected` – an optional boolean

EXAMPLES:

```
sage: Constellations(4,2)
Connected constellations of length 4 and degree 2 on {1, 2}

sage: Constellations([[3,2,1],[3,3],[3,3]])
Connected constellations with profile ([3, 2, 1], [3, 3], [3, 3]) on {1, 2, 3, 4, 5,
↪ 6}
```

class `sage.combinat.constellation.Constellations_ld`(*length, degree, sym=None, connected=True*)
 Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Constellations of given length and degree.

EXAMPLES:

```
sage: C = Constellations(2,3); C
Connected constellations of length 2 and degree 3 on {1, 2, 3}
sage: C([[2,3,1],[3,1,2]])
Constellation of length 2 and degree 3
g0 (1,2,3)
g1 (1,3,2)
sage: C.cardinality()
2
sage: Constellations(2,3,connected=False).cardinality()
6
```

Element

alias of `Constellation_class`

braid_group_action()

Return a list of graphs that corresponds to the braid group action on `self` up to isomorphism.

OUTPUT:

- list of graphs

EXAMPLES:

```
sage: C = Constellations(3,3)
sage: C.braid_group_action()
[Looped multi-digraph on 3 vertices,
Looped multi-digraph on 1 vertex,
Looped multi-digraph on 3 vertices]
```

braid_group_orbits()

Return the orbits under the action of braid group.

EXAMPLES:

```

sage: C = Constellations(3,3)
sage: O = C.braid_group_orbits()
sage: len(O)
3
sage: [x.profile() for x in O[0]]
[[[1, 1, 1], [3], [3]], ([3], [1, 1, 1], [3]), ([3], [3], [1, 1, 1])]
sage: [x.profile() for x in O[1]]
[[[3], [3], [3]]]
sage: [x.profile() for x in O[2]]
[[[2, 1], [2, 1], [3]], ([2, 1], [3], [2, 1]), ([3], [2, 1], [2, 1])]

```

is_empty()

Return whether this set of constellations is empty.

EXAMPLES:

```

sage: Constellations(2, 3).is_empty()
False
sage: Constellations(1, 2).is_empty()
True
sage: Constellations(1, 2, connected=False).is_empty()
False

```

random_element(*mutable=False*)

Return a random element.

This is found by trial and rejection, starting from a random list of permutations.

EXAMPLES:

```

sage: const = Constellations(3,3)
sage: const.random_element()
Constellation of length 3 and degree 3
...
...
...
sage: c = const.random_element()
sage: c.degree() == 3 and c.length() == 3
True

```

class sage.combinat.constellation.**Constellations_p**(*profile, domain=None, connected=True*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Constellations with fixed profile.

EXAMPLES:

```

sage: C = Constellations([[3,1],[3,1],[2,2]]); C
Connected constellations with profile ([3, 1], [3, 1], [2, 2]) on {1, 2, 3, 4}
sage: C.cardinality()
24
sage: C.first()
Constellation of length 3 and degree 4
g0 (1)(2,3,4)
g1 (1,2,3)(4)

```

(continues on next page)

(continued from previous page)

```

g2 (1,2)(3,4)
sage: C.last()
Constellation of length 3 and degree 4
g0 (1,4,3)(2)
g1 (1,4,2)(3)
g2 (1,2)(3,4)

```

Note that the cardinality can also be computed using characters of the symmetric group (Frobenius formula):

```

sage: P = Partitions(4)
sage: p1 = Partition([3,1])
sage: p2 = Partition([3,1])
sage: p3 = Partition([2,2])
sage: i1 = P.cardinality() - P.rank(p1) - 1
sage: i2 = P.cardinality() - P.rank(p2) - 1
sage: i3 = P.cardinality() - P.rank(p3) - 1
sage: s = 0
sage: for c in SymmetricGroup(4).irreducible_characters():
.....:     v = c.values()
.....:     s += v[i1] * v[i2] * v[i3] / v[0]
sage: c1 = p1.conjugacy_class_size()
sage: c2 = p2.conjugacy_class_size()
sage: c3 = p3.conjugacy_class_size()
sage: c1 * c2 * c3 / factorial(4)**2 * s
1

```

The number obtained above is up to isomorphism. And we can check:

```

sage: len(C.isomorphism_representatives())
1

```

`isomorphism_representatives()`

Return a set of isomorphism representative of `self`.

EXAMPLES:

```

sage: C = Constellations([[5], [4,1], [3,2]])
sage: C.cardinality()
240
sage: ir = sorted(C.isomorphism_representatives())
sage: len(ir)
2
sage: ir[0]
Constellation of length 3 and degree 5
g0 (1,2,3,4,5)
g1 (1)(2,3,4,5)
g2 (1,5,3)(2,4)
sage: ir[1]
Constellation of length 3 and degree 5
g0 (1,2,3,4,5)
g1 (1)(2,5,3,4)
g2 (1,5)(2,3,4)

```

`sage.combinat.constellation.perm_conjugate(p, s)`
Return the conjugate of the permutation p by the permutation s .

INPUT:

two permutations of $\{0, \dots, n-1\}$ given by lists of values

OUTPUT:

a permutation of $\{0, \dots, n-1\}$ given by a list of values

EXAMPLES:

```
sage: from sage.combinat.constellation import perm_conjugate
sage: perm_conjugate([3,1,2,0], [3,2,0,1])
[0, 3, 2, 1]
```

`sage.combinat.constellation.perm_invert(p)`
Return the inverse of the permutation p .

INPUT:

a permutation of $\{0, \dots, n-1\}$ given by a list of values

OUTPUT:

a permutation of $\{0, \dots, n-1\}$ given by a list of values

EXAMPLES:

```
sage: from sage.combinat.constellation import perm_invert
sage: perm_invert([3,2,0,1])
[2, 3, 1, 0]
```

`sage.combinat.constellation.perm_sym_domain(g)`
Return the domain of a single permutation (before initialization).

EXAMPLES:

```
sage: from sage.combinat.constellation import perm_sym_domain
sage: perm_sym_domain([1,2,3,4])
{1, 2, 3, 4}
sage: perm_sym_domain(((1,2),(0,4)))
{0, 1, 2, 4}
sage: sorted(perm_sym_domain('(1,2,0,5)'))
[0, 1, 2, 5]
```

`sage.combinat.constellation.perms_are_connected(g, n)`
Checks that the action of the generated group is transitive

INPUT:

- a list of permutations of $[0, n - 1]$ (in a `SymmetricGroup`)
- an integer n

EXAMPLES:

```
sage: from sage.combinat.constellation import perms_are_connected
sage: S = SymmetricGroup(range(3))
sage: perms_are_connected([S([0,1,2]), S([0,2,1])], 3)
```

(continues on next page)

(continued from previous page)

```
False
sage: perms_are_connected([S([0,1,2]),S([1,2,0])],3)
True
```

`sage.combinat.constellation.perms_canonical_labels(p, e=None)`

Relabel a list with a common conjugation such that two conjugated lists are relabeled the same way.

INPUT:

- *p* is a list of at least 2 permutations
- *e* is None or a list of integer in the domain of the permutations. If provided, then the renumbering algorithm is only performed from the elements of *e*.

OUTPUT:

- a pair made of a list of permutations (as a list of lists) and a list that corresponds to the conjugacy used.

EXAMPLES:

```
sage: from sage.combinat.constellation import perms_canonical_labels
sage: l0 = [[2,0,3,1], [3,1,2,0], [0,2,1,3]]
sage: l, m = perms_canonical_labels(l0); l
[[1, 2, 3, 0], [0, 3, 2, 1], [2, 1, 0, 3]]

sage: S = SymmetricGroup(range(4))
sage: [~S(m) * S(u) * S(m) for u in l0] == list(map(S, l))
True

sage: perms_canonical_labels([])
Traceback (most recent call last):
...
ValueError: input must have length >= 2
```

`sage.combinat.constellation.perms_canonical_labels_from(x, y, j0, verbose=False)`

Return canonical labels for *x*, *y* that starts at *j0*

Warning: The group generated by *x* and the elements of *y* should be transitive.

INPUT:

- *x* – list - a permutation of $[0, \dots, n]$ as a list
- *y* – list of permutations of $[0, \dots, n]$ as a list of lists
- *j0* – an index in $[0, \dots, n]$

OUTPUT:

mapping: a permutation that specify the new labels

EXAMPLES:

```
sage: from sage.combinat.constellation import perms_canonical_labels_from
sage: perms_canonical_labels_from([0,1,2],[[1,2,0]], 0)
[0, 1, 2]
sage: perms_canonical_labels_from([1,0,2],[[2,0,1]], 0)
```

(continues on next page)

(continued from previous page)

```
[0, 1, 2]
sage: perms_canonical_labels_from([1,0,2], [[2,0,1]], 1)
[1, 0, 2]
sage: perms_canonical_labels_from([1,0,2], [[2,0,1]], 2)
[2, 1, 0]
```

`sage.combinat.constellation.perms_sym_init(g, sym=None)`
Initialize a list of permutations (in the same symmetric group).

OUTPUT:

- `sym` – a symmetric group
- `gg` – a list of permutations

EXAMPLES:

```
sage: from sage.combinat.constellation import perms_sym_init
sage: S, g = perms_sym_init([[0,2,1,3], [1,3,2,0]])
sage: S.domain()
{0, 1, 2, 3}
sage: g
[(1,2), (0,1,3)]

sage: S, g = perms_sym_init(['(2,1)', '(0,3)'])
sage: S.domain()
{0, 1, 2, 3}
sage: g
[(1,2), (0,3)]

sage: S, g = perms_sym_init([(1,0), (2,1)])
sage: S.domain()
{0, 1, 2}
sage: g
[(0,1), (1,2)]

sage: S, g = perms_sym_init([(1,0),(2,3)], '(0,1,4)')
sage: S.domain()
{0, 1, 2, 3, 4}
sage: g
[(0,1)(2,3), (0,1,4)]
```

5.1.32 Cores

A k -core is a partition from which no rim hook of size k can be removed. Alternatively, a k -core is an integer partition such that the Ferrers diagram for the partition contains no cells with a hook of size (a multiple of) k .

Authors:

- Anne Schilling and Mike Zabrocki (2011): initial version
- Travis Scrimshaw (2012): Added latex output for Core class

class `sage.combinat.core.Core`(*parent*, *core*)
Bases: `sage.combinat.combinat.CombinatorialElement`

A k -core is an integer partition from which no rim hook of size k can be removed.

EXAMPLES:

```
sage: c = Core([2,1],4); c
[2, 1]
sage: c = Core([3,1],4); c
Traceback (most recent call last):
...
ValueError: [3, 1] is not a 4-core
```

affine_symmetric_group_action(w , *transposition=False*)

Return the (left) action of the affine symmetric group on *self*.

INPUT:

- w is a tuple of integers $[w_1, \dots, w_m]$ with $0 \leq w_j < k$. If *transposition* is set to be *True*, then $w = [w_0, w_1]$ is interpreted as a transposition t_{w_0, w_1} (see `_transposition_to_reduced_word()`).

The output is the (left) action of the product of the corresponding simple transpositions on *self*, that is $s_{w_1} \cdots s_{w_m}(\text{self})$. See `affine_symmetric_group_simple_action()`.

EXAMPLES:

```
sage: c = Core([4,2],3)
sage: c.affine_symmetric_group_action([0,1,0,2,1])
[8, 6, 4, 2]
sage: c.affine_symmetric_group_action([0,2], transposition=True)
[4, 2, 1, 1]

sage: c = Core([11,8,5,5,3,3,1,1,1],4)
sage: c.affine_symmetric_group_action([2,5], transposition=True)
[11, 8, 7, 6, 5, 4, 3, 2, 1]
```

affine_symmetric_group_simple_action(i)

Return the action of the simple transposition s_i of the affine symmetric group on *self*.

This gives the action of the affine symmetric group of type $A_k^{(1)}$ on the k -core *self*. If *self* has outside (resp. inside) corners of content i modulo k , then these corners are added (resp. removed). Otherwise the action is trivial.

EXAMPLES:

```
sage: c = Core([4,2],3)
sage: c.affine_symmetric_group_simple_action(0)
[3, 1]
sage: c.affine_symmetric_group_simple_action(1)
[5, 3, 1]
sage: c.affine_symmetric_group_simple_action(2)
[4, 2]
```

This action corresponds to the left action by the i -th simple reflection in the affine symmetric group:

```
sage: c = Core([4,2],3)
sage: W = c.to_grassmannian().parent()
sage: i = 0
sage: c.affine_symmetric_group_simple_action(i).to_grassmannian() == W.simple_
reflection(i)*c.to_grassmannian()
```

(continues on next page)

(continued from previous page)

```
True
sage: i = 1
sage: c.affine_symmetric_group_simple_action(i).to_grassmannian() == W.simple_
↳reflection(i)*c.to_grassmannian()
True
```

contains(*other*)

Checks whether `self` contains `other`.

INPUT:

- `other` – another k -core or a list

OUTPUT: a boolean

This returns True if the Ferrers diagram of `self` contains the Ferrers diagram of `other`.

EXAMPLES:

```
sage: c = Core([4,2],3)
sage: x = Core([4,2,2,1,1],3)
sage: x.contains(c)
True
sage: c.contains(x)
False
```

k()

Return k of the k -core `self`.

EXAMPLES:

```
sage: c = Core([2,1],4)
sage: c.k()
4
```

length()

Return the length of `self`.

The length of a k -core is the size of the corresponding $(k - 1)$ -bounded partition which agrees with the length of the corresponding Grassmannian element, see [to_grassmannian\(\)](#).

EXAMPLES:

```
sage: c = Core([4,2],3); c.length()
4
sage: c.to_grassmannian().length()
4

sage: Core([9,5,3,2,1,1], 5).length()
13
```

size()

Return the size of `self` as a partition.

EXAMPLES:

```
sage: Core([2,1],4).size()
3
sage: Core([4,2],3).size()
6
```

strong_covers()

Return a list of all elements that cover `self` in strong order.

EXAMPLES:

```
sage: c = Core([1],3)
sage: c.strong_covers()
[[2], [1, 1]]
sage: c = Core([4,2],3)
sage: c.strong_covers()
[[5, 3, 1], [4, 2, 1, 1]]
```

strong_down_list()

Return a list of all elements that are covered by `self` in strong order.

EXAMPLES:

```
sage: c = Core([1],3)
sage: c.strong_down_list()
[[]]
sage: c = Core([5,3,1],3)
sage: c.strong_down_list()
[[4, 2], [3, 1, 1]]
```

strong_le(*other*)

Strong order (Bruhat) comparison on cores.

INPUT:

- `other` – another k -core

OUTPUT: a boolean

This returns whether `self` \leq `other` in Bruhat (or strong) order.

EXAMPLES:

```
sage: c = Core([4,2],3)
sage: x = Core([4,2,2,1,1],3)
sage: c.strong_le(x)
True
sage: c.strong_le([4,2,2,1,1])
True

sage: x = Core([4,1],4)
sage: c.strong_le(x)
Traceback (most recent call last):
...
ValueError: The two cores do not have the same k
```

to_bounded_partition()

Bijection between k -cores and $(k - 1)$ -bounded partitions.

This maps the k -core `self` to the corresponding $(k - 1)$ -bounded partition. This bijection is achieved by deleting all cells in `self` of hook length greater than k .

EXAMPLES:

```
sage: gamma = Core([9,5,3,2,1,1], 5)
sage: gamma.to_bounded_partition()
[4, 3, 2, 2, 1, 1]
```

`to_grassmannian()`

Bijection between k -cores and Grassmannian elements in the affine Weyl group of type $A_{k-1}^{(1)}$.

For further details, see the documentation of the method `from_kbounded_to_reduced_word()` and `from_kbounded_to_grassmannian()`.

EXAMPLES:

```
sage: c = Core([3,1,1],3)
sage: w = c.to_grassmannian(); w
[-1  1  1]
[-2  2  1]
[-2  1  2]
sage: c.parent()
3-Cores of length 4
sage: w.parent()
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root space)

sage: c = Core([],3)
sage: c.to_grassmannian()
[1 0 0]
[0 1 0]
[0 0 1]
```

`to_partition()`

Turn the core `self` into the partition identical to `self`.

EXAMPLES:

```
sage: mu = Core([2,1,1],3)
sage: mu.to_partition()
[2, 1, 1]
```

`weak_covers()`

Return a list of all elements that cover `self` in weak order.

EXAMPLES:

```
sage: c = Core([1],3)
sage: c.weak_covers()
[[1, 1], [2]]

sage: c = Core([4,2],3)
sage: c.weak_covers()
[[5, 3, 1]]
```

`weak_le(other)`

Weak order comparison on cores.

INPUT:

- `other` – another k -core

OUTPUT: a boolean

This returns whether `self <= other` in weak order.

EXAMPLES:

```
sage: c = Core([4,2],3)
sage: x = Core([5,3,1],3)
sage: c.weak_le(x)
True
sage: c.weak_le([5,3,1])
True

sage: x = Core([4,2,2,1,1],3)
sage: c.weak_le(x)
False

sage: x = Core([5,3,1],6)
sage: c.weak_le(x)
Traceback (most recent call last):
...
ValueError: The two cores do not have the same k
```

`sage.combinat.core.Cores`(k , `length=None`, `**kwargs`)

A k -core is a partition from which no rim hook of size k can be removed. Alternatively, a k -core is an integer partition such that the Ferrers diagram for the partition contains no cells with a hook of size (a multiple of) k .

The k -cores generally have two notions of size which are useful for different applications. One is the number of cells in the Ferrers diagram with hook less than k , the other is the total number of cells of the Ferrers diagram. In the implementation in Sage, the first of notion is referred to as the `length` of the k -core and the second is the `size` of the k -core. The class of Cores requires that either the size or the length of the elements in the class is specified.

EXAMPLES:

We create the set of the 4-cores of length 6. Here the length of a k -core is the size of the corresponding $(k-1)$ -bounded partition, see also `length()`:

```
sage: C = Cores(4, 6); C
4-Cores of length 6
sage: C.list()
[[6, 3], [5, 2, 1], [4, 1, 1, 1], [4, 2, 2], [3, 3, 1, 1], [3, 2, 1, 1, 1], [2, 2, 2, 1, 1]]
sage: C.cardinality()
7
sage: C.an_element()
[6, 3]
```

We may also list the set of 4-cores of size 6, where the size is the number of boxes in the core, see also `size()`:

```
sage: C = Cores(4, size=6); C
4-Cores of size 6
sage: C.list()
```

(continues on next page)

(continued from previous page)

```

[[4, 1, 1], [3, 2, 1], [3, 1, 1, 1]]
sage: C.cardinality()
3
sage: C.an_element()
[4, 1, 1]

```

class `sage.combinat.core.Cores_length(k, n)`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The class of k -cores of length n .

Element

alias of `Core`

from_partition($part$)

Converts the partition `part` into a core (as the identity map).

This is the inverse method to `to_partition()`.

EXAMPLES:

```

sage: C = Cores(3,4)
sage: c = C.from_partition([4,2]); c
[4, 2]

sage: mu = Partition([2,1,1])
sage: C = Cores(3,3)
sage: C.from_partition(mu).to_partition() == mu
True

sage: mu = Partition([])
sage: C = Cores(3,0)
sage: C.from_partition(mu).to_partition() == mu
True

```

list()

Return the list of all k -cores of length n .

EXAMPLES:

```

sage: C = Cores(3,4)
sage: C.list()
[[4, 2], [3, 1, 1], [2, 2, 1, 1]]

```

class `sage.combinat.core.Cores_size(k, n)`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The class of k -cores of size n .

Element

alias of `Core`

from_partition($part$)

Convert the partition `part` into a core (as the identity map).

This is the inverse method to `to_partition()`.

EXAMPLES:

```
sage: C = Cores(3,size=4)
sage: c = C.from_partition([2,1,1]); c
[2, 1, 1]

sage: mu = Partition([2,1,1])
sage: C = Cores(3,size=4)
sage: C.from_partition(mu).to_partition() == mu
True

sage: mu = Partition([])
sage: C = Cores(3,size=0)
sage: C.from_partition(mu).to_partition() == mu
True
```

list()Return the list of all k -cores of size n .

EXAMPLES:

```
sage: C = Cores(3, size = 4)
sage: C.list()
[[3, 1], [2, 1, 1]]
```

5.1.33 Counting

- [The On-Line Encyclopedia of Integer Sequences \(OEIS\)](#)
- *Functions that compute some of the sequences in Sloane's tables*
- *Compute Bell and Uppuluri-Carpenter numbers*
- *q -Analogues, q -Bernoulli Numbers and Polynomials*
- *Binary Recurrence Sequences*
- *C -Finite Sequences*
- *Combinatorial Functions*

Todo: Mention sage/combinat/degree_sequences?

5.1.34 Affine Crystals

```
class sage.combinat.crystals.affine.AffineCrystalFromClassical(cartan_type, classical_crystal,
                                                                category=None)
```

```
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.
parent.Parent
```

This abstract class can be used for affine crystals that are constructed from a classical crystal. The zero arrows can be implemented using different methods (for example using a Dynkin diagram automorphisms or virtual crystals).

This is a helper class, mostly used to implement Kirillov-Reshetikhin crystals (see: [KirillovReshetikhinCrystal\(\)](#)).

For general information about crystals see `sage.combinat.crystals`.

INPUT:

- `cartan_type` – the Cartan type of the resulting affine crystal
- `classical_crystal` – instance of a classical crystal

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: A.list()
[[[1]], [[2]], [[3]]]
sage: A.cartan_type()
['A', 2, 1]
sage: A.index_set()
(0, 1, 2)
sage: b = A(rows=[[1]])
sage: b.weight()
-Lambda[0] + Lambda[1]
sage: b.classical_weight()
(1, 0, 0)
sage: [x.s(0) for x in A.list()]
[[[3]], [[2]], [[1]]]
sage: [x.s(1) for x in A.list()]
[[[2]], [[1]], [[3]]]
```

Element

alias of [AffineCrystalFromClassicalElement](#)

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: C = crystals.Tableaux(['A',3],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',3,1],C,pr,pr_inverse,1)
sage: A.cardinality() == C.cardinality()
True
```

lift(*affine_elt*)

Lift an affine crystal element to the corresponding classical crystal element.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
```

(continues on next page)

(continued from previous page)

```

sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A.list()[0]
sage: A.lift(b)
[[1]]
sage: A.lift(b).parent()
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]

```

retract(*classical_elt*)

Transform a classical crystal element to the corresponding affine crystal element.

EXAMPLES:

```

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: t = C(rows=[[1]])
sage: t.parent()
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]
sage: A.retract(t)
[[1]]
sage: A.retract(t).parent() is A
True

```

```

class sage.combinat.crystals.affine.AffineCrystalFromClassicalAndPromotion(cartan_type,
                                                                           classical_crystal,
                                                                           p_automorphism,
                                                                           p_inverse_automorphism,
                                                                           dynkin_node,
                                                                           category=None)

```

Bases: *sage.combinat.crystals.affine.AffineCrystalFromClassical*

Crystals that are constructed from a classical crystal and a Dynkin diagram automorphism σ . In type A_n , the Dynkin diagram automorphism is $i \rightarrow i + 1 \pmod{n} + 1$ and the corresponding map on the crystal is the promotion operation pr on tableaux. The affine crystal operators are given by $f_0 = \text{pr}^{-1} f_{\sigma(0)} \text{pr}$.

INPUT:

- *cartan_type* – the Cartan type of the resulting affine crystal
- *classical_crystal* – instance of a classical crystal
- *automorphism*, *inverse_automorphism* – a function on the elements of the *classical_crystal*
- *dynkin_node* – an integer specifying the classical node in the image of the zero node under the automorphism σ

EXAMPLES:

```

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: A.list()

```

(continues on next page)

(continued from previous page)

```

[[[1]], [[2]], [[3]]]
sage: A.cartan_type()
['A', 2, 1]
sage: A.index_set()
(0, 1, 2)
sage: b = A(rows=[[1]])
sage: b.weight()
-Lambda[0] + Lambda[1]
sage: b.classical_weight()
(1, 0, 0)
sage: [x.s(0) for x in A.list()]
[[[3]], [[2]], [[1]]]
sage: [x.s(1) for x in A.list()]
[[[2]], [[1]], [[3]]]

```

Elementalias of *AffineCrystalFromClassicalAndPromotionElement***automorphism(*x*)**

Give the analogue of the affine Dynkin diagram automorphism on the level of crystals.

EXAMPLES:

```

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A.list()[0]
sage: A.automorphism(b)
[[2]]

```

inverse_automorphism(*x*)

Give the analogue of the inverse of the affine Dynkin diagram automorphism on the level of crystals.

EXAMPLES:

```

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A.list()[0]
sage: A.inverse_automorphism(b)
[[3]]

```

class `sage.combinat.crystals.affine.AffineCrystalFromClassicalAndPromotionElement`Bases: *sage.combinat.crystals.affine.AffineCrystalFromClassicalElement*

Elements of crystals that are constructed from a classical crystal and a Dynkin diagram automorphism. In type *A*, the automorphism is the promotion operation on tableaux.

This class is not instantiated directly but rather `__call__`-ed from *AffineCrystalFromClassicalAndPromotion*. The syntax of this is governed by the (classical) crystal.

Since this class inherits from *AffineCrystalFromClassicalElement*, the methods that need to be implemented are *e0()*, *f0()* and possibly *epsilon0()* and *phi0()* if more efficient algorithms exist.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[1]])
sage: b._repr_()
'[[1]]'
```

e0()

Implement e_0 using the automorphism as $e_0 = \text{pr}^{-1} e_{\text{dynkin}_n \text{ode}} \text{pr}$

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[1]])
sage: b.e0()
[[3]]
```

epsilon0()

Implement ϵ_{00} using the automorphism.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: [x.epsilon0() for x in A.list()]
[1, 0, 0]
```

f0()

Implement f_0 using the automorphism as $f_0 = \text{pr}^{-1} f_{\text{dynkin}_n \text{ode}} \text{pr}$

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[3]])
sage: b.f0()
[[1]]
```

phi0()

Implement ϕ_{00} using the automorphism.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: [x.phi0() for x in A.list()]
[0, 0, 1]
```

class `sage.combinat.crystals.affine.AffineCrystalFromClassicalElement`

Bases: `sage.structure.element_wrapper.ElementWrapper`

Elements of crystals that are constructed from a classical crystal.

The elements inherit many of their methods from the classical crystal using lift and retract.

This class is not instantiated directly but rather `__call__`-ed from `AffineCrystalFromClassical`. The syntax of this is governed by the (classical) crystal.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[1]])
sage: b._repr_()
'[[1]]'
```

classical_weight()

Return the classical weight corresponding to `self`.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[1]])
sage: b.classical_weight()
(1, 0, 0)
```

e(i)

Return the action of e_i on `self`.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[1]])
sage: b.e(0)
```

(continues on next page)

(continued from previous page)

```
[[3]]
sage: b.e(1)
```

e0()Assumes that e_0 is implemented separately.**epsilon(i)**Return the maximal time the crystal operator e_i can be applied to self.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: [x.epsilon(0) for x in A.list()]
[1, 0, 0]
sage: [x.epsilon(1) for x in A.list()]
[0, 1, 0]
```

epsilon0()Uses ε_0 from the super class, but should be implemented if a faster implementation exists.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: [x.epsilon0() for x in A.list()]
[1, 0, 0]
```

f(i)Return the action of f_i on self.

EXAMPLES:

```
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[3]])
sage: b.f(0)
[[1]]
sage: b.f(2)
```

f0()Assumes that f_0 is implemented separately.**lift()**

Lift an affine crystal element to the corresponding classical crystal element.

EXAMPLES:

```

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A.list()[0]
sage: b.lift()
[[1]]
sage: b.lift().parent()
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]

```

phi(i)

Returns the maximal time the crystal operator f_i can be applied to self.

EXAMPLES:

```

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: [x.phi(0) for x in A.list()]
[0, 0, 1]
sage: [x.phi(1) for x in A.list()]
[1, 0, 0]

```

phi0()

Uses φ_0 from the super class, but should be implemented if a faster implementation exists.

EXAMPLES:

```

sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: [x.phi0() for x in A.list()]
[0, 0, 1]

```

pp()

Method for pretty printing.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['D',3,2],1,1)
sage: t=K(rows=[[1]])
sage: t.pp()
1

```

5.1.35 Affine factorization crystal of type A

class sage.combinat.crystals.affine_factorization.AffineFactorizationCrystal($w, n, x=None$)
 Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The crystal on affine factorizations with a cut-point, as introduced by [MS2015].

INPUT:

- w – an element in an (affine) Weyl group or a skew shape of k -bounded partitions (if k was specified)
- n – the number of factors in the factorization
- x – (default: None) the cut point; if not specified it is determined as the minimal missing residue in w
- k – (default: None) positive integer, specifies that w is k -bounded or a $k + 1$ -core when specified

EXAMPLES:

```
sage: W = WeylGroup(['A', 3, 1], prefix='s')
sage: w = W.from_reduced_word([2, 3, 2, 1])
sage: B = crystals.AffineFactorization(w, 3); B
Crystal on affine factorizations of type A2 associated to s2*s3*s2*s1
sage: B.list()
[(1, s2, s3*s2*s1),
 (1, s3*s2, s3*s1),
 (1, s3*s2*s1, s3),
 (s3, s2, s3*s1),
 (s3, s2*s1, s3),
 (s3*s2, s1, s3),
 (s3*s2*s1, 1, s3),
 (s3*s2*s1, s3, 1),
 (s3*s2, 1, s3*s1),
 (s3*s2, s3, s1),
 (s3*s2, s3*s1, 1),
 (s2, 1, s3*s2*s1),
 (s2, s3, s2*s1),
 (s2, s3*s2, s1),
 (s2, s3*s2*s1, 1)]
```

We can also access the crystal by specifying a skew shape in terms of k -bounded partitions:

```
sage: crystals.AffineFactorization([[3, 1, 1], [1]], 3, k=3)
Crystal on affine factorizations of type A2 associated to s2*s3*s2*s1
```

We can compute the highest weight elements:

```
sage: hw = [w for w in B if w.is_highest_weight()]
sage: hw
[(1, s2, s3*s2*s1)]
sage: hw[0].weight()
(3, 1, 0)
```

And show that this crystal is isomorphic to the tableau model of the same weight:

```

sage: C = crystals.Tableaux(['A', 2], shape=[3, 1])
sage: GC = C.digraph()
sage: GB = B.digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
True

```

The crystal operators themselves move elements between adjacent factors:

```

sage: b = hw[0]; b
(1, s2, s3*s2*s1)
sage: b.f(1)
(1, s3*s2, s3*s1)

```

The cut point x is not supposed to occur in the reduced words for w :

```

sage: B = crystals.AffineFactorization([[3, 2], [2]], 4, x=0, k=3)
Traceback (most recent call last):
...
ValueError: x cannot be in reduced word of s0*s3*s2

```

class Element

Bases: `sage.structure.element_wrapper.ElementWrapper`

bracketing(i)

Removes all bracketed letters between i -th and $i + 1$ -th entry.

EXAMPLES:

```

sage: B = crystals.AffineFactorization([[3, 1], [1]], 3, k=3, x=4)
sage: W = B.w.parent()
sage: t = B((W.one(), W.from_reduced_word([3]), W.from_reduced_word([2, 1])));
↪ t
(1, s3, s2*s1)
sage: t.bracketing(1)
[[3], [2, 1]]

```

$e(i)$

Return the action of e_i on self.

EXAMPLES:

```

sage: B = crystals.AffineFactorization([[3, 1], [1]], 4, k=3)
sage: W = B.w.parent()
sage: t = B((W.one(), W.one(), W.from_reduced_word([3]), W.from_reduced_
↪ word([2, 1]))); t
(1, 1, s3, s2*s1)
sage: t.e(1)
(1, 1, 1, s3*s2*s1)

```

$f(i)$

Return the action of f_i on self.

EXAMPLES:

```

sage: B = crystals.AffineFactorization([[3, 1], [1]], 4, k=3)
sage: W = B.w.parent()

```

(continues on next page)

(continued from previous page)

```

sage: t = B((W.one(),W.one(),W.from_reduced_word([3]),W.from_reduced_
↳word([2,1])))
(1, 1, s3, s2*s1)
sage: t.f(2)
(1, s3, 1, s2*s1)
sage: t.f(1)
(1, 1, s3*s2, s1)

```

to_tableau()

Return the tableau representation of self.

Uses the recording tableau of a minor variation of Edelman-Greene insertion. See Theorem 4.11 in [MS2015].

EXAMPLES:

```

sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: for x in B:
.....:     x
.....:     x.to_tableau().pp()
(1, s2*s1, s3*s2)
  1 1
  2 2
(s2, s1, s3*s2)
  1 1
  2 3
(s2, s3*s1, s2)
  1 2
  2 3
(s2*s1, 1, s3*s2)
  1 1
  3 3
(s2*s1, s3, s2)
  1 2
  3 3
(s2*s1, s3*s2, 1)
  2 2
  3 3

```

```

class sage.combinat.crystals.affine_factorization.FactorizationToTableaux(parent,
                                                                           cartan_type=None,
                                                                           virtualiza-
                                                                           tion=None,
                                                                           scal-
                                                                           ing_factors=None)

```

Bases: `sage.categories.crystals.CrystalMorphism`

is_embedding()

Return True as this is an isomorphism.

EXAMPLES:

```

sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
True

```

is_isomorphism()

Return True as this is an isomorphism.

EXAMPLES:

```

sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
True

```

is_surjective()

Return True as this is an isomorphism.

EXAMPLES:

```

sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
True

```

`sage.combinat.crystals.affine_factorization.affine_factorizations(w, l, weight=None)`

Return all factorizations of w into l factors or of weight $weight$.

INPUT:

- w – an (affine) permutation or element of the (affine) Weyl group
- l – nonnegative integer
- $weight$ – (default: None) tuple of nonnegative integers specifying the length of the factors

EXAMPLES:

```

sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([3,2,3,1,0,1])
sage: from sage.combinat.crystals.affine_factorization import affine_factorizations
sage: affine_factorizations(w,4)
[[s2, s3, s0, s2*s1*s0],
 [s2, s3, s2*s0, s1*s0],
 [s2, s3, s2*s1*s0, s1],
 [s2, s3*s2, s0, s1*s0],
 [s2, s3*s2, s1*s0, s1],
 [s2, s3*s2*s1, s0, s1],
 [s3*s2, s3, s0, s1*s0],
 [s3*s2, s3, s1*s0, s1],
 [s3*s2, s3*s1, s0, s1],

```

(continues on next page)

(continued from previous page)

```

[s3*s2*s1, s3, s0, s1]]
sage: W = WeylGroup(['A',2], prefix='s')
sage: w0 = W.long_element()
sage: affine_factorizations(w0,3)
[[1, s1, s2*s1],
 [1, s2*s1, s2],

 [s3, s2, s1, s3, s2, s3],
 [s3, s2, s3, s1, s2, s3]]
sage: affine_factorizations(w0,6,(0,0,0,1,2,3))
[[1, 1, 1, s1, s2*s1, s3*s2*s1]]

```

5.1.36 Affinization Crystals

`class sage.combinat.crystals.affinization.AffinizationOfCrystal(B)`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

An affinization of a crystal.

Let \mathfrak{g} be a Kac-Moody algebra of affine type. The affinization of a finite $U'_q(\mathfrak{g})$ -crystal B is the (infinite) $U_q(\mathfrak{g})$ -crystal with underlying set:

$$B^{\text{aff}} = \{b(m) \mid b \in B, m \in \mathbf{Z}\}$$

and crystal structure determined by:

$$e_i(b(m)) = \begin{cases} (e_0b)(m+1) & i = 0, \\ (e_ib)(m) & i \neq 0, \end{cases}$$

$$f_i(b(m)) = \begin{cases} (f_0b)(m-1) & i = 0, \\ (f_ib)(m) & i \neq 0, \end{cases}$$

$$\text{wt}(b(m)) = \text{wt}(b) + m\delta.$$

EXAMPLES:

We first construct a Kirillov-Reshetikhin crystal and then take its corresponding affinization:

```
sage: K = crystals.KirillovReshetikhin(['A', 2, 1], 2, 2)
sage: A = K.affinization()
```

Next we construct an affinization crystal from a tensor product of KR crystals:

```
sage: KT = crystals.TensorProductOfKirillovReshetikhinTableaux(['C', 2, 1], [[1, 2], [2,
↪ 1]])
sage: A = crystals.AffinizationOf(KT)
```

REFERENCES:

- [HK2002] Chapter 10

class `Element`(*parent*, *b*, *m*)

Bases: `sage.structure.element.Element`

An element in an affinization crystal.

e(*i*)

Return the action of e_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: A = crystals.KirillovReshetikhin(['A', 2, 1], 2, 2).affinization()
sage: mg = A.module_generators[0]
sage: mg.e(0)
[[1, 2], [2, 3]](1)
sage: mg.e(1)
sage: mg.e(0).e(1)
[[1, 1], [2, 3]](1)
```

epsilon(*i*)

Return ε_i of self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: A = crystals.KirillovReshetikhin(['A', 2, 1], 2, 2).affinization()
sage: mg = A.module_generators[0]
sage: mg.epsilon(0)
2
```

(continues on next page)

(continued from previous page)

```
sage: mg.epsilon(1)
0
```

f(i)

Return the action of f_i on self.

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.f(2)
[[1, 1], [2, 3]](0)
sage: mg.f(2).f(2).f(0)
sage: mg.f_string([2,1,1])
sage: mg.f_string([2,1])
[[1, 2], [2, 3]](0)
sage: mg.f_string([2,1,0])
[[1, 1], [2, 2]](-1)
```

phi(i)

Return φ_i of self.

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.phi(0)
0
sage: mg.phi(2)
2
```

weight()

Return the weight of self.

The weight wt of an element is:

$$wt(b(m)) = wt(b) + m\delta,$$

where δ is the null root.

EXAMPLES:

```
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.weight()
-2*Lambda[0] + 2*Lambda[2]
sage: mg.e(0).weight()
-Lambda[1] + Lambda[2] + delta
sage: mg.e(0).e(0).weight()
2*Lambda[0] - 2*Lambda[1] + 2*delta
```

5.1.37 Alcove paths

AUTHORS:

- Brant Jones (2008): initial version
- Arthur Lubovsky (2013-03-07): rewritten to implement affine type
- Travis Scrimshaw (2016-06-23): implemented $\mathcal{B}(\infty)$

Special thanks to: Nicolas Borie, Anne Schilling, Travis Scrimshaw, and Nicolas Thiéry.

```
class sage.combinat.crystals.alcove_path.CrystalOfAlcovePaths(starting_weight,
                                                             highest_weight_crystal)
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.
           parent.Parent
```

Crystal of alcove paths generated from a “straight-line” path to the negative of a given dominant weight.

INPUT:

- `cartan_type` – Cartan type of a finite or affine untwisted root system.
- `weight` – Dominant weight as a list of (integral) coefficients of the fundamental weights.
- `highest_weight_crystal` – (Default: True) If True returns the highest weight crystal. If False returns an object which is close to being isomorphic to the tensor product of Kirillov-Reshetikhin crystals of column shape in the following sense: We get all the vertices, but only some of the edges. We’ll call the included edges pseudo-Demazure. They are all non-zero edges and the 0-edges not at the end of a 0-string of edges, i.e. not those with $f_0(b) = b'$ with $\varphi_0(b) = 1$. (Whereas Demazure 0-edges are those that are not at the beginning of a zero string.) In this case the weight $[c_1, c_2, \dots, c_k]$ represents $\sum_{i=1}^k c_i \omega_i$.

Note: If `highest_weight_crystal = False`, since we do not get the full crystal, `TestSuite` will fail on the Stembridge axioms.

See also:

- [Crystals](#)

EXAMPLES:

The following example appears in Figure 2 of [LP2008]:

```
sage: C = crystals.AlcovePaths(['G', 2], [0, 1])
sage: G = C.digraph()
sage: GG = DiGraph({
.....:      ()      : {(0)          : 2 },
.....:      (0)     : {(0, 8)       : 1 },
.....:      (0, 1)  : {(0, 1, 7)    : 2 },
.....:      (0, 1, 2) : {(0, 1, 2, 9) : 1 },
.....:      (0, 1, 2, 3) : {(0, 1, 2, 3, 4) : 2 },
.....:      (0, 1, 2, 6) : {(0, 1, 2, 3) : 1 },
.....:      (0, 1, 2, 9) : {(0, 1, 2, 6) : 1 },
.....:      (0, 1, 7)  : {(0, 1, 2)   : 2 },
.....:      (0, 1, 7, 9) : {(0, 1, 2, 9) : 2 },
.....:      (0, 5)    : {(0, 1)     : 1, (0, 5, 7) : 2 },
.....:      (0, 5, 7)  : {(0, 5, 7, 9) : 1 },
.....:      (0, 5, 7, 9) : {(0, 1, 7, 9) : 1 },
```

(continues on next page)

(continued from previous page)

```

.....:      (0,8)      : {(0,5)      : 1 },
.....:      }
sage: G.is_isomorphic(GG)
True
sage: for (u,v,i) in G.edges(sort=True):
.....:      print((u.integer_sequence() , v.integer_sequence(), i))
([], [0], 2)
([0], [0, 8], 1)
([0, 1], [0, 1, 7], 2)
([0, 1, 2], [0, 1, 2, 9], 1)
([0, 1, 2, 3], [0, 1, 2, 3, 4], 2)
([0, 1, 2, 6], [0, 1, 2, 3], 1)
([0, 1, 2, 9], [0, 1, 2, 6], 1)
([0, 1, 7], [0, 1, 2], 2)
([0, 1, 7, 9], [0, 1, 2, 9], 2)
([0, 5], [0, 1], 1)
([0, 5], [0, 5, 7], 2)
([0, 5, 7], [0, 5, 7, 9], 1)
([0, 5, 7, 9], [0, 1, 7, 9], 1)
([0, 8], [0, 5], 1)

```

Alcove path crystals are a discrete version of Littelmann paths. We verify that the alcove path crystal is isomorphic to the LS path crystal:

```

sage: C1 = crystals.AlcovePaths(['C',3],[2,1,0])
sage: g1 = C1.digraph() #long time
sage: C2 = crystals.LSPaths(['C',3],[2,1,0])
sage: g2 = C2.digraph() #long time
sage: g1.is_isomorphic(g2, edge_labels=True) #long time
True

```

The preferred initialization method is via explicit weights rather than a Cartan type and the coefficients of the fundamental weights:

```

sage: R = RootSystem(['C',3])
sage: P = R.weight_lattice()
sage: La = P.fundamental_weights()
sage: C = crystals.AlcovePaths(2*La[1]+La[2]); C
Highest weight crystal of alcove paths of type ['C', 3] and weight 2*Lambda[1] +
↳Lambda[2]
sage: C1==C
True

```

We now explain the data structure:

```

sage: C = crystals.AlcovePaths(['A',2],[2,0]) ; C
Highest weight crystal of alcove paths of type ['A', 2] and weight 2*Lambda[1]
sage: C._R.lambda_chain()
[(alpha[1], 0), (alpha[1] + alpha[2], 0), (alpha[1], 1), (alpha[1] + alpha[2], 1)]

```

The previous list gives the initial “straight line” path from the fundamental alcove A_o to its translation $A_o - \lambda$ where $\lambda = 2\omega_1$ in this example. The initial path for weight λ is called the λ -chain. This path is constructed from the ordered pairs (β, k) , by crossing the hyperplane orthogonal to β at height $-k$. We can view a plot of this

path as follows:

```
sage: x=C( )
sage: x.plot() # not tested - outputs a pdf
```

An element of the crystal is given by a subset of the λ -chain. This subset indicates the hyperplanes where the initial path should be folded. The highest weight element is given by the empty subset.

```
sage: x
()
sage: x.f(1).f(2)
((alpha[1], 1), (alpha[1] + alpha[2], 1))
sage: x.f(1).f(2).integer_sequence()
[2, 3]
sage: C([2,3])
((alpha[1], 1), (alpha[1] + alpha[2], 1))
sage: C([2,3]).is_admissible() #check if a valid vertex
True
sage: C([1,3]).is_admissible() #check if a valid vertex
False
```

Alcove path crystals now works in affine type (trac ticket #14143):

```
sage: C = crystals.AlcovePaths(['A',2,1],[1,0,0]) ; C
Highest weight crystal of alcove paths of type ['A', 2, 1] and weight Lambda[0]
sage: x=C( )
sage: x.f(0)
((alpha[0], 0),)
sage: C.R
Root system of type ['A', 2, 1]
sage: C.weight
Lambda[0]
```

Test that the tensor products of Kirillov-Reshetikhin crystals minus non-pseudo-Demazure arrows is in bijection with alcove path construction:

```
sage: K = crystals.KirillovReshetikhin(['B',3,1],2,1)
sage: T = crystals.TensorProduct(K,K)
sage: g = T.digraph() #long time
sage: for e in g.edges(sort=False): #long time
.....:     if e[0].phi(0) == 1 and e[2] == 0: #long time
.....:         g.delete_edge(e) #long time

sage: C = crystals.AlcovePaths(['B',3,1],[0,2,0], highest_weight_crystal=False)
sage: g2 = C.digraph() #long time
sage: g.is_isomorphic(g2, edge_labels = True) #long time
True
```

Note: In type $C_n^{(1)}$, the Kirillov-Reshetikhin crystal is not connected when restricted to pseudo-Demazure arrows, hence the previous example will fail for type $C_n^{(1)}$ crystals.

```

sage: R = RootSystem(['B', 3])
sage: P = R.weight_lattice()
sage: La = P.fundamental_weights()
sage: D = crystals.AlcovePaths(2*La[2], highest_weight_crystal=False)
sage: C == D
True

```

Warning: Weights from finite root systems index non-highest weight crystals.

Element

alias of *CrystalOfAlcovePathsElement*

vertices()

Return a list of all the vertices of the crystal.

The vertices are represented as lists of integers recording the folding positions.

One can compute all vertices of the crystal by finding all the admissible subsets of the λ -chain (see method `is_admissible`, for definition). We use the breadth first search algorithm.

Warning: This method is (currently) only useful for the case when `highest_weight_crystal = False`, where you cannot always reach all vertices of the crystal using crystal operators, starting from the highest weight vertex. This method is typically slower than generating the crystal graph using crystal operators.

EXAMPLES:

```

sage: C = crystals.AlcovePaths(['C', 2], [1, 0])
sage: C.vertices()
[[], [0], [0, 1], [0, 1, 2]]
sage: C = crystals.AlcovePaths(['C', 2, 1], [2, 1], False)
sage: len(C.vertices())
80

```

The number of elements reachable using the crystal operators from the module generator:

```

sage: len(list(C))
55

```

class `sage.combinat.crystals.alcove_path.CrystalOfAlcovePathsElement`

Bases: `sage.structure.element_wrapper.ElementWrapper`

Crystal of alcove paths element.

INPUT:

- `data` – a list of folding positions in the lambda chain (indexing starts at 0) or a tuple of *RootsWithHeight* giving folding positions in the lambda chain.

EXAMPLES:

```

sage: C = crystals.AlcovePaths(['A', 2], [3, 2])
sage: x = C ( )

```

(continues on next page)

(continued from previous page)

```

sage: x.f(1).f(2)
((alpha[1], 2), (alpha[1] + alpha[2], 4))
sage: x.f(1).f(2).integer_sequence()
[8, 9]
sage: C[[8,9]]
((alpha[1], 2), (alpha[1] + alpha[2], 4))

```

e(i)Return the i -th crystal raising operator on self.

INPUT:

- i – element of the index set of the underlying root system.

EXAMPLES:

```

sage: C = crystals.AlcovePaths(['A',2],[2,0]); C
Highest weight crystal of alcove paths of type ['A', 2] and weight 2*Lambda[1]
sage: x = C( () )
sage: x.e(1)
sage: x.f(1) == x.f(1).f(2).e(2)
True

```

epsilon(i)Return the distance to the start of the i -string.

EXAMPLES:

```

sage: C = crystals.AlcovePaths(['A',2],[1,1])
sage: [c.epsilon(1) for c in C]
[0, 1, 0, 0, 1, 0, 1, 2]
sage: [c.epsilon(2) for c in C]
[0, 0, 1, 2, 1, 1, 0, 0]

```

f(i)Returns the i -th crystal lowering operator on self.

INPUT:

- i – element of the index_set of the underlying root_system.

EXAMPLES:

```

sage: C=crystals.AlcovePaths(['B',2],[1,1])
sage: x=C( () )
sage: x.f(1)
((alpha[1], 0),)
sage: x.f(1).f(2)
((alpha[1], 0), (alpha[1] + alpha[2], 2))

```

integer_sequence()Return a list of integers corresponding to positions in the λ -chain where it is folded.

Todo: Incorporate this method into the `_repr_` for finite Cartan type.

Note: Only works for finite Cartan types and indexing starts at 0.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A', 2], [3, 2])
sage: x = C( () )
sage: x.f(1).f(2).integer_sequence()
[8, 9]
```

is_admissible()

Diagnostic test to check if `self` is a valid element of the crystal.

If `self.value` is given by

$$(\beta_1, i_1), (\beta_2, i_2), \dots, (\beta_k, i_k),$$

for highest weight crystals this checks if the sequence

$$1 \rightarrow s_{\beta_1} \rightarrow s_{\beta_1} s_{\beta_2} \rightarrow \dots \rightarrow s_{\beta_1} s_{\beta_2} \dots s_{\beta_k}$$

is a path in the Bruhat graph. If `highest_weight_crystal=False`, then the method checks if the above sequence is a path in the quantum Bruhat graph.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A', 2], [1, 1]); C
Highest weight crystal of alcove paths of type ['A', 2] and weight Lambda[1] +
↳ Lambda[2]
sage: roots = sorted(C._R._root_lattice.positive_roots()); roots
[alpha[1], alpha[1] + alpha[2], alpha[2]]
sage: r1 = C._R(roots[0], 0); r1
(alpha[1], 0)
sage: r2 = C._R(roots[2], 0); r2
(alpha[2], 0)
sage: r3 = C._R(roots[1], 1); r3
(alpha[1] + alpha[2], 1)
sage: x = C( ( r1, r2 ) )
sage: x.is_admissible()
True
sage: x = C( ( r3, ) ); x
((alpha[1] + alpha[2], 1),)
sage: x.is_admissible()
False
sage: C = crystals.AlcovePaths(['C', 2, 1], [2, 1], False)
sage: C([7, 8]).is_admissible()
True
sage: C = crystals.AlcovePaths(['A', 2], [3, 2])
sage: C([2, 3]).is_admissible()
True
```

Todo: Better doctest

path()

Return the path in the (quantum) Bruhat graph corresponding to self.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['B', 3], [3,1,2])
sage: b = C.highest_weight_vector().f_string([1,3,2,1,3,1])
sage: b.path()
[1, s1, s3*s1, s2*s3*s1, s3*s2*s3*s1]
sage: b = C.highest_weight_vector().f_string([2,3,3,2])
sage: b.path()
[1, s2, s3*s2, s2*s3*s2]
sage: b = C.highest_weight_vector().f_string([2,3,3,2,1])
sage: b.path()
[1, s2, s3*s2, s2*s3*s2, s1*s2*s3*s2]
```

phi(i)

Return the distance to the end of the i -string.

This method overrides the generic implementation in the category of crystals since this computation is more efficient.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A', 2], [1,1])
sage: [c.phi(1) for c in C]
[1, 0, 0, 1, 0, 2, 1, 0]
sage: [c.phi(2) for c in C]
[1, 2, 1, 0, 0, 0, 0, 1]
```

plot()

Return a plot self.

Note: Currently only implemented for types A_2 , B_2 , and C_2 .

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A', 2], [2,0])
sage: x = C( ) .f(1).f(2)
sage: x.plot() # Not tested - creates a pdf
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A', 2], [2,0])
sage: for i in C: i.weight()
(2, 0, 0)
(1, 1, 0)
(0, 2, 0)
(0, -1, 0)
(-1, 0, 0)
(-2, -2, 0)
sage: B = crystals.AlcovePaths(['A', 2, 1], [1,0,0])
```

(continues on next page)

(continued from previous page)

```
sage: p = B.module_generators[0].f_string([0,1,2])
sage: p.weight()
Lambda[0] - delta
```

class sage.combinat.crystals.alcove_path.**InfinityCrystalOfAlcovePaths**(*cartan_type*)
 Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

$\mathcal{B}(\infty)$ crystal of alcove paths.

class **Element**(*parent, elt, shift*)

Bases: sage.structure.element_wrapper.ElementWrapper

Initialize self.

EXAMPLES:

```
sage: A = crystals.infinity.AlcovePaths(['F',4])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([2,3,1,4,4,2,3,1])
sage: TestSuite(x).run()
```

e(*i*)

Return the action of e_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: A = crystals.infinity.AlcovePaths(['D',5,1])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1,3,4,2,5,4,5,5])
sage: x.f(4).e(5) == x.e(5).f(4)
True
```

epsilon(*i*)

Return ε_i of self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: A = crystals.infinity.AlcovePaths(['A',7,2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1,0,2,3,4,4,4,2,3,3])
sage: [x.epsilon(i) for i in A.index_set()]
[0, 0, 0, 3, 0]
sage: x = mg.f_string([2,2,1,1,0,1,0,2,3,3,4])
sage: [x.epsilon(i) for i in A.index_set()]
[1, 2, 0, 1, 1]
```

f(*i*)

Return the action of f_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```

sage: A = crystals.infinity.AlcovePaths(['E',7,1])
sage: mg = A.highest_weight_vector()
sage: mg.f_string([1,3,5,6,4,2,0,2,1,0,2,4,7,4,2])
((alpha[2], -3), (alpha[5], -1), (alpha[1], -1),
 (alpha[0] + alpha[1], -2),
 (alpha[2] + alpha[4] + alpha[5], -2),
 (alpha[5] + alpha[6], -1), (alpha[1] + alpha[3], -1),
 (alpha[5] + alpha[6] + alpha[7], -1),
 (alpha[0] + alpha[1] + alpha[3], -1),
 (alpha[1] + alpha[3] + alpha[4] + alpha[5], -1))

```

phi(i)

Return φ_i of self.

Let $A \in \mathcal{B}(\infty)$ Define $\varphi_i(A) := \varepsilon_i(A) + \langle h_i, \text{wt}(A) \rangle$, where h_i is the i -th simple coroot and $\text{wt}(A)$ is the *weight()* of A .

INPUT:

- i – an element of the index set

EXAMPLES:

```

sage: A = crystals.infinity.AlcovePaths(['A',8,2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1,0,2,3,4,4,4,2,3,3,3])
sage: [x.phi(i) for i in A.index_set()]
[1, 1, 1, 3, -2]
sage: x = mg.f_string([2,2,1,1,0,1,0,2,3,3,3,4])
sage: [x.phi(i) for i in A.index_set()]
[4, -1, 0, 0, 2]

```

projection(k=None)

Return the projection self onto $B(k\rho)$.

INPUT:

- k – (optional) if not given, defaults to the smallest value such that self is not None under the projection

EXAMPLES:

```

sage: A = crystals.infinity.AlcovePaths(['G',2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([2,1,1,2,2,2,1,1]); x
((alpha[2], -3), (alpha[1] + alpha[2], -3),
 (3*alpha[1] + 2*alpha[2], -1), (2*alpha[1] + alpha[2], -1))
sage: x.projection()
((alpha[2], 0), (alpha[1] + alpha[2], 9),
 (3*alpha[1] + 2*alpha[2], 8), (2*alpha[1] + alpha[2], 14))
sage: x.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight 3*Lambda[1] + 3*Lambda[2]

sage: mg.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight 0
sage: mg.f(1).projection().parent()

```

(continues on next page)

(continued from previous page)

```

Highest weight crystal of alcove paths of type ['G', 2]
and weight Lambda[1] + Lambda[2]
sage: mg.f(1).f(2).projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight Lambda[1] + Lambda[2]
sage: b = mg.f_string([1,2,2,1,2])
sage: b.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight 2*Lambda[1] + 2*Lambda[2]
sage: b.projection(3).parent()
Highest weight crystal of alcove paths of type ['G', 2]
and weight 3*Lambda[1] + 3*Lambda[2]
sage: b.projection(1)

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: A = crystals.infinity.AlcovePaths(['E',6])
sage: mg = A.highest_weight_vector()
sage: fstr = [1,3,4,2,1,2,3,6,5,3,2,6,2]
sage: x = mg.f_string(fstr)
sage: al = A.weight_lattice_realization().simple_roots()
sage: x.weight() == -sum(al[i]*fstr.count(i) for i in A.index_set())
True

```

class sage.combinat.crystals.alcove_path.RootsWithHeight(*weight*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Data structure of the ordered pairs (β, k) , where β is a positive root and k is a non-negative integer. A total order is implemented on this set, and depends on the weight.

INPUT:

- `cartan_type` – Cartan type of a finite or affine untwisted root system
- `weight` – dominant weight as a list of (integral) coefficients of the fundamental weights

EXAMPLES:

```

sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: R = RootsWithHeight(['A',2],[1,1]); R
Roots with height of Cartan type ['A', 2] and dominant weight Lambda[1] + Lambda[2]

sage: r1 = R._root_lattice.from_vector(vector([1,0])); r1
alpha[1]
sage: r2 = R._root_lattice.from_vector(vector([1,1])); r2
alpha[1] + alpha[2]

sage: x = R(r1,0); x
(alpha[1], 0)
sage: y = R(r2,1); y
(alpha[1] + alpha[2], 1)

```

(continues on next page)

(continued from previous page)

```
sage: x < y
True
```

Elementalias of *RootsWithHeightElement***lambda_chain()**Return the unfolded λ -chain.

Note: Only works in root systems of finite type.

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: R = RootsWithHeight(['A', 2], [1, 1]); R
Roots with height of Cartan type ['A', 2] and dominant weight Lambda[1] +
↳ Lambda[2]
sage: R.lambda_chain()
[(alpha[2], 0), (alpha[1] + alpha[2], 0), (alpha[1], 0), (alpha[1] + alpha[2],
↳ 1)]
```

word()Gives the initial alcove path (λ -chain) in terms of simple roots. Used for plotting the path.

Note: Currently only implemented for finite Cartan types.

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: R = RootsWithHeight(['A', 2], [3, 2])
sage: R.word()
[2, 1, 2, 0, 1, 2, 1, 0, 1, 2]
```

class `sage.combinat.crystals.alcove_path.RootsWithHeightElement`(*parent, root, height*)Bases: `sage.structure.element.Element`Element of *RootsWithHeight*.

INPUT:

- *root* – A positive root β in our root system
- *height* – Is an integer, such that $0 \leq l \leq \langle \lambda, \beta^\vee \rangle$

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: rl = RootSystem(['A', 2]).root_lattice()
sage: x = rl.from_vector(vector([1, 1])); x
alpha[1] + alpha[2]
sage: R = RootsWithHeight(['A', 2], [1, 1]); R
Roots with height of Cartan type ['A', 2] and dominant weight Lambda[1] + Lambda[2]
sage: y = R(x, 1); y
(alpha[1] + alpha[2], 1)
```

`sage.combinat.crystals.alcove_path.compare_graphs(g1, g2, node1, node2)`

Compare two edge-labeled `graphs` obtained from `Crystal.digraph()`, starting from the root nodes of each graph.

- `g1` – `graphs`, first digraph
- `g2` – `graphs`, second digraph
- `node1` – element of `g1`
- `node2` – element of `g2`

Traverse `g1` starting at `node1` and compare this graph with the one obtained by traversing `g2` starting with `node2`. If the graphs match (including labels) then return `True`. Return `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import compare_graphs
sage: G1 = crystals.Tableaux(['A', 3], shape=[1, 1]).digraph()
sage: C = crystals.AlcovePaths(['A', 3], [0, 1, 0])
sage: G2 = C.digraph()
sage: compare_graphs(G1, G2, C( ( ) ), G2.vertices(sort=True)[0])
True
```

5.1.39 Benkart-Kang-Kashiwara crystals for the general-linear Lie superalgebra

`class sage.combinat.crystals.bkk_crystals.CrystalOfBKKTTableaux(ct, shape)`

Bases: `sage.combinat.crystals.tensor_product.CrystalOfWords`

Crystal of tableaux for type $A(m|n)$.

This is an implementation of the tableaux model of the Benkart-Kang-Kashiwara crystal [BKK2000] for the Lie superalgebra $gl(m+1, n+1)$.

INPUT:

- `ct` – a super Lie Cartan type of type $A(m|n)$

- `shape` – shape specifying the highest weight; this should be a partition contained in a hook of height $n + 1$ and width $m + 1$

EXAMPLES:

```
sage: T = crystals.Tableaux(['A', [1,1]], shape = [2,1])
sage: T.cardinality()
20
```

class Element

Bases: `sage.combinat.crystals.tensor_product_element.CrystalOfBKKTableauxElement`

genuine_highest_weight_vectors(*index_set=None*)

Return a tuple of genuine highest weight elements.

A *fake highest weight vector* is one which is annihilated by e_i for all i in the index set, but whose weight is not bigger in dominance order than all other elements in the crystal. A *genuine highest weight vector* is a highest weight element that is not fake.

EXAMPLES:

```
sage: B = crystals.Tableaux(['A', [1,1]], shape=[3,2,1])
sage: B.genuine_highest_weight_vectors()
([[-2, -2, -2], [-1, -1], [1]],)
sage: B.highest_weight_vectors()
([[-2, -2, -2], [-1, -1], [1]],
 [[-2, -2, -2], [-1, 2], [1]],
 [[-2, -2, 2], [-1, -1], [1]])
```

shape()

Return the shape of `self`.

EXAMPLES:

```
sage: T = crystals.Tableaux(['A', [1, 2]], shape=[2,1])
sage: T.shape()
[2, 1]
```

5.1.40 Catalog Of Crystals

Let I be an index set and let $(A, \Pi, \Pi^\vee, P, P^\vee)$ be a Cartan datum associated with generalized Cartan matrix $A = (a_{ij})_{i,j \in I}$. An *abstract crystal* associated to this Cartan datum is a set B together with maps

$$e_i, f_i: B \rightarrow B \cup \{0\}, \quad \varepsilon_i, \varphi_i: B \rightarrow \mathbf{Z} \cup \{-\infty\}, \quad \text{wt}: B \rightarrow P,$$

subject to the following conditions:

1. $\varphi_i(b) = \varepsilon_i(b) + \langle h_i, \text{wt}(b) \rangle$ for all $b \in B$ and $i \in I$;
2. $\text{wt}(e_i b) = \text{wt}(b) + \alpha_i$ if $e_i b \in B$;
3. $\text{wt}(f_i b) = \text{wt}(b) - \alpha_i$ if $f_i b \in B$;
4. $\varepsilon_i(e_i b) = \varepsilon_i(b) - 1$, $\varphi_i(e_i b) = \varphi_i(b) + 1$ if $e_i b \in B$;
5. $\varepsilon_i(f_i b) = \varepsilon_i(b) + 1$, $\varphi_i(f_i b) = \varphi_i(b) - 1$ if $f_i b \in B$;
6. $f_i b = b'$ if and only if $b = e_i b'$ for $b, b' \in B$ and $i \in I$;
7. if $\varphi_i(b) = -\infty$ for $b \in B$, then $e_i b = f_i b = 0$.

- *LSPaths*
- *RiggedConfigurations*

5.1.44 An introduction to crystals

Informally, a crystal \mathcal{B} is an oriented graph with edges colored in some set I such that, for each $i \in I$, each node x has:

- at most one i -successor, denoted $f_i x$;
- at most one i -predecessor, denoted $e_i x$.

By convention, one writes $f_i x = \emptyset$ and $e_i x = \emptyset$ when x has no successor resp. predecessor.

One may think of \mathcal{B} as essentially a deterministic automaton whose dual is also deterministic; in this context, the f_i 's and e_i 's are respectively the transition functions of the automaton and of its dual, and \emptyset is the sink.

A crystal comes further endowed with a weight function $\text{wt} : \mathcal{B} \rightarrow L$ which satisfies appropriate conditions.

In combinatorial representation theory, crystals are used as combinatorial data to model representations of Lie algebra.

Axiomatic definition

Let C be a Cartan type (*CartanType*) with index set I , and L be a realization of the weight lattice of the type C . Let α_i and α_i^\vee denote the simple roots and coroots respectively.

A type C crystal is a non-empty set \mathcal{B} endowed with maps $\text{wt} : \mathcal{B} \rightarrow L$, $e_i, f_i : \mathcal{B} \rightarrow \mathcal{B} \cup \{\emptyset\}$, and $\varepsilon_i, \varphi_i : \mathcal{B} \rightarrow \mathbf{Z} \cup \{-\infty\}$ for $i \in I$ satisfying the following properties for all $i \in I$:

- for $b, b' \in \mathcal{B}$, we have $f_i b' = b$ if and only if $e_i b = b'$;
- if $e_i b \in \mathcal{B}$, then:
 - $\text{wt}(e_i b) = \text{wt}(b) + \alpha_i$,
 - $\varepsilon_i(e_i b) = \varepsilon_i(b) - 1$,
 - $\varphi_i(e_i b) = \varphi_i(b) + 1$;
- if $f_i b \in \mathcal{B}$, then:
 - $\text{wt}(f_i b) = \text{wt}(b) - \alpha_i$,
 - $\varepsilon_i(f_i b) = \varepsilon_i(b) + 1$,
 - $\varphi_i(f_i b) = \varphi_i(b) - 1$;
- $\varphi_i(b) = \varepsilon_i(b) + \langle \alpha_i^\vee, \text{wt}(b) \rangle$,
- if $\varphi_i(b) = -\infty$ for $b \in \mathcal{B}$, then $e_i b = f_i b = \emptyset$.

Some further conditions are required to guarantee that this data indeed models a representation of a Lie algebra. For finite simply laced types a complete characterization is given by Stembridge's local axioms [Ste2003].

EXAMPLES:

We construct the type A_5 crystal on letters (or in representation theoretic terms, the highest weight crystal of type A_5 corresponding to the highest weight Λ_1):

```
sage: C = crystals.Letters(['A', 5]); C
The crystal of letters for type ['A', 5]
```

It has a single highest weight element:

```
sage: C.highest_weight_vectors()
(1,)
```

A crystal is an enumerated set (see [EnumeratedSets](#)); and we can count and list its elements in the usual way:

```
sage: C.cardinality()
6
sage: C.list()
[1, 2, 3, 4, 5, 6]
```

as well as use it in for loops:

```
sage: [x for x in C]
[1, 2, 3, 4, 5, 6]
```

Here are some more elaborate crystals (see their respective documentations):

```
sage: Tens = crystals.TensorProduct(C, C)
sage: Spin = crystals.Spins(['B', 3])
sage: Tab = crystals.Tableaux(['A', 3], shape = [2,1,1])
sage: Fast = crystals.FastRankTwo(['B', 2], shape = [3/2, 1/2])
sage: KR = crystals.KirillovReshetikhin(['A', 2, 1], 1, 1)
```

One can get (currently) crude plotting via:

```
sage: Tab.plot()
Graphics object consisting of 52 graphics primitives
```

If dot2tex is installed, one can obtain nice latex pictures via:

```
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 1, 1)
sage: view(K, pdflatex=True) # optional - dot2tex graphviz, not tested (opens external_
↪window)
```

or with colored edges:

```
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 1, 1)
sage: G = K.digraph()
sage: G.set_latex_options(color_by_label={0:"black", 1:"red", 2:"blue", 3:"green"})
sage: view(G, pdflatex=True) # optional - dot2tex graphviz, not tested (opens external_
↪window)
```

For rank two crystals, there is an alternative method of getting metapost pictures. For more information see [C.metapost?](#).

The overview of crystal features in Sage

Todo:

- Vocabulary and conventions:
 - For a classical crystal: connected / highest weight / irreducible
 - ...
- Layout instructions for plot() for rank 2 types
- RestrictionOfCrystal

The crystals library in Sage grew up from an initial implementation in MuPAD-Combinat (see <MuPAD-Combinat>/lib/COMBINAT/crystals.mu).

class `sage.combinat.crystals.crystals.CrystalBacktracker`(*crystal, index_set=None*)

Bases: `sage.combinat.backtrack.GenericBacktracker`

Time complexity: $O(nF)$ amortized for each produced element, where n is the size of the index set, and F is the cost of computing e and f operators.

Memory complexity: $O(D)$ where D is the depth of the crystal.

Principle of the algorithm:

Let C be a classical crystal. It's an acyclic graph where each connected component has a unique element without predecessors (the highest weight element for this component). Let's assume for simplicity that C is irreducible (i.e. connected) with highest weight element u .

One can define a natural spanning tree of C by taking u as the root of the tree, and for any other element y taking as ancestor the element x such that there is an i -arrow from x to y with i minimal. Then, a path from u to y describes the lexicographically smallest sequence i_1, \dots, i_k such that $(f_{i_k} \circ \dots \circ f_{i_1})(u) = y$.

Morally, the iterator implemented below just does a depth first search walk through this spanning tree. In practice, this can be achieved recursively as follows: take an element x , and consider in turn each successor $y = f_i(x)$, ignoring those such that $y = f_j(x')$ for some x' and $j < i$ (this can be tested by computing $e_j(y)$ for $j < i$).

EXAMPLES:

```
sage: from sage.combinat.crystals.crystals import CrystalBacktracker
sage: C = crystals.Tableaux(['B', 3], shape=[3, 2, 1])
sage: CB = CrystalBacktracker(C)
sage: len(list(CB))
1617
sage: CB = CrystalBacktracker(C, [1, 2])
sage: len(list(CB))
8
```

5.1.45 Direct Sum of Crystals

class `sage.combinat.crystals.direct_sum.DirectSumOfCrystals`(*crystals, facade, keepkey, category, **options*)

Bases: `sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets`

Direct sum of crystals.

Given a list of crystals B_0, \dots, B_k of the same Cartan type, one can form the direct sum $B_0 \oplus \dots \oplus B_k$.

INPUT:

- `crystals` – a list of crystals of the same Cartan type
- `keepkey` – a boolean

The option `keepkey` is by default set to `False`, assuming that the crystals are all distinct. In this case the elements of the direct sum are just represented by the elements in the crystals B_i . If the crystals are not all distinct, one should set the `keepkey` option to `True`. In this case, the elements of the direct sum are represented as tuples (i, b) where $b \in B_i$.

EXAMPLES:

```

sage: C = crystals.Letters(['A',2])
sage: C1 = crystals.Tableaux(['A',2],shape=[1,1])
sage: B = crystals.DirectSum([C,C1])
sage: B.list()
[1, 2, 3, [[1], [2]], [[1], [3]], [[2], [3]]]
sage: [b.f(1) for b in B]
[2, None, None, None, [[2], [3]], None]
sage: B.module_generators
(1, [[1], [2]])

```

```

sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: B.list()
[(0, 1), (0, 2), (0, 3), (1, 1), (1, 2), (1, 3)]
sage: B.module_generators
((0, 1), (1, 1))
sage: b = B( tuple([0,C(1)] ) )
sage: b
(0, 1)
sage: b.weight()
(1, 0, 0)

```

The following is required, because *DirectSumOfCrystals* takes the same arguments as *DisjointUnionEnumeratedSets* (which see for details).

class Element

Bases: `sage.structure.element_wrapper.ElementWrapper`

A class for elements of direct sums of crystals.

$e(i)$

Return the action of e_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: [[b, b.e(2)] for b in B]
[[ (0, 1), None ], [ (0, 2), None ], [ (0, 3), (0, 2) ], [ (1, 1), None ], [ (1, 2), ↵
↵None ], [ (1, 3), (1, 2) ]]

```

$\epsilon(i)$

EXAMPLES:

```

sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: b = B( tuple([0,C(2)] ) )
sage: b.epsilon(2)
0

```

$f(i)$

Return the action of f_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: [[b,b.f(1)] for b in B]
[[(\0, 1), (\0, 2)], [(\0, 2), None], [(\0, 3), None], [(1, 1), (1, 2)], [(1, \
↪2), None], [(1, 3), None]]

```

phi(i)

EXAMPLES:

```

sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: b = B( tuple([\0,C(2)] ) )
sage: b.phi(2)
1

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: b = B( tuple([\0,C(2)] ) )
sage: b
(\0, 2)
sage: b.weight()
(\0, 1, 0)

```

weight_lattice_realization()

Return the weight lattice realization used to express weights.

The weight lattice realization is the common parent which all weight lattice realizations of the crystals of self coerce into.

EXAMPLES:

```

sage: LaZ = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_
↪weights()
sage: LaQ = RootSystem(['A',2,1]).weight_space(extended=True).fundamental_

5.1.46 Elementary Crystals

Let λ be a weight. The crystals T_λ , R_λ , B_i , and C are important objects in the tensor category of crystals. For example, the crystal T_0 is the neutral object in this category; i.e., $T_0 \otimes B \cong B \otimes T_0 \cong B$ for any crystal B . We list some other properties of these crystals:

- The crystal $T_\lambda \otimes B(\infty)$ is the crystal of the Verma module with highest weight λ , where λ is a dominant integral weight.
- Let u_∞ be the highest weight vector of $B(\infty)$ and λ be a dominant integral weight. There is an embedding of crystals $B(\lambda) \rightarrow T_\lambda \otimes B(\infty)$ sending $u_\lambda \mapsto t_\lambda \otimes u_\infty$ which is not strict, but the embedding $B(\lambda) \rightarrow C \otimes T_\lambda \otimes B(\infty)$ by $u_\lambda \mapsto c \otimes t_\lambda \otimes u_\infty$ is a strict embedding.
- For any dominant integral weight λ , there is a surjective crystal morphism $\Psi_\lambda: R_\lambda \otimes B(\infty) \rightarrow B(\lambda)$. More precisely, if $B = \{r_\lambda \otimes b \in R_\lambda \otimes B(\infty) : \Psi_\lambda(r_\lambda \otimes b) \neq 0\}$, then $B \cong B(\lambda)$ as crystals.
- For all Cartan types and all weights λ , we have $R_\lambda \cong C \otimes T_\lambda$ as crystals.
- For each i , there is a strict crystal morphism $\Psi_i: B(\infty) \rightarrow B_i \otimes B(\infty)$ defined by $u_\infty \mapsto b_i(0) \otimes u_\infty$, where u_∞ is the highest weight vector of $B(\infty)$.

For more information on $B(\infty)$, see [InfinityCrystalOfTableaux](#).

Note: As with [TensorProductOfCrystals](#), we are using the opposite of Kashiwara's convention.

AUTHORS:

- Ben Salisbury: Initial version

REFERENCES:

- [Ka1993]
- [NZ1997]

class `sage.combinat.crystals.elementary_crystals.AbstractSingleCrystalElement`

Bases: `sage.structure.element.Element`

Abstract base class for elements in crystals with a single element.

e(*i*)

Return e_i of `self`, which is `None` for all i .

INPUT:

- *i* – An element of the index set

EXAMPLES:

```
sage: ct = CartanType(['A', 2])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct, la[1])
sage: t = T.highest_weight_vector()
sage: t.e(1)
sage: t.e(2)
```

f(*i*)

Return f_i of `self`, which is `None` for all i .

INPUT:

- *i* – An element of the index set

EXAMPLES:

```
sage: ct = CartanType(['A',2])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct,la[1])
sage: t = T.highest_weight_vector()
sage: t.f(1)
sage: t.f(2)
```

class `sage.combinat.crystals.elementary_crystals.ComponentCrystal`(*cartan_type*, *P*)
 Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The component crystal.

Defined in [Ka1993], the component crystal $C = \{c\}$ is the single element crystal whose crystal structure is defined by

$$\text{wt}(c) = 0, \quad e_i c = f_i c = 0, \quad \varepsilon_i(c) = \varphi_i(c) = 0.$$

Note $C \cong B(0)$, where $B(0)$ is the highest weight crystal of highest weight 0.

INPUT:

- *cartan_type* – a Cartan type

class `Element`

Bases: `sage.combinat.crystals.elementary_crystals.AbstractSingleCrystalElement`

Element of a component crystal.

epsilon(*i*)

Return ε_i of `self`, which is 0 for all *i*.

INPUT:

- *i* – An element of the index set

EXAMPLES:

```
sage: C = crystals.elementary.Component("C5")
sage: c = C.highest_weight_vector()
sage: [c.epsilon(i) for i in C.index_set()]
[0, 0, 0, 0, 0]
```

phi(*i*)

Return φ_i of `self`, which is 0 for all *i*.

INPUT:

- *i* – An element of the index set

EXAMPLES:

```
sage: C = crystals.elementary.Component("C5")
sage: c = C.highest_weight_vector()
sage: [c.phi(i) for i in C.index_set()]
[0, 0, 0, 0, 0]
```

weight()

Return the weight of `self`, which is always 0.

EXAMPLES:

```
sage: C = crystals.elementary.Component("F4")
sage: c = C.highest_weight_vector()
sage: c.weight()
(0, 0, 0, 0)
```

cardinality()

Return the cardinality of `self`, which is always 1.

EXAMPLES:

```
sage: C = crystals.elementary.Component("E6")
sage: c = C.highest_weight_vector()
sage: C.cardinality()
1
```

weight_lattice_realization()

Return the weight lattice realization of `self`.

EXAMPLES:

```
sage: C = crystals.elementary.Component("A2")
sage: C.weight_lattice_realization()
Ambient space of the Root system of type ['A', 2]

sage: P = RootSystem(['A', 2]).weight_lattice()
sage: C = crystals.elementary.Component(P)
sage: C.weight_lattice_realization() is P
True
```

class `sage.combinat.crystals.elementary_crystals.ElementaryCrystal`(*cartan_type*, *i*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The elementary crystal B_i .

For i an element of the index set of type X , the crystal B_i of type X is the set

$$B_i = \{b_i(m) : m \in \mathbf{Z}\},$$

where the crystal structure is given by

$$\begin{aligned} \text{wt}(b_i(m)) &= m\alpha_i \\ \varphi_j(b_i(m)) &= \begin{cases} m & \text{if } j = i, \\ -\infty & \text{if } j \neq i, \end{cases} \\ \varepsilon_j(b_i(m)) &= \begin{cases} -m & \text{if } j = i, \\ -\infty & \text{if } j \neq i, \end{cases} \\ e_j b_i(m) &= \begin{cases} b_i(m+1) & \text{if } j = i, \\ 0 & \text{if } j \neq i, \end{cases} \\ f_j b_i(m) &= \begin{cases} b_i(m-1) & \text{if } j = i, \\ 0 & \text{if } j \neq i. \end{cases} \end{aligned}$$

The *Kashiwara embedding theorem* asserts there is a unique strict crystal embedding of crystals

$$B(\infty) \hookrightarrow B_i \otimes B(\infty),$$

satisfying certain properties (see [Ka1993]). The above embedding may be iterated to obtain a new embedding

$$B(\infty) \hookrightarrow B_{i_N} \otimes B_{i_{N-1}} \otimes \cdots \otimes B_{i_2} \otimes B_{i_1} \otimes B(\infty),$$

which is a foundational object in the study of *polyhedral realizations of crystals* (see, for example, [NZ1997]).

class `Element`(*parent*, *m*)

Bases: `sage.structure.element.Element`

Element of a B_i crystal.

e(*i*)

Return the action of e_i on self.

INPUT:

- *i* – An element of the index set

EXAMPLES:

```
sage: B = crystals.elementary.Elementary(['E',7],1)
sage: B(3).e(1)
4
sage: B(172).e_string([1]*171)
343
sage: B(0).e(2)
```

epsilon(*i*)

Return ε_i of self.

INPUT:

- *i* – An element of the index set

EXAMPLES:

```
sage: B = crystals.elementary.Elementary(['F',4],3)
sage: [[B(j).epsilon(i) for i in B.index_set()] for j in range(5)]
[[-inf, -inf, 0, -inf],
 [-inf, -inf, -1, -inf],
 [-inf, -inf, -2, -inf],
 [-inf, -inf, -3, -inf],
 [-inf, -inf, -4, -inf]]
```

f(*i*)

Return the action of f_i on self.

INPUT:

- *i* – An element of the index set

EXAMPLES:

```
sage: B = crystals.elementary.Elementary(['E',7],1)
sage: B(3).f(1)
2
sage: B(172).f_string([1]*171)
1
sage: B(0).e(2)
```

phi(*i*)

Return φ_i of self.

INPUT:

- i – An element of the index set

EXAMPLES:

```
sage: B = crystals.elementary.Elementary(['E', 8, 1], 4)
sage: [[B(m).phi(j) for j in B.index_set()] for m in range(44, 49)]
[[-inf, -inf, -inf, -inf, 44, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 45, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 46, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 47, -inf, -inf, -inf, -inf],
 [-inf, -inf, -inf, -inf, 48, -inf, -inf, -inf, -inf]]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: B = crystals.elementary.Elementary(['C', 14], 12)
sage: B(-385).weight()
-385*alpha[12]
```

weight_lattice_realization()

Return a realization of the lattice containing the weights of self.

EXAMPLES:

```
sage: B = crystals.elementary.Elementary(['A', 4, 1], 2)
sage: B.weight_lattice_realization()
Root lattice of the Root system of type ['A', 4, 1]
```

class sage.combinat.crystals.elementary_crystals.**RCrystal**(cartan_type, weight, dual)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The crystal R_λ .

For a fixed weight λ , the crystal $R_\lambda = \{r_\lambda\}$ is a single element crystal with the crystal structure defined by

$$\text{wt}(r_\lambda) = \lambda, \quad e_i r_\lambda = f_i r_\lambda = 0, \quad \varepsilon_i(r_\lambda) = -\langle h_i, \lambda \rangle, \quad \varphi_i(r_\lambda) = 0,$$

where $\{h_i\}$ are the simple coroots.

Tensoring R_λ with a crystal B results in shifting the weights of the vertices in B by λ and may also cut a subset out of the original graph of B . That is, $\text{wt}(r_\lambda \otimes b) = \text{wt}(b) + \lambda$, where $b \in B$, provided $r_\lambda \otimes b \neq 0$. For example, the crystal graph of $B(\lambda)$ is the same as the crystal graph of $R_\lambda \otimes B(\infty)$ generated from the component $r_\lambda \otimes u_\infty$.

There is also a dual version of this crystal given by $R_\lambda^\vee = \{r_\lambda^\vee\}$ with the crystal structure defined by

$$\text{wt}(r_\lambda^\vee) = \lambda, \quad e_i r_\lambda^\vee = f_i r_\lambda^\vee = 0, \quad \varepsilon_i(r_\lambda^\vee) = 0, \quad \varphi_i(r_\lambda^\vee) = \langle h_i, \lambda \rangle.$$

INPUT:

- `cartan_type` – a Cartan type
- `weight` – an element of the weight lattice of type `cartan_type`
- `dual` – (default: False) boolean

EXAMPLES:

We check by tensoring R_λ with $B(\infty)$ results in a component of $B(\lambda)$:

```

sage: B = crystals.infinity.Tableaux("A2")
sage: R = crystals.elementary.R("A2", B.Lambda()[1]+B.Lambda()[2])
sage: T = crystals.TensorProduct(R, B)
sage: mg = T(R.highest_weight_vector(), B.highest_weight_vector())
sage: S = T.subcrystal(generators=[mg])
sage: sorted([x.weight() for x in S], key=str)
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1),
 (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: C = crystals.Tableaux("A2", shape=[2,1])
sage: sorted([x.weight() for x in C], key=str)
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1),
 (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: GT = T.digraph(subset=S)
sage: GC = C.digraph()
sage: GT.is_isomorphic(GC, edge_labels=True)
True

```

class Element

Bases: *sage.combinat.crystals.elementary_crystals.AbstractSingleCrystalElement*

Element of a R_λ crystal.

epsilon(i)

Return ε_i of self.

We have $\varepsilon_i(r_\lambda) = -\langle h_i, \lambda \rangle$ for all i , where h_i is a simple coroot.

INPUT:

- i – An element of the index set

EXAMPLES:

```

sage: la = RootSystem(['A', 2]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R("A2", la[1])
sage: r = R.highest_weight_vector()
sage: [r.epsilon(i) for i in R.index_set()]
[-1, 0]

sage: R = crystals.elementary.R("A2", la[1], dual=True)
sage: r = R.highest_weight_vector()
sage: [r.epsilon(i) for i in R.index_set()]
[0, 0]

```

phi(i)

Return φ_i of self, which is 0 for all i .

INPUT:

- i – An element of the index set

EXAMPLES:

```

sage: la = RootSystem("C5").weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R("C5", la[4]+la[5])
sage: r = R.highest_weight_vector()
sage: [r.phi(i) for i in R.index_set()]
[0, 0, 0, 0, 0]

```

(continues on next page)

(continued from previous page)

```
sage: R = crystals.elementary.R("C5", la[4]+la[5], dual=True)
sage: r = R.highest_weight_vector()
sage: [r.phi(i) for i in R.index_set()]
[0, 0, 0, 1, 1]
```

weight()

Return the weight of `self`, which is always λ .

EXAMPLES:

```
sage: ct = CartanType(['C', 5])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct, la[4]+la[5]-la[1]-la[2])
sage: t = T.highest_weight_vector()
sage: t.weight()
-Lambda[1] - Lambda[2] + Lambda[4] + Lambda[5]
```

cardinality()

Return the cardinality of `self`, which is always 1.

EXAMPLES:

```
sage: La = RootSystem(['C', 12]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(['C', 12], La[9])
sage: R.cardinality()
1
```

weight_lattice_realization()

Return a realization of the lattice containing the weights of `self`.

EXAMPLES:

```
sage: La = RootSystem(['C', 12]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(['C', 12], La[9])
sage: R.weight_lattice_realization()
Weight lattice of the Root system of type ['C', 12]

sage: ct = CartanMatrix([[2, -4], [-5, 2]])
sage: La = RootSystem(ct).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(ct, La[1])
sage: R.weight_lattice_realization()
Weight lattice of the Root system of type
[ 2 -4]
[-5  2]
```

class `sage.combinat.crystals.elementary_crystals.TCrystal`(*cartan_type*, *weight*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The crystal T_λ .

Let λ be a weight. As defined in [Ka1993] the crystal $T_\lambda = \{t_\lambda\}$ is a single element crystal with the crystal structure defined by

$$\text{wt}(t_\lambda) = \lambda, \quad e_i t_\lambda = f_i t_\lambda = 0, \quad \varepsilon_i(t_\lambda) = \varphi_i(t_\lambda) = -\infty.$$

The crystal T_λ shifts the weights of the vertices in a crystal B by λ when tensored with B , but leaves the graph structure of B unchanged. That is to say, for all $b \in B$, we have $\text{wt}(b \otimes t_\lambda) = \text{wt}(b) + \lambda$.

INPUT:

- `cartan_type` – A Cartan type
- `weight` – An element of the weight lattice of type `cartan_type`

EXAMPLES:

```
sage: ct = CartanType(['A', 2])
sage: C = crystals.Tableaux(ct, shape=[1])
sage: for x in C: x.weight()
(1, 0, 0)
(0, 1, 0)
(0, 0, 1)
sage: La = RootSystem(ct).ambient_space().fundamental_weights()
sage: TLa = crystals.elementary.T(ct, 3*(La[1] + La[2]))
sage: TP = crystals.TensorProduct(TLa, C)
sage: for x in TP: x.weight()
(7, 3, 0)
(6, 4, 0)
(6, 3, 1)
sage: G = C.digraph()
sage: H = TP.digraph()
sage: G.is_isomorphic(H, edge_labels=True)
True
```

class Element

Bases: `sage.combinat.crystals.elementary_crystals.AbstractSingleCrystalElement`

Element of a T_λ crystal.

`epsilon(i)`

Return ε_i of `self`, which is $-\infty$ for all i .

INPUT:

- `i` – An element of the index set

EXAMPLES:

```
sage: ct = CartanType(['C', 5])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct, la[4]+la[5]-la[1]-la[2])
sage: t = T.highest_weight_vector()
sage: [t.epsilon(i) for i in T.index_set()]
[-inf, -inf, -inf, -inf, -inf]
```

`phi(i)`

Return φ_i of `self`, which is $-\infty$ for all i .

INPUT:

- `i` – An element of the index set

EXAMPLES:

```
sage: ct = CartanType(['C', 5])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct, la[4]+la[5]-la[1]-la[2])
```

(continues on next page)

(continued from previous page)

```
sage: t = T.highest_weight_vector()
sage: [t.phi(i) for i in T.index_set()]
[-inf, -inf, -inf, -inf, -inf]
```

weight()

Return the weight of `self`, which is always λ .

EXAMPLES:

```
sage: ct = CartanType(['C', 5])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct, la[4]+la[5]-la[1]-la[2])
sage: t = T.highest_weight_vector()
sage: t.weight()
-Lambda[1] - Lambda[2] + Lambda[4] + Lambda[5]
```

cardinality()

Return the cardinality of `self`, which is always 1.

EXAMPLES:

```
sage: La = RootSystem(['C', 12]).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(['C', 12], La[9])
sage: T.cardinality()
1
```

weight_lattice_realization()

Return a realization of the lattice containing the weights of `self`.

EXAMPLES:

```
sage: La = RootSystem(['C', 12]).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(['C', 12], La[9])
sage: T.weight_lattice_realization()
Weight lattice of the Root system of type ['C', 12]

sage: ct = CartanMatrix([[2, -4], [-5, 2]])
sage: La = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct, La[1])
sage: T.weight_lattice_realization()
Weight lattice of the Root system of type
[ 2 -4]
[-5  2]
```

5.1.47 Fast Rank Two Crystals

class `sage.combinat.crystals.fast_crystals.FastCrystal`(*ct, shape, format*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

An alternative implementation of rank 2 crystals. The root operators are implemented in memory by table lookup. This means that in comparison with the `CrystalsOfTableaux`, these crystals are slow to instantiate but faster for computation. Implemented for types A_2 , B_2 , and C_2 .

INPUT:

- `cartan_type` – the Cartan type and must be either type A_2 , B_2 , or C_2
- `shape` – A shape is of the form `[l1,l2]` where `l1` and `l2` are either integers or (in type B_2) half integers such that `l1 - l2` is integral. It is assumed that `l1 >= l2 >= 0`. If `l1` and `l2` are integers, this will produce a crystal isomorphic to the one obtained by `crystals.Tableaux(type, shape=[l1,l2])`. Furthermore `crystals.FastRankTwo(['B', 2], l1+1/2, l2+1/2)` produces a crystal isomorphic to the following crystal T:

```
sage: C = crystals.Tableaux(['B',2], shape=[l1,l2])           # not tested
sage: D = crystals.Spins(['B',2])                          # not tested
sage: T = crystals.TensorProduct(C, D, C.list()[0], D.list()[0]) # not tested
```

- `format` – (default: `'string'`) the default representation of elements is in term of the Berenstein-Zelevinsky-Littelmann (BZL) strings `[a1, a2, ...]` described under `metapost` in `crystals`. Alternative representations may be obtained by the options `'dual_string'` or `'simple'`. In the `'simple'` format, the element is represented by an integer, and in the `'dual_string'` format, it is represented by the BZL string, but the underlying decomposition of the long Weyl group element into simple reflections is changed.

class `Element`(*parent, value, format*)

Bases: `sage.structure.element.Element`

EXAMPLES:

```
sage: C = crystals.FastRankTwo(['A',2], shape=[2,1])
sage: c = C(0); c
[0, 0, 0]
sage: C[0].parent()
The fast crystal for A2 with shape [2,1]
sage: TestSuite(c).run()
```

e(*i*)

Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.FastRankTwo(['A',2], shape=[2,1])
sage: C(1).e(1)
[0, 0, 0]
sage: C(0).e(1) is None
True
```

f(*i*)

Return the action of f_i on self.

EXAMPLES:

```

sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: C(6).f(1)
[1, 2, 1]
sage: C(7).f(1) is None
True

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: [v.weight() for v in crystals.FastRankTwo(['A',2], shape=[2,1])]
[(2, 1, 0), (1, 2, 0), (1, 1, 1), (1, 0, 2), (0, 1, 2), (2, 0, 1), (1, 1, -1), (0, 2, 1)]
sage: [v.weight() for v in crystals.FastRankTwo(['B',2], shape=[1,0])]
[(1, 0), (0, 1), (0, 0), (0, -1), (-1, 0)]
sage: [v.weight() for v in crystals.FastRankTwo(['B',2], shape=[1/2,1/2])]
[(1/2, 1/2), (1/2, -1/2), (-1/2, 1/2), (-1/2, -1/2)]
sage: [v.weight() for v in crystals.FastRankTwo(['C',2], shape=[1,0])]
[(1, 0), (0, 1), (0, -1), (-1, 0)]
sage: [v.weight() for v in crystals.FastRankTwo(['C',2], shape=[1,1])]
[(1, 1), (1, -1), (0, 0), (-1, 1), (-1, -1)]

```

cmp_elements(x, y)

Return True if and only if there is a path from x to y in the crystal graph.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:

```

sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: x = C(0)
sage: y = C(1)
sage: C.cmp_elements(x,y)
-1
sage: C.cmp_elements(y,x)
1
sage: C.cmp_elements(x,x)
0

```

digraph()

Return the digraph associated to self.

EXAMPLES:

```

sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: C.digraph()
Digraph on 8 vertices

```

5.1.48 Fully commutative stable Grothendieck crystal

AUTHORS:

- Jianping Pan (2020-08-31): initial version
- Wencin Poh (2020-08-31): initial version
- Anne Schilling (2020-08-31): initial version

class `sage.combinat.crystals.fully_commutative_stable_grothendieck.DecreasingHeckeFactorization`(*parent*, *t*)

Bases: `sage.structure.element.Element`

Class of decreasing factorizations in the 0-Hecke monoid.

INPUT:

- `t` – decreasing factorization inputted as list of lists
- `max_value` – maximal value of entries

EXAMPLES:

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import \
↳DecreasingHeckeFactorization
sage: t = [[3, 2], [], [2, 1]]
sage: h = DecreasingHeckeFactorization(t, 3); h
(3, 2)()(2, 1)
sage: h.excess
1
sage: h.factors
3
sage: h.max_value
3
sage: h.value
((3, 2), (), (2, 1))

sage: u = [[3, 2, 1], [3], [2, 1]]
sage: h = DecreasingHeckeFactorization(u); h
(3, 2, 1)(3)(2, 1)
sage: h.weight()
(2, 1, 3)
sage: h.parent()
Decreasing Hecke factorizations with 3 factors associated to [2, 1, 3, 2, 1] with \
↳excess 1
```

to_increasing_hecke_biword()

Return the associated increasing Hecke biword of self.

EXAMPLES:

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import \
↳DecreasingHeckeFactorization
sage: t = [[2], [], [2, 1],[4, 3, 1]]
sage: h = DecreasingHeckeFactorization(t, 4)
sage: h.to_increasing_hecke_biword()
[[1, 1, 1, 2, 2, 4], [1, 3, 4, 1, 2, 2]]
```

to_word()

Return the word associated to `self` in the 0-Hecke monoid.

EXAMPLES:

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import
↳DecreasingHeckeFactorization
sage: t = [[2], [], [2, 1], [4, 3, 1]]
sage: h = DecreasingHeckeFactorization(t)
sage: h.to_word()
[2, 2, 1, 4, 3, 1]
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import
↳DecreasingHeckeFactorization
sage: t = [[2], [2, 1], [], [4, 3, 1]]
sage: h = DecreasingHeckeFactorization(t, 6)
sage: h.weight()
(3, 0, 2, 1)
```

```
class sage.combinat.crystals.fully_commutative_stable_grothendieck.DecreasingHeckeFactorizations(w,
fac-
tors,
ex-
cess)
```

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Set of decreasing factorizations in the 0-Hecke monoid.

INPUT:

- `w` – an element in the symmetric group
- `factors` – the number of factors in the factorization
- `excess` – the total number of letters in the factorization minus the length of a reduced word for `w`

EXAMPLES:

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import
↳DecreasingHeckeFactorizations
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2, 1])
sage: F = DecreasingHeckeFactorizations(w, 3, 3); F
Decreasing Hecke factorizations with 3 factors associated to [1, 3, 2, 1] with
↳excess 3
sage: F.list()
[(3, 1)(3, 1)(3, 2, 1), (3, 1)(3, 2, 1)(2, 1), (3, 2, 1)(2, 1)(2, 1)]
```

Element

alias of `DecreasingHeckeFactorization`

list()

Return list of all elements of `self`.

EXAMPLES:

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorizations
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2, 1])
sage: F = DecreasingHeckeFactorizations(w, 3, 3)
sage: F.list()
[(3, 1)(3, 1)(3, 2, 1), (3, 1)(3, 2, 1)(2, 1), (3, 2, 1)(2, 1)(2, 1)]
```

`class sage.combinat.crystals.fully_commutative_stable_grothendieck.FullyCommutativeStableGrothendieckCr`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The crystal on fully commutative decreasing factorizations in the 0-Hecke monoid, as introduced by [MPPS2020].

INPUT:

- `w` – an element in the symmetric group or a (skew) shape
- `factors` – the number of factors in the factorization
- `excess` – the total number of letters in the factorization minus the length of a reduced word for `w`
- `shape` – (default: `False`) indicator for input `w`, `True` if `w` is entered as a (skew) shape and `False` otherwise.

EXAMPLES:

```
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2); B
Fully commutative stable Grothendieck crystal of type A_2 associated to [1, 3, 2]
↳with excess 2
sage: B.list()
[(1)(3, 1)(3, 2),
 (3, 1)(1)(3, 2),
 (3, 1)(3, 1)(2),
 (3)(3, 1)(3, 2),
 (3, 1)(3)(3, 2),
 (3, 1)(3, 2)(2)]
```

We can also access the crystal by specifying a skew shape:

```
sage: crystals.FullyCommutativeStableGrothendieck([[2, 2], [1]], 4, 1, shape=True)
Fully commutative stable Grothendieck crystal of type A_3 associated to [2, 1, 3]
↳with excess 1
```

We can compute the highest weight elements:

```
sage: hw = [w for w in B if w.is_highest_weight()]
sage: hw
[(1)(3, 1)(3, 2), (3)(3, 1)(3, 2)]
```

(continues on next page)

(continued from previous page)

```
sage: hw[0].weight()
(2, 2, 1)
```

The crystal operators themselves move elements between adjacent factors:

```
sage: b = hw[0]; b
(1)(3, 1)(3, 2)
sage: b.f(2)
(3, 1)(1)(3, 2)
```

class `Element`(*parent*, *t*)

Bases: `sage.combinat.crystals.fully_commutative_stable_grothendieck.DecreasingHeckeFactorization`

Create an instance `self` of element `t`.

This method takes into account the constraints on the word, the number of factors, and excess statistic associated to the parent class.

EXAMPLES:

```
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import _
    ↪DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[3, 1], [3], [3, 2]], 4)
sage: u = B(h); u.value
((3, 1), (3,), (3, 2))
sage: v = B([[3, 1], [3], [3, 2]]); v.value
((3, 1), (3,), (3, 2))
```

bracketing(*i*)

Remove all bracketed letters between *i*-th and (*i* + 1)-th entry.

EXAMPLES:

```
sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([3, 2, 1, 4, 3])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: h = B([[3], [4, 2, 1], [4, 3, 1]])
sage: h.bracketing(1)
[[], []]
sage: h.bracketing(2)
[[], [2, 1]]
```

e(*i*)

Return the action of e_i on `self` using the rules described in [MPPS2020].

EXAMPLES:

```
sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([2, 1, 4, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 4, 3)
sage: h = B([[4, 2], [4, 2, 1], [3, 2], [2]]); h
```

(continues on next page)

(continued from previous page)

```
(4, 2)(4, 2, 1)(3, 2)(2)
sage: h.e(1)
(4, 2)(4, 2, 1)(3)(3, 2)
sage: h.e(2)
(4, 2)(2, 1)(4, 3, 2)(2)
sage: h.e(3)
```

f(i)Return the action of f_i on `self` using the rules described in [MPPS2020].

EXAMPLES:

```
sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([3, 2, 1, 4, 3])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 4, 3)
sage: h = B([[3, 2], [2, 1], [4, 3], [3, 1]]); h
(3, 2)(2, 1)(4, 3)(3, 1)
sage: h.f(1)
(3, 2)(2, 1)(4, 3, 1)(3)
sage: h.f(2)
sage: h.f(3)
(3, 2, 1)(1)(4, 3)(3, 1)
```

module_generators()Return generators for `self` as a crystal.

EXAMPLES:

```
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: B.module_generators
((1)(3, 1)(3, 2), (3)(3, 1)(3, 2))
sage: C = crystals.FullyCommutativeStableGrothendieck(w, 4, 2)
sage: C.module_generators
(())(1)(3, 1)(3, 2),
()(3)(3, 1)(3, 2),
(1)(1)(1)(3, 2),
(1)(1)(3)(3, 2),
(1)(3)(3)(3, 2))
```

5.1.49 Crystals of Generalized Young Walls

AUTHORS:

- Lucas David-Roesler: Initial version
- Ben Salisbury: Initial version
- Travis Scrimshaw: Initial version

Generalized Young walls are certain generalizations of Young tableaux introduced in [KS2010] and designed to be a realization of the crystals $\mathcal{B}(\infty)$ and $\mathcal{B}(\lambda)$ in type $A_n^{(1)}$.

REFERENCES:

- [KLRS2016]
- [KS2010]

class `sage.combinat.crystals.generalized_young_walls.CrystalOfGeneralizedYoungWalls(n, La)`
 Bases: `sage.combinat.crystals.generalized_young_walls.InfinityCrystalOfGeneralizedYoungWalls`

The crystal $\mathcal{Y}(\lambda)$ of generalized Young walls of the given type with highest weight λ .

These were characterized in Theorem 4.1 of [KS2010]. See `GeneralizedYoungWall.in_highest_weight_crystal()`.

INPUT:

- n – type $A_n^{(1)}$
- weight – dominant integral weight

EXAMPLES:

```
sage: La = RootSystem(['A', 3, 1]).weight_lattice(extended=True).fundamental_
↳weights()[1]
sage: YLa = crystals.GeneralizedYoungWalls(3, La)
sage: y = YLa([[0], [1, 0, 3, 2, 1], [2, 1, 0], [3]])
sage: y.pp()
      3|
    0|1|2|
1|2|3|0|1|
      0|
sage: y.weight()
-Lambda[0] + Lambda[2] + Lambda[3] - 3*delta
sage: y.in_highest_weight_crystal(La)
True
sage: y.f(1)
[[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1]]
sage: y.f(1).f(1)
sage: yy = crystals.infinity.GeneralizedYoungWalls(3)([[0], [1, 0, 3, 2, 1], [2, 1, 0],
↳[3], [], [1]])
sage: yy.f(1)
[[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1], [], [], [], [1]]
sage: yyy = yy.f(1)
sage: yyy.in_highest_weight_crystal(La)
False

sage: LS = crystals.LSPaths(['A', 3, 1], [1, 0, 0, 0])
sage: C = LS.subcrystal(max_depth=4)
sage: G = LS.digraph(subset=C)
sage: P = RootSystem(['A', 3, 1]).weight_lattice(extended=True)
sage: La = P.fundamental_weights()
sage: YW = crystals.GeneralizedYoungWalls(3, La[0])
sage: CW = YW.subcrystal(max_depth=4)
sage: GW = YW.digraph(subset=CW)
sage: GW.is_isomorphic(G, edge_labels=True)
True
```

To display the crystal down to a specified depth:

```
sage: S = YLa.subcrystal(max_depth=4)
sage: G = YLa.digraph(subset=S)
sage: view(G) # not tested
```

Element

alias of *CrystalOfGeneralizedYoungWallsElement*

class sage.combinat.crystals.generalized_young_walls.**CrystalOfGeneralizedYoungWallsElement**(parent, data)

Bases: *sage.combinat.crystals.generalized_young_walls.GeneralizedYoungWall*

Element of the highest weight crystal of generalized Young walls.

e(i)

Compute the action of e_i restricted to the highest weight crystal.

EXAMPLES:

```
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_
↳weights()[1]
sage: hwy = crystals.GeneralizedYoungWalls(2, La)([[], [1, 0], [2, 1]])
sage: hwy.e(1)
[[], [1, 0], [2]]
sage: hwy.e(2)
sage: hwy.e(3)
```

f(i)

Compute the action of f_i restricted to the highest weight crystal.

EXAMPLES:

```
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_
↳weights()[1]
sage: GYW = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = GYW([[], [1, 0], [2, 1]])
sage: y.f(1)
[[], [1, 0], [2, 1], [], [1]]
sage: hwy = crystals.GeneralizedYoungWalls(2, La)([[], [1, 0], [2, 1]])
sage: hwy.f(1)
```

phi(i)

Return the value $\varepsilon_i(Y) + \langle h_i, \text{wt}(Y) \rangle$, where h_i is the i -th simple coroot and Y is self.

EXAMPLES:

```
sage: La = RootSystem(['A', 3, 1]).weight_lattice(extended=True).fundamental_
↳weights()
sage: y = crystals.GeneralizedYoungWalls(3, La[0])([])
sage: y.phi(1)
0
sage: y.phi(2)
0
```

weight()

Return the weight of self in the highest weight crystal as an element of the weight lattice $\bigoplus_{i=0}^n \mathbb{Z}\Lambda_i$.

EXAMPLES:

```

sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_
↪weights()[1]
sage: hwy = crystals.GeneralizedYoungWalls(2, La)([[[]], [1, 0], [2, 1]])
sage: hwy.weight()
Lambda[0] - Lambda[1] + Lambda[2] - delta

```

class sage.combinat.crystals.generalized_young_walls.**GeneralizedYoungWall**(parent, data)
 Bases: *sage.combinat.combinat.CombinatorialElement*

A generalized Young wall.

For more information, see *InfinityCrystalOfGeneralizedYoungWalls*.

EXAMPLES:

```

sage: Y = crystals.infinity.GeneralizedYoungWalls(4)
sage: mg = Y.module_generators[0]; mg.pp()
0
sage: mg.f_string([1, 2, 0, 1]).pp()
1|2|
0|1|
|

```

Epsilon()

Return $\sum_{i=0}^n \varepsilon_i(Y) \Lambda_i$ where Y is self.

EXAMPLES:

```

sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0], [1, 0, 3, 2], [2, 1], [3, 2,
↪1, 0, 3, 2], [0], [], [2]])
sage: y.Epsilon()
Lambda[0] + 3*Lambda[2]

```

Phi()

Return $\sum_{i=0}^n \varphi_i(Y) \Lambda_i$ where Y is self.

EXAMPLES:

```

sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0], [1, 0, 3, 2], [2, 1], [3, 2,
↪1, 0, 3, 2], [0], [], [2]])
sage: y.Phi()
-Lambda[0] + 3*Lambda[1] - Lambda[2] + 3*Lambda[3]

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[[]], [1, 0, 3, 2], [2, 1], [3, 2, 1,
↪0, 3, 2], [], [], [2]])
sage: x.Phi()
2*Lambda[0] + Lambda[1] - Lambda[2] + Lambda[3]

```

a(i, k)

Return the number $a_i(k)$ of i -colored boxes in the k -th column of self.

EXAMPLES:

```

sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0], [1, 0, 3, 2], [2, 1], [3, 2,
↪1, 0, 3, 2], [0], [], [2]])
sage: y.a(1, 2)

```

(continues on next page)

(continued from previous page)

```

1
sage: y.a(0,2)
1
sage: y.a(3,2)
0

```

column(*k*)Return the list of boxes from the *k*-th column of `self`.

EXAMPLES:

```

sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0],[1,0,3,2],[2,1],[3,2,
↔1,0,3,2],[0],[],[2]])
sage: y.column(2)
[None, 0, 1, 2, None, None, None]

sage: hw = crystals.infinity.GeneralizedYoungWalls(5)([])
sage: hw.column(1)
[]

```

content()Return total number of blocks in `self`.

EXAMPLES:

```

sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0],[1,0],[2,1,0,2],[],[
↔[1]])
sage: y.content()
8

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[],[1,0,3,2],[2,1],[3,2,1,
↔0,3,2],[],[],[2]])
sage: x.content()
13

```

e(*i*)Return the application of the Kashiwara raising operator e_i on `self`.This will remove the *i*-colored box corresponding to the rightmost + in `self.signature(i)`.

EXAMPLES:

```

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[],[1,0,3,2],[2,1],[3,2,1,
↔0,3,2],[],[],[2]])
sage: x.e(2)
[[[1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2]]]
sage: _.e(2)
[[[1, 0, 3], [2, 1], [3, 2, 1, 0, 3, 2]]]
sage: _.e(2)
[[[1, 0, 3], [2, 1], [3, 2, 1, 0, 3]]]
sage: _.e(2)
[[[1, 0, 3], [2, 1], [3, 2, 1, 0, 3]]]

```

epsilon(*i*)Return the number of *i*-colored arrows in the *i*-string above `self` in the crystal graph.

EXAMPLES:

```

sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1,
↪ 0, 3, 2], [], [], [2]])
sage: y.epsilon(1)
0
sage: y.epsilon(2)
3
sage: y.epsilon(0)
0

```

f(i)

Return the application of the Kashiwara lowering operator f_i on `self`.

This will add an i -colored colored box to the site corresponding to the leftmost plus in `self.signature(i)`.

EXAMPLES:

```

sage: hw = crystals.infinity.GeneralizedYoungWalls(2)([])
sage: hw.f(1)
[[], [1]]
sage: _.f(2)
[[], [1], [2]]
sage: _.f(0)
[[], [1, 0], [2]]
sage: _.f(0)
[[0], [1, 0], [2]]

```

generate_signature(i)

The i -signature of `self` (with whitespace where cancellation occurs) together with the unreduced sequence from $\{+, -\}$. The result also records to the row and column position of the sign.

EXAMPLES:

```

sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0], [1, 0], [2, 1, 0, 2], [],
↪ [1]])
sage: y.generate_signature(1)
([[ '+', 2, 5], [ '-', 4, 1]], ' ')

```

in_highest_weight_crystal(La)

Return a boolean indicating if the generalized Young wall element is in the highest weight crystal cut out by the given highest weight La .

By Theorem 4.1 of [KS2010], a generalized Young wall Y represents a vertex in the highest weight crystal $Y(\lambda)$, with $\lambda = \Lambda_{i_1} + \Lambda_{i_2} + \dots + \Lambda_{i_\ell}$ a dominant integral weight of level $\ell > 0$, if it satisfies the following condition. For each positive integer k , if there exists $j \in I$ such that $a_j(k) - a_{j-1}(k) > 0$, then for some $p = 1, \dots, \ell$,

$$j + k \equiv i_p + 1 \pmod{n + 1} \text{ and } a_j(k) - a_{j-1}(k) \leq \lambda(h_{i_p}),$$

where $\{h_0, h_1, \dots, h_n\}$ is the set of simple coroots attached to $A_n^{(1)}$.

EXAMPLES:

```

sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_
↪ weights()[1]
sage: GYW = crystals.infinity.GeneralizedYoungWalls(2)

```

(continues on next page)

(continued from previous page)

```

sage: y = GYW([[[]], [1,0], [2,1]])
sage: y.in_highest_weight_crystal(La)
True
sage: x = GYW([[[]], [1], [2], [], [], [2], [], [], [2]])
sage: x.in_highest_weight_crystal(La)
False

```

latex_large()

Generate LaTeX code for self but the output is larger. Requires TikZ.

EXAMPLES:

```

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[[]], [1,0,3,2], [2,1], [3,2,1,
↪0,3,2], [], [], [2]])
sage: x.latex_large()
'\begin{tikzpicture}[baseline=5,scale=.45] \n \foreach \x [count=\s from 0]
↪in \n{ {}, {1,0,3,2}, {2,1}, {3,2,1,0,3,2}, {}, {}, {2} } \n \foreach \y [count=\t
↪from 0] in \x { \node[font=\scriptsize] at (-\t,\s) {\$y\$}; \n \draw
↪(-\t+.5,\s+.5) to (-\t-.5,\s+.5); \n \draw (-\t+.5,\s-.5) to (-\t-.5,\
↪\s-.5); \n \draw (-\t-.5,\s-.5) to (-\t-.5,\s+.5); } \n \draw[-,thick]
↪(.5,\s+1) to (.5,-.5) to (-\t-1,-.5); } \n \end{tikzpicture} \n'

```

number_of_parts()

Return the value of \mathcal{N} on self.

In [KLRS2016], the statistic \mathcal{N} was defined on elements in $\mathcal{Y}(\infty)$ which counts how many parts are in the corresponding Kostant partition. Specifically, the computation of $\mathcal{N}(Y)$ is done using the following algorithm:

- If Y has no rows whose right-most box is colored n and such that the length of this row is a multiple of $n + 1$, then $\mathcal{N}(Y)$ is the total number of distinct rows in Y , not counting multiplicity.
- Otherwise, search Y for the longest row such that the right-most box is colored n and such that the total number of boxes in the row is $k(n + 1)$ for some $k \geq 1$. Replace this row by $n + 1$ distinct rows of length k , reordering all rows, if necessary, so that the result is a proper wall. (Note that the resulting wall may no longer be reduced.) Repeat the search and replace process for all other rows of the above form for each $k' < k$. Then $\mathcal{N}(Y)$ is the number of distinct rows, not counting multiplicity, in the wall resulting from this process.

EXAMPLES:

```

sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: y = Y([[0], [], [], [], [0], [], [], [0]])
sage: y.number_of_parts()
1
sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: y = Y([[0,3,2], [1,0], [], [], [0,3], [1,0], [], [], [0]])
sage: y.number_of_parts()
4
sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = Y([[0,2,1], [1,0], [2,1,0,2,1,0,2,1,0], [], [2,1,0,2,1,0]])
sage: y.number_of_parts()
8

```

phi(i)

Return the value $\varepsilon_i(Y) + \langle h_i, \text{wt}(Y) \rangle$, where h_i is the i -th simple coroot and Y is self.

EXAMPLES:

```
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0], [1, 0, 3, 2], [2, 1], [3, 2,
↪ 1, 0, 3, 2], [0], [], [2]])
sage: y.phi(1)
3
sage: y.phi(2)
-1
```

pp()

Pretty print self.

EXAMPLES:

```
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0, 2, 1], [1, 0, 2, 1, 0], [],
↪ [0], [1, 0, 2], [], [], [1]])
sage: y.pp()
      1 |
      |
      |
    2 | 0 | 1 |
      0 |
      |
0 | 1 | 2 | 0 | 1 |
  1 | 2 | 0 |
```

raw_signature(i)

Return the sequence from $\{+, -\}$ obtained from all i -admissible slots and removable i -boxes without canceling any $(+, -)$ -pairs. The result also notes the row and column of the sign.

EXAMPLES:

```
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1,
↪ 0, 3, 2], [], [], [2]])
sage: x.raw_signature(2)
[['-', 3, 6], ['-', 1, 4], ['-', 6, 1]]
```

signature(i)

Return the i -signature of self.

The signature is obtained by reading self in columns bottom to top starting from the left. Then add a $-$ at every i -box which may be removed from self and still obtain a legal generalized Young wall, and add a $+$ at each site for which an i -box may be added and still obtain a valid generalized Young wall. Then successively cancel any $(+, -)$ -pair to obtain a sequence of the form $- \cdots - + \cdots +$. This resulting sequence is the output.

EXAMPLES:

```
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0], [1, 0], [2, 1, 0, 2], [],
↪ [1]])
sage: y.signature(1)
''
```

(continues on next page)

(continued from previous page)

```

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[[], [1,0,3,2], [2,1], [3,2,1,
↪0,3,2], [], [], [2]])
sage: x.signature(2)
'----'

```

sum_of_weighted_row_lengths()Return the value of \mathcal{M} on self.

Let $\mathcal{Y}_0 \subset \mathcal{Y}(\infty)$ be the set of generalized Young walls which have no rows whose right-most box is colored n . For $Y \in \mathcal{Y}_0$,

$$\mathcal{M}(Y) = \sum_{i=1}^n (i+1)M_i(Y),$$

where $M_i(Y)$ is the number of nonempty rows in Y whose right-most box is colored $i-1$.

EXAMPLES:

```

sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = Y([[0,2,1,0,2], [1,0,2], [], [0,2], [1,0], [], [0], [1,0]])
sage: y.sum_of_weighted_row_lengths()
15

```

weight(root_lattice=False)

Return the weight of self.

INPUT:

- `root_lattice` – boolean determining whether weight should appear in root lattice or not in extended affine weight lattice.

EXAMPLES:

```

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[[], [1,0,3,2], [2,1], [3,2,1,
↪0,3,2], [], [], [2]])
sage: x.weight()
2*Lambda[0] + Lambda[1] - 4*Lambda[2] + Lambda[3] - 2*delta
sage: x.weight(root_lattice=True)
-2*alpha[0] - 3*alpha[1] - 5*alpha[2] - 3*alpha[3]

```

class `sage.combinat.crystals.generalized_young_walls.InfinityCrystalOfGeneralizedYoungWalls`(n , category)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The crystal $\mathcal{Y}(\infty)$ of generalized Young walls of type $A_n^{(1)}$ as defined in [KS2010].

A generalized Young wall is a collection of boxes stacked on a fixed board, such that color of the box at the site located in the j -th row from the bottom and the i -th column from the right is $j-1 \pmod{n+1}$. There are several growth conditions on elements in $Y \in \mathcal{Y}(\infty)$:

- Walls grow in rows from right to left. That is, for every box $y \in Y$ that is not in the rightmost column, there must be a box immediately to the right of y .
- For all $p > q$ such that $p - q \equiv 0 \pmod{n+1}$, the p -th row has most as many boxes as the q -th row.

- There does not exist a column in the wall such that if one i -colored box, for every $i = 0, 1, \dots, n$, is removed from that column, then the result satisfies the above conditions.

There is a crystal structure on $\mathcal{Y}(\infty)$ defined as follows. Define maps

$$e_i, f_i: \mathcal{Y}(\infty) \longrightarrow \mathcal{Y}(\infty) \sqcup \{0\}, \quad \varepsilon_i, \varphi_i: \mathcal{Y}(\infty) \longrightarrow \mathbf{Z}, \quad \text{wt}: \mathcal{Y}(\infty) \longrightarrow \bigoplus_{i=0}^n \mathbf{Z}\Lambda_i \oplus \mathbf{Z}\delta,$$

by

$$\text{wt}(Y) = - \sum_{i=0}^n m_i(Y) \alpha_i,$$

where $m_i(Y)$ is the number of i -boxes in Y , $\varepsilon_i(Y)$ is the number of $-$ in the i -signature of Y , and

$$\varphi_i(Y) = \varepsilon_i(Y) + \langle h_i, \text{wt}(Y) \rangle.$$

See `GeneralizedYoungWall.e()`, `GeneralizedYoungWall.f()`, and `GeneralizedYoungWall.signature()` for more about e_i , f_i , and i -signatures.

INPUT:

- n -type $A_n^{(1)}$

EXAMPLES:

```
sage: Yinf = crystals.infinity.GeneralizedYoungWalls(3)
sage: y = Yinf([[0],[1,0,3,2],[],[3,2,1],[0],[1,0]])
sage: y.pp()
  0|1|
    |
  0|
  1|2|3|
    |
  2|3|0|1|
    0|
sage: y.weight(root_lattice=True)
-4*alpha[0] - 3*alpha[1] - 2*alpha[2] - 2*alpha[3]
sage: y.f(0)
[[0], [1, 0, 3, 2], [], [3, 2, 1], [0], [1, 0], [], [], [0]]
sage: y.e(0).pp()
  0|1|
    |
  1|2|3|
    |
  2|3|0|1|
    0|
```

To display the crystal down to depth 3:

```
sage: S = Yinf.subcrystal(max_depth=3)
sage: G = Yinf.digraph(subset=S) # long time
sage: view(G) # not tested
```

Element

alias of `GeneralizedYoungWall`

5.1.50 Highest weight crystals

class `sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE`(*dominant_weight*)
 Bases: `sage.combinat.crystals.tensor_product.TensorProductOfCrystals`

Commonalities for all finite dimensional type E highest weight crystals.

Subclasses should setup an attribute `column_crystal` in their `__init__` method before calling the `__init__` method of this class.

Element

alias of `sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement`

module_generator()

This yields the module generator (or highest weight element) of the classical crystal of given dominant weight in self.

EXAMPLES:

```
sage: C=CartanType(['E',6])
sage: La=C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[2])
sage: T.module_generator()
[[2, -1), (1,)]
sage: T = crystals.HighestWeight(0*La[2])
sage: T.module_generator()
[]

sage: C=CartanType(['E',7])
sage: La=C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.module_generator()
[[-7, 1), (7,)]
```

class `sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE6`(*dominant_weight*)
 Bases: `sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE`

Class of finite dimensional highest weight crystals of type E_6 .

EXAMPLES:

```
sage: C=CartanType(['E',6])
sage: La=C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[2]); T
Finite dimensional highest weight crystal of type ['E', 6] and highest weight
↪Lambda[2]
sage: B1 = T.column_crystal[1]; B1
The crystal of letters for type ['E', 6]
sage: B6 = T.column_crystal[6]; B6
The crystal of letters for type ['E', 6] (dual)
sage: t = T(B6([-1]),B1([-1,3])); t
[(-1,), (-1, 3)]
sage: [t.epsilon(i) for i in T.index_set()]
[2, 0, 0, 0, 0, 0]
sage: [t.phi(i) for i in T.index_set()]
[0, 0, 1, 0, 0, 0]
sage: TestSuite(t).run()
```

class sage.combinat.crystals.highest_weight_crystals.**FiniteDimensionalHighestWeightCrystal_TypeE7**(*dominant_weight*, *model=None*)
 Bases: *sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE*

Class of finite dimensional highest weight crystals of type E_7 .

EXAMPLES:

```
sage: C=CartanType(['E',7])
sage: La=C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
133
sage: B7 = T.column_crystal[7]; B7
The crystal of letters for type ['E', 7]
sage: t = T(B7([-5, 6]), B7([-2, 3])); t
[(-5, 6), (-2, 3)]
sage: [t.epsilon(i) for i in T.index_set()]
[0, 1, 0, 0, 1, 0, 0]
sage: [t.phi(i) for i in T.index_set()]
[0, 0, 1, 0, 0, 1, 0]
sage: TestSuite(t).run()
```

sage.combinat.crystals.highest_weight_crystals.HighestWeightCrystal(*dominant_weight*, *model=None*)

Return the highest weight crystal of highest weight *dominant_weight* of the given *model*.

INPUT:

- *dominant_weight* – a dominant weight
- *model* – (optional) if not specified, then we have the following default models:
 - types A_n, B_n, C_n, D_n, G_2 - *tableaux*
 - types $E_{6,7}$ - *type E finite dimensional crystal*
 - all other types - *LS paths*

otherwise can be one of the following:

- 'Tableaux' - *KN tableaux*
- 'TypeE' - *type E finite dimensional crystal*
- 'NakajimaMonomials' - *Nakajima monomials*
- 'LSPaths' - *LS paths*
- 'AlcovePaths' - *alcove paths*
- 'GeneralizedYoungWalls' - *generalized Young walls*
- 'RiggedConfigurations' - *rigged configurations*

EXAMPLES:

```
sage: La = RootSystem(['A',2]).weight_lattice().fundamental_weights()
sage: wt = La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['A', 2] and shape(s) [[2, 1]]

sage: La = RootSystem(['C',2]).weight_lattice().fundamental_weights()
```

(continues on next page)

(continued from previous page)

```

sage: wt = 5*La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['C', 2] and shape(s) [[6, 1]]

sage: La = RootSystem(['B', 2]).weight_lattice().fundamental_weights()
sage: wt = La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['B', 2] and shape(s) [[3/2, 1/2]]

```

Some type E examples:

```

sage: C = CartanType(['E', 6])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
27
sage: T = crystals.HighestWeight(La[6])
sage: T.cardinality()
27
sage: T = crystals.HighestWeight(La[2])
sage: T.cardinality()
78
sage: T = crystals.HighestWeight(La[4])
sage: T.cardinality()
2925
sage: T = crystals.HighestWeight(La[3])
sage: T.cardinality()
351
sage: T = crystals.HighestWeight(La[5])
sage: T.cardinality()
351

sage: C = CartanType(['E', 7])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
133
sage: T = crystals.HighestWeight(La[2])
sage: T.cardinality()
912
sage: T = crystals.HighestWeight(La[3])
sage: T.cardinality()
8645
sage: T = crystals.HighestWeight(La[4])
sage: T.cardinality()
365750
sage: T = crystals.HighestWeight(La[5])
sage: T.cardinality()
27664
sage: T = crystals.HighestWeight(La[6])
sage: T.cardinality()
1539

```

(continues on next page)

(continued from previous page)

```
sage: T = crystals.HighestWeight(La[7])
sage: T.cardinality()
56
```

An example with an affine type:

```
sage: C = CartanType(['C', 2, 1])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: sorted(T.subcrystal(max_depth=3), key=str)
[(-Lambda[0] + 3*Lambda[1] - Lambda[2] - delta,),
 (-Lambda[0] + Lambda[1] + Lambda[2] - delta,),
 (-Lambda[1] + 2*Lambda[2] - delta,),
 (2*Lambda[0] - Lambda[1],),
 (Lambda[0] + Lambda[1] - Lambda[2],),
 (Lambda[0] - Lambda[1] + Lambda[2],),
 (Lambda[1],)]
```

Using the various models:

```
sage: La = RootSystem(['F', 4]).weight_lattice().fundamental_weights()
sage: wt = La[1] + La[4]
sage: crystals.HighestWeight(wt)
The crystal of LS paths of type ['F', 4] and weight Lambda[1] + Lambda[4]
sage: crystals.HighestWeight(wt, model='NakajimaMonomials')
Highest weight crystal of modified Nakajima monomials of
Cartan type ['F', 4] and highest weight Lambda[1] + Lambda[4]
sage: crystals.HighestWeight(wt, model='AlcovePaths')
Highest weight crystal of alcove paths of type ['F', 4] and weight Lambda[1] +
↳ Lambda[4]
sage: crystals.HighestWeight(wt, model='RiggedConfigurations')
Crystal of rigged configurations of type ['F', 4] and weight Lambda[1] + Lambda[4]
sage: La = RootSystem(['A', 3, 1]).weight_lattice().fundamental_weights()
sage: wt = La[0] + La[2]
sage: crystals.HighestWeight(wt, model='GeneralizedYoungWalls')
Highest weight crystal of generalized Young walls of
Cartan type ['A', 3, 1] and highest weight Lambda[0] + Lambda[2]
```

5.1.51 Induced Crystals

We construct a crystal structure on a set induced by a bijection Φ .

AUTHORS:

- Travis Scrimshaw (2014-05-15): Initial implementation

```
class sage.combinat.crystals.induced_structure.InducedCrystal(X, phi, inverse)
```

```
    Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.
           parent.Parent
```

A crystal induced from an injection.

Let X be a set and let C be crystal and consider any injection $\Phi : X \rightarrow C$. We induce a crystal structure on X by considering Φ to be a crystal morphism.

Alternatively we can induce a crystal structure on some (sub)set of X by considering an injection $\Phi : C \rightarrow X$ considered as a crystal morphism. This form is also useful when the set X is not explicitly known.

INPUT:

- X – the base set
- ϕ – the map Φ
- inverse – (optional) the inverse map Φ^{-1}
- from_crystal – (default: False) if the induced structure is of the second type $\Phi : C \rightarrow X$

EXAMPLES:

We construct a crystal structure of Gelfand-Tsetlin patterns by going through their bijection with semistandard tableaux:

```
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: I.digraph().is_isomorphic(D.digraph(), edge_labels=True)
True
```

Now we construct the above example but inducing the structure going the other way (from tableaux to Gelfand-Tsetlin patterns). This can also give us more information coming from the crystal.

```
sage: D2 = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G2 = GelfandTsetlinPatterns(4, 1)
sage: phi2 = lambda x: D2(x.to_tableau())
sage: phi2_inv = lambda x: G2(x.to_tableau())
sage: I2 = crystals.Induced(D2, phi2_inv, phi2, from_crystal=True)
sage: I2.module_generators
([[0, 0, 0, 0], [0, 0, 0], [0, 0], [0]],
 [[1, 0, 0, 0], [1, 0, 0], [1, 0], [1]],
 [[1, 1, 0, 0], [1, 1, 0], [1, 1], [1]],
 [[1, 1, 1, 0], [1, 1, 1], [1, 1], [1]],
 [[1, 1, 1, 1], [1, 1, 1], [1, 1], [1]])
```

We check an example when the codomain is larger than the domain (although here the crystal structure is trivial):

```
sage: P = Permutations(4)
sage: D = crystals.Tableaux(['A',3], shapes=Partitions(4))
sage: T = crystals.TensorProduct(D, D)
sage: phi = lambda p: T(D(RSK(p)[0]), D(RSK(p)[1]))
sage: phi_inv = lambda d: RSK_inverse(d[0].to_tableau(), d[1].to_tableau(), output=
->'permutation')
sage: all(phi_inv(phi(p)) == p for p in P) # Check it really is the inverse
True
sage: I = crystals.Induced(P, phi, phi_inv)
sage: I.digraph()
Digraph on 24 vertices
```

We construct an example without a specified inverse map:

```

sage: X = Words(2,4)
sage: L = crystals.Letters(['A',1])
sage: T = crystals.TensorProduct(*[L]*4)
sage: Phi = lambda x : T(*[L(i) for i in x])
sage: I = crystals.Induced(X, Phi)
sage: I.digraph()
Digraph on 16 vertices

```

class Element

Bases: `sage.structure.element_wrapper.ElementWrapper`

An element of an induced crystal.

e(i)

Return e_i of self.

EXAMPLES:

```

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.e(1)
sage: elt.e(2)
[[1, 1, 0, 0], [1, 1, 0], [1, 1], [1]]
sage: elt.e(3)

```

epsilon(i)

Return ε_i of self.

EXAMPLES:

```

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]

```

f(i)

Return f_i of self.

EXAMPLES:

```

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.f(1)
[[1, 1, 0, 0], [1, 1, 0], [1, 0], [0]]

```

(continues on next page)

(continued from previous page)

```
sage: elt.f(2)
sage: elt.f(3)
[[1, 1, 0, 0], [1, 0, 0], [1, 0], [1]]
```

phi(i)Return φ_i of self.

EXAMPLES:

```
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: [elt.phi(i) for i in I.index_set()]
[1, 0, 1]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.weight()
(1, 0, 1, 0)
```

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: P = Permutations(4)
sage: D = crystals.Tableaux(['A',3], shapes=Partitions(4))
sage: T = crystals.TensorProduct(D, D)
sage: phi = lambda p: T(D(RSK(p)[0]), D(RSK(p)[1]))
sage: phi_inv = lambda d: RSK_inverse(d[0].to_tableau(), d[1].to_tableau(),
↳ output='permutation')
sage: I = crystals.Induced(P, phi, phi_inv)
sage: I.cardinality() == factorial(4)
True
```

class sage.combinat.crystals.induced_structure.InducedFromCrystal(*X, phi, inverse*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A crystal induced from an injection.

Alternatively we can induce a crystal structure on some (sub)set of X by considering an injection $\Phi : C \rightarrow X$ considered as a crystal morphism.

See also:

[InducedCrystal](#)

INPUT:

- X – the base set
- ϕ – the map Φ
- inverse – (optional) the inverse map Φ^{-1}

EXAMPLES:

We construct a crystal structure on generalized permutations with a fixed first row by using RSK:

```
sage: C = crystals.Tableaux(['A', 3], shape=[2, 1])
sage: def psi(x):
.....:     ret = RSK_inverse(x.to_tableau(), Tableau([[1, 1], [2]]))
.....:     return tuple(ret[0]), tuple(ret[1])
sage: psi_inv = lambda x: C(RSK(*x)[0])
sage: I = crystals.Induced(C, psi, psi_inv, from_crystal=True)
```

class Element

Bases: `sage.structure.element_wrapper.ElementWrapper`

An element of an induced crystal.

$e(i)$

Return e_i of self.

EXAMPLES:

```
sage: D = crystals.Tableaux(['A', 3], shapes=PartitionsInBox(4, 1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.e(1)
sage: elt.e(2)
[[1, 1, 0, 0], [1, 1, 0], [1, 1], [1]]
sage: elt.e(3)
```

$\epsilon(i)$

Return ϵ_i of self.

EXAMPLES:

```
sage: D = crystals.Tableaux(['A', 3], shapes=PartitionsInBox(4, 1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]
```

$f(i)$

Return f_i of self.

EXAMPLES:

```

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.f(1)
[[1, 1, 0, 0], [1, 1, 0], [1, 0], [0]]
sage: elt.f(2)
sage: elt.f(3)
[[1, 1, 0, 0], [1, 0, 0], [1, 0], [1]]

```

phi(i)Return φ_i of self.

EXAMPLES:

```

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.weight()
(1, 0, 1, 0)

```

cardinality()

Return the cardinality of self.

EXAMPLES:

```

sage: C = crystals.Tableaux(['A',3], shape=[2,1])
sage: def psi(x):
....:     ret = RSK_inverse(x.to_tableau(), Tableau([[1,1],[2]]))
....:     return (tuple(ret[0]), tuple(ret[1]))
sage: psi_inv = lambda x: C(RSK(*x)[0])
sage: I = crystals.Induced(C, psi, psi_inv, from_crystal=True)
sage: I.cardinality() == C.cardinality()
True

```

5.1.52 $\mathcal{B}(\infty)$ Crystals of Tableaux in Nonexceptional Types and G_2

A tableau model for $\mathcal{B}(\infty)$. For more information, see [InfinityCrystalOfTableaux](#).

AUTHORS:

- Ben Salisbury: Initial version
- Travis Scrimshaw: Initial version

```
class sage.combinat.crystals.infinity_crystals.DualInfinityQueerCrystalOfTableaux(cartan_type)
    Bases: sage.combinat.crystals.tensor\_product.CrystalOfWords
```

Initialize self.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['A',2])
sage: TestSuite(B).run() # long time
```

```
class Element
```

Bases: [sage.combinat.crystals.tensor_product_element.InfinityQueerCrystalOfTableauxElement](#)

```
index_set()
```

Return the index set of self.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(["Q",3])
sage: B.index_set()
(1, 2, -1)
```

```
module_generator()
```

Return the module generator (or highest weight element) of self.

The module generator is the unique semistandard hook tableau of shape $(n, n-1, \dots, 2, 1)$ with weight 0.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(["Q",5])
sage: B.module_generator()
[[5, 5, 5, 5, 5], [4, 4, 4, 4], [3, 3, 3], [2, 2], [1]]
```

```
class sage.combinat.crystals.infinity_crystals.InfinityCrystalOfTableaux(cartan_type)
```

Bases: [sage.combinat.crystals.tensor_product.CrystalOfWords](#)

$\mathcal{B}(\infty)$ crystal of tableaux.

A tableaux model $\mathcal{T}(\infty)$ for the crystal $\mathcal{B}(\infty)$ is introduced by Hong and Lee in [HL2008]. This model is currently valid for types A_n , B_n , C_n , D_n , and G_2 , and builds on the tableaux model given by Kashiwara and Nakashima [KN1994] in types A_n , B_n , C_n , and D_n , and by Kang and Misra [KM1994] in type G_2 .

Note: We are using the English convention for our tableaux.

We say a tableau T is *marginally large* if:

- for each $1 \leq i \leq n$, the leftmost box in the i -th row from the top in T is an i -box,
- for each $1 \leq i \leq n$, the number of i -boxes in the i -th row from the top in T is greater than the total number of boxes in the $(i+1)$ -th row by exactly one.

We now will describe this tableaux model type-by-type.

Type A_n

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly n rows over the alphabet $\{1 \prec 2 \prec \cdots \prec n+1\}$.

Type B_n

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly n rows over the alphabet $\{1 \prec \cdots \prec n \prec 0 \prec \bar{n} \prec \cdots \prec \bar{1}\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the i -th row are $\preceq \bar{i}$,
- the entry 0 can appear at most once in a single row.

Type C_n

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly n rows over the alphabet $\{1 \prec \cdots \prec n \prec \bar{n} \prec \cdots \prec \bar{1}\}$ and for each $1 \leq i \leq n$, the contents of the boxes in the i -th row are $\preceq \bar{i}$.

Type D_n

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly $n-1$ rows over the alphabet $\{1 \prec \cdots \prec n, \bar{n} \prec \cdots \prec \bar{1}\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the i -th row are $\preceq \bar{i}$,
- the entries n and \bar{n} may not appear simultaneously in a single row.

Type G_2

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly 2 rows over the ordered alphabet $\{1 \prec 2 \prec 3 \prec 0 \prec \bar{3} \prec \bar{2} \prec \bar{1}\}$ and subject to the following constraints:

- the contents of the boxes in the first row are $\preceq \bar{i}$,
- the contents of the boxes in the second row are $\preceq 3$,
- the entry 0 can appear at most once in the first row and not at all in the second row.

In particular, the shape of the tableaux is not fixed in any instance of $\mathcal{T}(\infty)$; the row lengths of a tableau can be arbitrarily long.

INPUT:

- `cartan_type` – One of `['A', n]`, `['B', n]`, `['C', n]`, `['D', n]`, or `['G', 2]`, where n is a positive integer

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['A', 2])
sage: b = B.highest_weight_vector(); b.pp()
1 1
2
sage: b.f_string([2, 1, 1, 2, 2, 2]).pp()
```

(continues on next page)

(continued from previous page)

```

1 1 1 1 1 2 3
2 3 3 3

sage: B = crystals.infinity.Tableaux(['G',2])
sage: b = B(rows=[[1,1,1,1,1,2,3,3,0,-3,-1,-1],[2,3,3,3]])
sage: b.e_string([2,1,1,1,1,1]).pp()
1 1 1 1 2 3 3 3 3 -2 -2 -2
2 3 3
sage: b.e_string([2,1,1,1,1,1,1,1])

```

We check that a few classical crystals embed into $\mathcal{T}(\infty)$:

```

sage: def crystal_test(B, C):
.....:     T = crystals.elementary.T(C.cartan_type(), C.module_generators[0].
↪weight())
.....:     TP = crystals.TensorProduct(T, B)
.....:     mg = TP(T[0], B.module_generators[0])
.....:     g = {C.module_generators[0]: mg}
.....:     f = C.crystal_morphism(g, category=HighestWeightCrystals())
.....:     G = B.digraph(subset=[f(x) for x in C])
.....:     return G.is_isomorphic(C.digraph(), edge_labels=True)
sage: B = crystals.infinity.Tableaux(['A',2])
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['A',2], shape=[6,2])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['B',2])
sage: C = crystals.Tableaux(['B',2], shape=[3])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['B',2], shape=[2,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['C',3])
sage: C = crystals.Tableaux(['C',3], shape=[2,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['D',4])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['D',4], shape=[1,1,1,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['G',2])
sage: C = crystals.Tableaux(['G',2], shape=[3])
sage: crystal_test(B, C)
True

```

class Element

Bases: *sage.combinat.crystals.tensor_product_element.InfinityCrystalOfTableauxElement*

Elements in $\mathcal{B}(\infty)$ crystal of tableaux.

content()

Return the content of `self`.

The content $|T|$ of $T \in \mathcal{B}(\infty)$ is the number of blocks added to the highest weight to obtain T with any \bar{i} -boxes in the i -th row counted with multiplicity 2 provided the underlying Cartan type is of type B , D , or G .

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("D5")
sage: b = B.highest_weight_vector().f_string([5,4,3,1,1,3,4,5,3,4,5,1,4,5,2,
↪3,5,3,2,4])
sage: b.content()
13

sage: B = crystals.infinity.Tableaux("B2")
sage: b = B(rows=[[1,1,1,1,1,1,2,2,2,-2,-2],[2,0,-2,-2,-2]])
sage: b.content()
12

sage: B = crystals.infinity.Tableaux("C2")
sage: b = B(rows=[[1,1,1,1,1,1,2,2,2,-2,-2],[2,-2,-2,-2]])
sage: b.content()
8
```

phi(i)

Return φ_i of `self`.

Let $T \in \mathcal{B}(\infty)$. Define $\varphi_i(T) := \varepsilon_i(T) + \langle h_i, \text{wt}(T) \rangle$, where h_i is the i -th simple coroot and $\text{wt}(T)$ is the `weight()` of T .

INPUT:

- i – An element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("A3")
sage: [B.highest_weight_vector().f_string([1,3,2,3,1,3,2,1]).phi(i) for i_
↪in B.index_set()]
[-3, 4, -3]

sage: B = crystals.infinity.Tableaux("G2")
sage: [B.highest_weight_vector().f_string([2,2,1,2,1,1,1,2]).phi(i) for i_
↪in B.index_set()]
[5, -3]
```

reduced_form()

Return the reduced form of `self`.

The reduced form of a tableaux $T \in \mathcal{T}(\infty)$ is the (not necessarily semistandard) tableaux obtained from T by removing all i -boxes in the i -th row, subject to the condition that if the row is empty, a $*$ is put as a placeholder. This is described in [BN2010] and [LS2012].

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['A',3])
sage: b = B.highest_weight_vector().f_string([2,2,2,3,3,3,3,3])
sage: b.pp()
1 1 1 1 1 1 1 1
2 2 2 2 4 4 4
3 4 4
sage: b.reduced_form()
[['*'], [4, 4, 4], [4, 4]]

```

seg()

Returns the statistic `seg` of `self`.

More precisely, following [LS2012], define a k -segment of a tableau T in $\mathcal{B}(\infty)$ to be a maximal string of k -boxes in a single row of T . Set $\text{seg}'(T)$ to be the number of k -segments in T , as k varies over all possible values. Then $\text{seg}(T)$ is determined type-by-type.

- In types A_n and C_n , define $\text{seg}(T) := \text{seg}'(T)$.
- In types B_n and G_2 , set $e(T)$ to be the number of rows in T which contain both a 0-box and an \bar{i} -box. Define $\text{seg}(T) := \text{seg}'(T) - e(T)$.
- In type D_n , set $d(T)$ to be the number of rows in T which contain an \bar{i} -box, but no n -box nor \bar{n} -box. Define $\text{seg}(T) := \text{seg}'(T) + d(T)$.

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['A',3])
sage: b = B.highest_weight_vector().f_string([1,3,2,2,3,1,1,3])
sage: b.pp()
1 1 1 1 1 1 2 2 4
2 2 2 2 3
3 4 4
sage: b.seg()
4

sage: B = crystals.infinity.Tableaux(['D',4])
sage: b = B(rows=[[1,1,1,1,1,1,3,-2,-1],[2,2,2,4,-2],[3,3],[4]])
sage: b.pp()
1 1 1 1 1 1 3 -2 -1
2 2 2 4 -2
3 3
4
sage: b.seg()
6

sage: B = crystals.infinity.Tableaux(['G',2])
sage: b = B.highest_weight_vector().f_string([2,1,1,1,2,1,2,2,1,2,2,2,1,2,2,
↪1])
sage: b.pp()
1 1 1 1 1 1 1 1 2 3 0 -3
2 3 3 3 3 3 3
sage: b.seg()
5

```

weight()

Return the weight of `self`.

From the definition of a crystal and that the highest weight element b_∞ of $\mathcal{B}(\infty)$ is 0, the weight of $T \in \mathcal{B}(\infty)$ can be defined as $\text{wt}(T) := -\sum_j \alpha_{i_j}$ where $\tilde{e}_{i_1} \cdots \tilde{e}_{i_\ell} T = b_\infty$ and $\{\alpha_i\}$ is the set of

simple roots. (Note that the weight is independent of the path chosen to get to the highest weight.)

However we can also take advantage of the fact that $\rho: R_\lambda \otimes \mathcal{B}(\infty) \rightarrow B(\lambda)$, where λ is the shape of T , preserves the tableau representation of T . Therefore

$$\text{wt}(T) = \text{wt}(\rho(T)) - \lambda$$

where $\text{wt}(\rho(T))$ is just the usual weight of the tableau T .

Let Λ_i be the i -th fundamental weight. In type D , the height $n-1$ columns corresponds to $\Lambda_{n-1} + \Lambda_n$ and the in type B , the height n columns corresponds to $2\Lambda_n$.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("C7")
sage: b = B.highest_weight_vector().f_string([1,6,4,7,4,2,4,6,2,4,6,7,1,2,4,
↪7])
sage: b.weight()
(-2, -1, 3, -5, 5, -3, -3)
```

Check that the definitions agree:

```
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
sage: b.weight() == -2*alpha[1] - 3*alpha[2] - 5*alpha[4] - 3*alpha[6] -
↪3*alpha[7]
True
```

Check that it works for type B :

```
sage: B = crystals.infinity.Tableaux("B2")
sage: B.highest_weight_vector().weight()
(0, 0)
sage: b = B.highest_weight_vector().f_string([1,2,2,2,1,2])
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
sage: b.weight() == -2*alpha[1] - 4*alpha[2]
True
```

Check that it works for type D :

```
sage: B = crystals.infinity.Tableaux("D4")
sage: B.highest_weight_vector().weight()
(0, 0, 0, 0)
sage: b = B.highest_weight_vector().f_string([1,4,4,2,4,3,2,4,1,3,2,4])
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
sage: b.weight() == -2*alpha[1] - 3*alpha[2] - 2*alpha[3] - 5*alpha[4]
True
```

`module_generator()`

Return the module generator (or highest weight element) of `self`.

The module generator is the unique tableau of shape $(n, n-1, \dots, 2, 1)$ with weight 0.

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux(['A', 3])
sage: T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

class `sage.combinat.crystals.infinity_crystals.InfinityCrystalOfTableauxTypeD`(*cartan_type*)
 Bases: `sage.combinat.crystals.infinity_crystals.InfinityCrystalOfTableaux`

$\mathcal{B}(\infty)$ crystal of tableaux for type D_n .

This is the set $\mathcal{T}(\infty)$ of marginally large semistandard tableaux with exactly $n - 1$ rows over the alphabet $\{1 \prec \dots \prec n, \bar{n} \prec \dots \prec \bar{1}\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the i -th row are $\preceq \bar{i}$,
- the entries n and \bar{n} may not appear simultaneously in a single row.

For more information, see [InfinityCrystalOfTableaux](#).

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("D4")
sage: b = B.highest_weight_vector().f_string([4, 3, 2, 1, 4])
sage: b.pp()
1 1 1 1 1 1 2
2 2 2 2 3
3 -4 -3
sage: b.weight()
(-1, 0, -2, -1)
```

class `Element`

Bases: `sage.combinat.crystals.tensor_product_element.InfinityCrystalOfTableauxElementTypeD`,
`sage.combinat.crystals.infinity_crystals.InfinityCrystalOfTableaux.Element`

Elements in $\mathcal{B}(\infty)$ crystal of tableaux for type D_n .

module_generator()

Return the module generator (or highest weight element) of `self`.

The module generator is the unique tableau of shape $(n - 1, \dots, 2, 1)$ with weight 0.

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux(['D', 4])
sage: T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

5.1.53 Crystals of Kac modules of the general-linear Lie superalgebra

class `sage.combinat.crystals.kac_modules.CrystalOfKacModule`(*cartan_type*, *la*, *mu*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Crystal of a Kac module.

Let \mathfrak{g} be the general linear Lie superalgebra $\mathfrak{gl}(m|n)$. Let λ and μ be dominant weights for \mathfrak{g}_m and \mathfrak{g}_n , respectively. Let K be the module $K = \langle f_\alpha \rangle$, where α ranges over all odd positive roots. A *Kac module* is the

$U_q(\mathfrak{g})$ -module constructed from the highest weight $U_q(\mathfrak{gl}_m \oplus \mathfrak{gl}_n)$ -module $V(\lambda, \mu)$ (induced to a $U_q(\mathfrak{g})$ -module in the natural way) by

$$K(\lambda, \mu) := K \otimes_L V(\lambda, \mu),$$

where L is the subalgebra generated by e_0 and $U_q(\mathfrak{gl}_m \oplus \mathfrak{gl}_n)$.

The Kac module admits a $U_q(\mathfrak{g})$ -crystal structure by taking the crystal structure of K as given by [CrystalOfOddNegativeRoots](#) and the crystal $B(\lambda, \mu)$ (the natural crystal structure of $V(\lambda, \mu)$).

Note: Our notation differs slightly from [Kwon2012] in that our last tableau is transposed.

EXAMPLES:

```
sage: K = crystals.KacModule(['A', [1,2]], [2], [1,1])
sage: K.cardinality()
576
sage: K.cardinality().factor()
2^6 * 3^2
sage: len(K.cartan_type().root_system().ambient_space().positive_odd_roots())
6
sage: mg = K.module_generator()
sage: mg
({}, [[-2, -2]], [[1], [2]])
sage: mg.weight()
(2, 0, 1, 1, 0)
sage: mg.f(-1)
({}, [[-2, -1]], [[1], [2]])
sage: mg.f(0)
({-e[-1]+e[1]}, [[-2, -2]], [[1], [2]])
sage: mg.f(1)
({}, [[-2, -2]], [[1], [3]])

sage: sorted(K.highest_weight_vectors(), key=str)
[({-e[-1]+e[3]}, [[-2, -1]], [[1], [2]]),
 ({-e[-1]+e[3]}, [[-2, -2]], [[1], [2]]),
 ({} , [[-2, -2]], [[1], [2]])]
```

```
sage: K = crystals.KacModule(['A', [1,1]], [2], [1])
sage: K.cardinality()
96
sage: K.cardinality().factor()
2^5 * 3
sage: len(K.cartan_type().root_system().ambient_space().positive_odd_roots())
4

sage: sorted(K.highest_weight_vectors(), key=str)
[({-e[-1]+e[2]}, [[-2, -1]], [[1]]),
 ({-e[-1]+e[2]}, [[-2, -2]], [[1]]),
 ({} , [[-2, -2]], [[1]])]
sage: K.genuine_lowest_weight_vectors()
(({-e[-2]+e[1], -e[-2]+e[2], -e[-1]+e[1], -e[-1]+e[2]}, [[-1, -1]], [[2]]),)
```

(continues on next page)

(continued from previous page)

```
sage: sorted(K.lowest_weight_vectors(), key=str)
[({-e[-1]+e[1], -e[-1]+e[2]}, [[-1, -1]], [[2]]),
 ({-e[-2]+e[1], -e[-2]+e[2], -e[-1]+e[1], -e[-1]+e[2]}, [[-1, -1]], [[2]]),
 ({-e[-2]+e[2], -e[-1]+e[1], -e[-1]+e[2]}, [[-1, -1]], [[1]]),
 ({-e[-2]+e[2], -e[-1]+e[1], -e[-1]+e[2]}, [[-1, -1]], [[2]])]
```

REFERENCES:

- [Kwon2012]

class ElementBases: `sage.structure.element_wrapper.ElementWrapper`

An element of a Kac module crystal.

e(i)Return the action of the crystal operator e_i on `self`.

EXAMPLES:

```
sage: K = crystals.KacModule(['A', [2,2]], [2,1], [1])
sage: mg = K.module_generator()
sage: mg.e(0)
sage: mg.e(1)
sage: mg.e(-1)
sage: b = mg.f_string([1,0,1,-1,-2,0,1,2,0,-2,-1,-1,-1]); b
({-e[-3]+e[2], -e[-2]+e[1], -e[-2]+e[2]}, [[-3, -1], [-2]], [[3]])
sage: b.e(-2)
sage: b.e(-1)
({-e[-3]+e[2], -e[-2]+e[1], -e[-2]+e[2]}, [[-3, -2], [-2]], [[3]])
sage: b.e(0)
sage: b.e(1)
({-e[-3]+e[1], -e[-2]+e[1], -e[-2]+e[2]}, [[-3, -1], [-2]], [[3]])
sage: b.e(2)
({-e[-3]+e[2], -e[-2]+e[1], -e[-2]+e[2]}, [[-3, -1], [-2]], [[2]])
```

f(i)Return the action of the crystal operator f_i on `self`.

EXAMPLES:

```
sage: K = crystals.KacModule(['A', [2,2]], [2,1], [1])
sage: mg = K.module_generator()
sage: mg.f(-2)
({}, [[-3, -2], [-2]], [[1]])
sage: mg.f(-1)
({}, [[-3, -3], [-1]], [[1]])
sage: mg.f(0)
({-e[-1]+e[1]}, [[-3, -3], [-2]], [[1]])
sage: mg.f(1)
({}, [[-3, -3], [-2]], [[2]])
sage: mg.f(2)
sage: b = mg.f_string([1,0,1,-1,-2,0,1,2,0,-2,-1,2,0]); b
({-e[-3]+e[3], -e[-2]+e[1], -e[-1]+e[1], -e[-1]+e[2]},
 [[-3, -2], [-2]], [[3]])
```

weight()

Return weight of self.

EXAMPLES:

```
sage: K = crystals.KacModule(['A', [3,2]], [2,1], [5,1])
sage: mg = K.module_generator()
sage: mg.weight()
(2, 1, 0, 0, 5, 1, 0)
sage: mg.weight().is_dominant()
True
sage: mg.f(0).weight()
(2, 1, 0, -1, 6, 1, 0)
sage: b = mg.f_string([2,1,-3,-2,-1,1,1,0,-2,-1,2,1,1,1,0,2,-3,-2,-1])
sage: b.weight()
(0, 0, 0, 1, 1, 4, 3)
```

module_generator()

Return the module generator of self.

EXAMPLES:

```
sage: K = crystals.KacModule(['A', [2,1]], [2,1], [1])
sage: K.module_generator()
({}, [[-3, -3], [-2]], [[1]])
```

class sage.combinat.crystals.kac_modules.CrystalOfOddNegativeRoots(*cartan_type*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Crystal of the set of odd negative roots.

Let \mathfrak{g} be the general-linear Lie superalgebra $\mathfrak{gl}(m|n)$. This is the crystal structure on the set of negative roots as given by [Kwon2012].

More specifically, this is the crystal basis of the subalgebra of $U_q^-(\mathfrak{g})$ generated by f_α , where α ranges over all odd positive roots. As $\mathbf{Q}(q)$ -modules, we have

$$U_q^-(\mathfrak{g}) \cong K \otimes U_q^-(\mathfrak{gl}_m \oplus \mathfrak{gl}_n).$$

EXAMPLES:

```
sage: S = crystals.OddNegativeRoots(['A', [2,1]])
sage: mg = S.module_generator(); mg
{}
sage: mg.f(0)
{-e[-1]+e[1]}
sage: mg.f_string([0,-1,0,1,2,1,0])
{-e[-2]+e[3], -e[-1]+e[1], -e[-1]+e[2]}
```

class Element

Bases: `sage.structure.element_wrapper.ElementWrapper`

An element of the crystal of odd negative roots.

e(*i*)

Return the action of the crystal operator e_i on self.

EXAMPLES:

```

sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: mg.e(0)
sage: mg.e(1)
sage: b = mg.f_string([0,1,2,-1,0])
sage: b.e(-1)
sage: b.e(0)
{-e[-2]+e[3]}
sage: b.e(1)
sage: b.e(2)
{-e[-2]+e[2], -e[-1]+e[1]}
sage: b.e_string([2,1,0,-1,0])
{}

```

epsilon(*i*)

Return ε_i of self.

EXAMPLES:

```

sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: [mg.epsilon(i) for i in S.index_set()]
[0, 0, 0, 0, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1,-2,-2]); b
{-e[-3]+e[1], -e[-3]+e[2], -e[-1]+e[1]}
sage: [b.epsilon(i) for i in S.index_set()]
[2, 0, 1, 0, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1,-2,-2,2,-1,0]); b
{-e[-3]+e[1], -e[-3]+e[3], -e[-2]+e[1], -e[-1]+e[1]}
sage: [b.epsilon(i) for i in S.index_set()]
[1, 0, 1, 0, 1]

```

f(*i*)

Return the action of the crystal operator f_i on self.

EXAMPLES:

```

sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: mg.f(0)
{-e[-1]+e[1]}
sage: mg.f(1)
sage: b = mg.f_string([0,1,2,-1,0]); b
{-e[-2]+e[3], -e[-1]+e[1]}
sage: b.f(-2)
{-e[-3]+e[3], -e[-1]+e[1]}
sage: b.f(-1)
sage: b.f(0)
sage: b.f(1)
{-e[-2]+e[3], -e[-1]+e[2]}

```

phi(*i*)

Return φ_i of self.

EXAMPLES:

```

sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: [mg.phi(i) for i in S.index_set()]
[0, 0, 1, 0, 0]
sage: b = mg.f(0)
sage: [b.phi(i) for i in S.index_set()]
[0, 1, 0, 1, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1]); b
{-e[-2]+e[1], -e[-2]+e[2], -e[-1]+e[1]}
sage: [b.phi(i) for i in S.index_set()]
[2, 0, 0, 1, 1]

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: mg.weight()
(0, 0, 0, 0, 0)
sage: mg.f_string([0,1,2,-1,-2]).weight()
(-1, 0, 0, 0, 1)
sage: mg.f_string([0,1,2,-1,-2,0,1,0,2]).weight()
(-1, 0, -2, 1, 0, 2)

```

module_generator()

Return the module generator of self.

EXAMPLES:

```

sage: S = crystals.OddNegativeRoots(['A', [2,1]])
sage: S.module_generator()
{}

```

sage.combinat.crystals.kac_modules.latex_dual(elt)

Return a latex representation of a type A_n crystal tableau *elt* expressed in terms of dual letters.

The dual letter of k is expressed as $\overline{n+2-k}$.

EXAMPLES:

```

sage: from sage.combinat.crystals.kac_modules import latex_dual
sage: T = crystals.Tableaux(['A', 2], shape=[2,1])
sage: print(latex_dual(T[0]))
{\def\lr#1{\multicolumn{1}{|@{\hspace{.6ex}}c@{\hspace{.6ex}}|}{\raisebox{-.3ex}{\$#1
\rightarrow}}}}
\raisebox{-.6ex}{\$\begin{array}[b]{*{2}c}\cline{1-2}
\lr{\overline{3}}&\lr{\overline{3}}\\\cline{1-2}
\lr{\overline{2}}\\\cline{1-1}
\end{array}}$}
}

```

sage.combinat.crystals.kac_modules.to_dual_tableau(elt)

Return a type A_n crystal tableau *elt* as a tableau expressed in terms of dual letters.

The dual letter of k is expressed as $\overline{n+2-k}$ represented as $-(n+2-k)$.

EXAMPLES:

```
sage: from sage.combinat.crystals.kac_modules import to_dual_tableau
sage: T = crystals.Tableaux(['A', 2], shape=[2, 1])
sage: ascii_art([to_dual_tableau(t) for t in T])
[ -3 -3  -3 -2  -3 -1  -3 -1  -2 -1  -3 -3  -3 -2  -2 -2 ]
[ -2   ,  -2   ,  -2   ,  -1   ,  -1   ,  -1   ,  -1   ,  -1   ]
```

5.1.54 Kirillov-Reshetikhin Crystals

```
class sage.combinat.crystals.kirillov_reshetikhin.AmbientRetractMap(base, ambient, pdict_inv,
                                                                    index_set, similarity_factor_domain=None,
                                                                    automorphism=None)
```

Bases: `sage.categories.map.Map`

The retraction map from the ambient crystal.

Consider a crystal embedding $\phi : X \rightarrow Y$, then the elements X can be considered as a subcrystal of the ambient crystal Y . The ambient retract is the partial map $\tilde{\phi} : Y \rightarrow X$ such that $\tilde{\phi} \circ \phi$ is the identity on X .

```
class sage.combinat.crystals.kirillov_reshetikhin.CrystalDiagramAutomorphism(C, on_hw, index_set=None,
                                                                                automorphism=None,
                                                                                cache=True)
```

Bases: `sage.categories.crystals.CrystalMorphism`

The crystal automorphism induced from the diagram automorphism.

For example, in type $A_n^{(1)}$ this is the promotion operator and in type $D_n^{(1)}$, this corresponds to the automorphism induced from interchanging the 0 and 1 nodes in the Dynkin diagram.

INPUT:

- `C` – a crystal
- `on_hw` – a function for the images of the `index_set`-highest weight elements
- `index_set` – (default: the empty set) the index set
- `automorphism` – (default: the identity) the twisting automorphism
- `cache` – (default: True) cache the result

is_embedding()

Return True as `self` is a crystal isomorphism.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2)
sage: K.promotion().is_isomorphism()
True
```

is_isomorphism()

Return True as `self` is a crystal isomorphism.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```

is_strict()

Return True as self is a crystal isomorphism.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```

is_surjective()

Return True as self is a crystal isomorphism.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```

class sage.combinat.crystals.kirillov_reshetikhin.**CrystalOfTableaux_E7**(cartan_type, shapes)

Bases: *sage.combinat.crystals.tensor_product.CrystalOfTableaux*

The type E_7 crystal $B(s\Lambda_7)$.

This is a helper class for the corresponding class: $KR\text{crystal} < \text{sage.combinat.crystals.kirillov_reshetikhin.KR_typeE7} > B^{7,s}$.

module_generator(shape)

Return the module generator of self with shape shape.

Note: Only implemented for single rows (i.e., highest weight $s\Lambda_7$).

EXAMPLES:

```
sage: from sage.combinat.crystals.kirillov_reshetikhin import CrystalOfTableaux_
↳E7
sage: T = CrystalOfTableaux_E7(CartanType(['E',7]), shapes=(Partition([5]),))
sage: T.module_generator([5])
[[ (7, ), (7, ), (7, ), (7, ), (7, ) ]]
```

class sage.combinat.crystals.kirillov_reshetikhin.**KR_type_A**(cartan_type, r, s)

Bases: *sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotion*

Class of Kirillov-Reshetikhin crystals of type $A_n^{(1)}$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: b = K(rows=[[1,2],[2,4]])
sage: b.f(0)
[[1, 1], [2, 2]]
```

classical_decomposition()

Specifies the classical crystal underlying the KR crystal of type A.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['A', 3] and shape(s) [[2, 2]]
```

`dynkin_diagram_automorphism(i)`

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements. The automorphism needs to map node 0 to some other Dynkin node.

For type A we use the Dynkin diagram automorphism which $i \mapsto i + 1 \pmod{n + 1}$, where n is the rank.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2)
sage: K.dynkin_diagram_automorphism(0)
1
sage: K.dynkin_diagram_automorphism(3)
0
```

`promotion()`

Specifies the promotion operator used to construct the affine type A crystal.

For type A this corresponds to the Dynkin diagram automorphism which $i \mapsto i + 1 \pmod{n + 1}$, where n is the rank.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2)
sage: b = K.classical_decomposition()(rows=[[1, 2], [3, 4]])
sage: K.promotion()(b)
[[1, 3], [2, 4]]
```

`promotion_inverse()`

Specifies the inverse promotion operator used to construct the affine type A crystal.

For type A this corresponds to the Dynkin diagram automorphism which $i \mapsto i - 1 \pmod{n + 1}$, where n is the rank.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2)
sage: b = K.classical_decomposition()(rows=[[1, 3], [2, 4]])
sage: K.promotion_inverse()(b)
[[1, 2], [3, 4]]
sage: b = K.classical_decomposition()(rows=[[1, 2], [3, 3]])
sage: K.promotion_inverse()(K.promotion()(b))
[[1, 2], [3, 3]]
```

class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2`(*cartan_type*, *r*, *s*, *dual=None*)

Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal`

Class of Kirillov-Reshetikhin crystals $B^{r,s}$ of type $A_{2n}^{(2)}$ for $1 \leq r \leq n$ in the realization with classical subalgebra B_n . The Cartan type in this case is inputted as the dual of $A_{2n}^{(2)}$.

This is an alternative implementation to `KR_type_box` that uses the classical decomposition into type C_n crystals.

EXAMPLES:

```

sage: C = CartanType(['A', 4, 2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: K
Kirillov-Reshetikhin crystal of type ['BC', 2, 2]^* with (r,s)=(1,1)
sage: b = K(rows=[[-1]])
sage: b.f(0)
[[1]]
sage: b.e(0)

```

We can now check whether the two KR crystals of type $A_4^{(2)}$ (namely the KR crystal and its dual construction) are isomorphic up to relabelling of the edges:

```

sage: C = CartanType(['A', 4, 2])
sage: K = crystals.KirillovReshetikhin(C, 1, 1)
sage: Kdual = crystals.KirillovReshetikhin(C.dual(), 1, 1)
sage: G = K.digraph()
sage: Gdual = Kdual.digraph()
sage: f = {0:2, 1:1, 2:0}
sage: Gnew = DiGraph(); Gnew.add_vertices(Gdual.vertices(sort=True)); Gnew.add_
->edges([(u,v,f[i]) for (u,v,i) in Gdual.edges(sort=True)])
sage: G.is_isomorphic(Gnew, edge_labels = True)
True

```

Element

alias of `KR_type_A2Element`

ambient_crystal()

Return the ambient crystal $B^{r,s}$ of type $B_{n+1}^{(1)}$ associated to the Kirillov-Reshetikhin crystal of type $A_{2n}^{(2)}$ dual.

This ambient crystal is used to construct the zero arrows.

EXAMPLES:

```

sage: C = CartanType(['A', 4, 2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 3)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(2,3)

```

ambient_dict_pm_diagrams()

Return a dictionary of all self-dual \pm diagrams for the ambient crystal whose keys are their inner shape.

EXAMPLES:

```

sage: C = CartanType(['A', 4, 2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: K.ambient_dict_pm_diagrams()
{[1]: [[0, 0], [1]]}
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: K.ambient_dict_pm_diagrams()
{[]: [[1, 1], [0]], [2]: [[0, 0], [2]]}
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 2)
sage: K.ambient_dict_pm_diagrams()
{[]: [[1, 1], [0, 0], [0]],

```

(continues on next page)

(continued from previous page)

```
[2]: [[0, 0], [1, 1], [0]],
[2, 2]: [[0, 0], [0, 0], [2]]}]
```

ambient_highest_weight_dict()

Return a dictionary of all $\{2, \dots, n+1\}$ -highest weight vectors in the ambient crystal.

The key is the inner shape of their corresponding \pm diagram, or equivalently, their $\{2, \dots, n+1\}$ weight.

EXAMPLES:

```
sage: C = CartanType(['A', 4, 2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: K.ambient_highest_weight_dict()
{[]: [[1, -1]], [2]: [[2, 2]]}
```

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type $A_{2n}^{(2)}$ with B_n as classical subdiagram.

It is given by $B^{r,s} \cong \bigoplus_{\Lambda} B(\Lambda)$, where $B(\Lambda)$ is a highest weight crystal of type B_n of highest weight Λ . The sum is over all weights Λ obtained from a rectangle of width s and height r by removing horizontal dominoes. Here we identify the fundamental weight Λ_i with a column of height i .

EXAMPLES:

```
sage: C = CartanType(['A', 4, 2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 2] and shape(s) [[], [2], [2, 2]]
```

from_ambient_crystal()

Return a map from the ambient crystal of type $B_{n+1}^{(1)}$ to the Kirillov-Reshetikhin crystal of type $A_{2n}^{(2)}$.

Note that this map is only well-defined on type $A_{2n}^{(2)}$ elements that are in the image under `to_ambient_crystal()`.

EXAMPLES:

```
sage: C = CartanType(['A', 4, 2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: b = K.ambient_crystal()(rows=[[2, 2]])
sage: K.from_ambient_crystal()(b)
[[1, 1]]
```

highest_weight_dict()

Return a dictionary of the classical highest weight vectors of `self` whose keys are their shape.

EXAMPLES:

```
sage: C = CartanType(['A', 4, 2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: K.highest_weight_dict()
{[]: [], [2]: [[1, 1]]}
```

module_generator()

Return the unique module generator of classical weight $s\Lambda_r$ of a Kirillov-Reshetikhin crystal $B^{r,s}$.

EXAMPLES:

```
sage: ct = CartanType(['A',8,2]).dual()
sage: K = crystals.KirillovReshetikhin(ct, 3, 5)
sage: K.module_generator()
[[1, 1, 1, 1, 1], [2, 2, 2, 2, 2], [3, 3, 3, 3, 3]]
```

to_ambient_crystal()Return a map from the Kirillov-Reshetikhin crystal of type $A_{2n}^{(2)}$ to the ambient crystal of type $B_{n+1}^{(1)}$.

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: b=K(rows=[[1,1]])
sage: K.to_ambient_crystal()(b)
[[2, 2]]
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 2)
sage: b=K(rows=[[1,1]])
sage: K.to_ambient_crystal()(b)
[[1, 2], [2, -1]]
sage: K.to_ambient_crystal()(b).parent()
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(2,2)
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2ElementBases: [sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement](#)Class for the elements in the Kirillov-Reshetikhin crystals $B^{r,s}$ of type $A_{2n}^{(2)}$ for $r < n$ with underlying classical algebra B_n .

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2_with_category.
↪element_class'>
```

e0()Return e_0 on `self` by mapping `self` to the ambient crystal, calculating $e_1 e_0$ there and pulling the element back.

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[1]])
sage: b.e(0) # indirect doctest
[[-1]]
```

epsilon0()Calculate ϵ_0 of `self` by mapping the element to the ambient crystal and calculating `\varepsilon_1` there.

EXAMPLES:

```

sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b=K(rows=[[1]])
sage: b.epsilon(0) # indirect doctest
1

```

f0()

Return f_0 on `self` by mapping `self` to the ambient crystal, calculating $f_1 f_0$ there and pulling the element back.

EXAMPLES:

```

sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[-1]])
sage: b.f(0) # indirect doctest
[[1]]

```

phi0()

Calculate φ_0 of `self` by mapping the element to the ambient crystal and calculating φ_1 there.

EXAMPLES:

```

sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[-1]])
sage: b.phi(0) # indirect doctest
1

```

class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_Bn`(*cartan_type*, *r*, *s*, *dual=None*)
 Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal`

Class of Kirillov-Reshetikhin crystals $B^{n,s}$ of type $B_n^{(1)}$.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(3,2)
sage: b = K(rows=[[1],[2],[3]])
sage: b.f(0)
sage: b.e(0)
[[3]]

sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: [b.weight() for b in K if b.is_highest_weight([1,2,3])]
[-Lambda[0] + Lambda[1], -2*Lambda[0] + 2*Lambda[3]]
sage: [b.weight() for b in K if b.is_highest_weight([0,2,3])]
[Lambda[0] - Lambda[1], -2*Lambda[1] + 2*Lambda[3]]

```

Element

alias of `KR_type_BnElement`

ambient_crystal()

Return the ambient crystal $B^{n,s}$ of type $A_{2n-1}^{(2)}$ associated to the Kirillov-Reshetikhin crystal.

The ambient crystal is used to construct the zero arrows.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 2)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['B', 3, 1]^* with (r,s)=(3,2)
```

`ambient_highest_weight_dict()`

Return a dictionary of the classical highest weight vectors of the ambient crystal of `self` whose keys are their shape.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 2)
sage: K.ambient_highest_weight_dict()
{(2,): [[1, 1]], (2, 1, 1): [[1, 1], [2], [3]], (2, 2, 2): [[1, 1], [2, 2], [3, ↵
↵3]]}

sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 3)
sage: K.ambient_highest_weight_dict()
{(3,): [[1, 1, 1]],
 (3, 1, 1): [[1, 1, 1], [2], [3]],
 (3, 2, 2): [[1, 1, 1], [2, 2], [3, 3]],
 (3, 3, 3): [[1, 1, 1], [2, 2, 2], [3, 3, 3]]}
```

`classical_decomposition()`

Return the classical crystal underlying the Kirillov-Reshetikhin crystal $B^{n,s}$ of type $B_n^{(1)}$.

It is the same as for $r < n$, given by $B^{n,s} \cong \bigoplus_{\Lambda} B(\Lambda)$, where Λ are weights obtained from a rectangle of width $s/2$ and height n by removing horizontal dominoes. Here we identify the fundamental weight Λ_i with a column of height i for $i < n$ and a column of width $1/2$ for $i = n$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[1], [1, 1, 1]]
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 3)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[3/2, 1/2, 1/2], [3/2, 3/
↵2, 3/2]]
```

`from_ambient_crystal()`

Return a map from the ambient crystal of type $A_{2n-1}^{(2)}$ to the Kirillov-Reshetikhin crystal `self`.

Note that this map is only well-defined on elements that are in the image under `to_ambient_crystal()`.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 1)
sage: [b == K.from_ambient_crystal()(K.to_ambient_crystal()(b)) for b in K]
[True, True, True, True, True, True, True, True]
sage: b = K.ambient_crystal()(rows=[[1], [2], [-3]])
sage: K.from_ambient_crystal()(b)
[+-, []]
```

`highest_weight_dict()`

Return a dictionary of the classical highest weight vectors of `self` whose keys are 2 times their shape.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 2)
sage: K.highest_weight_dict()
{(2,): [[1]], (2, 2, 2): [[1], [2], [3]]}
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 3)
sage: K.highest_weight_dict()
{(3, 1, 1): [+++], [[1]]}, (3, 3, 3): [+++], [[1], [2], [3]]}
```

similarity_factor()

Sets the similarity factor used to map to the ambient crystal.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 2)
sage: K.similarity_factor()
{1: 2, 2: 2, 3: 1}
```

to_ambient_crystal()

Return a map from self to the ambient crystal of type $A_{2n-1}^{(2)}$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 1)
sage: [K.to_ambient_crystal()(b) for b in K]
[[[1], [2], [3]], [[1], [2], [-3]], [[1], [3], [-2]], [[2], [3], [-1]], [[1], [-3], [-2]],
[[2], [-3], [-1]], [[3], [-2], [-1]], [[-3], [-2], [-1]]]
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_BnElement

Bases: *sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement*

Class for the elements in the Kirillov-Reshetikhin crystals $B^{n,s}$ of type $B_n^{(1)}$.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['B', 3, 1], 3, 2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Bn_with_category.
↳element_class'>
```

e0()

Return e_0 on self by mapping self to the ambient crystal, calculating e_0 there and pulling the element back.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['B', 3, 1], 3, 1)
sage: b = K.module_generators[0]
sage: b.e(0) # indirect doctest
[--+, []]
```

epsilon0()

Calculate ε_0 of self by mapping the element to the ambient crystal and calculating ε_0 there.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.epsilon(0) # indirect doctest
1
```

f0()

Return f_0 on self by mapping self to the ambient crystal, calculating f_0 there and pulling the element back.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.f(0) # indirect doctest
```

phi0()

Calculate φ_0 of self by mapping the element to the ambient crystal and calculating φ_0 there.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0) # indirect doctest
0
```

class sage.combinat.crystals.kirillov_reshetikhin.**KR_type_C**(cartan_type, r, s, dual=None)

Bases: *sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal*

Class of Kirillov-Reshetikhin crystals $B^{r,s}$ of type $C_n^{(1)}$ for $r < n$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: K
Kirillov-Reshetikhin crystal of type ['C', 2, 1] with (r,s)=(1,2)
sage: b = K(rows=[])
sage: b.f(0)
[[1, 1]]
sage: b.e(0)
[[-1, -1]]
```

Element

alias of *KR_type_CElement*

ambient_crystal()

Return the ambient crystal $B^{r,s}$ of type $A_{2n+1}^{(2)}$ associated to the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$.

This ambient crystal is used to construct the zero arrows.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,3)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['B', 4, 1]^* with (r,s)=(2,3)
```

ambient_dict_pm_diagrams()

Return a dictionary of all self-dual \pm diagrams for the ambient crystal whose keys are their inner shape.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C', 2, 1], 1, 2)
sage: K.ambient_dict_pm_diagrams()
{[]: [[1, 1], [0]], [2]: [[0, 0], [2]]}
sage: K = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2)
sage: K.ambient_dict_pm_diagrams()
{[]: [[1, 1], [0, 0], [0]],
 [2]: [[0, 0], [1, 1], [0]],
 [2, 2]: [[0, 0], [0, 0], [2]]}
sage: K = crystals.KirillovReshetikhin(['C', 3, 1], 2, 3)
sage: K.ambient_dict_pm_diagrams()
{[1, 1]: [[1, 1], [0, 0], [1]],
 [3, 1]: [[0, 0], [1, 1], [1]],
 [3, 3]: [[0, 0], [0, 0], [3]]}
```

ambient_highest_weight_dict()

Return a dictionary of all $\{2, \dots, n+1\}$ -highest weight vectors in the ambient crystal.

The key is the inner shape of their corresponding \pm diagram, or equivalently, their $\{2, \dots, n+1\}$ weight.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2)
sage: K.ambient_highest_weight_dict()
{[]: [[2], [-2]], [2]: [[1, 2], [2, -1]], [2, 2]: [[2, 2], [3, 3]]}
```

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$.

It is given by $B^{r,s} \cong \bigoplus_{\Lambda} B(\Lambda)$, where Λ are weights obtained from a rectangle of width s and height r by removing horizontal dominoes. Here we identify the fundamental weight Λ_i with a column of height i .

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 3] and shape(s) [[], [2], [2, 2]]
```

from_ambient_crystal()

Return a map from the ambient crystal of type $A_{2n+1}^{(2)}$ to the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$.

Note that this map is only well-defined on type $C_n^{(1)}$ elements that are in the image under `to_ambient_crystal()`.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2)
sage: b = K.ambient_crystal()(rows=[[2, 2], [3, 3]])
sage: K.from_ambient_crystal()(b)
[[1, 1], [2, 2]]
```

highest_weight_dict()

Return a dictionary of the classical highest weight vectors of `self` whose keys are their shape.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2)
sage: K.highest_weight_dict()
{[]: [], [2]: [[1, 1]], [2, 2]: [[1, 1], [2, 2]]}
```

to_ambient_crystal()

Return a map from the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$ to the ambient crystal of type $A_{2n+1}^{(2)}$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2)
sage: b=K(rows=[[1, 1]])
sage: K.to_ambient_crystal()(b)
[[1, 2], [2, -1]]
sage: b=K(rows=[])
sage: K.to_ambient_crystal()(b)
[[2], [-2]]
sage: K.to_ambient_crystal()(b).parent()
Kirillov-Reshetikhin crystal of type ['B', 4, 1]^* with (r,s)=(2,2)
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_CElement

Bases: *sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement*

Class for the elements in the Kirillov-Reshetikhin crystals $B^{r,s}$ of type $C_n^{(1)}$ for $r < n$.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['C', 3, 1], 1, 2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_C_with_category.element_
->class'>
```

e0()

Return e_0 on *self* by mapping *self* to the ambient crystal, calculating $e_1 e_0$ there and pulling the element back.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['C', 3, 1], 1, 2)
sage: b = K(rows=[])
sage: b.e(0) # indirect doctest
[[-1, -1]]
```

epsilon0()

Calculate ε_0 of *self* by mapping the element to the ambient crystal and calculating ε_1 there.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C', 2, 1], 1, 2)
sage: b=K(rows=[[1, 1]])
sage: b.epsilon(0) # indirect doctest
2
```

f0()

Return f_0 on *self* by mapping *self* to the ambient crystal, calculating $f_1 f_0$ there and pulling the element back.

EXAMPLES:

```

sage: K=crystals.KirillovReshetikhin(['C',3,1],1,2)
sage: b = K(rows=[])
sage: b.f(0) # indirect doctest
[[1, 1]]

```

phi0()

Calculate φ_0 of `self` by mapping the element to the ambient crystal and calculating φ_1 there.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: b=K(rows=[[-1,-1]])
sage: b.phi(0) # indirect doctest
2

```

class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_Cn`(*cartan_type, r, s, dual=None*)
 Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal`

Class of Kirillov-Reshetikhin crystals $B^{n,s}$ of type $C_n^{(1)}$.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: [[b,b.f(0)] for b in K]
[[[1], [2], [3]], None], [[1], [2], [-3]], None],
[[1], [3], [-3]], None], [[2], [3], [-3]], None],
[[1], [3], [-2]], None], [[2], [3], [-2]], None],
[[2], [3], [-1]], [[1], [2], [3]]], [[1], [-3], [-2]], None],
[[2], [-3], [-2]], None], [[2], [-3], [-1]], [[1], [2], [-3]]],
[[3], [-3], [-2]], None], [[3], [-3], [-1]], [[1], [3], [-3]]],
[[3], [-2], [-1]], [[1], [3], [-2]]],
[[[-3], [-2], [-1]], [[1], [-3], [-2]]]]

```

Element

alias of `KR_type_CnElement`

classical_decomposition()

Specifies the classical crystal underlying the Kirillov-Reshetikhin crystal $B^{n,s}$ of type $C_n^{(1)}$.

The classical decomposition is given by $B^{n,s} \cong B(s\Lambda_n)$.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 3] and shape(s) [[2, 2, 2]]

```

from_highest_weight_vector_to_pm_diagram(b)

This gives the bijection between an element `b` in the classical decomposition of the KR crystal that is $2, 3, \dots, n$ -highest weight and \pm diagrams.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: T = K.classical_decomposition()
sage: b = T(rows=[[2, 2], [3, 3], [-3, -1]])

```

(continues on next page)

(continued from previous page)

```

sage: pm = K.from_highest_weight_vector_to_pm_diagram(b); pm
[[0, 0], [1, 0], [0, 1], [0]]
sage: pm.pp()
. .
. +
- -

sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3]) ]
sage: all(K.from_pm_diagram_to_highest_weight_vector(K.from_highest_weight_
↪vector_to_pm_diagram(b)) == b for b in hw)
True

```

from_pm_diagram_to_highest_weight_vector(*pm*)

This gives the bijection between a \pm diagram and an element b in the classical decomposition of the KR crystal that is $\{2, 3, \dots, n\}$ -highest weight.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['C', 3, 1], 3, 2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[0, 0], [1, ↪
↪0], [0, 1], [0]])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[[2, 2], [3, 3], [-3, -1]]

```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_CnElementBases: *sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement*Class for the elements in the Kirillov-Reshetikhin crystals $B^{n,s}$ of type $C_n^{(1)}$.

EXAMPLES:

```

sage: K=crystals.KirillovReshetikhin(['C', 3, 1], 3, 2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Cn_with_category.
↪element_class'>

```

e0()

Return e_0 on *self* by going to the \pm -diagram corresponding to the $\{2, \dots, n\}$ -highest weight vector in the component of *self*, then applying [Definition 6.1, 4], and pulling back from \pm -diagrams.

EXAMPLES:

```

sage: K=crystals.KirillovReshetikhin(['C', 3, 1], 3, 2)
sage: b = K.module_generators[0]
sage: b.e(0) # indirect doctest
[[1, 2], [2, 3], [3, -1]]
sage: b = K(rows=[[1, 2], [2, 3], [3, -1]])
sage: b.e(0)
[[2, 2], [3, 3], [-1, -1]]
sage: b=K(rows=[[1, -3], [3, -2], [-3, -1]])
sage: b.e(0)
[[3, -3], [-3, -2], [-1, -1]]

```

epsilon0()

Calculate ε_0 of *self* using Lemma 6.1 of [4].

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.epsilon(0) # indirect doctest
1
```

f0()

Return e_0 on `self` by going to the \pm -diagram corresponding to the $\{2, \dots, n\}$ -highest weight vector in the component of `self`, then applying [Definition 6.1, 4], and pulling back from \pm -diagrams.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.f(0) # indirect doctest
```

phi0()

Calculate φ_0 of `self`.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0) # indirect doctest
0
```

class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_D_tri1(ct, s)`

Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal`

Class of Kirillov-Reshetikhin crystals $B^{1,s}$ of type $D_4^{(3)}$.

The crystal structure was defined in Section 4 of [KMOY2007] using the coordinate representation.

class `Element`

Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement`

coordinates()

Return `self` as coordinates.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 3)
sage: all(K.from_coordinates(x.coordinates()) == x for x in K)
True
```

e0()

Return the action of e_0 on `self`.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1,1)
sage: [x.e0() for x in K]
[[[-1]], [], [[-3]], [[-2]], None, None, None, None]
```

epsilon0()

Return ε_0 of `self`.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: [mg.epsilon0() for mg in K.module_generators]
[5, 6, 7, 8, 9, 10]
```

f0()

Return the action of f_0 on self.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1,1)
sage: [x.f0() for x in K]
[[[1]], None, None, None, None, [[2]], [[3]], []]
```

phi0()

Return φ_0 of self.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: [mg.phi0() for mg in K.module_generators]
[5, 4, 3, 2, 1, 0]
```

classical_decomposition()

Return the classical decomposition of self.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: K.classical_decomposition()
The crystal of tableaux of type ['G', 2]
and shape(s) [[], [1], [2], [3], [4], [5]]
```

from_coordinates(coords)

Return an element of self from the coordinates coords.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: K.from_coordinates((0, 2, 3, 1, 0, 1))
[[2, 2, 3, 0, -1]]
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_Dn_twisted(*cartan_type*, *r*, *s*,
dual=None)

Bases: [sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal](#)

Class of Kirillov-Reshetikhin crystals $B^{n,s}$ of type $D_{n+1}^{(2)}$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: [[b,b.f(0)] for b in K]
[[[+++], []], None], [[+--], []], None], [[+-+], []], None], [[-++], []],
[+++], []], [[+-+], []], None], [[-+-], []], [++-], []], [[-+-], []], [+--], []],
[---], []], [+--], []]]
```

Element

alias of [KR_type_Dn_twistedElement](#)

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal $B^{n,s}$ of type $D_{n+1}^{(2)}$.

The classical decomposition is given by $B^{n,s} \cong B(s\Lambda_n)$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[1/2, 1/2, 1/2]]
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[1, 1, 1]]
```

from_highest_weight_vector_to_pm_diagram(b)

This gives the bijection between an element b in the classical decomposition of the KR crystal that is $\{2, 3, \dots, n\}$ -highest weight and \pm diagrams.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: T = K.classical_decomposition()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3]) ]
sage: [K.from_highest_weight_vector_to_pm_diagram(b) for b in hw]
[[[0, 0], [0, 0], [1, 0], [0]], [[0, 0], [0, 0], [0, 1], [0]]]

sage: K = crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: T = K.classical_decomposition()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3]) ]
sage: [K.from_highest_weight_vector_to_pm_diagram(b) for b in hw]
[[[0, 0], [0, 0], [2, 0], [0]], [[0, 0], [0, 0], [0, 0], [2]],
 [[0, 0], [2, 0], [0, 0], [0]], [[0, 0], [0, 0], [0, 2], [0]]]
```

Note that, since the classical decomposition of this crystal is of type B_n , there can be (at most one) entry 0 in the $\{2, 3, \dots, n\}$ -highest weight elements at height n . In the following implementation this is realized as an empty column of height n since this uniquely specifies the existence of the 0.

EXAMPLES:

```
sage: b = hw[1]
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b)
sage: pm.pp()
. .
. .
. .
```

from_pm_diagram_to_highest_weight_vector(pm)

This gives the bijection between a \pm diagram and an element b in the classical decomposition of the KR crystal that is $\{2, 3, \dots, n\}$ -highest weight.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[0, 0], [0, 0],
  ←0], [0, 0], [2]])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[[2], [3], [0]]
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_Dn_twistedElement

Bases: *sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement*

Class for the elements in the Kirillov-Reshetikhin crystals $B^{n,s}$ of type $D_{n+1}^{(2)}$.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Dn_twisted_with_
->category.element_class'>
```

e0()

Return e_0 on *self* by going to the \pm -diagram corresponding to the $\{2, \dots, n\}$ -highest weight vector in the component of *self*, then applying [Definition 6.2, 4], and pulling back from \pm -diagrams.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['D',4,2],3,3)
sage: b = K.module_generators[0]
sage: b.e(0) # indirect doctest
[+++ , [[2], [3], [0]]]
```

epsilon0()

Calculate ε_0 of *self* using Lemma 6.2 of [4].

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: b = K.module_generators[0]
sage: b.epsilon(0) # indirect doctest
1
```

f0()

Return e_0 on *self* by going to the \pm -diagram corresponding to the $\{2, \dots, n\}$ -highest weight vector in the component of *self*, then applying [Definition 6.2, 4], and pulling back from \pm -diagrams.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: b = K.module_generators[0]
sage: b.f(0) # indirect doctest
```

phi0()

Calculate φ_0 of *self*.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0) # indirect doctest
0
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_E6(*cartan_type*, *r*, *s*)

Bases: *sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotion*

Class of Kirillov-Reshetikhin crystals of type $E_6^{(1)}$ for $r = 1, 2, 6$.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.module_generator().e(0)
[]
sage: K.module_generator().e(0).f(0)
[[2, -1], (1,)]
sage: K = crystals.KirillovReshetikhin(['E',6,1], 1,1)
sage: b = K.module_generator()
sage: b
[(1,)]
sage: b.e(0)
[(-2, 1)]
sage: b = [t for t in K if t.epsilon(1) == 1 and t.phi(3) == 1 and t.phi(2) == 0
↳and t.epsilon(2) == 0][0]
sage: b
[(-1, 3)]
sage: b.e(0)
[(-1, -2, 3)]

```

The elements of the Kirillov-Reshetikhin crystals can be constructed from a classical crystal element using `retract()`.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: La = K.cartan_type().classical().root_system().weight_lattice().fundamental_
↳weights()
sage: H = crystals.HighestWeight(La[2])
sage: t = H.module_generator()
sage: t
[[2, -1], (1,)]
sage: type(K.retract(t))
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_E6_with_category.
↳element_class'>
sage: K.retract(t).e(0)
[]

```

affine_weight(*b*)

Return the affine level zero weight corresponding to the element *b* of the classical crystal underlying `self`.

For the coefficients to calculate the level, see Table Aff 1 in [Ka1990].

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: [K.affine_weight(x.lift()) for x in K
.....: if all(x.epsilon(i) == 0 for i in [2,3,4,5])]
[(0, 0, 0, 0, 0, 0, 0),
 (-2, 0, 1, 0, 0, 0, 0),
 (-1, -1, 0, 0, 0, 1, 0),
 (0, 0, 0, 0, 0, 0, 0),
 (0, 0, 0, 0, 0, 1, -2),
 (0, -1, 1, 0, 0, 0, -1),
 (-1, 0, 0, 1, 0, 0, -1),
 (-1, -1, 0, 0, 1, 0, -1),

```

(continues on next page)

(continued from previous page)

```
(0, 0, 0, 0, 0, 0, 0),
(0, -2, 0, 1, 0, 0, 0)]
```

automorphism_on_affine_weight(*weight*)

Act with the Dynkin diagram automorphism on affine weights as outputted by the `affine_weight` method.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: sorted([x[0], K.automorphism_on_affine_weight(x[0])])
.....: for x in K.highest_weight_dict().values()
[[(-2, 0, 1, 0, 0, 0, 0), (0, -2, 0, 1, 0, 0, 0)],
 [(-1, 0, 0, 1, 0, 0, -1), (-1, -1, 0, 0, 0, 1, 0)],
 [(0, 0, 0, 0, 0, 0, 0), (0, 0, 0, 0, 0, 0, 0)],
 [(0, 0, 0, 0, 0, 0, 0), (0, 0, 0, 0, 0, 0, 0)],
 [(0, 0, 0, 0, 0, 1, -2), (-2, 0, 1, 0, 0, 0, 0)]]
```

classical_decomposition()

Specifies the classical crystal underlying the KR crystal of type $E_6^{(1)}$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2,2)
sage: K.classical_decomposition()
Direct sum of the crystals Family
(Finite dimensional highest weight crystal of type ['E', 6] and highest weight_
↪0,
 Finite dimensional highest weight crystal of type ['E', 6] and highest weight_
↪Lambda[2],
 Finite dimensional highest weight crystal of type ['E', 6] and highest weight_
↪2*Lambda[2])
sage: K = crystals.KirillovReshetikhin(['E',6,1], 1,2)
sage: K.classical_decomposition()
Direct sum of the crystals Family
(Finite dimensional highest weight crystal of type ['E', 6] and highest weight_
↪2*Lambda[1],)
```

dynkin_diagram_automorphism(*i*)

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements.

Here we use the Dynkin diagram automorphism of order 3 which maps node 0 to node 1.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: [K.dynkin_diagram_automorphism(i) for i in K.index_set()]
[1, 6, 3, 5, 4, 2, 0]
```

highest_weight_dict()

Return a dictionary between $\{1, 2, 3, 4, 5\}$ -highest weight elements, and a tuple of affine weights and its classical component.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: sorted(K.highest_weight_dict().items(), key=str)
[[[(2, -1), (1,)], ((-2, 0, 1, 0, 0, 0, 0), 1)],
 [[(3, -1, -6), (1,)], ((-1, 0, 0, 1, 0, 0, -1), 1)],
 [[(5, -2, -6), (-6, 2)], ((0, 0, 0, 0, 0, 1, -2), 1)],
 [[(6, -2), (-6, 2)], ((0, 0, 0, 0, 0, 0, 0), 1)],
 ([], ((0, 0, 0, 0, 0, 0, 0), 0))]

```

highest_weight_dict_inv()

Return a dictionary between a tuple of affine weights and a classical component, and $\{2, 3, 4, 5, 6\}$ -highest weight elements.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.highest_weight_dict_inv()
{((-2, 0, 1, 0, 0, 0, 0), 1): [[(2, -1), (1,)]],
 ((-1, -1, 0, 0, 0, 1, 0), 1): [[(5, -3), (-1, 3)]],
 ((0, -2, 0, 1, 0, 0, 0), 1): [[(-1, ), (-1, 3)]],
 ((0, 0, 0, 0, 0, 0, 0), 0): [],
 ((0, 0, 0, 0, 0, 0, 0), 1): [[(1, -3), (-1, 3)]]}

```

hw_auxiliary()

Return the 2, 3, 4, 5 highest weight elements of self.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.hw_auxiliary()
([], [[(2, -1), (1,)]],
 [[(5, -3), (-1, 3)]],
 [[(6, -2), (-6, 2)]],
 [[(5, -2, -6), (-6, 2)]],
 [[(-1, ), (-6, 2)]],
 [[(3, -1, -6), (1,)]],
 [[(4, -3, -6), (-1, 3)]],
 [[(1, -3), (-1, 3)]],
 [[(-1, ), (-1, 3)]]

```

promotion()

Specifies the promotion operator used to construct the affine type $E_6^{(1)}$ crystal.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',6,1], 2,1)
sage: promotion = K.promotion()
sage: all(promotion(promotion(promotion(b))) == b for b in K.classical_
↳decomposition())
True
sage: K = crystals.KirillovReshetikhin(['E',6,1],1,1)
sage: promotion = K.promotion()
sage: all(promotion(promotion(promotion(b))) == b for b in K.classical_
↳decomposition())
True

```

promotion_inverse()

Return the inverse promotion. Since promotion is of order 3, the inverse promotion is the same as promotion applied twice.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2,1)
sage: p = K.promotion()
sage: p_inv = K.promotion_inverse()
sage: all(p_inv(p(b)) == b for b in K.classical_decomposition())
True
```

promotion_on_highest_weight_vectors()

Return a dictionary of the promotion map on $\{1, 2, 3, 4, 5\}$ -highest weight elements to $\{2, 3, 4, 5, 6\}$ -highest weight elements in self.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2, 1)
sage: dic = K.promotion_on_highest_weight_vectors()
sage: sorted(dic.items(), key=str)
[[[(2, -1), (1,)], [(-1,), (-1, 3)]],
 [[(3, -1, -6), (1,)], [(5, -3), (-1, 3)]],
 [[(5, -2, -6), (-6, 2)], [(2, -1), (1,)]],
 [(6, -2), (-6, 2)], [],
 [], [(1, -3), (-1, 3)]]
```

promotion_on_highest_weight_vectors_function()

Return a lambda function on x defined by `self.promotion_on_highest_weight_vectors()[x]`.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2, 1)
sage: f = K.promotion_on_highest_weight_vectors_function()
sage: f(K.module_generator().lift())
[(-1,), (-1, 3)]
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_E7(ct, r, s)

Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal`

The Kirillov-Reshetikhin crystal $B^{7,s}$ of type $E_7^{(1)}$.

A7_decomposition()

Return the decomposition of self into A_7 highest weight crystals.

The A_7 decomposition of $B^{7,s}$ is given by the parameters $m_4, m_5, m_6, m_7 \geq 0$ such that $m_4 + m_5 \leq m_7$ and $s = m_4 + m_5 + m_6 + m_7$. The corresponding A_7 highest weight crystal has highest weight $\lambda = (m_7 - m_4 - m_5)\Lambda_6 + m_5\Lambda_4 + m_6\Lambda_2$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 3)
sage: K.A7_decomposition()
The crystal of tableaux of type ['A', 7] and shape(s)
[[3, 3, 3, 3, 3, 3], [3, 3, 2, 2, 2, 2], [3, 3, 1, 1, 1, 1], [3, 3],
 [2, 2, 2, 2, 1, 1], [2, 2, 1, 1], [1, 1, 1, 1, 1, 1], [1, 1]]
```

class ElementBases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement`**e0()**Return the action of e_0 on self.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: mg = K.module_generator()
sage: mg.e0()
[[ (7, ), (-1, 7) ]]
sage: mg.e0().e0()
[[ (-1, 7), (-1, 7) ]]
sage: mg.e_string([0,0,0]) is None
True

```

f0()Return the action of f_0 on self.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: mg = K.module_generator()
sage: x = mg.f_string([7,6,5,4,3,2,4,5,6,1,3,4,5,2,4,3,1])
sage: x.f0()
[[ (7, ), (7, ) ]]
sage: mg.f0() is None
True

```

classical_decomposition()

Return the classical decomposition of self.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 4)
sage: K.classical_decomposition()
The crystal of tableaux of type ['E', 7] and shape(s) [[4]]

```

from_A7_crystal()Return the inclusion of the KR crystal $B^{7,s}$ of type $E_7^{(1)}$ into type A_7 highest weight crystals.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: K.from_A7_crystal()
['A', 6] -> ['E', 7, 1] Virtual Crystal morphism:
From: The crystal of tableaux of type ['A', 7] and shape(s)
[[2, 2, 2, 2, 2, 2], [2, 2, 1, 1, 1, 1], [2, 2], [1, 1, 1, 1], []]
To: Kirillov-Reshetikhin crystal of type ['E', 7, 1] with (r,s)=(7,2)
Defn: ...

```

to_A7_crystal()Return the map decomposing the KR crystal $B^{7,s}$ of type $E_7^{(1)}$ into type A_7 highest weight crystals.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: K.to_A7_crystal()
['A', 6] relabelled by {1: 1, 2: 3, 3: 4, 4: 5, 5: 6, 6: 7} -> ['A', 7] Virtual_
↪Crystal morphism:
  From: Kirillov-Reshetikhin crystal of type ['E', 7, 1] with (r,s)=(7,2)
  To:   The crystal of tableaux of type ['A', 7] and shape(s)
        [[2, 2, 2, 2, 2, 2], [2, 2, 1, 1, 1, 1], [2, 2], [1, 1, 1, 1], []]
  Defn: ...

```

class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_box`(*cartan_type*, *r*, *s*)
 Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal`,
`sage.combinat.crystals.affine.AffineCrystalFromClassical`

Class of Kirillov-Reshetikhin crystals $B^{r,s}$ of type $A_{2n}^{(2)}$ for $r \leq n$ and type $D_{n+1}^{(2)}$ for $r < n$.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['A',4,2], 1,1)
sage: K
Kirillov-Reshetikhin crystal of type ['BC', 2, 2] with (r,s)=(1,1)
sage: b = K(rows=[])
sage: b.f(0)
[[1]]
sage: b.e(0)
[[-1]]

```

Element

alias of `KR_type_boxElement`

ambient_crystal()

Return the ambient crystal $B^{r,2s}$ of type $C_n^{(1)}$ associated to the Kirillov-Reshetikhin crystal.

The ambient crystal is used to construct the zero arrows.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['A',4,2], 2,2)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['C', 2, 1] with (r,s)=(2,4)

```

ambient_highest_weight_dict()

Return a dictionary of the classical highest weight vectors of the ambient crystal of `self` whose keys are their shape.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['A',6,2], 2,2)
sage: K.ambient_highest_weight_dict()
{[]: [],
 [2]: [[1, 1]],
 [2, 2]: [[1, 1], [2, 2]],
 [4]: [[1, 1, 1, 1]],
 [4, 2]: [[1, 1, 1, 1], [2, 2]],
 [4, 4]: [[1, 1, 1, 1], [2, 2, 2, 2]]}

```

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type $A_{2n}^{(2)}$ and $D_{n+1}^{(2)}$.

It is given by $B^{r,s} \cong \bigoplus_{\Lambda} B(\Lambda)$, where Λ are weights obtained from a rectangle of width s and height r by removing boxes. Here we identify the fundamental weight Λ_i with a column of height i .

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',4,2], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 2] and shape(s) [[], [1], [2], [1, 1], [2,
↪ 1], [2, 2]]
sage: K = crystals.KirillovReshetikhin(['D',4,2], 2,3)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[], [1], [2], [1, 1], [
↪ 3], [2, 1], [3, 1], [2, 2], [3, 2], [3, 3]]
```

from_ambient_crystal()

Return a map from the ambient crystal of type $C_n^{(1)}$ to the Kirillov-Reshetikhin crystal `self`.

Note that this map is only well-defined on elements that are in the image under `to_ambient_crystal()`.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,2], 1,1)
sage: b = K.ambient_crystal()(rows=[[3, -3]])
sage: K.from_ambient_crystal()(b)
[[0]]
sage: K = crystals.KirillovReshetikhin(['A',4,2], 1,1)
sage: b = K.ambient_crystal()(rows=[])
sage: K.from_ambient_crystal()(b)
[]
```

highest_weight_dict()

Return a dictionary of the classical highest weight vectors of `self` whose keys are 2 times their shape.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',6,2], 2,2)
sage: K.highest_weight_dict()
{[]: [],
 [2]: [[1]],
 [2, 2]: [[1], [2]],
 [4]: [[1, 1]],
 [4, 2]: [[1, 1], [2]],
 [4, 4]: [[1, 1], [2, 2]]}
```

similarity_factor()

Sets the similarity factor used to map to the ambient crystal.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',6,2], 2,2)
sage: K.similarity_factor()
{1: 2, 2: 2, 3: 2}
sage: K = crystals.KirillovReshetikhin(['D',5,2], 1,1)
```

(continues on next page)

(continued from previous page)

```
sage: K.similarity_factor()
{1: 2, 2: 2, 3: 2, 4: 1}
```

to_ambient_crystal()

Return a map from `self` to the ambient crystal of type $C_n^{(1)}$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,2], 1,1)
sage: [K.to_ambient_crystal()(b) for b in K]
[[], [[1, 1]], [[2, 2]], [[3, 3]], [[3, -3]], [[-3, -3]], [[-2, -2]], [[-1, -
↪1]]]
sage: K = crystals.KirillovReshetikhin(['A',4,2], 1,1)
sage: [K.to_ambient_crystal()(b) for b in K]
[[], [[1, 1]], [[2, 2]], [[-2, -2]], [[-1, -1]]]
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_boxElement

Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement`

Class for the elements in the Kirillov-Reshetikhin crystals $B^{r,s}$ of type $A_{2n}^{(2)}$ for $r \leq n$ and type $D_{n+1}^{(2)}$ for $r < n$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',4,2],1,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_box_with_category.
↪element_class'>
```

e0()

Return e_0 on `self` by mapping `self` to the ambient crystal, calculating e_0 there and pulling the element back.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',4,2],1,1)
sage: b = K(rows=[])
sage: b.e(0) # indirect doctest
[[-1]]
```

epsilon0()

Return ε_0 of `self` by mapping the element to the ambient crystal and calculating ε_0 there.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',4,2], 1,1)
sage: b = K(rows=[[1]])
sage: b.epsilon(0) # indirect doctest
2
```

f0()

Return f_0 on `self` by mapping `self` to the ambient crystal, calculating f_0 there and pulling the element back.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['A',4,2],1,1)
sage: b = K(rows=[])
sage: b.f(0) # indirect doctest
[[1]]

```

phi0()

Return φ_0 of self by mapping the element to the ambient crystal and calculating φ_0 there.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['D',3,2],1,1)
sage: b = K(rows=[[-1]])
sage: b.phi(0) # indirect doctest
2

```

class sage.combinat.crystals.kirillov_reshetikhin.**KR_type_spin**(cartan_type, r, s)

Bases: *sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotion*

Class of Kirillov-Reshetikhin crystals $B^{n,s}$ of type $D_n^{(1)}$.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1); K
Kirillov-Reshetikhin crystal of type ['D', 4, 1] with (r,s)=(4,1)
sage: [[b,b.f(0)] for b in K]
[[[++++, []], None], [[+---, []], None], [[+---, []], None],
 [[-+--, []], None], [[-+--, []], None], [[-+--, []], None],
 [[-+--, []], [++++, []]], [[----, []], [++--, []]]]

sage: K = crystals.KirillovReshetikhin(['D',4,1],4,2); K
Kirillov-Reshetikhin crystal of type ['D', 4, 1] with (r,s)=(4,2)
sage: [[b,b.f(0)] for b in K]
[[[1], [2], [3], [4]], None], [[1], [2], [-4], [4]], None],
 [[1], [3], [-4], [4]], None], [[2], [3], [-4], [4]], None],
 [[1], [4], [-4], [4]], None], [[2], [4], [-4], [4]], None],
 [[3], [4], [-4], [4]], [[1], [2], [3], [4]]],
 [[-4], [4], [-4], [4]], [[1], [2], [-4], [4]]],
 [[-4], [4], [-4], [-3]], [[1], [2], [-4], [-3]]],
 [[-4], [4], [-4], [-2]], [[1], [3], [-4], [-3]]],
 [[-4], [4], [-4], [-1]], [[2], [3], [-4], [-3]]],
 [[-4], [4], [-3], [-2]], [[1], [4], [-4], [-3]]],
 [[-4], [4], [-3], [-1]], [[2], [4], [-4], [-3]]],
 [[-4], [4], [-2], [-1]], [[-4], [4], [-4], [4]]],

[[[3], [4], [-3], [-1]], [[2], [4], [-4], [4]]],
[[[3], [4], [-2], [-1]], [[3], [4], [-4], [4]]]]
```

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal $B^{r,s}$ of type $D_n^{(1)}$ for $r = n - 1, n$.

The classical decomposition is given by $B^{n,s} \cong B(s\Lambda_r)$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1/2, 1/2, 1/2, 1/2]]
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1/2, 1/2, 1/2, -1/2]]
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1, 1, 1, -1]]
```

dynkin_diagram_automorphism(i)

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements.

Here we use the Dynkin diagram automorphism which interchanges nodes 0 and 1 and leaves all other nodes unchanged.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1)
sage: K.dynkin_diagram_automorphism(0)
1
sage: K.dynkin_diagram_automorphism(1)
0
sage: K.dynkin_diagram_automorphism(4)
4
```

promotion()

Return the promotion operator on $B^{r,s}$ of type $D_n^{(1)}$ for $r = n - 1, n$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: T = K.classical_decomposition()
sage: promotion = K.promotion()
sage: for t in T:
.....:     print("{} {}".format(t, promotion(t)))
[+++-, []] [-++-, []]
[++-+, []] [-+-+, []]
[+-+++, []] [-+++, []]
[-++++, []] [+++++, []]
[+----, []] [-----, []]
[-+---, []] [-+---, []]
[--+-, []] [-+---, []]
[----+, []] [-+---, []]
```

promotion_inverse()

Return the inverse promotion operator on $B^{r,s}$ of type $D_n^{(1)}$ for $r = n - 1, n$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: T = K.classical_decomposition()
sage: promotion = K.promotion()
sage: promotion_inverse = K.promotion_inverse()
sage: all(promotion_inverse(promotion(t)) == t for t in T)
True
```

promotion_on_highest_weight_vectors()

Return the promotion operator on $\{2, 3, \dots, n\}$ -highest weight vectors.

A $\{2, 3, \dots, n\}$ -highest weight vector in $B(s\Lambda_n)$ of weight $w = (w_1, \dots, w_n)$ is mapped to a $\{2, 3, \dots, n\}$ -highest weight vector in $B(s\Lambda_{n-1})$ of weight $(-w_1, w_2, \dots, w_n)$ and vice versa.

See also:

- [promotion_on_highest_weight_vectors_inverse\(\)](#)
- [promotion\(\)](#)

EXAMPLES:

```
sage: KR = crystals.KirillovReshetikhin(['D',4,1],4,2)
sage: prom = KR.promotion_on_highest_weight_vectors()
sage: T = KR.classical_decomposition()
sage: HW = [t for t in T if t.is_highest_weight([2,3,4])]
sage: for t in HW:
.....:     print("{} {}".format(t, prom[t]))
[[1], [2], [3], [4]] [[2], [3], [4], [-1]]
[[2], [3], [-4], [4]] [[2], [3], [4], [-4]]
[[2], [3], [-4], [-1]] [[1], [2], [3], [-4]]

sage: KR = crystals.KirillovReshetikhin(['D',4,1],4,1)
sage: prom = KR.promotion_on_highest_weight_vectors()
sage: T = KR.classical_decomposition()
sage: HW = [t for t in T if t.is_highest_weight([2,3,4])]
sage: for t in HW:
.....:     print("{} {}".format(t, prom[t]))
[++++, []] [-++++, []]
[-++-, []] [++++-, []]
```

promotion_on_highest_weight_vectors_inverse()

Return the inverse promotion operator on $\{2, 3, \dots, n\}$ -highest weight vectors.

See also:

- [promotion_on_highest_weight_vectors\(\)](#)
- [promotion_inverse\(\)](#)

EXAMPLES:

```

sage: KR = crystals.KirillovReshetikhin(['D',4,1],3,2)
sage: prom = KR.promotion_on_highest_weight_vectors()
sage: prom_inv = KR.promotion_on_highest_weight_vectors_inverse()
sage: T = KR.classical_decomposition()
sage: HW = [t for t in T if t.is_highest_weight([2,3,4])]
sage: all(prom_inv[prom[t]] == t for t in HW)
True

```

class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_vertical`(*cartan_type*, *r*, *s*)
 Bases: `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotion`

Class of Kirillov-Reshetikhin crystals $B^{r,s}$ of type $D_n^{(1)}$ for $r \leq n-2$, $B_n^{(1)}$ for $r < n$, and $A_{2n-1}^{(2)}$ for $r \leq n$.

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: b = K(rows=[])
sage: b.f(0)
[[1], [2]]
sage: b.f(0).f(0)
[[1, 1], [2, 2]]
sage: b.e(0)
[[-2], [-1]]
sage: b.e(0).e(0)
[[-2, -2], [-1, -1]]

sage: K = crystals.KirillovReshetikhin(['D',5,1], 3,1)
sage: b = K(rows=[[1]])
sage: b.e(0)
[[3], [-3], [-2]]

sage: K = crystals.KirillovReshetikhin(['B',3,1], 1,1)
sage: [[b,b.f(0)] for b in K]
[[[[1]], None], [[2]], None], [[3]], None], [[0]], None],
 [[-3]], None], [[-2]], [[1]], [[-1]], [[2]]]]

sage: K = crystals.KirillovReshetikhin(['A',5,2], 1,1)
sage: [[b,b.f(0)] for b in K]
[[[[1]], None], [[2]], None], [[3]], None], [[-3]], None],
 [[-2]], [[1]], [[-1]], [[2]]]]

```

classical_decomposition()

Specifies the classical crystal underlying the Kirillov-Reshetikhin crystal of type $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$.

It is given by $B^{r,s} \cong \bigoplus_{\Lambda} B(\Lambda)$, where Λ are weights obtained from a rectangle of width s and height r by removing vertical dominoes. Here we identify the fundamental weight Λ_i with a column of height i .

EXAMPLES:

```

sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[], [1, 1], [2, 2]]

```

dynkin_diagram_automorphism(*i*)

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements. The

automorphism needs to map node 0 to some other Dynkin node.

Here we use the Dynkin diagram automorphism which interchanges nodes 0 and 1 and leaves all other nodes unchanged.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1],1,1)
sage: K.dynkin_diagram_automorphism(0)
1
sage: K.dynkin_diagram_automorphism(1)
0
sage: K.dynkin_diagram_automorphism(4)
4
```

from_highest_weight_vector_to_pm_diagram(*b*)

This gives the bijection between an element *b* in the classical decomposition of the KR crystal that is 2, 3, ..., *n*-highest weight and \pm diagrams.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: T = K.classical_decomposition()
sage: b = T(rows=[[2],[-2]])
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b); pm
[[1, 1], [0, 0], [0]]
sage: pm.pp()
+
-
sage: b = T(rows=[])
sage: pm=K.from_highest_weight_vector_to_pm_diagram(b); pm
[[0, 2], [0, 0], [0]]
sage: pm.pp()

sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3,4]) ]
sage: all(K.from_pm_diagram_to_highest_weight_vector(K.from_highest_weight_
↪vector_to_pm_diagram(b)) == b for b in hw)
True
```

from_pm_diagram_to_highest_weight_vector(*pm*)

This gives the bijection between a \pm diagram and an element *b* in the classical decomposition of the KR crystal that is 2, 3, ..., *n*-highest weight.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[1, 1], [0, ↪
↪0], [0]])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[[2], [-2]]
```

promotion()

Specifies the promotion operator used to construct the affine type $D_n^{(1)}$ etc. crystal.

This corresponds to the Dynkin diagram automorphism which interchanges nodes 0 and 1, and leaves all other nodes unchanged. On the level of crystals it is constructed using \pm diagrams.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: promotion = K.promotion()
sage: b = K.classical_decomposition()(rows=[])
sage: promotion(b)
[[1, 2], [-2, -1]]
sage: b = K.classical_decomposition()(rows=[[1,3],[2,-1]])
sage: promotion(b)
[[1, 3], [2, -1]]
sage: b = K.classical_decomposition()(rows=[[1],[-3]])
sage: promotion(b)
[[2, -3], [-2, -1]]
```

`promotion_inverse()`

Return inverse of promotion.

In this case promotion is an involution, so promotion inverse equals promotion.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: promotion = K.promotion()
sage: promotion_inverse = K.promotion_inverse()
sage: all( promotion_inverse(promotion(b.lift())) == b.lift() for b in K )
True
```

`promotion_on_highest_weight_vector(b)`

Calculates promotion on a 2, 3, ..., n highest weight vector b .

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: T = K.classical_decomposition()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3,4]) ]
sage: [K.promotion_on_highest_weight_vector(b) for b in hw]
[[[1, 2], [-2, -1]], [[2, 2], [-2, -1]], [[1, 2], [3, -1]],
 [[2], [-2]], [[1, 2], [2, -2]], [[2, 2], [-1, -1]],
 [[2, 2], [3, -1]], [[2, 2], [3, 3]], [], [[1], [2]],
 [[1, 1], [2, 2]], [[2], [-1]], [[1, 2], [2, -1]],
 [[2], [3]], [[1, 2], [2, 3]]]
```

`sage.combinat.crystals.kirillov_reshetikhin.KashiwaraNakashimaTableaux(cartan_type, r, s)`
Return the Kashiwara-Nakashima model for the Kirillov-Reshetikhin crystal $B^{r,s}$ in the given type.

The Kashiwara-Nakashima (KN) model constructs the KR crystal from the KN tableaux model for the corresponding classical crystals. This model is named for the underlying KN tableaux.

Many Kirillov-Reshetikhin crystals are constructed from a classical crystal together with an automorphism p on the level of crystals which corresponds to a Dynkin diagram automorphism mapping node 0 to some other node i . The action of f_0 and e_0 is then constructed using $f_0 = p^{-1} \circ f_i \circ p$.

For example, for type $A_n^{(1)}$ the Kirillov-Reshetikhin crystal $B^{r,s}$ is obtained from the classical crystal $B(s\omega_r)$ using the promotion operator. For other types, see [Shi2002], [Sch2008], and [JS2010].

Other Kirillov-Reshetikhin crystals are constructed using similarity methods. See Section 4 of [FOS2009].

For more information on Kirillov-Reshetikhin crystals, see `KirillovReshetikhinCrystal()`.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2, 1)
sage: K2 = crystals.kirillov_reshetikhin.KashiwaraNakashimaTableaux(['A',3,1], 2, 1)
sage: K is K2
True
```

`sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystal`(*cartan_type*, *r*, *s*, *model='KN'*)

Return the Kirillov-Reshetikhin crystal $B^{r,s}$ of the given type in the given model.

For more information about general crystals see [sage.combinat.crystals.crystals](#).

There are a variety of models for Kirillov-Reshetikhin crystals. There is one using the classical crystal with *Kashiwara-Nakashima tableaux*. There is one using *rigged configurations*. Another tableaux model comes from the bijection between rigged configurations and tensor products of tableaux called *Kirillov-Reshetikhin tableaux*. Lastly there is a model of Kirillov-Reshetikhin crystals for $s = 1$ from crystals of *LS paths*.

INPUT:

- `cartan_type` – an affine Cartan type
- `r` – a label of finite Dynkin diagram
- `s` – a positive integer
- `model` – (default: 'KN') can be one of the following:
 - 'KN' or 'KashiwaraNakashimaTableaux' - use the Kashiwara-Nakashima tableaux model
 - 'KR' or 'KirillovReshetikhinTableaux' - use the Kirillov-Reshetikhin tableaux model
 - 'RC' or 'RiggedConfiguration' - use the rigged configuration model
 - 'LSPaths' - use the LS path model

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2, 1)
sage: K.index_set()
(0, 1, 2, 3)
sage: K.list()
[[[1], [2]], [[1], [3]], [[2], [3]], [[1], [4]], [[2], [4]], [[3], [4]]]
sage: b=K(rows=[[1],[2]])
sage: b.weight()
-Lambda[0] + Lambda[2]

sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.automorphism(K.module_generators[0])
[[2, 2], [3, 3]]
sage: K.module_generators[0].e(0)
[[1, 2], [2, 4]]
sage: K.module_generators[0].f(2)
[[1, 1], [2, 3]]
sage: K.module_generators[0].f(1)
sage: K.module_generators[0].phi(0)
0
sage: K.module_generators[0].phi(1)
```

(continues on next page)

(continued from previous page)

```

0
sage: K.module_generators[0].phi(2)
2
sage: K.module_generators[0].epsilon(0)
2
sage: K.module_generators[0].epsilon(1)
0
sage: K.module_generators[0].epsilon(2)
0
sage: b = K(rows=[[1,2],[2,3]])
sage: b
[[1, 2], [2, 3]]
sage: b.f(2)
[[1, 2], [3, 3]]

sage: K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
sage: K.cartan_type()
['D', 4, 1]
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_vertical_with_category.
↪element_class'>

```

The following gives some tests with regards to Lemma 3.11 in [LOS2012].

`sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromLSPaths`(*cartan_type*, *r*, *s=1*)

Single column Kirillov-Reshetikhin crystals.

This yields the single column Kirillov-Reshetikhin crystals from the projected level zero LS paths, see [CrystalOfLSPaths](#). This works for all types (even exceptional types). The weight of the canonical element in this crystal is Λ_r . For other implementation see [KirillovReshetikhinCrystal\(\)](#).

EXAMPLES:

```

sage: K = crystals.kirillov_reshetikhin.LSPaths(['A',2,1],2) # indirect doctest
sage: KR = crystals.KirillovReshetikhin(['A',2,1],2,1)
sage: G = K.digraph()
sage: GR = KR.digraph()
sage: G.is_isomorphic(GR, edge_labels = True)
True

sage: K = crystals.kirillov_reshetikhin.LSPaths(['C',3,1],2)
sage: KR = crystals.KirillovReshetikhin(['C',3,1],2,1)
sage: G = K.digraph()
sage: GR = KR.digraph()

```

(continues on next page)

(continued from previous page)

```

sage: G.is_isomorphic(GR, edge_labels = True)
True

sage: K = crystals.kirillov_reshetikhin.LSPaths(['E',6,1],1)
sage: KR = crystals.KirillovReshetikhin(['E',6,1],1,1)
sage: G = K.digraph()
sage: GR = KR.digraph()
sage: G.is_isomorphic(GR, edge_labels = True)
True
sage: K.cardinality()
27

sage: K = crystals.kirillov_reshetikhin.LSPaths(['G',2,1],1)
sage: K.cardinality()
7

sage: K = crystals.kirillov_reshetikhin.LSPaths(['B',3,1],2)

class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotion(cartan_type,
                                                                                               r,
                                                                                               s)

```

Bases: [sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal](#),
[sage.combinat.crystals.affine.AffineCrystalFromClassicalAndPromotion](#)

This generic class assumes that the Kirillov-Reshetikhin crystal is constructed from a classical crystal using the `classical_decomposition` and an automorphism promotion and its inverse, which corresponds to a Dynkin diagram automorphism `dynkin_diagram_automorphism`.

Each instance using this class needs to implement the methods:

- `classical_decomposition`
- `promotion`
- `promotion_inverse`
- `dynkin_diagram_automorphism`

Element

alias of [KirillovReshetikhinCrystalFromPromotionElement](#)

```

class sage.combinat.crystals.kirillov_reshetikhin.
KirillovReshetikhinCrystalFromPromotionElement

```

Bases: [sage.combinat.crystals.affine.AffineCrystalFromClassicalAndPromotionElement](#),
[sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement](#)

Element for a Kirillov-Reshetikhin crystal from promotion.

`class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal`(*cartan_type*,
r, *s*,
dual=None)

Bases: `sage.combinat.crystals.affine.AffineCrystalFromClassical`

Generic class for Kirillov-Reshetikhin crystal $B^{r,s}$ of the given type.

Input is a Dynkin node *r*, a positive integer *s*, and a Cartan type *cartan_type*.

Element

alias of `KirillovReshetikhinGenericCrystalElement`

classically_highest_weight_vectors()

Return the classically highest weight vectors of self.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
sage: K.classically_highest_weight_vectors()
([], [[1], [2]], [[1, 1], [2, 2]])
```

kirillov_reshetikhin_tableaux()

Return the corresponding set of `KirillovReshetikhinTableaux`.

EXAMPLES:

```
sage: KRC = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
sage: KRC.kirillov_reshetikhin_tableaux()
Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and shape (2, 2)
```

module_generator()

Return the unique module generator of classical weight $s\Lambda_r$ of a Kirillov-Reshetikhin crystal $B^{r,s}$

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C', 2, 1], 1, 2)
sage: K.module_generator()
[[1, 1]]
sage: K = crystals.KirillovReshetikhin(['E', 6, 1], 1, 1)
sage: K.module_generator()
[(1,)]
sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1)
sage: K.module_generator()
[[1], [2]]
```

r()

Return *r* of the underlying Kirillov-Reshetikhin crystal $B^{r,s}$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1)
sage: K.r()
2
```

s()

Return *s* of the underlying Kirillov-Reshetikhin crystal $B^{r,s}$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
sage: K.s()
1
```

class

sage.combinat.crystals.kirillov_reshetikhin.**KirillovReshetikhinGenericCrystalElement**

Bases: *sage.combinat.crystals.affine.AffineCrystalFromClassicalElement*

Abstract class for all Kirillov-Reshetikhin crystal elements.

lusztig_involution()

Return the classical Lusztig involution on self.

EXAMPLES:

```
sage: KRC = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: elt = KRC(-1,2); elt
[[2], [-1]]
sage: elt.lusztig_involution()
[[1], [-2]]
```

pp()

Pretty print self.

EXAMPLES:

```
sage: C = crystals.KirillovReshetikhin(['D',4,1], 2,1)
sage: C(2,1).pp()
1
2
sage: C = crystals.KirillovReshetikhin(['B',3,1], 3,3)
sage: C.module_generators[0].pp()
+ (X) 1
+
+
```

to_kirillov_reshetikhin_tableau()

Construct the corresponding *KirillovReshetikhinTableauxElement* from self.

We construct the Kirillov-Reshetikhin tableau element as follows:

1. Let λ be the shape of self.
2. Determine a path $e_{i_1}e_{i_2}\cdots e_{i_k}$ to the highest weight.
3. Apply $f_{i_k}\cdots f_{i_2}f_{i_1}$ to a highest weight KR tableau from filling the shape λ .

EXAMPLES:

```
sage: KRC = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1)
sage: KRC(columns=[[2,1]]).to_kirillov_reshetikhin_tableau()
[[1], [2]]
sage: KRC = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1)
sage: KRC(rows=[]).to_kirillov_reshetikhin_tableau()
[[1], [-1]]
```

to_tableau()

Return the *Tableau* corresponding to self.

EXAMPLES:

```

sage: C = crystals.KirillovReshetikhin(['D',4,1], 2,1)
sage: t = C(2,1).to_tableau(); t
[[1], [2]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>

```

class `sage.combinat.crystals.kirillov_reshetikhin.PMDiagram`(*pm_diagram*, *from_shapes=None*)
 Bases: `sage.combinat.combinat.CombinatorialObject`

Class of \pm diagrams. These diagrams are in one-to-one bijection with X_{n-1} highest weight vectors in an X_n highest weight crystal $X = B, C, D$. See Section 4.1 of [Sch2008].

The input is a list $pm = [[a_0, b_0], [a_1, b_1], \dots, [a_{n-1}, b_{n-1}], [b_n]]$ of pairs and a last 1-tuple (or list of length 1). The pair $[a_i, b_i]$ specifies the number of $a_i +$ and $b_i -$ in the i -th row of the \pm diagram if $n - i$ is odd and the number of $a_i \pm$ pairs above row i and b_i columns of height i not containing any $+$ or $-$ if $n - i$ is even.

Setting the option `from_shapes = True` one can also input a \pm diagram in terms of its outer, intermediate, and inner shape by specifying a list `[n, s, outer, intermediate, inner]` where `s` is the width of the \pm diagram, and `outer`, `intermediate`, and `inner` are the outer, intermediate, and inner shapes, respectively.

EXAMPLES:

```

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0,1],[1,2],[1]])
sage: pm.pm_diagram
[[0, 1], [1, 2], [1]]
sage: pm._list
[1, 1, 2, 0, 1]
sage: pm.n
2
sage: pm.width
5
sage: pm.pp()
. . . .
. + - -
sage: PMDiagram([2,5,[4,4],[4,2],[4,1]], from_shapes=True)
[[0, 1], [1, 2], [1]]

```

heights_of_addable_plus()

Return a list with the heights of all addable plus in the \pm diagram.

EXAMPLES:

```

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.heights_of_addable_plus()
[1, 1, 2, 3, 4, 5]
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.heights_of_addable_plus()
[1, 2, 3, 4]

```

heights_of_minus()

Return a list with the heights of all minus in the \pm diagram.

EXAMPLES:

```

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.heights_of_minus()
[5, 5, 3, 3, 1, 1]
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.heights_of_minus()
[4, 4, 2, 2]

```

inner_shape()

Return the inner shape of the pm diagram

EXAMPLES:

```

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0,1],[1,2],[1]])
sage: pm.inner_shape()
[4, 1]
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.inner_shape()
[7, 5, 3, 1]
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.inner_shape()
[10, 7, 5, 3, 1]

```

intermediate_shape()

Return the intermediate shape of the pm diagram (inner shape plus positions of plusses)

EXAMPLES:

```

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0,1],[1,2],[1]])
sage: pm.intermediate_shape()
[4, 2]
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.intermediate_shape()
[8, 6, 4, 2]
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.intermediate_shape()
[11, 8, 6, 4, 2]
sage: pm = PMDiagram([[1,0],[0,1],[2,0],[0,0],[0]])
sage: pm.intermediate_shape()
[4, 2, 2]
sage: pm = PMDiagram([[1,0],[0,0],[0,0],[0,0],[0]])
sage: pm.intermediate_shape()
[1]

```

outer_shape()

Return the outer shape of the \pm diagram

EXAMPLES:

```

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0,1],[1,2],[1]])
sage: pm.outer_shape()
[4, 4]

```

(continues on next page)

(continued from previous page)

```

sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.outer_shape()
[8, 8, 4, 4]
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.outer_shape()
[13, 8, 8, 4, 4]

```

pp()

Pretty print self.

EXAMPLES:

```

sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[1,0],[0,1],[2,0],[0,0],[0]])
sage: pm.pp()
. . . +
. . - -
+ +
- -
sage: pm = PMDiagram([[0,2],[0,0],[0]])
sage: pm.pp()

```

sigma()

Return sigma on pm diagrams as needed for the analogue of the Dynkin diagram automorphism that interchanges nodes 0 and 1 for type $D_n(1)$, $B_n(1)$, $A_{2n-1}(2)$ for Kirillov-Reshetikhin crystals.

EXAMPLES:

```

sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[0,1],[1,2],
↔[1]])
sage: pm.sigma()
[[1, 0], [2, 1], [1]]

```

`sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(r, s)`

Returns all partitions obtained from a rectangle of width *s* and height *r* by removing horizontal dominoes.

EXAMPLES:

```

sage: sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(2,2)
[[], [2], [2, 2]]
sage: sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(3,2)
[[], [2], [2, 2], [2, 2, 2]]

```

`sage.combinat.crystals.kirillov_reshetikhin.partitions_in_box(r, s)`

Returns all partitions in a box of width *s* and height *r*.

EXAMPLES:

```

sage: sage.combinat.crystals.kirillov_reshetikhin.partitions_in_box(3,2)
[[], [1], [2], [1, 1], [2, 1], [1, 1, 1], [2, 2], [2, 1, 1],
[2, 2, 1], [2, 2, 2]]

```

`sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(r, s)`

Returns all partitions obtained from a rectangle of width *s* and height *r* by removing vertical dominoes.

EXAMPLES:

```

sage: sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(2,2)
[[], [1, 1], [2, 2]]
sage: sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(3,2)
[[2], [2, 1, 1], [2, 2, 2]]
sage: sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(4,2)
[[], [1, 1], [1, 1, 1, 1], [2, 2], [2, 2, 1, 1], [2, 2, 2, 2]]

```

5.1.55 Kyoto Path Model for Affine Highest Weight Crystals

class `sage.combinat.crystals.kyoto_path_model.KyotoPathModel`(*crystals, weight, P*)

Bases: `sage.combinat.crystals.tensor_product.TensorProductOfCrystals`

The Kyoto path model for an affine highest weight crystal.

Note: Here we are using anti-Kashiwara notation and might differ from some of the literature.

Consider a Kac–Moody algebra \mathfrak{g} of affine Cartan type X , and we want to model the $U'_q(\mathfrak{g})$ -crystal $B(\lambda)$. First we consider the set of fundamental weights $\{\Lambda_i\}_{i \in I}$ of \mathfrak{g} and let $\{\bar{\Lambda}_i\}_{i \in I_0}$ be the corresponding fundamental weights of the corresponding classical Lie algebra \mathfrak{g}_0 . To model $B(\lambda)$, we start with a sequence of perfect $U'_q(\mathfrak{g})$ -crystals $(B^{(i)})_i$ of level l such that

$$\lambda \in \bar{P}_l^+ = \left\{ \mu \in \bar{P}^+ \mid \langle c, \mu \rangle = l \right\}$$

where c is the canonical central element of $U'_q(\mathfrak{g})$ and \bar{P}^+ is the nonnegative weight lattice spanned by $\{\bar{\Lambda}_i \mid i \in I\}$.

Next we consider the crystal isomorphism $\Phi_0 : B(\lambda_0) \rightarrow B^{(0)} \otimes B(\lambda_1)$ defined by $u_{\lambda_0} \mapsto b_{\lambda_0}^{(0)} \otimes u_{\lambda_1}$ where $b_{\lambda_0}^{(0)}$ is the unique element in $B^{(0)}$ such that $\varphi(b_{\lambda_0}^{(0)}) = \lambda_0$ and $\lambda_1 = \varepsilon(b_{\lambda_0}^{(0)})$ and u_{μ} is the highest weight element in $B(\mu)$. Iterating this, we obtain the following isomorphism:

$$\Phi_n : B(\lambda) \rightarrow B^{(0)} \otimes B^{(1)} \otimes \cdots \otimes B^{(N)} \otimes B(\lambda_{N+1}).$$

We note by Lemma 10.6.2 in [HK2002] that for any $b \in B(\lambda)$ there exists a finite N such that

$$\Phi_N(b) = \left(\bigotimes_{k=0}^{N-1} b^{(k)} \right) \otimes u_{\lambda_N}.$$

Therefore we can model elements $b \in B(\lambda)$ as a $U'_q(\mathfrak{g})$ -crystal by considering an infinite list of elements $b^{(k)} \in B^{(k)}$ and defining the crystal structure by:

$$\begin{aligned} \overline{\text{wt}}(b) &= \lambda_N + \sum_{k=0}^{N-1} \overline{\text{wt}}(b^{(k)}) \\ e_i(b) &= e_i(b' \otimes b^{(N)}) \otimes u_{\lambda_N}, \\ f_i(b) &= f_i(b' \otimes b^{(N)}) \otimes u_{\lambda_N}, \\ \varepsilon_i(b) &= \max(\varepsilon_i(b') - \varphi_i(b^{(N)}), 0), \\ \varphi_i(b) &= \varphi_i(b') + \max(\varphi_i(b^{(N)}) - \varepsilon_i(b'), 0), \end{aligned}$$

where $b' = b^{(0)} \otimes \dots \otimes b^{(N-1)}$. To translate this into a finite list, we consider a finite sequence $b^{(0)} \otimes \dots \otimes b^{(N-1)} \otimes b_{\lambda_N}^{(N)}$ and if

$$f_i \left(b^{(0)} \otimes \dots \otimes b^{(N-1)} \otimes b_{\lambda_N}^{(N)} \right) = b_0 \otimes \dots \otimes b^{(N-1)} \otimes f_i \left(b_{\lambda_N}^{(N)} \right),$$

then we take the image as $b^{(0)} \otimes \dots \otimes f_i \left(b_{\lambda_N}^{(N)} \right) \otimes b_{\lambda_{N+1}}^{(N+1)}$. Similarly we remove $b_{\lambda_N}^{(N)}$ if we have $b_0 \otimes \dots \otimes b^{(N-1)} \otimes b_{\lambda_{N-1}}^{(N-1)} \otimes b_{\lambda_N}^{(N)}$. Additionally if

$$e_i \left(b^{(0)} \otimes \dots \otimes b^{(N-1)} \otimes b_{\lambda_N}^{(N)} \right) = b^{(0)} \otimes \dots \otimes b^{(N-1)} \otimes e_i \left(b_{\lambda_N}^{(N)} \right),$$

then we consider this to be 0.

We can then lift the $U'_q(\mathfrak{g})$ -crystal structure to a $U_q(\mathfrak{g})$ -crystal structure by using a tensor product of the *affinization* of the of crystals $B^{(i)}$ for all i .

INPUT:

- B – a single or list of U'_q perfect crystal(s) of level l
- weight – a weight in \overline{P}_l^+

EXAMPLES:

```
sage: B = crystals.KirillovReshetikhin(['A', 2, 1], 1, 1)
sage: La = RootSystem(['A', 2, 1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[3]]]
sage: mg.f_string([0, 1, 2, 2])
[[[3]], [[3]], [[1]]]
sage: x = mg.f_string([0, 1, 2]); x
[[[2]], [[3]], [[1]]]
sage: x.weight()
Lambda[0]
```

An example of type $A_5^{(2)}$:

```
sage: B = crystals.KirillovReshetikhin(['A', 5, 2], 1, 1)
sage: La = RootSystem(['A', 5, 2]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[-1]]]
sage: mg.f_string([0, 2, 1, 3])
[[[-3]], [[2]], [[-1]]]
sage: mg.f_string([0, 2, 3, 1])
[[[-3]], [[2]], [[-1]]]
```

An example of type $D_3^{(2)}$:

```
sage: B = crystals.KirillovReshetikhin(['D', 3, 2], 1, 1)
sage: La = RootSystem(['D', 3, 2]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[]]]
sage: mg.f_string([0, 1, 2, 0])
[[[0]], [[1]], []]
```

An example using multiple crystals of the same level:

```
sage: B1 = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A',2,1], 2,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1, B2, B1], La[0])
sage: mg = C.module_generators[0]; mg
[[[3]]]
sage: mg.f_string([0,1,2,2])
[[[3]], [[1], [3]], [[3]]]
sage: mg.f_string([0,1,2,2,2])
sage: mg.f_string([0,1,2,2,1,0])
[[[3]], [[2], [3]], [[1]], [[2]]]
sage: mg.f_string([0,1,2,2,1,0,0,2])
[[[3]], [[1], [2]], [[1]], [[3]], [[1], [3]]]
```

By using the extended weight lattice, the Kyoto path model lifts the perfect crystals to their affinizations:

```
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: La = P.fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[3]](0)]
sage: x = mg.f_string([0,1,2]); x
[[[2]](-1), [[3]](0), [[1]](0)]
sage: x.weight()
Lambda[0] - delta
```

class Element

Bases: *sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement*

An element in the Kyoto path model.

e(i)

Return the action of e_i on self.

EXAMPLES:

```
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: all(mg.e(i) is None for i in C.index_set())
True
sage: mg.f(0).e(0) == mg
True
```

epsilon(i)

Return ε_i of self.

EXAMPLES:

```
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
```

(continues on next page)

(continued from previous page)

```

sage: mg = C.module_generators[0]
sage: [mg.epsilon(i) for i in C.index_set()]
[0, 0, 0]
sage: elt = mg.f(0)
sage: [elt.epsilon(i) for i in C.index_set()]
[1, 0, 0]
sage: elt = mg.f_string([0,1,2])
sage: [elt.epsilon(i) for i in C.index_set()]
[0, 0, 1]
sage: elt = mg.f_string([0,1,2,2])
sage: [elt.epsilon(i) for i in C.index_set()]
[0, 0, 2]

```

f(i)Return the action of f_i on self.

EXAMPLES:

```

sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: mg.f(2)
sage: mg.f(0)
[[[1]], [[2]]]
sage: mg.f_string([0,1,2])
[[[2]], [[3]], [[1]]]

```

phi(i)Return φ_i of self.

EXAMPLES:

```

sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: [mg.phi(i) for i in C.index_set()]
[1, 0, 0]
sage: elt = mg.f(0)
sage: [elt.phi(i) for i in C.index_set()]
[0, 1, 1]
sage: elt = mg.f_string([0,1])
sage: [elt.phi(i) for i in C.index_set()]
[0, 0, 2]

```

truncate(k=None)

Truncate self to have length k and return as an element in a (finite) tensor product of crystals.

INPUT:

- k – (optional) the length to truncate to; if not specified, then returns one more than the current non-ground-state elements (i.e. the current list in self)

EXAMPLES:

```

sage: B1 = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A',2,1], 2,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1,B2,B1], La[0])
sage: mg = C.highest_weight_vector()
sage: elt = mg.f_string([0,1,2,2,1,0]); elt
[[[3]], [[2], [3]], [[1]], [[2]]]
sage: t = elt.truncate(); t
[[[3]], [[2], [3]], [[1]], [[2]]]
sage: t.parent() is C.finite_tensor_product(4)
True
sage: elt.truncate(2)
[[[3]], [[2], [3]]]
sage: elt.truncate(10)
[[[3]], [[2], [3]], [[1]], [[2]], [[1], [3]],
 [[2]], [[1]], [[2], [3]], [[1]], [[3]]]

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: La = P.fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: mg.weight()
Lambda[0]
sage: mg.f_string([0,1,2]).weight()
Lambda[0] - delta

```

finite_tensor_product(k)

Return the finite tensor product of crystals of length k from truncating self.

EXAMPLES:

```

sage: B1 = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A',2,1], 2,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1,B2,B1], La[0])
sage: C.finite_tensor_product(5)
Full tensor product of the crystals
[Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(2,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
 Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(2,1)]

```

weight_lattice_realization()

Return the weight lattice realization used to express weights.

EXAMPLES:

```

sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: C.weight_lattice_realization()
Weight lattice of the Root system of type ['A', 2, 1]

sage: P = RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: C = crystals.KyotoPathModel(B, P.fundamental_weight(0))
sage: C.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]

```

5.1.56 Crystals of letters

class `sage.combinat.crystals.letters.BKKLetter`

Bases: `sage.combinat.crystals.letters.Letter`

e(*i*)

Return the action of e_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', [2, 1]])
sage: c = C(-2)
sage: c.e(-2)
-3
sage: c = C(1)
sage: c.e(0)
-1
sage: c = C(2)
sage: c.e(1)
1
sage: c.e(-2)

```

f(*i*)

Return the action of f_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', [2, 1]])
sage: c = C.an_element()
sage: c.f(-2)
-2
sage: c = C(-1)
sage: c.f(0)
1
sage: c = C(1)
sage: c.f(1)
2
sage: c.f(-2)

```

weight()

Return weight of self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', [2, 1]])
sage: c = C(-1)
sage: c.weight()
(0, 0, 1, 0, 0)
sage: c = C(2)
sage: c.weight()
(0, 0, 0, 0, 1)

```

```

class sage.combinat.crystals.letters.ClassicalCrystalOfLetters(cartan_type, element_class,
                                                                element_print_style=None,
                                                                dual=None)

```

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

A generic class for classical crystals of letters.

All classical crystals of letters should be instances of this class or of subclasses. To define a new crystal of letters, one only needs to implement a class for the elements (which subclasses `Letter`), with appropriate e_i and f_i operations. If the module generator is not 1, one also needs to define the subclass `ClassicalCrystalOfLetters` for the crystal itself.

The basic assumption is that crystals of letters are small, but used intensively as building blocks. Therefore, we explicitly build in memory the list of all elements, the crystal graph and its transitive closure, so as to make the following operations constant time: `list`, `cmp`, (todo: `phi`, `epsilon`, `e`, and `f` with caching)

list()

Return a list of the elements of `self`.

EXAMPLES:

```

sage: C = crystals.Letters(['A', 5])
sage: C.list()
[1, 2, 3, 4, 5, 6]

```

lt_elements(x, y)

Return True if and only if there is a path from `x` to `y` in the crystal graph, when `x` is not equal to `y`.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:

```

sage: C = crystals.Letters(['A', 5])
sage: x = C(1)
sage: y = C(2)
sage: C.lt_elements(x,y)
True
sage: C.lt_elements(y,x)
False
sage: C.lt_elements(x,x)
False
sage: C = crystals.Letters(['D', 4])
sage: C.lt_elements(C(4),C(-4))
False
sage: C.lt_elements(C(-4),C(4))
False

```

class `sage.combinat.crystals.letters.ClassicalCrystalOfLettersWrapped`(*cartan_type*)

Bases: `sage.combinat.crystals.letters.ClassicalCrystalOfLetters`

Crystal of letters by wrapping another crystal.

This is used for a crystal of letters of type E_8 and F_4 .

This class follows the same output as the other crystal of letters, where b is represented by the “letter” with $\varphi_i(b)$ (resp., ε_i) number of i ’s (resp., $-i$ ’s or \bar{i} ’s). However, this uses an auxiliary crystal to construct these letters to avoid hardcoding the crystal elements and the corresponding edges; in particular, the 248 nodes of E_8 .

class `sage.combinat.crystals.letters.CrystalOfBKKLetters`(*ct*, *dual*)

Bases: `sage.combinat.crystals.letters.ClassicalCrystalOfLetters`

Crystal of letters for Benkart-Kang-Kashiwara supercrystals.

This implements the $\mathfrak{gl}(m|n)$ crystal of Benkart, Kang and Kashiwara [BKK2000].

EXAMPLES:

```
sage: C = crystals.Letters(['A', [1, 1]]); C
The crystal of letters for type ['A', [1, 1]]

sage: C = crystals.Letters(['A', [2, 4]], dual=True); C
The crystal of letters for type ['A', [2, 4]] (dual)
```

Element

alias of `BKKLetter`

`sage.combinat.crystals.letters.CrystalOfLetters`(*cartan_type*, *element_print_style=None*, *dual=None*)

Return the crystal of letters of the given type.

For classical types, this is a combinatorial model for the crystal with highest weight Λ_1 (the first fundamental weight).

Any irreducible classical crystal appears as the irreducible component of the tensor product of several copies of this crystal (plus possibly one copy of the spin crystal, see `CrystalOfSpins`). See [KN1994]. Elements of this irreducible component have a fixed shape, and can be fit inside a tableau shape. Otherwise said, any irreducible classical crystal is isomorphic to a crystal of tableaux with cells filled by elements of the crystal of letters (possibly tensored with the crystal of spins).

We also have the crystal of fundamental representation of the general linear Lie superalgebra, which are used as letters inside of tableaux following [BKK2000]. Similarly, all of these crystals appear as a subcrystal of a sufficiently large tensor power of this crystal.

INPUT:

- T – a Cartan type

EXAMPLES:

```
sage: C = crystals.Letters(['A', 5])
sage: C.list()
[1, 2, 3, 4, 5, 6]
sage: C.cartan_type()
['A', 5]
```

For type E_6 , one can also specify how elements are printed. This option is usually set to None and the default representation is used. If one chooses the option ‘compact’, the elements are printed in the more compact convention with 27 letters +abcdefghijklmnopqrstuvwxyz and the 27 letters -ABCDEFGHIJKLMNPOQRSTUVWXYZ for the dual crystal.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], element_print_style = 'compact')
sage: C
The crystal of letters for type ['E', 6]
sage: C.list()
[+, a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z]
sage: C = crystals.Letters(['E',6], element_print_style = 'compact', dual = True)
sage: C
The crystal of letters for type ['E', 6] (dual)
sage: C.list()
[-, A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, U, V, W, X, Y, Z]
```

class `sage.combinat.crystals.letters.CrystalOfQueerLetters(ct)`
 Bases: `sage.combinat.crystals.letters.ClassicalCrystalOfLetters`

Queer crystal of letters elements.

The index set is of the form $\{-n, \dots, -1, 1, \dots, n\}$. For $1 < i \leq n$, the operators e_{-i} and f_{-i} are defined as

$$f_{-i} = s_{w_i}^{-1} f_{-1} s_{w_i}, \quad e_{-i} = s_{w_i}^{-1} e_{-1} s_{w_i},$$

where $w_i = s_2 \cdots s_i s_1 \cdots s_{i-1}$ and s_i is the reflection along the i -string in the crystal. See [GJK+2014].

Element

alias of `QueerLetter_element`

index_set()

Return index set of self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: Q.index_set()
(1, 2, -2, -1)
```

class `sage.combinat.crystals.letters.Crystal_of_letters_type_A_element`

Bases: `sage.combinat.crystals.letters.Letter`

Type A crystal of letters elements.

e(*i*)

Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['A',4])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1), (3, 2, 2), (4, 3, 3), (5, 4, 4)]
```

epsilon(*i*)

Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['A',4])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (3, 2), (4, 3), (5, 4)]
```

f(i)Return the action of f_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['A',4])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2), (2, 2, 3), (3, 3, 4), (4, 4, 5)]
```

phi(i)Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['A',4])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (2, 2), (3, 3), (4, 4)]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Letters(['A',3])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_B_elementBases: [sage.combinat.crystals.letters.Letter](#)Type B crystal of letters elements.**e(i)**Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['B',4])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (0, 4, 4),
 (-4, 4, 0)]
```

epsilon(i)Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['B',3])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (0, 3), (-3, 3)]
```

f(i)Return the actions of f_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['B',4])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2),
 (-2, 1, -1),
 (2, 2, 3),
 (-3, 2, -2),
 (3, 3, 4),
 (-4, 3, -3),
 (4, 4, 0),
 (0, 4, -4)]
```

phi(*i*)

Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['B',3])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3), (0, 3)]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Letters(['B',3])]
[(1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (0, 0, 0),
 (0, 0, -1),
 (0, -1, 0),
 (-1, 0, 0)]
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_C_element

Bases: [sage.combinat.crystals.letters.Letter](#)

Type *C* crystal of letters elements.

e(*i*)

Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['C',4])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (-4, 4, 4)]
```

epsilon(*i*)Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['C',3])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (-3, 3)]
```

f(*i*)Return the action of f_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['C',4])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2), (-2, 1, -1), (2, 2, 3),
 (-3, 2, -2), (3, 3, 4), (-4, 3, -3), (4, 4, -4)]
```

phi(*i*)Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['C',3])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3)]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Letters(['C',3])]
[(1, 0, 0), (0, 1, 0), (0, 0, 1), (0, 0, -1), (0, -1, 0), (-1, 0, 0)]
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_D_elementBases: *sage.combinat.crystals.letters.Letter*Type *D* crystal of letters elements.**e(*i*)**Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['D',5])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3),
 (4, 3, 3),
 (-3, 3, -4),
 (5, 4, 4),
 (-4, 4, -5),
 (-5, 5, 4),
 (-4, 5, 5)]
```

epsilon(i)Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['D',4])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (4, 3), (-3, 3), (-4, 4), (-3, 4)]
```

f(i)Return the action of f_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['D',5])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2),
 (-2, 1, -1),
 (2, 2, 3),
 (-3, 2, -2),
 (3, 3, 4),
 (-4, 3, -3),
 (4, 4, 5),
 (-5, 4, -4),
 (4, 5, -5),
 (5, 5, -4)]
```

phi(i)Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['D',4])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3), (-4, 3), (3, 4), (4, 4)]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Letters(['D',4])]
[(1, 0, 0, 0),
 (0, 1, 0, 0),
 (0, 0, 1, 0),
 (0, 0, 0, 1),
 (0, 0, 0, -1),
 (0, 0, -1, 0),
 (0, -1, 0, 0),
 (-1, 0, 0, 0)]
```

class sage.combinat.crystals.letters.**Crystal_of_letters_type_E6_element**

Bases: *sage.combinat.crystals.letters.LetterTuple*Type E_6 crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_1)$.**e(i)**Return the action of e_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['E',6])
sage: C((-1,3)).e(1)
(1,)
sage: C((-2,-3,4)).e(2)
(-3, 2)
sage: C((1,)).e(1)

```

f(i)Return the action of f_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['E',6])
sage: C((1,)).f(1)
(-1, 3)
sage: C((-6,)).f(1)

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: [v.weight() for v in crystals.Letters(['E',6])]
[(0, 0, 0, 0, 0, -2/3, -2/3, 2/3),
 (-1/2, 1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, 1/2, -1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, -1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (0, 0, 0, 0, 1, 1/3, 1/3, -1/3),
 (1/2, 1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (-1/2, 1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (0, 0, 0, 1, 0, 1/3, 1/3, -1/3),
 (-1/2, 1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (0, 0, 1, 0, 0, 1/3, 1/3, -1/3),
 (1/2, 1/2, -1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (0, 1, 0, 0, 0, 1/3, 1/3, -1/3),
 (1, 0, 0, 0, 0, 1/3, 1/3, -1/3),
 (0, -1, 0, 0, 0, 1/3, 1/3, -1/3),
 (0, 0, -1, 0, 0, 1/3, 1/3, -1/3),
 (0, 0, 0, -1, 0, 1/3, 1/3, -1/3),
 (0, 0, 0, 0, -1, 1/3, 1/3, -1/3),
 (-1/2, -1/2, -1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (-1, 0, 0, 0, 0, 1/3, 1/3, -1/3)]

```

```

class sage.combinat.crystals.letters.Crystal_of_letters_type_E6_element_dual

```

```

    Bases: sage.combinat.crystals.letters.LetterTuple

```

Type E_6 crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_6)$. This crystal is dual to $B(\Lambda_1)$ of type E_6 .

e(i)

Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: C((-1,)).e(1)
(1, -3)
```

f(i)

Return the action of f_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: C((6,)).f(6)
(5, -6)
sage: C((6,)).f(1)
```

lift()

Lift an element of self to the crystal of letters `crystals.Letters(['E',6])` by taking its inverse weight.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: b = C.module_generators[0]
sage: b.lift()
(-6,)
```

retract(p)

Retract element p, which is an element in `crystals.Letters(['E',6])` to an element in `crystals.Letters(['E',6], dual=True)` by taking its inverse weight.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6])
sage: Cd = crystals.Letters(['E',6], dual = True)
sage: b = Cd.module_generators[0]
sage: p = C((-1,3))
sage: b.retract(p)
(1, -3)
sage: b.retract(None)
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: b=C.module_generators[0]
sage: b.weight()
(0, 0, 0, 0, 1, -1/3, -1/3, 1/3)
sage: [v.weight() for v in C]
```

(continues on next page)

(0, 0, 0, 0, 0, 2/3, 2/3, -2/3)]
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_E7_element

Bases: `sage.combinat.crystals.letters.LetterTuple`

Type E_7 crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_7)$.

e(*i*)

Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 7])
sage: C((7,)).e(7)
sage: C((-7, 6)).e(7)
(7,)
```

f(*i*)

Return the action of f_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 7])
sage: C((-7,)).f(7)
sage: C((7,)).f(7)
(-7, 6)
```

weight()

Return the weight of self.

EXAMPLES:

```

sage: [v.weight() for v in crystals.Letters(['E',7])]
[(0, 0, 0, 0, 0, 1, -1/2, 1/2), (0, 0, 0, 0, 1, 0, -1/2, 1/2), (0, 0, 0,
1, 0, 0, -1/2, 1/2), (0, 0, 1, 0, 0, 0, -1/2, 1/2), (0, 1, 0, 0, 0, 0,
-1/2, 1/2), (-1, 0, 0, 0, 0, 0, -1/2, 1/2), (1, 0, 0, 0, 0, 0, -1/2,
1/2), (1/2, 1/2, 1/2, 1/2, 1/2, 1/2, 0, 0), (0, -1, 0, 0, 0, 0, -1/2,
1/2), (-1/2, -1/2, 1/2, 1/2, 1/2, 1/2, 0, 0), (0, 0, -1, 0, 0, 0, -1/2,
1/2), (-1/2, 1/2, -1/2, 1/2, 1/2, 1/2, 0, 0), (1/2, -1/2, -1/2, 1/2,
1/2, 1/2, 0, 0), (0, 0, 0, -1, 0, 0, -1/2, 1/2), (-1/2, 1/2, 1/2, -1/2,
1/2, 1/2, 0, 0), (1/2, -1/2, 1/2, -1/2, 1/2, 1/2, 0, 0), (1/2, 1/2,
-1/2, -1/2, 1/2, 1/2, 0, 0), (-1/2, -1/2, -1/2, -1/2, 1/2, 1/2, 0, 0),
(0, 0, 0, 0, -1, 0, -1/2, 1/2), (-1/2, 1/2, 1/2, 1/2, -1/2, 1/2, 0, 0),
(1/2, -1/2, 1/2, 1/2, -1/2, 1/2, 0, 0), (1/2, 1/2, -1/2, 1/2, -1/2, 1/2,
0, 0), (-1/2, -1/2, -1/2, 1/2, -1/2, 1/2, 0, 0), (1/2, 1/2, 1/2, -1/2,
-1/2, 1/2, 0, 0), (-1/2, -1/2, 1/2, -1/2, -1/2, 1/2, 0, 0), (-1/2, 1/2,

-1/2), (0, 0, 0, 0, -1, 0, 1/2, -1/2), (0, 0, 0, 0, 0, -1, 1/2, -1/2),
(-1/2, -1/2, -1/2, -1/2, -1/2, -1/2, 0, 0), (-1, 0, 0, 0, 0, 0, 1/2,
-1/2)]

```

class sage.combinat.crystals.letters.Crystal_of_letters_type_G_element

Bases: [sage.combinat.crystals.letters.Letter](#)

Type G_2 crystal of letters elements.

e(*i*)

Return the action of e_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['G',2])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
(0, 1, 3),
(-3, 1, 0),
(-1, 1, -2),
(3, 2, 2),
(-2, 2, -3)]

```

epsilon(*i*)

Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['G',2])
sage: [(c,i,c.epsilon(i)) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1, 1), (0, 1, 1), (-3, 1, 2), (-1, 1, 1), (3, 2, 1), (-2, 2, 1)]
```

f(i)Return the action of f_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['G',2])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2),
 (3, 1, 0),
 (0, 1, -3),
 (-2, 1, -1),
 (2, 2, 3),
 (-3, 2, -2)]
```

phi(i)Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['G',2])
sage: [(c,i,c.phi(i)) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1, 1), (3, 1, 2), (0, 1, 1), (-2, 1, 1), (2, 2, 1), (-3, 2, 1)]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Letters(['G',2])]
[(1, 0, -1), (1, -1, 0), (0, 1, -1), (0, 0, 0), (0, -1, 1), (-1, 1, 0), (-1, 0, 1)]
```

class sage.combinat.crystals.letters.**EmptyLetter**Bases: `sage.structure.element.Element`The affine letter \emptyset thought of as a classical crystal letter in classical type B_n and C_n .

Warning: This is not a classical letter.

Used in the rigged configuration bijections.

e(i)Return e_i of self which is None.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').e(1)
```

epsilon(*i*)Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').epsilon(1)
0
```

f(*i*)Return f_i of self which is None.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').f(1)
```

phi(*i*)Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').phi(1)
0
```

value**weight()**

Return the weight of self.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').weight()
(0, 0, 0)
```

class sage.combinat.crystals.letters.LetterBases: `sage.structure.element.Element`

A class for letters.

Like `ElementWrapper`, plus delegates `__lt__` (comparison) to the parent.

EXAMPLES:

```
sage: from sage.combinat.crystals.letters import Letter
sage: a = Letter(ZZ, 1)
sage: Letter(ZZ, 1).parent()
Integer Ring

sage: Letter(ZZ, 1)._repr_()
'1'

sage: parent1 = ZZ # Any fake value ...
sage: parent2 = QQ # Any fake value ...
sage: l11 = Letter(parent1, 1)
sage: l12 = Letter(parent1, 2)
```

(continues on next page)

(continued from previous page)

```

sage: l21 = Letter(parent2, 1)
sage: l22 = Letter(parent2, 2)
sage: l11 == l11
True
sage: l11 == l12
False
sage: l11 == l21 # not tested
False

sage: C = crystals.Letters(['B', 3])
sage: C(0) != C(0)
False
sage: C(1) != C(-1)
True

```

value**class** sage.combinat.crystals.letters.**LetterTuple**

Bases: sage.structure.element.Element

Abstract class for type E letters.**epsilon**(i)Return ε_i of self.

EXAMPLES:

```

sage: C = crystals.Letters(['E', 6])
sage: C((-6,)).epsilon(1)
0
sage: C((-6,)).epsilon(6)
1

```

phi(i)Return φ_i of self.

EXAMPLES:

```

sage: C = crystals.Letters(['E', 6])
sage: C((1,)).phi(1)
1
sage: C((1,)).phi(6)
0

```

value**class** sage.combinat.crystals.letters.**LetterWrapped**

Bases: sage.structure.element.Element

Element which uses another crystal implementation and converts those elements to a tuple with $\pm i$.**e**(i)Return e_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 8])
sage: C((-8,)).e(1)
sage: C((-8,)).e(8)
(-7, 8)
```

epsilon(*i*)

Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 8])
sage: C((-8,)).epsilon(1)
0
sage: C((-8,)).epsilon(8)
1
```

f(*i*)

Return f_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 8])
sage: C((8,)).f(6)
sage: C((8,)).f(8)
(7, -8)
```

phi(*i*)

Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 8])
sage: C((8,)).phi(8)
1
sage: C((8,)).phi(6)
0
```

value

class sage.combinat.crystals.letters.QueerLetter_element

Bases: [sage.combinat.crystals.letters.Letter](#)

Queer supercrystal letters elements.

e(*i*)

Return the action of e_i on self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q', 3])
sage: [(c,i,c.e(i)) for i in Q.index_set() for c in Q if c.e(i) is not None]
[(2, 1, 1), (3, 2, 2), (3, -2, 2), (2, -1, 1)]
```

epsilon(*i*)

Return ε_i of self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i) for i in Q.index_set() for c in Q if c.epsilon(i) != 0]
[(2, 1), (3, 2), (3, -2), (2, -1)]
```

f(i)Return the action of f_i on self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i,c.f(i)) for i in Q.index_set() for c in Q if c.f(i) is not None]
[(1, 1, 2), (2, 2, 3), (2, -2, 3), (1, -1, 2)]
```

phi(i)Return φ_i of self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i) for i in Q.index_set() for c in Q if c.phi(i) != 0]
[(1, 1), (2, 2), (2, -2), (1, -1)]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Letters(['Q',4])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]
```

5.1.57 Littelmann paths

AUTHORS:

- Mark Shimozono, Anne Schilling (2012): Initial version
- Anne Schilling (2013): Implemented *CrystalOfProjectedLevelZeroLSPaths*
- Travis Scrimshaw (2016): Implemented *InfinityCrystalOfLSPaths*

class sage.combinat.crystals.littelmann_path.**CrystalOfLSPaths**(*starting_weight*,
starting_weight_parent)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Crystal graph of LS paths generated from the straight-line path to a given weight.

INPUT:

- *cartan_type* – (optional) the Cartan type of a finite or affine root system
- *starting_weight* – a weight; if *cartan_type* is given, then the weight should be given as a list of coefficients of the fundamental weights, otherwise it should be given in the *weight_space* basis; for affine highest weight crystals, one needs to use the extended weight space.

The crystal class of piecewise linear paths in the weight space, generated from a straight-line path from the origin to a given element of the weight lattice.

OUTPUT:

- a tuple of weights defining the directions of the piecewise linear segments

EXAMPLES:

```
sage: R = RootSystem(['A', 2, 1])
sage: La = R.weight_space(extended = True).basis()
sage: B = crystals.LSPaths(La[2]-La[0]); B
The crystal of LS paths of type ['A', 2, 1] and weight -Lambda[0] + Lambda[2]

sage: C = crystals.LSPaths(['A', 2, 1], [-1, 0, 1]); C
The crystal of LS paths of type ['A', 2, 1] and weight -Lambda[0] + Lambda[2]
sage: B == C
True
sage: c = C.module_generators[0]; c
(-Lambda[0] + Lambda[2],)
sage: [c.f(i) for i in C.index_set()]
[None, None, (Lambda[1] - Lambda[2],)]

sage: R = C.R; R
Root system of type ['A', 2, 1]
sage: Lambda = R.weight_space().basis(); Lambda
Finite family {0: Lambda[0], 1: Lambda[1], 2: Lambda[2]}
sage: b=C(tuple([-Lambda[0]+Lambda[2]]))
sage: b==c
True
sage: b.f(2)
(Lambda[1] - Lambda[2],)
```

For classical highest weight crystals we can also compare the results with the tableaux implementation:

```
sage: C = crystals.LSPaths(['A', 2], [1, 1])
sage: sorted(C, key=str)
[(-2*Lambda[1] + Lambda[2],), (-Lambda[1] + 1/2*Lambda[2], Lambda[1] - 1/
↪ 2*Lambda[2]),
(-Lambda[1] + 2*Lambda[2],), (-Lambda[1] - Lambda[2],),
(1/2*Lambda[1] - Lambda[2], -1/2*Lambda[1] + Lambda[2]), (2*Lambda[1] - Lambda[2],
↪),
(Lambda[1] + Lambda[2],), (Lambda[1] - 2*Lambda[2],)]
sage: C.cardinality()
8
sage: B = crystals.Tableaux(['A', 2], shape=[2, 1])
sage: B.cardinality()
8
sage: B.digraph().is_isomorphic(C.digraph())
True
```

Make sure you use the weight space and not the weight lattice for your weights:

```
sage: R = RootSystem(['A', 2, 1])
sage: La = R.weight_lattice(extended = True).basis()
sage: B = crystals.LSPaths(La[2]); B
Traceback (most recent call last):
...
ValueError: Please use the weight space, rather than weight lattice for your weights
```

REFERENCES:

class ElementBases: `sage.structure.element_wrapper.ElementWrapper`**compress()**

Merges consecutive positively parallel steps present in the path.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A', 2], [1, 1])
sage: Lambda = C.R.weight_space().fundamental_weights(); Lambda
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: c = C(tuple([1/2*Lambda[1]+1/2*Lambda[2], 1/2*Lambda[1]+1/
↪2*Lambda[2]]))
sage: c.compress()
(Lambda[1] + Lambda[2],)
```

dualize()

Returns dualized path.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A', 2], [1, 1])
sage: for c in C:
.....:     print("{} {}".format(c, c.dualize()))
(Lambda[1] + Lambda[2],) (-Lambda[1] - Lambda[2],)
(-Lambda[1] + 2*Lambda[2],) (Lambda[1] - 2*Lambda[2],)
(1/2*Lambda[1] - Lambda[2], -1/2*Lambda[1] + Lambda[2]) (1/2*Lambda[1] -
↪Lambda[2], -1/2*Lambda[1] + Lambda[2])
(Lambda[1] - 2*Lambda[2],) (-Lambda[1] + 2*Lambda[2],)
(-Lambda[1] - Lambda[2],) (Lambda[1] + Lambda[2],)
(2*Lambda[1] - Lambda[2],) (-2*Lambda[1] + Lambda[2],)
(-Lambda[1] + 1/2*Lambda[2], Lambda[1] - 1/2*Lambda[2]) (-Lambda[1] + 1/
↪2*Lambda[2], Lambda[1] - 1/2*Lambda[2])
(-2*Lambda[1] + Lambda[2],) (2*Lambda[1] - Lambda[2],)
```

e(*i*, power=1, to_string_end=False, length_only=False)Returns the *i*-th crystal raising operator on self.

INPUT:

- *i* – element of the index set of the underlying root system
- *power* – positive integer; specifies the power of the raising operator to be applied (default: 1)
- *to_string_end* – boolean; if set to True, returns the dominant end of the *i*-string of self. (default: False)
- *length_only* – boolean; if set to True, returns the distance to the dominant end of the *i*-string of self.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A', 2], [1, 1])
sage: c = C[2]; c
(1/2*Lambda[1] - Lambda[2], -1/2*Lambda[1] + Lambda[2])
sage: c.e(1)
sage: c.e(2)
(-Lambda[1] + 2*Lambda[2],)
sage: c.e(2, to_string_end=True)
```

(continues on next page)

(continued from previous page)

```
(-Lambda[1] + 2*Lambda[2],)
sage: c.e(1,to_string_end=True)
(1/2*Lambda[1] - Lambda[2], -1/2*Lambda[1] + Lambda[2])
sage: c.e(1,length_only=True)
0
```

endpoint()

Computes the endpoint of the path.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: b = C.module_generators[0]
sage: b.endpoint()
Lambda[1] + Lambda[2]
sage: b.f_string([1,2,2,1])
(-Lambda[1] - Lambda[2],)
sage: b.f_string([1,2,2,1]).endpoint()
-Lambda[1] - Lambda[2]
sage: b.f_string([1,2])
(1/2*Lambda[1] - Lambda[2], -1/2*Lambda[1] + Lambda[2])
sage: b.f_string([1,2]).endpoint()
0
sage: b = C([])
sage: b.endpoint()
0
```

epsilon(*i*)

Returns the distance to the beginning of the *i*-string.

This method overrides the generic implementation in the category of crystals since this computation is more efficient.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: [c.epsilon(1) for c in C]
[0, 1, 0, 0, 1, 0, 1, 2]
sage: [c.epsilon(2) for c in C]
[0, 0, 1, 2, 1, 1, 0, 0]
```

f(*i*, power=1, to_string_end=False, length_only=False)

Returns the *i*-th crystal lowering operator on self.

INPUT:

- *i* – element of the index set of the underlying root system
- *power* – positive integer; specifies the power of the lowering operator to be applied (default: 1)
- *to_string_end* – boolean; if set to True, returns the anti-dominant end of the *i*-string of self. (default: False)
- *length_only* – boolean; if set to True, returns the distance to the anti-dominant end of the *i*-string of self.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: c = C.module_generators[0]
```

(continues on next page)

(continued from previous page)

```

sage: c.f(1)
(-Lambda[1] + 2*Lambda[2],)
sage: c.f(1,power=2)
sage: c.f(2)
(2*Lambda[1] - Lambda[2],)
sage: c.f(2,to_string_end=True)
(2*Lambda[1] - Lambda[2],)
sage: c.f(2,length_only=True)
1

sage: C = crystals.LSPaths(['A',2,1],[-1,-1,2])
sage: c = C.module_generators[0]
sage: c.f(2,power=2)
(Lambda[0] + Lambda[1] - 2*Lambda[2],)

```

phi(*i*)

Returns the distance to the end of the *i*-string.

This method overrides the generic implementation in the category of crystals since this computation is more efficient.

EXAMPLES:

```

sage: C = crystals.LSPaths(['A',2],[1,1])
sage: [c.phi(1) for c in C]
[1, 0, 0, 1, 0, 2, 1, 0]
sage: [c.phi(2) for c in C]
[1, 2, 1, 0, 0, 0, 0, 1]

```

reflect_step(*which_step*, *i*)

Apply the *i*-th simple reflection to the indicated step in `self`.

EXAMPLES:

```

sage: C = crystals.LSPaths(['A',2],[1,1])
sage: b = C.module_generators[0]
sage: b.reflect_step(0,1)
(-Lambda[1] + 2*Lambda[2],)
sage: b.reflect_step(0,2)
(2*Lambda[1] - Lambda[2],)

```

s(*i*)

Computes the reflection of `self` along the *i*-string.

This method is more efficient than the generic implementation since it uses powers of *e* and *f* in the Littelmann model directly.

EXAMPLES:

```

sage: C = crystals.LSPaths(['A',2],[1,1])
sage: c = C.module_generators[0]
sage: c.s(1)
(-Lambda[1] + 2*Lambda[2],)
sage: c.s(2)
(2*Lambda[1] - Lambda[2],)

```

(continues on next page)

(continued from previous page)

```

sage: C = crystals.LSPaths(['A', 2, 1], [-1, 0, 1])
sage: c = C.module_generators[0]; c
(-Lambda[0] + Lambda[2],)
sage: c.s(2)
(Lambda[1] - Lambda[2],)
sage: c.s(1)
(-Lambda[0] + Lambda[2],)
sage: c.f(2).s(1)
(Lambda[0] - Lambda[1],)

```

split_step(*which_step*, *r*)Splits indicated step into two parallel steps of relative lengths r and $1 - r$.

INPUT:

- *which_step* – a position in the tuple `self`
- *r* – a rational number between 0 and 1

EXAMPLES:

```

sage: C = crystals.LSPaths(['A', 2], [1, 1])
sage: b = C.module_generators[0]
sage: b.split_step(0, 1/3)
(1/3*Lambda[1] + 1/3*Lambda[2], 2/3*Lambda[1] + 2/3*Lambda[2])

```

weight()Return the weight of `self`.

EXAMPLES:

```

sage: B = crystals.LSPaths(['A', 1, 1], [1, 0])
sage: b = B.highest_weight_vector()
sage: b.f(0).weight()
-Lambda[0] + 2*Lambda[1] - delta

```

weight_lattice_realization()Return weight lattice realization of `self`.

EXAMPLES:

```

sage: B = crystals.LSPaths(['B', 3], [1, 1, 0])
sage: B.weight_lattice_realization()
Weight space over the Rational Field of the Root system of type ['B', 3]
sage: B = crystals.LSPaths(['B', 3, 1], [1, 1, 1, 0])
sage: B.weight_lattice_realization()
Extended weight space over the Rational Field of the Root system of type ['B', 3, 1]
↔3, 1]

```

class `sage.combinat.crystals.littelmann_path.CrystalOfProjectedLevelZeroLSPaths`(*starting_weight*,
starting_weight_parent)

Bases: `sage.combinat.crystals.littelmann_path.CrystalOfLSPaths`

Crystal of projected level zero LS paths.

INPUT:

- `weight` – a dominant weight of the weight space of an affine Kac-Moody root system

When `weight` is just a single fundamental weight Λ_r , this crystal is isomorphic to a Kirillov-Reshetikhin (KR) crystal, see also `sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinFromLSPaths()`. For general weights, it is isomorphic to a tensor product of single-column KR crystals.

EXAMPLES:

```
sage: R = RootSystem(['C', 3, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[3])
sage: LS.cardinality()
84
sage: GLS = LS.digraph()

sage: K1 = crystals.KirillovReshetikhin(['C', 3, 1], 1, 1)
sage: K3 = crystals.KirillovReshetikhin(['C', 3, 1], 3, 1)
sage: T = crystals.TensorProduct(K3, K1)
sage: T.cardinality()
84
sage: GT = T.digraph() # long time
sage: GLS.is_isomorphic(GT, edge_labels = True) # long time
True
```

class `Element`

Bases: `sage.combinat.crystals.littelmann_path.CrystalOfLSPaths.Element`

Element of a crystal of projected level zero LS paths.

`energy_function()`

Return the energy function of `self`.

The energy function $D(\pi)$ of the level zero LS path $\pi \in \mathbb{B}_{\text{cl}}(\lambda)$ requires a series of definitions; for simplicity the root system is assumed to be untwisted affine.

The LS path π is a piecewise linear map from the unit interval $[0, 1]$ to the weight lattice. It is specified by “times” $0 = \sigma_0 < \sigma_1 < \dots < \sigma_s = 1$ and “direction vectors” $x_u \lambda$ where $x_u \in W/W_J$ for $1 \leq u \leq s$, and W_J is the stabilizer of λ in the finite Weyl group W . Precisely,

$$\pi(t) = \sum_{u'=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1}) x_{u'} \lambda + (t - \sigma_{u-1}) x_u \lambda$$

for $1 \leq u \leq s$ and $\sigma_{u-1} \leq t \leq \sigma_u$.

For any $x, y \in W/W_J$, let

$$d : x = w_0 \overset{\beta_1}{\leftarrow} w_1 \overset{\beta_2}{\leftarrow} \dots \overset{\beta_n}{\leftarrow} w_n = y$$

be a shortest directed path in the parabolic quantum Bruhat graph. Define

$$\text{wt}(d) := \sum_{\substack{1 \leq k \leq n \\ \ell(w_{k-1}) < \ell(w_k)}} \beta_k^\vee.$$

It can be shown that $\text{wt}(d)$ depends only on x, y ; call its value $\text{wt}(x, y)$. The energy function $D(\pi)$ is defined by

$$D(\pi) = - \sum_{u=1}^{s-1} (1 - \sigma_u) \langle \lambda, \text{wt}(x_u, x_{u+1}) \rangle.$$

For more information, see [LNSS2013].

Note: In the dual-of-untwisted case the parabolic quantum Bruhat graph that is used is obtained by exchanging the roles of roots and coroots. Moreover, in the computation of the pairing the short roots must be doubled (or tripled for type G). This factor is determined by the translation factor of the corresponding root. Type BC is viewed as untwisted type, whereas the dual of BC is viewed as twisted. Except for the untwisted cases, these formulas are currently still conjectural.

EXAMPLES:

```
sage: R = RootSystem(['C', 3, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[3])
sage: b = LS.module_generators[0]
sage: c = b.f(1).f(3).f(2)
sage: c.energy_function()
0
sage: c=b.e(0)
sage: c.energy_function()
1

sage: R = RootSystem(['A', 2, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1])
sage: b = LS.module_generators[0]
sage: c = b.e(0)
sage: c.energy_function()
1
sage: for c in sorted(LS, key=str):
.....:     print("{} {}".format(c, c.energy_function()))
(-2*Lambda[0] + 2*Lambda[1],) 0
(-2*Lambda[1] + 2*Lambda[2],) 0
(-Lambda[0] + Lambda[1], -Lambda[1] + Lambda[2]) 1
(-Lambda[0] + Lambda[1], Lambda[0] - Lambda[2]) 1
(-Lambda[1] + Lambda[2], -Lambda[0] + Lambda[1]) 0
(-Lambda[1] + Lambda[2], Lambda[0] - Lambda[2]) 1
(2*Lambda[0] - 2*Lambda[2],) 0
(Lambda[0] - Lambda[2], -Lambda[0] + Lambda[1]) 0
(Lambda[0] - Lambda[2], -Lambda[1] + Lambda[2]) 0
```

The next test checks that the energy function is constant on classically connected components:

```
sage: R = RootSystem(['A', 2, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1]+La[2])
sage: G = LS.digraph(index_set=[1, 2])
sage: C = G.connected_components()
sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in_
->C]
[True, True, True, True]

sage: R = RootSystem(['D', 4, 2])
sage: La = R.weight_space().basis()
```

(continues on next page)

(continued from previous page)

```

sage: LS = crystals.ProjectedLevelZeroLSPaths(La[2])
sage: J = R.cartan_type().classical().index_set()
sage: hw = [x for x in LS if x.is_highest_weight(J)]
sage: [(x.weight(), x.energy_function()) for x in hw]
[(-2*Lambda[0] + Lambda[2], 0), (-2*Lambda[0] + Lambda[1], 1), (0, 2)]
sage: G = LS.digraph(index_set=J)
sage: C = G.connected_components()
sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in
↪C]
[True, True, True]

sage: R = RootSystem(CartanType(['G',2,1]).dual())
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[2])
sage: G = LS.digraph(index_set=[1,2])
sage: C = G.connected_components()
sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in
↪C] # long time
[True, True, True, True, True, True, True, True, True, True, True, True,
↪True, True, True, True]

sage: ct = CartanType(['BC',2,2]).dual()
sage: R = RootSystem(ct)
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1]+La[2])
sage: G = LS.digraph(index_set=R.cartan_type().classical().index_set())
sage: C = G.connected_components()
sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in
↪C] # long time
[True, True, True, True, True, True, True, True, True, True, True]

sage: R = RootSystem(['BC',2,2])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1]+La[2])
sage: G = LS.digraph(index_set=R.cartan_type().classical().index_set())
sage: C = G.connected_components()
sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in
↪C] # long time
[True, True, True, True, True, True, True, True, True, True, True, True,
↪True, True, True,
True, True, True, True, True, True, True, True, True, True, True,
↪True, True, True, True]

```

scalar_factors()

Obtain the scalar factors for `self`.

Each LS path (or `self`) can be written as a piecewise linear map

$$\pi(t) = \sum_{u'=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1}) \nu_{u'} + (t - \sigma_{u-1}) \nu_u$$

for $0 < \sigma_1 < \sigma_2 < \dots < \sigma_s = 1$ and $\sigma_{u-1} \leq t \leq \sigma_u$ and $1 \leq u \leq s$. This method returns the tuple of $(\sigma_1, \dots, \sigma_s)$.

EXAMPLES:

```
sage: R = RootSystem(['C', 3, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectLevelZeroLSPaths(La[1]+La[3])
sage: b = LS.module_generators[0]
sage: b.scalar_factors()
[1]
sage: c = b.f(1).f(3).f(2)
sage: c.scalar_factors()
[1/3, 1]
```

`weyl_group_representation()`

Transform the weights in the LS path `self` to elements in the Weyl group.

Each LS path can be written as the piecewise linear map:

$$\pi(t) = \sum_{u'=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1}) \nu_{u'} + (t - \sigma_{u-1}) \nu_u$$

for $0 < \sigma_1 < \sigma_2 < \dots < \sigma_s = 1$ and $\sigma_{u-1} \leq t \leq \sigma_u$ and $1 \leq u \leq s$. Each weight ν_u is also associated to a Weyl group element. This method returns the list of Weyl group elements associated to the ν_u for $1 \leq u \leq s$.

EXAMPLES:

```
sage: R = RootSystem(['C', 3, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectLevelZeroLSPaths(La[1]+La[3])
sage: b = LS.module_generators[0]
sage: c = b.f(1).f(3).f(2)
sage: c.weyl_group_representation()
[s2*s1*s3, s1*s3]
```

`classically_highest_weight_vectors()`

Return the classically highest weight vectors of `self`.

EXAMPLES:

```
sage: R = RootSystem(['A', 2, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectLevelZeroLSPaths(2*La[1])
sage: LS.classically_highest_weight_vectors()
((-2*Lambda[0] + 2*Lambda[1],),
 (-Lambda[0] + Lambda[1], -Lambda[1] + Lambda[2]))
```

`is_perfect(level=1)`

Check whether the crystal `self` is perfect (of level `level`).

INPUT:

- `level` – (default: 1) positive integer

A crystal \mathcal{B} is perfect of level ℓ if:

1. \mathcal{B} is isomorphic to the crystal graph of a finite-dimensional $U'_q(\mathfrak{g})$ -module.
2. $\mathcal{B} \otimes \mathcal{B}$ is connected.

3. There exists a $\lambda \in X$, such that $\text{wt}(\mathcal{B}) \subset \lambda + \sum_{i \in I} \mathbf{Z}_{\leq 0} \alpha_i$ and there is a unique element in \mathcal{B} of classical weight λ .
4. For all $b \in \mathcal{B}$, $\text{level}(\varepsilon(b)) \geq \ell$.
5. For all Λ dominant weights of level ℓ , there exist unique elements $b_\Lambda, b^\Lambda \in \mathcal{B}$, such that $\varepsilon(b_\Lambda) = \Lambda = \varphi(b^\Lambda)$.

Points (1)-(3) are known to hold. This method checks points (4) and (5).

EXAMPLES:

```

sage: C = CartanType(['C', 2, 1])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectLevelZeroLSPaths(La[1])
sage: LS.is_perfect()
False
sage: LS = crystals.ProjectLevelZeroLSPaths(La[2])
sage: LS.is_perfect()
True

sage: C = CartanType(['E', 6, 1])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectLevelZeroLSPaths(La[1])
sage: LS.is_perfect()
True
sage: LS.is_perfect(2)
False

sage: C = CartanType(['D', 4, 1])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: all(crystals.ProjectLevelZeroLSPaths(La[i]).is_perfect() for i in [1, 2,
↪ 3, 4])
True

sage: C = CartanType(['A', 6, 2])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectLevelZeroLSPaths(La[1]+La[2])
sage: LS.is_perfect()
True
sage: LS.is_perfect(2)
False

```

maximal_vector()

Return the maximal vector of self.

EXAMPLES:

```

sage: R = RootSystem(['A', 2, 1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectLevelZeroLSPaths(2*La[1]+La[2])
sage: LS.maximal_vector()

```

(continues on next page)

(continued from previous page)

```
(-3*Lambda[0] + 2*Lambda[1] + Lambda[2],)
```

one_dimensional_configuration_sum(*q=None, group_components=True*)

Compute the one-dimensional configuration sum.

INPUT:

- *q* – (default: None) a variable or None; if None, a variable *q* is set in the code
- *group_components* – (default: True) boolean; if True, then the terms are grouped by classical component

The one-dimensional configuration sum is the sum of the weights of all elements in the crystal weighted by the energy function. For untwisted types it uses the parabolic quantum Bruhat graph, see [LNSS2013]. In the dual-of-untwisted case, the parabolic quantum Bruhat graph is defined by exchanging the roles of roots and coroots (which is still conjectural at this point).

EXAMPLES:

```
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectLevelZeroLSPaths(2*La[1])
sage: LS.one_dimensional_configuration_sum() # long time
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
+ (q+1)*B[Lambda[1] - Lambda[2]] + B[2*Lambda[1]]
+ B[-2*Lambda[2]] + (q+1)*B[Lambda[2]]
sage: R.<t> = ZZ[]
sage: LS.one_dimensional_configuration_sum(t, False) # long time
B[-2*Lambda[1] + 2*Lambda[2]] + (t+1)*B[-Lambda[1]]
+ (t+1)*B[Lambda[1] - Lambda[2]] + B[2*Lambda[1]]
+ B[-2*Lambda[2]] + (t+1)*B[Lambda[2]]
```

class `sage.combinat.crystals.littelmann_path.InfinityCrystalOfLSPaths`(*cartan_type*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

LS path model for $\mathcal{B}(\infty)$.

Elements of $\mathcal{B}(\infty)$ are equivalence classes of paths $[\pi]$ in $\mathcal{B}(k\rho)$ for $k \gg 0$, where ρ is the Weyl vector. A canonical representative for an element of $\mathcal{B}(\infty)$ is chosen by taking k to be minimal such that the endpoint of π is strictly dominant but its representative in $\mathcal{B}((k-1)\rho)$ is on the wall of the dominant chamber.

REFERENCES:

- [LZ2011]

class `Element`

Bases: `sage.combinat.crystals.littelmann_path.CrystalOfLSPaths.Element`

e(*i, power=1, length_only=False*)

Return the *i*-th crystal raising operator on `self`.

INPUT:

- *i* – element of the index set
- *power* – (default: 1) positive integer; specifies the power of the lowering operator to be applied
- *length_only* – (default: False) boolean; if True, then return the distance to the anti-dominant end of the *i*-string of `self`

EXAMPLES:

```

sage: B = crystals.infinity.LSPaths(['B',3,1])
sage: mg = B.module_generator()
sage: mg.e(0)
sage: mg.e(1)
sage: mg.e(2)
sage: x = mg.f_string([1,0,2,1,0,2,1,1,0])
sage: all(x.f(i).e(i) == x for i in B.index_set())
True
sage: all(x.e(i).f(i) == x for i in B.index_set() if x.epsilon(i) > 0)
True

```

f(*i*, *power*=1, *length_only*=False)
Return the *i*-th crystal lowering operator on self.

INPUT:

- *i* – element of the index set
- *power* – (default: 1) positive integer; specifies the power of the lowering operator to be applied
- *length_only* – (default: False) boolean; if True, then return the distance to the anti-dominant end of the *i*-string of self

EXAMPLES:

```

sage: B = crystals.infinity.LSPaths(['D',3,2])
sage: mg = B.highest_weight_vector()
sage: mg.f(1)
(3*Lambda[0] - Lambda[1] + 3*Lambda[2],
 2*Lambda[0] + 2*Lambda[1] + 2*Lambda[2])
sage: mg.f(2)
(Lambda[0] + 2*Lambda[1] - Lambda[2],
 2*Lambda[0] + 2*Lambda[1] + 2*Lambda[2])
sage: mg.f(0)
(-Lambda[0] + 2*Lambda[1] + Lambda[2] - delta,
 2*Lambda[0] + 2*Lambda[1] + 2*Lambda[2])

```

phi(*i*)
Return φ_i of self.

Let $\pi \in \mathcal{B}(\infty)$. Define

$$\varphi_i(\pi) := \varepsilon_i(\pi) + \langle h_i, \text{wt}(\pi) \rangle,$$

where h_i is the *i*-th simple coroot and $\text{wt}(\pi)$ is the `weight()` of π .

INPUT:

- *i* – element of the index set

EXAMPLES:

```

sage: B = crystals.infinity.LSPaths(['D',4])
sage: mg = B.highest_weight_vector()
sage: x = mg.f_string([1,3,4,2,4,3,2,1,4])
sage: [x.phi(i) for i in B.index_set()]
[-1, 4, -2, -3]

```

weight()
Return the weight of self.

Todo: This is a generic algorithm. We should find a better description and implement it.

EXAMPLES:

```
sage: B = crystals.infinity.LSPaths(['E',6])
sage: mg = B.highest_weight_vector()
sage: f_seq = [1,4,2,6,4,2,3,1,5,5]
sage: x = mg.f_string(f_seq)
sage: x.weight()
-3*Lambda[1] - 2*Lambda[2] + 2*Lambda[3] + Lambda[4] - Lambda[5]

sage: al = B.cartan_type().root_system().weight_space().simple_roots()
sage: x.weight() == -sum(al[i] for i in f_seq)
True
```

module_generator()

Return the module generator (or highest weight element) of `self`.

The module generator is the unique path $\pi_\infty: t \mapsto t\rho$, for $t \in [0, \infty)$.

EXAMPLES:

```
sage: B = crystals.infinity.LSPaths(['A',6,2])
sage: mg = B.module_generator(); mg
(Lambda[0] + Lambda[1] + Lambda[2] + Lambda[3],)
sage: mg.weight()
0
```

weight_lattice_realization()

Return the weight lattice realization of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.LSPaths(['C',4])
sage: B.weight_lattice_realization()
Weight space over the Rational Field of the Root system of type ['C', 4]
```

`sage.combinat.crystals.littelmann_path.positively_parallel_weights(v, w)`

Check whether the vectors `v` and `w` are positive scalar multiples of each other.

EXAMPLES:

```
sage: from sage.combinat.crystals.littelmann_path import positively_parallel_weights
sage: La = RootSystem(['A',5,2]).weight_space(extended=True).fundamental_weights()
sage: rho = sum(La)
sage: positively_parallel_weights(rho, 4*rho)
True
sage: positively_parallel_weights(4*rho, rho)
True
sage: positively_parallel_weights(rho, -rho)
False
sage: positively_parallel_weights(rho, La[1] + La[2])
False
```

5.1.58 Crystals of Modified Nakajima Monomials

AUTHORS:

- Arthur Lubovsky: Initial version
- Ben Salisbury: Initial version

Let $Y_{i,k}$, for $i \in I$ and $k \in \mathbf{Z}$, be a commuting set of variables, and let $\mathbf{1}$ be a new variable which commutes with each $Y_{i,k}$. (Here, I represents the index set of a Cartan datum.) One may endow the structure of a crystal on the set $\widehat{\mathcal{M}}$ of monomials of the form

$$M = \prod_{(i,k) \in I \times \mathbf{Z}_{\geq 0}} Y_{i,k}^{y_i(k)} \mathbf{1}.$$

Elements of $\widehat{\mathcal{M}}$ are called *modified Nakajima monomials*. We will omit the $\mathbf{1}$ from the end of a monomial if there exists at least one $y_i(k) \neq 0$. The crystal structure on this set is defined by

$$\begin{aligned} \text{wt}(M) &= \sum_{i \in I} \left(\sum_{k \geq 0} y_i(k) \right) \Lambda_i, \\ \varphi_i(M) &= \max \left\{ \sum_{0 \leq j \leq k} y_i(j) : k \geq 0 \right\}, \\ \varepsilon_i(M) &= \varphi_i(M) - \langle h_i, \text{wt}(M) \rangle, \\ k_f &= k_f(M) = \min \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\}, \\ k_e &= k_e(M) = \max \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\}, \end{aligned}$$

where $\{h_i : i \in I\}$ and $\{\Lambda_i : i \in I\}$ are the simple coroots and fundamental weights, respectively. With a chosen set of integers $C = (c_{ij})_{i \neq j}$ such that $c_{ij} + c_{ji} = 1$, one defines

$$A_{i,k} = Y_{i,k} Y_{i,k+1} \prod_{j \neq i} Y_{j,k+c_{ji}}^{a_{ji}},$$

where (a_{ij}) is a Cartan matrix. Then

$$\begin{aligned} e_i M &= \begin{cases} 0 & \text{if } \varepsilon_i(M) = 0, \\ A_{i,k_e} M & \text{if } \varepsilon_i(M) > 0, \end{cases} \\ f_i M &= A_{i,k_f}^{-1} M. \end{aligned}$$

It is shown in [KKS2007] that the connected component of $\widehat{\mathcal{M}}$ containing the element $\mathbf{1}$, which we denote by $\mathcal{M}(\infty)$, is crystal isomorphic to the crystal $B(\infty)$.

Let $\widetilde{\mathcal{M}}$ be $\widehat{\mathcal{M}}$ as a set, and with crystal structure defined as on $\widehat{\mathcal{M}}$ with the exception that

$$f_i M = \begin{cases} 0 & \text{if } \varphi_i(M) = 0, \\ A_{i,k_f}^{-1} M & \text{if } \varphi_i(M) > 0. \end{cases}$$

Then Kashiwara [Ka2003] showed that the connected component in $\widetilde{\mathcal{M}}$ containing a monomial M such that $e_i M = 0$, for all $i \in I$, is crystal isomorphic to the irreducible highest weight crystal $B(\text{wt}(M))$.

WARNING:

Monomial crystals depend on the choice of positive integers $C = (c_{ij})_{i \neq j}$ satisfying the condition $c_{ij} + c_{ji} = 1$. We have chosen such integers uniformly such that $c_{ij} = 1$ if $i < j$ and $c_{ij} = 0$ if $i > j$.

class `sage.combinat.crystals.monomial_crystals.CrystalOfNakajimaMonomials(ct, La, c)`
 Bases: `sage.combinat.crystals.monomial_crystals.InfinityCrystalOfNakajimaMonomials`

Let $\widetilde{\mathcal{M}}$ be $\widehat{\mathcal{M}}$ as a set, and with crystal structure defined as on $\widehat{\mathcal{M}}$ with the exception that

$$f_i M = \begin{cases} 0 & \text{if } \varphi_i(M) = 0, \\ A_{i,k_f}^{-1} M & \text{if } \varphi_i(M) > 0. \end{cases}$$

Then Kashiwara [Ka2003] showed that the connected component in $\widetilde{\mathcal{M}}$ containing a monomial M such that $e_i M = 0$, for all $i \in I$, is crystal isomorphic to the irreducible highest weight crystal $B(\text{wt}(M))$.

INPUT:

- `ct` – a Cartan type
- `La` – an element of the weight lattice

EXAMPLES:

```
sage: La = RootSystem("A2").weight_lattice().fundamental_weights()

 Y(1,0)^2]

```

Elementalias of *CrystalOfNakajimaMonomialsElement***cardinality()**

Return the cardinality of self.

EXAMPLES:

```

sage: La = RootSystem(['A', 2]).weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials(['A', 2], La[1])
sage: M.cardinality()
3

sage: La = RootSystem(['D', 4, 2]).weight_lattice(extended=True).fundamental_
↪weights()
sage: M = crystals.NakajimaMonomials(['D', 4, 2], La[1])
sage: M.cardinality()
+Infinity

```

class sage.combinat.crystals.monomial_crystals.**CrystalOfNakajimaMonomialsElement**(parent, Y, A)

Bases: *sage.combinat.crystals.monomial_crystals.NakajimaMonomial*Element class for *CrystalOfNakajimaMonomials*.

The f_i operators need to be modified from the version in *monomial_crystalsNakajimaMonomial* in order to create irreducible highest weight realizations. This modified f_i is defined as

$$f_i M = \begin{cases} 0 & \text{if } \varphi_i(M) = 0, \\ A_{i,k_j}^{-1} M & \text{if } \varphi_i(M) > 0. \end{cases}$$

EXAMPLES:

```

sage: La = RootSystem(['A', 5, 2]).weight_lattice(extended=True).fundamental_weights()
sage: M = crystals.NakajimaMonomials(['A', 5, 2], 3*La[0])
sage: m = M.module_generators[0].f(0); m
Y(0,0)^2 Y(0,1)^-1 Y(2,0)
sage: TestSuite(m).run()

```

f(i)

Return the action of f_i on self.

INPUT:

- i – an element of the index set

EXAMPLES:

```

sage: La = RootSystem(['A', 5, 2]).weight_lattice(extended=True).fundamental_
↪weights()
sage: M = crystals.NakajimaMonomials(['A', 5, 2], 3*La[0])
sage: m = M.module_generators[0]
sage: [m.f(i) for i in M.index_set()]
[Y(0,0)^2 Y(0,1)^-1 Y(2,0), None, None, None]

```

```

sage: M = crystals.infinity.NakajimaMonomials("E8")
sage: M.set_variables('A')
sage: m = M.module_generators[0].f_string([4, 2, 3, 8])
sage: m
A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1
sage: [m.f(i) for i in M.index_set()]

 A(2,0)^-1 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,0)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(4,1)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(5,0)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(6,0)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(7,1)^-1 A(8,0)^-1,
 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-2]
sage: M.set_variables('Y')

```

weight()

Return the weight of self as an element of the weight lattice.

EXAMPLES:

```

sage: La = RootSystem("A2").weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials("A2", La[1]+La[2])
sage: M.module_generators[0].weight()
(2, 1, 0)

```

```

class sage.combinat.crystals.monomial_crystals.InfinityCrystalOfNakajimaMonomials(ct, c,
                                                                                       cate-
                                                                                       gory=None)

```

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Crystal $B(\infty)$ in terms of (modified) Nakajima monomials.

Let $Y_{i,k}$, for $i \in I$ and $k \in \mathbf{Z}$, be a commuting set of variables, and let $\mathbf{1}$ be a new variable which commutes with each $Y_{i,k}$. (Here, I represents the index set of a Cartan datum.) One may endow the structure of a crystal on the set $\widehat{\mathcal{M}}$ of monomials of the form

$$M = \prod_{(i,k) \in I \times \mathbf{Z}_{\geq 0}} Y_{i,k}^{y_i(k)} \mathbf{1}.$$

Elements of $\widehat{\mathcal{M}}$ are called *modified Nakajima monomials*. We will omit the $\mathbf{1}$ from the end of a monomial if there exists at least one $y_i(k) \neq 0$. The crystal structure on this set is defined by

$$\begin{aligned} \text{wt}(M) &= \sum_{i \in I} \left(\sum_{k \geq 0} y_i(k) \right) \Lambda_i, \\ \varphi_i(M) &= \max \left\{ \sum_{0 \leq j \leq k} y_i(j) : k \geq 0 \right\}, \\ \varepsilon_i(M) &= \varphi_i(M) - \langle h_i, \text{wt}(M) \rangle, \\ k_f = k_f(M) &= \min \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\}, \\ k_e = k_e(M) &= \max \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\}, \end{aligned}$$

where $\{h_i : i \in I\}$ and $\{\Lambda_i : i \in I\}$ are the simple coroots and fundamental weights, respectively. With a chosen set of non-negative integers $C = (c_{ij})_{i \neq j}$ such that $c_{ij} + c_{ji} = 1$, one defines

$$A_{i,k} = Y_{i,k} Y_{i,k+1} \prod_{j \neq i} Y_{j,k+c_{ji}}^{a_{ji}},$$

where $(a_{ij})_{i,j \in I}$ is a Cartan matrix. Then

$$\begin{aligned} e_i M &= \begin{cases} 0 & \text{if } \varepsilon_i(M) = 0, \\ A_{i,k_e} M & \text{if } \varepsilon_i(M) > 0, \end{cases} \\ f_i M &= A_{i,k_f}^{-1} M. \end{aligned}$$

It is shown in [KKS2007] that the connected component of $\widehat{\mathcal{M}}$ containing the element $\mathbf{1}$, which we denote by $\mathcal{M}(\infty)$, is crystal isomorphic to the crystal $B(\infty)$.

INPUT:

- `cartan_type` – a Cartan type
- `c` – (optional) the matrix $(c_{ij})_{i,j \in I}$ such that $c_{ii} = 0$ for all $i \in I$, $c_{ij} \in \mathbf{Z}_{>0}$ for all $i, j \in I$, and $c_{ij} + c_{ji} = 1$ for all $i \neq j$; the default is $c_{ij} = 0$ if $i < j$ and 0 otherwise

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("C3")
sage: S = B.subcrystal(max_depth=4)
sage: G = B.digraph(subset=S) # long time
sage: M = crystals.infinity.NakajimaMonomials("C3") # long time
sage: T = M.subcrystal(max_depth=4) # long time
sage: H = M.digraph(subset=T) # long time
sage: G.is_isomorphic(H, edge_labels=True) # long time
True
sage: M = crystals.infinity.NakajimaMonomials(['A', 2, 1])
```

(continues on next page)

(continued from previous page)

```

sage: T = M.subcrystal(max_depth=3)
sage: H = M.digraph(subset=T) # long time
sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: YS = Y.subcrystal(max_depth=3)
sage: YG = Y.digraph(subset=YS) # long time
sage: YG.is_isomorphic(H, edge_labels=True) # long time
True

sage: M = crystals.infinity.NakajimaMonomials("D4")
sage: B = crystals.infinity.Tableaux("D4")
sage: MS = M.subcrystal(max_depth=3)
sage: BS = B.subcrystal(max_depth=3)
sage: MG = M.digraph(subset=MS) # long time
sage: BG = B.digraph(subset=BS) # long time
sage: BG.is_isomorphic(MG, edge_labels=True) # long time
True

```

Elementalias of *NakajimaMonomial***c()**Return the matrix c_{ij} of self.

EXAMPLES:

```

sage: La = RootSystem(['B', 3]).weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials(La[1]+La[2])
sage: M.c()
[0 1 1]
[0 0 1]
[0 0 0]

sage: c = Matrix([[0,0,1],[1,0,0],[0,1,0]])
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_
weights()
sage: M = crystals.NakajimaMonomials(2*La[1], c=c)
sage: M.c() == c
True

```

cardinality()Return the cardinality of self, which is always ∞ .

EXAMPLES:

```

sage: M = crystals.infinity.NakajimaMonomials(['A', 5, 2])
sage: M.cardinality()
+Infinity

```

get_variables()

Return the type of monomials to use for the element output.

EXAMPLES:

```
sage: M = crystals.infinity.NakajimaMonomials(['A', 4])
sage: M.get_variables()
'Y'
```

set_variables(*letter*)

Set the type of monomials to use for the element output.

If the A variables are used, the output is written as $\prod_{i \in I} Y_{i,0}^{\lambda_i} \prod_{i,k} A_{i,k}^{c_{i,k}}$, where $\sum_{i \in I} \lambda_i \Lambda_i$ is the corresponding dominant weight.

INPUT:

- *letter* – can be one of the following:
 - 'Y' - use $Y_{i,k}$, corresponds to fundamental weights
 - 'A' - use $A_{i,k}$, corresponds to simple roots

EXAMPLES:

```
sage: M = crystals.infinity.NakajimaMonomials(['A', 4])
sage: elt = M.highest_weight_vector().f_string([2,1,3,2,3,2,4,3])
sage: elt
Y(1,2) Y(2,0)^-1 Y(2,2)^-1 Y(3,0)^-1 Y(3,2)^-1 Y(4,0)
sage: M.set_variables('A')
sage: elt
A(1,1)^-1 A(2,0)^-1 A(2,1)^-2 A(3,0)^-2 A(3,1)^-1 A(4,0)^-1
sage: M.set_variables('Y')
```

```
sage: La = RootSystem(['A', 2]).weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials(La[1]+La[2])
sage: lw = M.lowest_weight_vectors()[0]
sage: lw
Y(1,2)^-1 Y(2,1)^-1
sage: M.set_variables('A')
sage: lw
Y(1,0) Y(2,0) A(1,0)^-1 A(1,1)^-1 A(2,0)^-2
sage: M.set_variables('Y')
```

class `sage.combinat.crystals.monomial_crystals.NakajimaMonomial`(*parent*, *Y*, *A*)

Bases: `sage.structure.element.Element`

An element of the monomial crystal.

Monomials of the form $Y_{i_1, k_1}^{y_1} \cdots Y_{i_t, k_t}^{y_t}$, where i_1, \dots, i_t are elements of the index set, k_1, \dots, k_t are nonnegative integers, and y_1, \dots, y_t are integers.

EXAMPLES:

```
sage: M = crystals.infinity.NakajimaMonomials(['B', 3, 1])
sage: mg = M.module_generators[0]
sage: mg
1
sage: mg.f_string([1, 3, 2, 0, 1, 2, 3, 0, 0, 1])
Y(0,0)^-1 Y(0,1)^-1 Y(0,2)^-1 Y(0,3)^-1 Y(1,0)^-3
Y(1,1)^-2 Y(1,2) Y(2,0)^3 Y(2,2) Y(3,0) Y(3,2)^-1
```

An example using the A variables:

```

sage: M = crystals.infinity.NakajimaMonomials("A3")
sage: M.set_variables('A')
sage: mg = M.module_generators[0]
sage: mg.f_string([1,2,3,2,1])
A(1,0)^-1 A(1,1)^-1 A(2,0)^-2 A(3,0)^-1
sage: mg.f_string([3,2,1])
A(1,2)^-1 A(2,1)^-1 A(3,0)^-1
sage: M.set_variables('Y')

```

e(i)

Return the action of e_i on self.

INPUT:

- i – an element of the index set

EXAMPLES:

```

sage: M = crystals.infinity.NakajimaMonomials(['E',7,1])
sage: m = M.module_generators[0].f_string([0,1,4,3])
sage: [m.e(i) for i in M.index_set()]
[None,
 None,
 None,
 Y(0,0)^-1 Y(1,1)^-1 Y(2,1) Y(3,0) Y(3,1) Y(4,0)^-1 Y(4,1)^-1 Y(5,0),
 None,
 None,
 None,
 None]

sage: M = crystals.infinity.NakajimaMonomials("C5")
sage: m = M.module_generators[0].f_string([1,3])
sage: [m.e(i) for i in M.index_set()]
[Y(2,1) Y(3,0)^-1 Y(3,1)^-1 Y(4,0),
 None,
 Y(1,0)^-1 Y(1,1)^-1 Y(2,0),
 None,
 None]

sage: M = crystals.infinity.NakajimaMonomials(['D',4,1])
sage: M.set_variables('A')
sage: m = M.module_generators[0].f_string([4,2,3,0])
sage: [m.e(i) for i in M.index_set()]
[A(2,1)^-1 A(3,1)^-1 A(4,0)^-1,
 None,
 None,
 A(0,2)^-1 A(2,1)^-1 A(4,0)^-1,
 None]
sage: M.set_variables('Y')

```

epsilon(i)

Return the value of ε_i on self.

INPUT:

- i – an element of the index set

EXAMPLES:

```

sage: M = crystals.infinity.NakajimaMonomials(['G',2,1])
sage: m = M.module_generators[0].f(2)
sage: [m.epsilon(i) for i in M.index_set()]
[0, 0, 1]

sage: M = crystals.infinity.NakajimaMonomials(['C',4,1])
sage: m = M.module_generators[0].f_string([4,2,3])
sage: [m.epsilon(i) for i in M.index_set()]
[0, 0, 0, 1, 0]

```

f(i)Return the action of f_i on self.

INPUT:

- i – an element of the index set

EXAMPLES:

```

sage: M = crystals.infinity.NakajimaMonomials("B4")
sage: m = M.module_generators[0].f_string([1,3,4])
sage: [m.f(i) for i in M.index_set()]
[Y(1,0)^-2 Y(1,1)^-2 Y(2,0)^2 Y(2,1) Y(3,0)^-1 Y(4,0) Y(4,1)^-1,
 Y(1,0)^-1 Y(1,1)^-1 Y(1,2) Y(2,0) Y(2,2)^-1 Y(3,0)^-1 Y(3,1) Y(4,0) Y(4,1)^-1,
 Y(1,0)^-1 Y(1,1)^-1 Y(2,0) Y(2,1)^2 Y(3,0)^-2 Y(3,1)^-1 Y(4,0)^3 Y(4,1)^-1,
 Y(1,0)^-1 Y(1,1)^-1 Y(2,0) Y(2,1) Y(3,0)^-1 Y(3,1) Y(4,1)^-2]

```

phi(i)Return the value of φ_i on self.

INPUT:

- i – an element of the index set

EXAMPLES:

```

sage: M = crystals.infinity.NakajimaMonomials(['D',4,3])
sage: m = M.module_generators[0].f(1)
sage: [m.phi(i) for i in M.index_set()]
[1, -1, 1]

sage: M = crystals.infinity.NakajimaMonomials(['C',4,1])
sage: m = M.module_generators[0].f_string([4,2,3])
sage: [m.phi(i) for i in M.index_set()]
[0, 1, -1, 2, -1]

```

weight()

Return the weight of self as an element of the weight lattice.

EXAMPLES:

```

sage: C = crystals.infinity.NakajimaMonomials(['A',1,1])
sage: v = C.highest_weight_vector()
sage: v.f(1).weight() + v.f(0).weight()
-delta

```

(continues on next page)

(continued from previous page)

```

sage: M = crystals.infinity.NakajimaMonomials(['A',4,2])
sage: m = M.highest_weight_vector().f_string([1,2,0,1])
sage: m.weight()
2*Lambda[0] - Lambda[1] - delta

```

weight_in_root_lattice()

Return the weight of self as an element of the root lattice.

EXAMPLES:

```

sage: M = crystals.infinity.NakajimaMonomials(['F',4])
sage: m = M.module_generators[0].f_string([3,3,1,2,4])
sage: m.weight_in_root_lattice()
-alpha[1] - alpha[2] - 2*alpha[3] - alpha[4]

sage: M = crystals.infinity.NakajimaMonomials(['B',3,1])
sage: mg = M.module_generators[0]
sage: m = mg.f_string([1,3,2,0,1,2,3,0,0,1])
sage: m.weight_in_root_lattice()
-3*alpha[0] - 3*alpha[1] - 2*alpha[2] - 2*alpha[3]

sage: M = crystals.infinity.NakajimaMonomials(['C',3,1])
sage: m = M.module_generators[0].f_string([3,0,1,2,0])
sage: m.weight_in_root_lattice()
-2*alpha[0] - alpha[1] - alpha[2] - alpha[3]

```

5.1.59 Crystal of Bernstein-Zelevinsky Multisegments

class sage.combinat.crystals.multisegments.**InfinityCrystalOfMultisegments**(*n*)

Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresentation

The type $A_n^{(1)}$ crystal $B(\infty)$ realized using Bernstein-Zelevinsky (BZ) multisegments.

Using (a modified version of the) notation from [JL2009], for $\ell \in \mathbf{Z}_{>0}$ and $i \in \mathbf{Z}/(n+1)\mathbf{Z}$, a segment of length ℓ and head i is the sequence of consecutive residues $[i, i+1, \dots, i+\ell-1]$. The notation for a segment of length ℓ and head i is simplified to $[i; \ell]$. Similarly, a segment of length ℓ and tail i is the sequence of consecutive residues $[i-\ell+1, \dots, i-1, i]$. The latter is denoted simply by $(\ell; i]$. Finally, a multisegment is a formal linear combination of segments, usually written in the form

$$\psi = \sum_{\substack{i \in \mathbf{Z}/(n+1)\mathbf{Z} \\ \ell \in \mathbf{Z}_{>0}}} m_{(\ell; i]}(\ell; i].$$

Such a multisegment is called aperiodic if, for every $\ell > 0$, there exists some $i \in \mathbf{Z}/(n+1)\mathbf{Z}$ such that $(\ell; i]$ does not appear in ψ . Denote the set of all periodic multisegments, together with the empty multisegment \emptyset , by Ψ . We define a crystal structure on multisegments as follows. Set $S_{\ell, i} = \sum_{k \geq \ell} (m_{(k; i-1]} - m_{(k; i]})$ and let ℓ_f be the minimal ℓ that attains the value $\min_{\ell > 0} S_{\ell, i}$. Then we have

$$f_i \psi = \begin{cases} \psi + (1; i] & \text{if } \ell_f = 1, \\ \psi + (\ell_f; i] - (\ell_f - 1; i - 1] & \text{if } \ell_f > 1. \end{cases}$$

Similarly, let ℓ_e be the maximal ℓ that attains the value $\min_{\ell>0} S_{\ell,i}$. Then we have

$$e_i\psi = \begin{cases} 0 & \text{if } \min_{\ell>0} S_{\ell,i} = 0, \\ \psi + (1; i] & \text{if } \ell_e = 1, \\ \psi - (\ell_e; i] + (\ell_e - 1; i - 1] & \text{if } \ell_e > 1. \end{cases}$$

Alternatively, the crystal operators may be defined using a signature rule, as detailed in Section 4 of [JL2009] (following [AJL2011]). For $\psi \in \Psi$ and $i \in \mathbf{Z}/(n+1)\mathbf{Z}$, encode all segments in ψ with tail i by the symbol R and all segments in ψ with tail $i - 1$ by A . For $\ell > 0$, set $w_{i,\ell} = R^{m(\ell;i)}A^{m(\ell;i-1)}$ and $w_i = \prod_{\ell \geq 1} w_{i,\ell}$. By successively canceling out as many RA factors as possible, set $\tilde{w}_i = A^{a_i(\psi)}R^{r_i(\psi)}$. If $a_i(\psi) > 0$, denote by $\ell_f > 0$ the length of the rightmost segment A in \tilde{w}_i . If $a_i(\psi) = 0$, set $\ell_f = 0$. Then

$$f_i\psi = \begin{cases} \psi + (1; i] & \text{if } a_i(\psi) = 0, \\ \psi + (\ell_f; i] - (\ell_f - 1; i - 1] & \text{if } a_i(\psi) > 0. \end{cases}$$

The rule for computing $e_i\psi$ is similar.

INPUT:

- n – for type $A_n^{(1)}$

EXAMPLES:

```
sage: B = crystals.infinity.Multisegments(2)
sage: x = B([(8,1),(6,0),(5,1),(5,0),(4,0),(4,1),(4,1),(3,0),(3,0),(3,1),(3,1),(1,
->0),(1,2),(1,2)]); x
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1]
+ 2 * (3; 0] + 2 * (3; 1] + (1; 0] + 2 * (1; 2]
sage: x.f(1)
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1]
+ 2 * (3; 0] + 2 * (3; 1] + (2; 1] + 2 * (1; 2]
sage: x.f(1).f(1)
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1]
+ 2 * (3; 0] + 2 * (3; 1] + (2; 1] + (1; 1] + 2 * (1; 2]
sage: x.e(1)
(7; 0] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1]
+ 2 * (3; 0] + 2 * (3; 1] + (1; 0] + 2 * (1; 2]
sage: x.e(1).e(1)
sage: x.f(0)
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1]
+ 2 * (3; 0] + 2 * (3; 1] + (2; 0] + (1; 0] + (1; 2]
```

We check an $\widehat{\mathfrak{sl}}_2$ example against the generalized Young walls:

```
sage: B = crystals.infinity.Multisegments(1)
sage: G = B.subcrystal(max_depth=4).digraph()
sage: C = crystals.infinity.GeneralizedYoungWalls(1)
sage: GC = C.subcrystal(max_depth=4).digraph()
sage: G.is_isomorphic(GC, edge_labels=True)
True
```

REFERENCES:

- [AJL2011]
- [JL2009]

- [LTV1999]

class Element(*parent, value*)

Bases: `sage.structure.element_wrapper.ElementWrapper`

An element in a BZ multisegments crystal.

e(*i*)

Return the action of e_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.e(0)
(4; 2] + (3; 0] + (3; 1] + (1; 1]
sage: b.e(1)
sage: b.e(2)
(3; 0] + 2 * (3; 1] + (1; 0] + (1; 1]
```

epsilon(*i*)

Return ε_i of self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.epsilon(0)
1
sage: b.epsilon(1)
0
sage: b.epsilon(2)
1
```

f(*i*)

Return the action of f_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.f(0)
(4; 2] + (3; 0] + (3; 1] + 2 * (1; 0] + (1; 1]
sage: b.f(1)
(4; 2] + (3; 0] + (3; 1] + (1; 0] + 2 * (1; 1]
sage: b.f(2)
2 * (4; 2] + (3; 0] + (1; 0] + (1; 1]
```

phi(*i*)

Return φ_i of self.

Let $\psi \in \Psi$. Define $\varphi_i(\psi) := \varepsilon_i(\psi) + \langle h_i, \text{wt}(\psi) \rangle$, where h_i is the i -th simple coroot and $\text{wt}(\psi)$ is the `weight()` of ψ .

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.phi(0)
1
sage: b.phi(1)
0
sage: mg = B.highest_weight_vector()
sage: mg.f(1).phi(0)
1
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.weight()
-4*delta
```

highest_weight_vector()

Return the highest weight vector of self.

EXAMPLES:

```
sage: B = crystals.infinity.Multisegments(2)
sage: B.highest_weight_vector()
0
```

weight_lattice_realization()

Return a realization of the weight lattice of self.

EXAMPLES:

```
sage: B = crystals.infinity.Multisegments(2)
sage: B.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

5.1.60 Crystal Of Mirković-Vilonen (MV) Polytopes

AUTHORS:

- Dinakar Muthiah, Travis Scrimshaw (2015-05-11): initial version

class `sage.combinat.crystals.mv_polytopes.MVPolytope`(*parent, lusztig_datum, long_word=None*)
 Bases: `sage.combinat.crystals.pbw_crystal.PBWCrystalElement`

A Mirković-Vilonen (MV) polytope.

EXAMPLES:

We can create an animation showing how the MV polytope changes under a string of crystal operators:

```

sage: MV = crystals.infinity.MVPolytopes(['C', 2])
sage: u = MV.highest_weight_vector()
sage: L = RootSystem(['C', 2, 1]).ambient_space()
sage: s = [1, 2, 1, 2, 2, 2, 1, 1, 1, 1, 2, 1, 2, 2, 1, 2]
sage: BB = [[-9, 2], [-10, 2]]
sage: p = L.plot(reflection_hyperplanes=False, bounding_box=BB) # long time
sage: frames = [p + L.plot_mv_polytope(u.f_string(s[:i]), # long time
.....:                                     circle_size=0.1,
.....:                                     wireframe='green',
.....:                                     fill='purple',
.....:                                     bounding_box=BB)
.....:          for i in range(len(s))]
sage: for f in frames: # long time
.....:     f.axes(False)
sage: animate(frames).show(delay=60) # optional -- ImageMagick # long time

```

plot($P=None$, ***options*)

Plot self.

INPUT:

- P – (optional) a space to realize the polytope; default is the weight lattice realization of the crystal

See also:

[`plot_mv_polytope\(\)`](#)

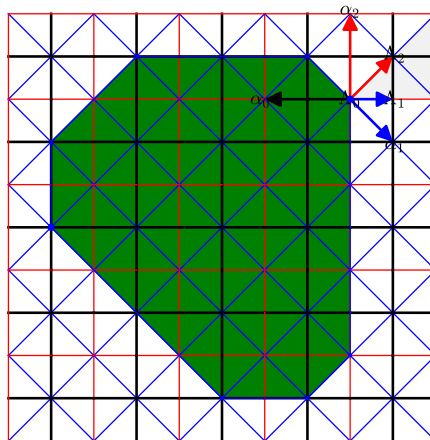

EXAMPLES:

```

sage: MV = crystals.infinity.MVPolytopes(['C', 2])
sage: b = MV.highest_weight_vector().f_string([1, 2, 1, 2, 2, 2, 1, 1, 1, 1, 2, 1])
sage: b.plot()
Graphics object consisting of 12 graphics primitives

```

Here is the above example placed inside the ambient space of type C_2 :

polytope($P=None$)

Return a polytope of self.

INPUT:

- P – (optional) a space to realize the polytope; default is the weight lattice realization of the crystal

EXAMPLES:

```
sage: MV = crystals.infinity.MVPolytopes(['C', 3])
sage: b = MV.module_generators[0].f_string([3,2,3,2,1])
sage: P = b.polytope(); P
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 6 vertices
sage: P.vertices()
(A vertex at (0, 0, 0),
 A vertex at (0, 1, -1),
 A vertex at (0, 1, 1),
 A vertex at (1, -1, 0),
 A vertex at (1, 1, -2),
 A vertex at (1, 1, 2))
```

class `sage.combinat.crystals.mv_polytopes.MVPolytopes`(*cartan_type*)

Bases: `sage.combinat.crystals.pbw_crystal.PBWCrystal`

The crystal of Mirković-Vilonen (MV) polytopes.

Let W denote the corresponding Weyl group and $P_{\mathbf{R}} = \mathbf{R} \otimes P$. Let $\Gamma = \{w\Lambda_i \mid w \in W, i \in I\}$. Consider $M = (M_\gamma \in \mathbf{Z})_{\gamma \in \Gamma}$ that satisfy the *tropical Plücker relations* (see Proposition 7.1 of [BZ01]). The *MV polytope* is defined as

$$P(M) = \{\alpha \in P_{\mathbf{R}} \mid \langle \alpha, \gamma \rangle \geq M_\gamma \text{ for all } \gamma \in \Gamma\}.$$

The vertices $\{\mu_w\}_{w \in W}$ are given by

$$\langle \mu_w, \gamma \rangle = M_\gamma$$

and are known as the GGMS datum of the MV polytope.

Each path from μ_e to μ_{w_0} corresponds to a reduced expression $\mathbf{i} = (i_1, \dots, i_m)$ for w_0 and the corresponding edge lengths $(n_k)_{k=1}^m$ from the Lusztig datum with respect to \mathbf{i} . Explicitly, we have

$$n_k = -M_{w_{k-1}\Lambda_{i_k}} - M_{w_k\Lambda_{i_k}} - \sum_{j \neq i} a_{ji} M_{w_k\Lambda_j},$$

$$\mu_{w_k} - \mu_{w_{k-1}} = n_k w_{k-1} \alpha_{i_k},$$

where $w_k = s_{i_1} \cdots s_{i_k}$ and (a_{ji}) is the Cartan matrix.

MV polytopes have a crystal structure that corresponds to the crystal structure, which is isomorphic to $\mathcal{B}(\infty)$ with $\mu_{w_0} = 0$, on *PBW data*. Specifically, we have $f_j P(M)$ as being the unique MV polytope given by shifting μ_e by $-\alpha_j$ and fixing the vertices μ_w when $s_j w < w$ (in Bruhat order) and the weight is given by μ_e . Furthermore, the $*$ -involution is given by negating $P(M)$.

INPUT:

- *cartan_type* – a Cartan type

EXAMPLES:

```
sage: MV = crystals.infinity.MVPolytopes(['B', 3])
sage: hw = MV.highest_weight_vector()
sage: x = hw.f_string([1,2,2,3,3,1,3,3,2,3,2,1,3,1,2,3,1,2,1,3,2]); x
MV polytope with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

Elements are expressed in terms of Lusztig datum for a fixed reduced expression of w_0 :

```

sage: MV.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: MV.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: x
MV polytope with Lusztig datum (3, 1, 1, 0, 1, 0, 1, 3, 4)
sage: MV.set_default_long_word([1, 3, 2, 3, 1, 2, 3, 1, 2])

```

We can construct elements by giving it Lusztig data (with respect to the default long word reduced expression):

```

sage: MV([1,1,1,3,1,0,0,1,1])
MV polytope with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)

```

We can also construct elements by passing in a reduced expression for a long word:

```

sage: x = MV([1,1,1,3,1,0,0,1,1], [3,2,1,3,2,3,2,1,2]); x
MV polytope with Lusztig datum (1, 1, 1, 0, 1, 0, 5, 1, 1)
sage: x.to_highest_weight()[1]
[1, 2, 2, 2, 2, 2, 1, 3, 3, 3, 3, 2, 3, 2, 3, 3, 2, 3, 3, 2, 1, 3]

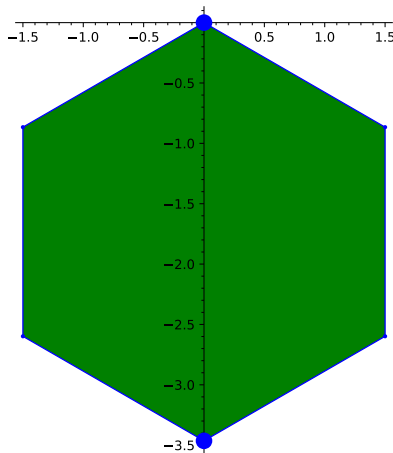

```

The highest weight crystal $B(\lambda) \subseteq B(\infty)$ is characterized by the MV polytopes that sit inside of $W\lambda$ (translating $\mu_{w_0} \mapsto \lambda$):

```

sage: MV = crystals.infinity.MVPolytopes(['A',2])
sage: La = MV.weight_lattice_realization().fundamental_weights()
sage: R = crystals.elementary.R(La[1]+La[2])
sage: T = tensor([R, MV])
sage: x = T(R.module_generators[0], MV.highest_weight_vector())
sage: lw = x.to_lowest_weight()[0]; lw
[(2, 1, 0), MV polytope with Lusztig datum (1, 1, 1)]
sage: lw[1].polytope().vertices()
(A vertex at (0, 0, 0),
 A vertex at (0, 1, -1),
 A vertex at (1, -1, 0),
 A vertex at (1, 1, -2),
 A vertex at (2, -1, -1),
 A vertex at (2, 0, -2))

```

REFERENCES:

- [Kam2007]
- [Kam2010]

Element

alias of *MVPolytope*

latex_options()

Return the latex options of *self*.

EXAMPLES:

```
sage: MV = crystals.infinity.MVPolytopes(['F', 4])
sage: MV.latex_options()
{'P': Ambient space of the Root system of type ['F', 4],
 'circle_size': 0.1,
 'mark_endpoints': True,
 'projection': True}
```

set_latex_options(kws)**

Set the latex options for the elements of *self*.

INPUT:

- *projection* – the projection; set to `True` to use the default projection of the specified weight lattice realization (initial: `True`)
- *P* – the weight lattice realization to use (initial: the weight lattice realization of *self*)
- *mark_endpoints* – whether to mark the endpoints (initial: `True`)
- *circle_size* – the size of the endpoint circles (initial: `0.1`)

EXAMPLES:

```
sage: MV = crystals.infinity.MVPolytopes(['C', 2])
sage: P = RootSystem(['C', 2]).weight_lattice()
sage: b = MV.highest_weight_vector().f_string([1,2,1,2])
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (0, -2) -- (-1, -3) -- (-1, -3) -- (-2, -2);
\draw (0, 0) -- (-1, 1) -- (-1, 1) -- (-2, 0) -- (-2, -2);
\draw[fill=black] (0, 0) circle (0.1);
\draw[fill=black] (-2, -2) circle (0.1);
\end{tikzpicture}
sage: MV.set_latex_options(P=P, circle_size=float(0.2))
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (2, -2) -- (2, -3) -- (2, -3) -- (0, -2);
\draw (0, 0) -- (-2, 1) -- (-2, 1) -- (-2, 0) -- (0, -2);
\draw[fill=black] (0, 0) circle (0.2);
\draw[fill=black] (0, -2) circle (0.2);
\end{tikzpicture}
sage: MV.set_latex_options(mark_endpoints=False)
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (2, -2) -- (2, -3) -- (2, -3) -- (0, -2);
\draw (0, 0) -- (-2, 1) -- (-2, 1) -- (-2, 0) -- (0, -2);
\end{tikzpicture}
```

(continues on next page)

(continued from previous page)

```

sage: MV.set_latex_options(P=MV.weight_lattice_realization(),
.....:                       circle_size=0.2,
.....:                       mark_endpoints=True)

```

5.1.61 $\mathcal{B}(\infty)$ Crystal Of PBW Monomials

AUTHORS:

- Dinakar Muthiah (2015-05-11): initial version

See also:

For information on PBW datum, see [PBW Data](#).

```

class sage.combinat.crystals.pbw_crystal.PBWCrystal(cartan_type)
    Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresentation

```

Crystal of $\mathcal{B}(\infty)$ given by PBW monomials.

A model of the crystal $\mathcal{B}(\infty)$ whose elements are PBW datum up to equivalence by the tropical Plücker relations. The crystal structure on Lusztig data $x = (x_1, \dots, x_m)$ for the reduced word $s_{i_1} \cdots s_{i_m} = w_0$ is given as follows. Suppose $i_1 = j$, then $f_j x = (x_1 + 1, x_2, \dots, x_m)$. If $i_1 \neq j$, then we use the tropical Plücker relations to change the reduced expression such that $i'_1 = j$ and then we change back to the original word.

EXAMPLES:

```

sage: PBW = crystals.infinity.PBW(['B', 3])
sage: hw = PBW.highest_weight_vector()
sage: x = hw.f_string([1,2,2,3,3,1,3,3,2,3,2,1,3,1,2,3,1,2,1,3,2]); x
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)

```

Elements are expressed in terms of Lusztig datum for a fixed reduced expression of w_0 :

```

sage: PBW.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: PBW.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: x
PBW monomial with Lusztig datum (3, 1, 1, 0, 1, 0, 1, 3, 4)
sage: PBW.set_default_long_word([1, 3, 2, 3, 1, 2, 3, 1, 2])

```

We can construct elements by giving it Lusztig data (with respect to the default long word):

```

sage: PBW([1,1,1,3,1,0,0,1,1])
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)

```

We can also construct elements by passing in a reduced expression for a long word:

```

sage: x = PBW([1,1,1,3,1,0,0,1,1], [3,2,1,3,2,3,2,1,2]); x
PBW monomial with Lusztig datum (1, 1, 1, 0, 1, 0, 5, 1, 1)
sage: x.to_highest_weight()[1]
[1, 2, 2, 2, 2, 2, 1, 3, 3, 3, 3, 2, 3, 2, 3, 3, 2, 3, 3, 2, 1, 3]

```

Element

alias of `PBWCrystalElement`

default_long_word()

Return the default long word used to express elements of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['E', 6])
sage: B.default_long_word()
[1, 3, 4, 5, 6, 2, 4, 5, 3, 4, 1, 3, 2, 4, 5, 6, 2, 4,
 5, 3, 4, 1, 3, 2, 4, 5, 3, 4, 1, 3, 2, 4, 1, 3, 2, 1]
```

set_default_long_word(word)

Set the default long word used to express elements of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['C', 3])
sage: B.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: x = B.highest_weight_vector().f_string([2,1,3,2,3,1,2,3,3,1])
sage: x
PBW monomial with Lusztig datum (1, 2, 2, 0, 0, 0, 0, 0, 1)
sage: B.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: B.default_long_word()
[2, 1, 3, 2, 1, 3, 2, 3, 1]
sage: x
PBW monomial with Lusztig datum (2, 0, 0, 0, 0, 0, 1, 3, 2)
```

class `sage.combinat.crystals.pbw_crystal.PBWCrystalElement`(*parent*, *lusztig_datum*,
long_word=None)

Bases: `sage.structure.element.Element`

A crystal element in the PBW model.

e(i)

Return the action of e_i on `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['B', 3])
sage: b = B.highest_weight_vector()
sage: c = b.f_string([2,1,3,2,1,3,2,2]); c
PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 2)
sage: c.e(2)
PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 1)
sage: c.e_string([2,2,1,3,2,1,3,2]) == b
True
```

epsilon(i)

Return ε_i of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(["A2"])
sage: s = B((3,0,0), (1,2,1))
sage: s.epsilon(1)
3
```

(continues on next page)

(continued from previous page)

```
sage: s.epsilon(2)
0
```

f(i)Return the action of f_i on self.

EXAMPLES:

```
sage: B = crystals.infinity.PBW("D4")
sage: b = B.highest_weight_vector()
sage: c = b.f_string([1,2,3,1,2,3,4]); c
PBW monomial with Lusztig datum (0, 1, 0, 0, 0, 0, 0, 2, 0, 0, 2, 0)
sage: c == b.f_string([1,2,4,1,2,3,3])
True
```

lusztig_datum(word=None)

Return the Lusztig datum of self with respect to the reduced expression of the long word word.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['A', 2])
sage: u = B.highest_weight_vector()
sage: b = u.f_string([2,1,2,2,2,2,1,1,2,1,2,1,2,2])
sage: b.lusztig_datum()
(6, 0, 10)
sage: b.lusztig_datum(word=[2,1,2])
(4, 6, 0)
```

phi(i)Return φ_i of self.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['A', 2])
sage: s = B((3,0,0), (1,2,1))
sage: s.phi(1)
-3
sage: s.phi(2)
3
```

star()

Return the starred crystal element corresponding to self.

Let b be an element of self with Lusztig datum (b_1, \dots, b_N) with respect to $w_0 = s_{i_1} \cdots s_{i_N}$. Then b^* is the element with Lusztig datum (b_N, \dots, b_1) with respect to $w_0 = s_{i_N^*} \cdots s_{i_1^*}$, where $i_j^* = \omega(i_j)$ with ω being the *automorphism* given by the action of w_0 on the simple roots.

EXAMPLES:

```
sage: P = crystals.infinity.PBW(['A', 2])
sage: P((1,2,3), (1,2,1)).star() == P((3,2,1), (2,1,2))
True

sage: B = crystals.infinity.PBW(['E', 6])
sage: b = B.highest_weight_vector()
```

(continues on next page)

(continued from previous page)

```

sage: c = b.f_string([1,2,6,3,4,2,5,2,3,4,1,6])
sage: c == c.star().star()
True

```

weight()

Return weight of self.

EXAMPLES:

```

sage: B = crystals.infinity.PBW(['A', 2])
sage: s = B((2,2,2), (1,2,1))
sage: s.weight()
(-4, 0, 4)

```

5.1.62 PBW Data

This contains helper classes and functions which encode PBW data in finite type.

AUTHORS:

- Dinakar Muthiah (2015-05): initial version
- Travis Scrimshaw (2016-06): simplified code and converted to Cython

class sage.combinat.crystals.pbw_datum.PBWData(*cartan_type*)
Bases: object

Helper class for the set of PBW data.

convert_to_new_long_word(*pbw_datum*, *new_long_word*)Convert the PBW datum *pbw_datum* from its long word to *new_long_word*.

EXAMPLES:

```

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
sage: datum = PBWDatum(P, (1,2,1), (1,0,1))
sage: new_datum = P.convert_to_new_long_word(datum, (2,1,2))
sage: new_datum
PBW Datum element of type ['A', 2] with long word (2, 1, 2)
and Lusztig datum (0, 1, 0)
sage: new_datum.long_word
(2, 1, 2)
sage: new_datum.lusztig_datum
(0, 1, 0)

```

class sage.combinat.crystals.pbw_datum.PBWDatum(*parent*, *long_word*, *lusztig_datum*)
Bases: object

Helper class which represents a PBW datum.

convert_to_long_word_with_first_letter(*i*)Return a new PBWDatum equivalent to *self* whose long word begins with *i*.

EXAMPLES:

```

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A3")
sage: datum = PBWDatum(P, (1,2,1,3,2,1), (1,0,1,4,2,3))
sage: datum.convert_to_long_word_with_first_letter(1)
PBW Datum element of type ['A', 3] with long word (1, 2, 3, 1, 2, 1)
and Lusztig datum (1, 0, 4, 1, 2, 3)
sage: datum.convert_to_long_word_with_first_letter(2)
PBW Datum element of type ['A', 3] with long word (2, 1, 2, 3, 2, 1)
and Lusztig datum (0, 1, 0, 4, 2, 3)
sage: datum.convert_to_long_word_with_first_letter(3)
PBW Datum element of type ['A', 3] with long word (3, 1, 2, 3, 1, 2)
and Lusztig datum (8, 1, 0, 4, 1, 2)

```

convert_to_new_long_word(*new_long_word*)

Return a new PBWDatum equivalent to self whose long word is *new_long_word*.

EXAMPLES:

```

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
sage: datum = PBWDatum(P, (1,2,1), (1,0,1))
sage: new_datum = datum.convert_to_new_long_word((2,1,2))
sage: new_datum.long_word
(2, 1, 2)
sage: new_datum.lusztig_datum
(0, 1, 0)

```

is_equivalent_to(*other_pbw_datum*)

Return whether self is equivalent to *other_pbw_datum*. modulo the tropical Plücker relations.

EXAMPLES:

```

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
sage: L1 = PBWDatum(P, (1,2,1), (1,0,1))
sage: L2 = PBWDatum(P, (2,1,2), (0,1,0))
sage: L1.is_equivalent_to(L2)
True
sage: L1 == L2
False

```

star()

Return the starred version of self, i.e., with reversed *long_word* and *lusztig_datum*

EXAMPLES:

```

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
sage: L1 = PBWDatum(P, (1,2,1), (1,2,3))
sage: L1.star() == PBWDatum(P, (2,1,2), (3,2,1))
True

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
sage: L = PBWDatum(P, (1,2,1), (1,1,1))
sage: L.weight()
-2*alpha[1] - 2*alpha[2]

```

`sage.combinat.crystals.pbw_datum.compute_new_lusztig_datum`(*enhanced_braid_chain*,
initial_lusztig_datum)

Return the Lusztig datum obtained by applying tropical Plücker relations along *enhanced_braid_chain* starting with *initial_lusztig_datum*.

EXAMPLES:

```

sage: from sage.combinat.root_system.braid_move_calculator import BraidMoveCalculator
sage: from sage.combinat.crystals.pbw_datum import enhance_braid_move_chain
sage: from sage.combinat.crystals.pbw_datum import compute_new_lusztig_datum
sage: ct = CartanType(['A', 2])
sage: W = CoxeterGroup(ct)
sage: B = BraidMoveCalculator(W)
sage: chain = B.chain_of_reduced_words((1,2,1),(2,1,2))
sage: enhanced_braid_chain = enhance_braid_move_chain(chain, ct)
sage: compute_new_lusztig_datum(enhanced_braid_chain,(1,0,1))
(0, 1, 0)

```

`sage.combinat.crystals.pbw_datum.enhance_braid_move_chain`(*braid_move_chain*, *cartan_type*)

Return a list of tuples that records the data of the long words in *braid_move_chain* plus the data of the intervals where the braid moves occur and the data of the off-diagonal entries of the 2×2 Cartan submatrices of each braid move.

INPUT:

- *braid_move_chain* – a chain of reduced words in the Weyl group of *cartan_type*
- *cartan_type* – a finite Cartan type

OUTPUT:

A list of 2-tuples (*interval_of_change*, *cartan_sub_matrix*) where

- *interval_of_change* is the (half-open) interval of indices where the braid move occurs; this is *None* for the first tuple
- *cartan_sub_matrix* is the off-diagonal entries of the 2×2 submatrix of the Cartan matrix corresponding to the braid move; this is *None* for the first tuple

For a matrix:

```

[2 a]
[b 2]

```

the *cartan_sub_matrix* is the pair (a, b).

`sage.combinat.crystals.pbw_datum.tropical_plucker_relation`(*a*, *lusztig_datum*)

Apply the tropical Plücker relation of type *a* to *lusztig_datum*.

The relations are obtained by tropicalizing the relations in Proposition 7.1 of [BZ01].

INPUT:

- a – a pair (x, y) of the off-diagonal entries of a 2×2 Cartan matrix

EXAMPLES:

```
sage: from sage.combinat.crystals.pbw_datum import tropical_plucker_relation
sage: tropical_plucker_relation((0,0), (2,3))
(3, 2)
sage: tropical_plucker_relation((-1,-1), (1,2,3))
(4, 1, 2)
sage: tropical_plucker_relation((-1,-2), (1,2,3,4))
(8, 1, 2, 3)
sage: tropical_plucker_relation((-2,-1), (1,2,3,4))
(6, 1, 2, 3)
```

5.1.63 Polyhedral Realization of $B(\infty)$

`class sage.combinat.crystals.polyhedral_realization.InfinityCrystalAsPolyhedralRealization`(*cartan_type*, *seq*)

Bases: `sage.combinat.crystals.tensor_product.TensorProductOfCrystals`

The polyhedral realization of $B(\infty)$.

Note: Here we are using anti-Kashiwara notation and might differ from some of the literature.

Consider a Kac-Moody algebra \mathfrak{g} of Cartan type X with index set I , and consider a finite sequence $J = (j_1, j_2, \dots, j_m)$ whose support equals I . We extend this to an infinite sequence by taking $\bar{J} = J \cdot J \cdot J \dots$, where \cdot denotes concatenation of sequences. Let

$$B_J = B_{j_m} \otimes \cdots \otimes B_{j_2} \otimes B_{j_1},$$

where B_i is an *ElementaryCrystal*.

As given in Theorem 2.1.1 of [Ka1993], there exists a strict crystal embedding $\Psi_i: B(\infty) \rightarrow B_i \otimes B(\infty)$ defined by $u_\infty \mapsto b_i(0) \otimes u_\infty$, where $b_i(0) \in B_i$ and u_∞ is the (unique) highest weight element in $B(\infty)$. This is sometimes known as the *Kashiwara embedding* [NZ1997] (though, in [NZ1997], the target of this map is denoted by \mathcal{Z}^∞). By iterating this embedding by taking $\Psi_J = \Psi_{j_n} \circ \Psi_{j_{n-1}} \circ \cdots \circ \Psi_{j_1}$, we obtain the following strict crystal embedding:

$$\Psi_J^n: B(\infty) \rightarrow B_J^{\otimes n} \otimes B(\infty).$$

We note there is a natural analog of Lemma 10.6.2 in [HK2002] that for any $b \in B(\infty)$, there exists a positive integer N such that

$$\Psi_J^N(b) = \left(\bigotimes_{k=1}^N b^{(k)} \right) \otimes u_\infty.$$

Therefore we can model elements $b \in B(\infty)$ by considering an infinite list of elements $b^{(k)} \in B_J$ and defining

the crystal structure by:

$$\begin{aligned} \text{wt}(b) &= \sum_{k=1}^N \text{wt}(b^{(k)}) \\ e_i(b) &= e_i \left(\left(\bigotimes_{k=1}^N b^{(k)} \right) \right) \otimes u_\infty, \\ f_i(b) &= f_i \left(\left(\bigotimes_{k=1}^N b^{(k)} \right) \right) \otimes u_\infty, \\ \varepsilon_i(b) &= \max_{e_i^k(b) \neq 0} k, \\ \varphi_i(b) &= \varepsilon_i(b) - \langle \text{wt}(b), h_i^\vee \rangle. \end{aligned}$$

To translate this into a finite list, we consider a finite sequence $b_1 \otimes \cdots \otimes b_N$ and if

$$f_i \left(b^{(1)} \otimes \cdots \otimes b^{(N-1)} \otimes b^{(N)} \right) = b^{(1)} \otimes \cdots \otimes b^{(N-1)} \otimes f_i \left(b^{(N)} \right),$$

then we take the image as $b^{(1)} \otimes \cdots \otimes f_i \left(b^{(N)} \right) \otimes b^{(N+1)}$. Similarly we remove $b^{(N)}$ if we have $b^{(N)} = \bigotimes_{k=1}^m b_{j_k}(0)$. Additionally if

$$e_i \left(b^{(1)} \otimes \cdots \otimes b^{(N-1)} \otimes b^{(N)} \right) = b^{(1)} \otimes \cdots \otimes b^{(N-1)} \otimes e_i \left(b^{(N)} \right),$$

then we consider this to be 0.

INPUT:

- `cartan_type` – a Cartan type
- `seq` – (default: None) a finite sequence whose support equals the index set of the Cartan type; if None, then this is the index set

EXAMPLES:

```
sage: B = crystals.infinity.PolyhedralRealization(['A', 2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2, 1, 2, 2])
[0, -3, -1, 0, 0, 0]
```

An example of type B_2 :

```
sage: B = crystals.infinity.PolyhedralRealization(['B', 2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2, 1, 2, 2])
[0, -2, -1, -1, 0, 0]
```

An example of type G_2 :

```
sage: B = crystals.infinity.PolyhedralRealization(['G', 2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2, 1, 2, 2])
[0, -3, -1, 0, 0, 0]
```

class Element

Bases: `sage.combinat.crystals.tensor_product_element.TensorProductOfCrystalsElement`

An element in the polyhedral realization of $B(\infty)$.

e(i)

Return the action of e_i on self.

EXAMPLES:

```
sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: mg = B.module_generators[0]
sage: all(mg.e(i) is None for i in B.index_set())
True
sage: mg.f(1).e(1) == mg
True
```

epsilon(i)

Return ε_i of self.

EXAMPLES:

```
sage: B = crystals.infinity.PolyhedralRealization(['A',2,1])
sage: mg = B.module_generators[0]
sage: [mg.epsilon(i) for i in B.index_set()]
[0, 0, 0]
sage: elt = mg.f(0)
sage: [elt.epsilon(i) for i in B.index_set()]
[1, 0, 0]
sage: elt = mg.f_string([0,1,2])
sage: [elt.epsilon(i) for i in B.index_set()]
[0, 0, 1]
sage: elt = mg.f_string([0,1,2,2])
sage: [elt.epsilon(i) for i in B.index_set()]
[0, 0, 2]
```

f(i)

Return the action of f_i on self.

EXAMPLES:

```
sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: mg = B.module_generators[0]
sage: mg.f(1)
[-1, 0, 0, 0]
sage: mg.f_string([1,2,2,1])
[-1, -2, -1, 0, 0, 0]
```

phi(i)

Return φ_i of self.

EXAMPLES:

```
sage: B = crystals.infinity.PolyhedralRealization(['A',2,1])
sage: mg = B.module_generators[0]
sage: [mg.phi(i) for i in B.index_set()]
[0, 0, 0]
```

(continues on next page)

(continued from previous page)

```

sage: elt = mg.f(0)
sage: [elt.phi(i) for i in B.index_set()]
[-1, 1, 1]
sage: elt = mg.f_string([0,1])
sage: [elt.phi(i) for i in B.index_set()]
[-1, 0, 2]
sage: elt = mg.f_string([0,1,2,2])
sage: [elt.phi(i) for i in B.index_set()]
[1, 1, 0]

```

truncate(*k=None*)

Truncate *self* to have length *k* and return as an element in a (finite) tensor product of crystals.

INPUT:

- *k* – (optional) the length of the truncation; if not specified, then returns one more than the current non-ground-state elements (i.e. the current list in *self*)

EXAMPLES:

```

sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: mg = B.module_generators[0]
sage: elt = mg.f_string([1,2,2,1]); elt
[-1, -2, -1, 0, 0, 0]
sage: t = elt.truncate(); t
[-1, -2, -1, 0, 0, 0]
sage: t.parent() is B.finite_tensor_product(6)
True
sage: elt.truncate(2)
[-1, -2]
sage: elt.truncate(10)
[-1, -2, -1, 0, 0, 0, 0, 0, 0, 0]

```

finite_tensor_product(*k*)

Return the finite tensor product of crystals of length *k* by truncating *self*.

EXAMPLES:

```

sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: B.finite_tensor_product(5)
Full tensor product of the crystals
[The 1-elementary crystal of type ['A', 2],
 The 2-elementary crystal of type ['A', 2],
 The 1-elementary crystal of type ['A', 2],
 The 2-elementary crystal of type ['A', 2],
 The 1-elementary crystal of type ['A', 2]]

```

5.1.64 Spin Crystals

These are the crystals associated with the three spin representations: the spin representations of odd orthogonal groups (or rather their double covers); and the $+$ and $-$ spin representations of the even orthogonal groups.

We follow Kashiwara and Nakashima (Journal of Algebra 165, 1994) in representing the elements of the spin crystal by sequences of signs \pm .

`sage.combinat.crystals.spins.CrystalOfSpins(ct)`

Return the spin crystal of the given type B .

This is a combinatorial model for the crystal with highest weight Λ_n (the n -th fundamental weight). It has 2^n elements, here called Spins. See also [CrystalOfLetters\(\)](#), [CrystalOfSpinsPlus\(\)](#), and [CrystalOfSpinsMinus\(\)](#).

INPUT:

- ['B', n] - A Cartan type B_n .

EXAMPLES:

```
sage: C = crystals.Spins(['B',3])
sage: C.list()
[+++ , +-+ , ++- , -++ , +-- , --+ , --- , ---]
sage: C.cartan_type()
['B', 3]
```

```
sage: [x.signature() for x in C]
['+++ ', '++- ', '+-- ', '-++ ', '+-- ', '-+- ', '--- ', '--- ']
```

`sage.combinat.crystals.spins.CrystalOfSpinsMinus(ct)`

Return the minus spin crystal of the given type D .

This is the crystal with highest weight Λ_{n-1} (the $(n-1)$ -st fundamental weight).

INPUT:

- ['D', n] - A Cartan type D_n .

EXAMPLES:

```
sage: E = crystals.SpinsMinus(['D',4])
sage: E.list()
[++++ , ++++ , +++- , -+++ , +--- , ---- , ---+ , ---+ ]
sage: [x.signature() for x in E]
['++++ ', '++++ ', '+++- ', '-+++ ', '+--- ', '---- ', '---+ ', '---+ ']
```

`sage.combinat.crystals.spins.CrystalOfSpinsPlus(ct)`

Return the plus spin crystal of the given type D .

This is the crystal with highest weight Λ_n (the n -th fundamental weight).

INPUT:

- ['D', n] - A Cartan type D_n .

EXAMPLES:

```
sage: D = crystals.SpinsPlus(['D',4])
sage: D.list()
[++++ , +++- , +--- , -+++ , +--- , -+++ , ---+ , ---+ ]
```

```
sage: [x.signature() for x in D]
['++++', '++--', '+-+-', '-+-+', '+++', '-+-+', '--++', '----']
```

class sage.combinat.crystals.spins.GenericCrystalOfSpins(*ct, element_class, case*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A generic crystal of spins.

lt_elements(*x, y*)

Return True if and only if there is a path from *x* to *y* in the crystal graph.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:

```
sage: C = crystals.Spins(['B', 3])
sage: x = C([1, 1, 1])
sage: y = C([-1, -1, -1])
sage: C.lt_elements(x, y)
True
sage: C.lt_elements(y, x)
False
sage: C.lt_elements(x, x)
False
```

class sage.combinat.crystals.spins.Spin

Bases: sage.structure.element.Element

A spin letter in the crystal of spins.

EXAMPLES:

```
sage: C = crystals.Spins(['B', 3])
sage: c = C([1, 1, 1])
sage: c
+++
sage: c.parent()
The crystal of spins for type ['B', 3]

sage: D = crystals.Spins(['B', 4])
sage: a = C([1, 1, 1])
sage: b = C([-1, -1, -1])
sage: c = D([1, 1, 1, 1])
sage: a == a
True
sage: a == b
False
sage: b == c
False
```

pp()

Pretty print self as a column.

EXAMPLES:

```
sage: C = crystals.Spins(['B',3])
sage: b = C([1,1,-1])
sage: b.pp()
+
+
-
```

signature()

Return the signature of self.

EXAMPLES:

```
sage: C = crystals.Spins(['B',3])
sage: C([1,1,1]).signature()
'+++'
sage: C([1,1,-1]).signature()
'++-'
```

value

Return self as a tuple with +1 and -1.

EXAMPLES:

```
sage: C = crystals.Spins(['B',3])
sage: C([1,1,1]).value
(1, 1, 1)
sage: C([1,1,-1]).value
(1, 1, -1)
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Spins(['B',3])]
[(1/2, 1/2, 1/2), (1/2, 1/2, -1/2),
 (1/2, -1/2, 1/2), (-1/2, 1/2, 1/2),
 (1/2, -1/2, -1/2), (-1/2, 1/2, -1/2),
 (-1/2, -1/2, 1/2), (-1/2, -1/2, -1/2)]
```

class sage.combinat.crystals.spins.Spin_crystal_type_B_element

Bases: [sage.combinat.crystals.spins.Spin](#)

Type B spin representation crystal element

e(i)

Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.Spins(['B',3])
sage: [[C[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, None, +++], [None, ++-, None], [++-, None, None],
 [None, None, ++-], [+-, None, -+-], [None, -+-, None], [None, None, --+]]
```

epsilon(i)

Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Spins(['B',3])
sage: [[C[m].epsilon(i) for i in range(1,4)] for m in range(8)]
[[0, 0, 0], [0, 0, 1], [0, 1, 0], [1, 0, 0],
 [0, 0, 1], [1, 0, 1], [0, 1, 0], [0, 0, 1]]
```

f(i)

Return the action of f_i on self.

EXAMPLES:

```
sage: C = crystals.Spins(['B',3])
sage: [[C[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, ++-], [None, ++-, None], [-+-, None, +--], [None, None, --+],
 [-+-, None, None], [None, --+, None], [None, None, ---], [None, None, None]]
```

phi(i)

Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.Spins(['B',3])
sage: [[C[m].phi(i) for i in range(1,4)] for m in range(8)]
[[0, 0, 1], [0, 1, 0], [1, 0, 1], [0, 0, 1],
 [1, 0, 0], [0, 1, 0], [0, 0, 1], [0, 0, 0]]
```

class sage.combinat.crystals.spins.Spin_crystal_type_D_element

Bases: [sage.combinat.crystals.spins.Spin](#)

Type D spin representation crystal element

e(i)

Return the action of e_i on self.

EXAMPLES:

```
sage: D = crystals.SpinsPlus(['D',4])
sage: [[D.list()[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, None, None], [None, +---, None], [+---, None, None],
 [None, None, +---], [+---, None, -+--], [None, -+--, None], [None, None, None]]
```

```
sage: E = crystals.SpinsMinus(['D',4])
sage: [[E[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, None, +++-], [None, +++-, None], [+++-, None, None],
 [None, None, None], [+---, None, None], [None, -+--, None], [None, None, -+--]]
```

epsilon(i)

Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.SpinsMinus(['D',4])
sage: [[C[m].epsilon(i) for i in C.index_set()] for m in range(8)]
[[0, 0, 0, 0], [0, 0, 1, 0], [0, 1, 0, 0], [1, 0, 0, 0],
 [0, 0, 0, 1], [1, 0, 0, 1], [0, 1, 0, 0], [0, 0, 1, 0]]
```

f(i)Return the action of f_i on self.

EXAMPLES:

```
sage: D = crystals.SpinsPlus(['D',4])
sage: [[D.list()[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, +---, None], [-+---, None, +---+], [None, None, -+---],
[-+---, None, None], [None, -+---, None], [None, None, None], [None, None, None]]
```

```
sage: E = crystals.SpinsMinus(['D',4])
sage: [[E[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, +---+], [None, +---+, None], [-+---, None, None], [None, None, None],
[-+---, None, None], [None, -+---, None], [None, None, -+---], [None, None, None]]
```

phi(i)Return φ_i of self.

EXAMPLES:

```
sage: C = crystals.SpinsPlus(['D',4])
sage: [[C[m].phi(i) for i in C.index_set()] for m in range(8)]
[[0, 0, 0, 1], [0, 1, 0, 0], [1, 0, 1, 0], [0, 0, 1, 0],
[1, 0, 0, 0], [0, 1, 0, 0], [0, 0, 0, 1], [0, 0, 0, 0]]
```

5.1.65 Star-Crystal Structure On $B(\infty)$

AUTHORS:

- Ben Salisbury: Initial version
- Travis Scrimshaw: Initial version

class sage.combinat.crystals.star_crystal.StarCrystal(*Binf*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The star-crystal or *-crystal version of a highest weight crystal.

The *-crystal structure on $B(\infty)$ is the structure induced by the algebra antiautomorphism $*$: $U_q(\mathfrak{g}) \longrightarrow U_q(\mathfrak{g})$ that stabilizes the negative half $U_{q^-}(\mathfrak{g})$. It is defined by

$$E_i^* = E_i, \quad F_i^* = F_i, \quad q^* = q, \quad (q^h)^* = q^{-h},$$

where E_i and F_i are the Chevalley generators of $U_q(\mathfrak{g})$ and h is an element of the Cartan subalgebra.The induced operation on the crystal $B(\infty)$ is called the *Kashiwara involution*. Its implementation here is based on the recursive algorithm from Theorem 2.2.1 of [Ka1993], which states that for any $i \in I$ there is a unique strict crystal embedding

$$\Psi_i: B(\infty) \longrightarrow B_i \otimes B(\infty)$$

such that

- $u_\infty \mapsto b_i(0) \otimes u_\infty$, where u_∞ is the highest weight vector in $B(\infty)$;
- if $\Psi_i(b) = f_i^m b_i(0) \otimes b_0$, then $\Psi_i(f_i^* b) = f_i^{m+1} b_i(0) \otimes b_0$ and $\varepsilon_i(b^*) = m$;
- the image of Ψ_i is $\{f_i^m b_i(0) \otimes b : \varepsilon_i(b^*) = 0, m \geq 0\}$.

Here, B_i is the i -th elementary crystal. See *ElementaryCrystal* for more information.

INPUT:

- `Binf` – a crystal from *catalog_infinity_crystals*

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['A', 2])
sage: Bstar = crystals.infinity.Star(B)
sage: mg = Bstar.highest_weight_vector()
sage: mg
[[1, 1], [2]]
sage: mg.f_string([1, 2, 1, 2, 2])
[[1, 1, 1, 1, 1, 2, 2], [2, 3, 3, 3]]
```

class Element

Bases: `sage.structure.element_wrapper.ElementWrapper`

`e(i)`

Return the action of e_i^* on `self`.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['E', 6, 1])
sage: RCstar = crystals.infinity.Star(RC)
sage: nuJ = RCstar.module_generators[0].f_string([0, 4, 6, 1, 2])
sage: ascii_art(nuJ.e(1))
-1[ ]-1  (/)  0[ ]1  (/)  -1[ ]-1  (/)  -2[ ]-1

sage: M = crystals.infinity.NakajimaMonomials(['B', 2, 1])
sage: Mstar = crystals.infinity.Star(M)
sage: m = Mstar.module_generators[0].f_string([0, 1, 2, 2, 1, 0])
sage: m.e(1)
Y(0, 0)^-1 Y(0, 2)^-1 Y(1, 1) Y(1, 2)^-1 Y(2, 1)^2
```

`epsilon(i)`

Return ε_i^* of `self`.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: Ystar = crystals.infinity.Star(Y)
sage: y = Ystar.module_generators[0].f_string([0, 1, 3, 2, 1, 0])
sage: [y.epsilon(i) for i in y.index_set()]
[1, 0, 1, 0]

sage: RC = crystals.infinity.RiggedConfigurations(['E', 6, 1])
sage: RCstar = crystals.infinity.Star(RC)
sage: nuJ = RCstar.module_generators[0].f_string([0, 4, 6, 1, 2])
sage: [nuJ.epsilon(i) for i in nuJ.index_set()]
[0, 1, 1, 0, 0, 0, 1]
```

f(i)

Return the action of f_i^* on self.

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux("G2")
sage: Tstar = crystals.infinity.Star(T)
sage: t = Tstar.module_generators[0].f_string([1,2,1,1,2])
sage: t
[[1, 1, 1, 2, 0], [2, 3]]

sage: M = crystals.infinity.NakajimaMonomials(['B',2,1])
sage: Mstar = crystals.infinity.Star(M)
sage: m = Mstar.module_generators[0].f_string([0,1,2,2,1,0])
sage: m
Y(0,0)^-1 Y(0,2)^-1 Y(1,0)^-1 Y(1,2)^-1 Y(2,0)^2 Y(2,1)^2
```

jump(i)

Return the i -jump of self.

For $b \in B(\infty)$,

$$\text{jump}_i(b) = \varepsilon_i(b) + \varepsilon_i^*(b) + \langle h_i, \text{wt}(b) \rangle,$$

where h_i is a simple coroot.

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations("D4")
sage: RCstar = crystals.infinity.Star(RC)
sage: nu0star = RCstar.module_generators[0]
sage: nustar = nu0star.f_string([2,1,3,4,2])
sage: [nustar.jump(i) for i in RC.index_set()]
[0, 1, 0, 0]
sage: nustar = nu0star.f_string([2,1,3,4,2,2,1,3,2]) # long time
sage: [nustar.jump(i) for i in RC.index_set()] # long time
[1, 0, 1, 2]
```

phi(i)

Return φ_i^* of self.

For $b \in B(\infty)$,

$$\varphi_i^*(b) = \varepsilon_i^*(b) + \langle h_i, \text{wt}(b) \rangle,$$

where h_i is a simple coroot.

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux("A2")
sage: Tstar = crystals.infinity.Star(T)
```

(continues on next page)

(continued from previous page)

```

sage: t = Tstar.module_generators[0].f_string([1,2,1,1,2])
sage: [t.phi(i) for i in t.index_set()]
[-3, 1]

sage: M = crystals.infinity.NakajimaMonomials(['B',2,1])
sage: Mstar = crystals.infinity.Star(M)
sage: m = Mstar.module_generators[0].f_string([0,1,2,2,1,0])
sage: [m.phi(i) for i in m.index_set()]
[-1, -1, 4]

```

weight()

Return the weight of self.

EXAMPLES:

```

sage: RC = crystals.infinity.RiggedConfigurations(['E',6,1])
sage: RCstar = crystals.infinity.Star(RC)
sage: nuJ = RCstar.module_generators[0].f_string([0,4,6,1,2])
sage: nuJ.weight()
-Lambda[0] - 2*Lambda[1] + 2*Lambda[3] - Lambda[4]
+ 2*Lambda[5] - 2*Lambda[6] - delta

```

5.1.66 Tensor Products of Crystals

Main entry points:

- *TensorProductOfCrystals*
- *CrystalOfTableaux*

AUTHORS:

- Anne Schilling, Nicolas Thiery (2007): Initial version
- Ben Salisbury, Travis Scrimshaw (2013): Refactored tensor products to handle non-regular crystals and created new subclass to take advantage of the regularity
- Travis Scrimshaw (2020): Added queer crystal

class `sage.combinat.crystals.tensor_product.CrystalOfQueerTableaux`(*cartan_type*, *shape*)Bases: `sage.combinat.crystals.tensor_product.CrystalOfWords`, `sage.combinat.crystals.tensor_product.QueerSuperCrystalsMixin`

A queer crystal of the semistandard decomposition tableaux of a given shape.

INPUT:

- *cartan_type* – a Cartan type
- *shape* – a shape

class `Element`Bases: `sage.combinat.crystals.tensor_product_element.TensorProductOfQueerSuperCrystalsElement`**rows()**

Return the list of rows of self.

EXAMPLES:

```
sage: B = crystals.Tableaux(['Q', 3], shape=[3, 2, 1])
sage: t = B.an_element()
sage: t.rows()
[[3, 3, 3], [2, 2], [1]]
```

class sage.combinat.crystals.tensor_product.**CrystalOfTableaux**(cartan_type, shapes)

Bases: [sage.combinat.crystals.tensor_product.CrystalOfWords](#)

A class for crystals of tableaux with integer valued shapes

INPUT:

- `cartan_type` – a Cartan type
- `shape` – a partition of length at most `cartan_type.rank()`
- `shapes` – a list of such partitions

This constructs a classical crystal with the given Cartan type and highest weight(s) corresponding to the given shape(s).

If the type is D_r , the shape is permitted to have a negative value in the r -th position. Thus if the shape equals $[s_1, \dots, s_r]$, then s_r may be negative but in any case $s_1 \geq \dots \geq s_{r-1} \geq |s_r|$. This crystal is related to that of shape $[s_1, \dots, |s_r|]$ by the outer automorphism of $SO(2r)$.

If the type is D_r or B_r , the shape is permitted to be of length r with all parts of half integer value. This corresponds to having one spin column at the beginning of the tableau. If several shapes are provided, they currently should all or none have this property.

Crystals of tableaux are constructed using an embedding into tensor products following Kashiwara and Nakashima [KN1994]. Sage's tensor product rule for crystals differs from that of Kashiwara and Nakashima by reversing the order of the tensor factors. Sage produces the same crystals of tableaux as Kashiwara and Nakashima. With Sage's convention, the tensor product of crystals is the same as the monoid operation on tableaux and hence the plactic monoid.

See also:

[sage.combinat.crystals.crystals](#) for general help on crystals, and in particular plotting and L^AT_EX output.

EXAMPLES:

We create the crystal of tableaux for type A_2 , with highest weight given by the partition $[2, 1, 1]$:

```
sage: T = crystals.Tableaux(['A', 3], shape = [2, 1, 1])
```

Here is the list of its elements:

```
sage: T.list()
[[[1, 1], [2], [3]], [[1, 2], [2], [3]], [[1, 3], [2], [3]],
 [[1, 4], [2], [3]], [[1, 4], [2], [4]], [[1, 4], [3], [4]],
 [[2, 4], [3], [4]], [[1, 1], [2], [4]], [[1, 2], [2], [4]],
 [[1, 3], [2], [4]], [[1, 3], [3], [4]], [[2, 3], [3], [4]],
 [[1, 1], [3], [4]], [[1, 2], [3], [4]], [[2, 2], [3], [4]]]
```

Internally, a tableau of a given Cartan type is represented as a tensor product of letters of the same type. The order in which the tensor factors appear is by reading the columns of the tableaux left to right, top to bottom (in French notation). As an example:

```

sage: T = crystals.Tableaux(['A', 2], shape = [3, 2])
sage: T.module_generators[0]
[[1, 1, 1], [2, 2]]
sage: list(T.module_generators[0])
[2, 1, 2, 1, 1]

```

To create a tableau, one can use:

```

sage: Tab = crystals.Tableaux(['A', 3], shape = [2, 2])
sage: Tab(rows=[[1, 2], [3, 4]])
[[1, 2], [3, 4]]
sage: Tab(columns=[[3, 1], [4, 2]])
[[1, 2], [3, 4]]

```

Todo: FIXME:

- Do we want to specify the columns increasingly or decreasingly? That is, should this be `Tab(columns = [[1, 3], [2, 4]])`?
- Make this fully consistent with `Tableau()`!

We illustrate the use of a shape with a negative last entry in type D :

```

sage: T = crystals.Tableaux(['D', 4], shape=[1, 1, 1, -1])
sage: T.cardinality()
35
sage: TestSuite(T).run()

```

We illustrate the construction of crystals of spin tableaux when the partitions have half integer values in type B and D :

```

sage: T = crystals.Tableaux(['B', 3], shape=[3/2, 1/2, 1/2]); T
The crystal of tableaux of type ['B', 3] and shape(s) [[3/2, 1/2, 1/2]]
sage: T.cardinality()
48
sage: T.module_generators
([+++, [[1]]],)
sage: TestSuite(T).run()

sage: T = crystals.Tableaux(['D', 3], shape=[3/2, 1/2, -1/2]); T
The crystal of tableaux of type ['D', 3] and shape(s) [[3/2, 1/2, -1/2]]
sage: T.cardinality()
20
sage: T.module_generators
([++-, [[1]]],)
sage: TestSuite(T).run()

```

We can also construct the tableaux for $g(m|n)$ as given by [BKK2000]:

```

sage: T = crystals.Tableaux(['A', [1, 2]], shape=[4, 2, 1, 1, 1])
sage: T.cardinality()
1392

```

We can also construct the tableaux for $q(n)$ as given by [GJK+2014]:

```
sage: T = crystals.Tableaux(['Q', 3], shape=[3,1])
sage: T.cardinality()
24
```

class Element

Bases: *sage.combinat.crystals.tensor_product_element.CrystalOfTableauxElement*

cartan_type()

Returns the Cartan type of the associated crystal

EXAMPLES:

```
sage: T = crystals.Tableaux(['A', 3], shape = [2,2])
sage: T.cartan_type()
['A', 3]
```

module_generator(shape)

This yields the module generator (or highest weight element) of a classical crystal of given shape. The module generator is the unique tableau with equal shape and content.

EXAMPLES:

```
sage: T = crystals.Tableaux(['D', 3], shape = [1,1])
sage: T.module_generator([1,1])
[[1], [2]]

sage: T = crystals.Tableaux(['D', 4], shape=[2,2,2,-2])
sage: T.module_generator(tuple([2,2,2,-2]))
[[1, 1], [2, 2], [3, 3], [-4, -4]]
sage: T.cardinality()
294

sage: T = crystals.Tableaux(['D', 4], shape=[2,2,2,2])
sage: T.module_generator(tuple([2,2,2,2]))
[[1, 1], [2, 2], [3, 3], [4, 4]]
sage: T.cardinality()
294
```

class sage.combinat.crystals.tensor_product.CrystalOfWords

Bases: *sage.structure.unique_representation.UniqueRepresentation*, *sage.structure.parent.Parent*

Auxiliary class to provide a call method to create tensor product elements. This class is shared with several tensor product classes and is also used in *CrystalOfTableaux* to allow tableaux of different tensor product structures in column-reading (and hence different shapes) to be considered elements in the same crystal.

class Element

Bases: *sage.combinat.crystals.tensor_product_element.TensorProductOfCrystalsElement*

class sage.combinat.crystals.tensor_product.FullTensorProductOfCrystals(crystals, **options)

Bases: *sage.combinat.crystals.tensor_product.TensorProductOfCrystals*

Full tensor product of crystals.

Todo: Merge this into *TensorProductOfCrystals*.

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: C = crystals.Letters(['A', 2])
sage: T = crystals.TensorProduct(C, C)
sage: T.cardinality()
9
```

weight_lattice_realization()

Return the weight lattice realization used to express weights.

The weight lattice realization is the common parent which all weight lattice realizations of the crystals of self coerce into.

EXAMPLES:

```
sage: B = crystals.elementary.B(['A', 4], 2)
sage: B.weight_lattice_realization()
Root lattice of the Root system of type ['A', 4]
sage: T = crystals.infinity.Tableaux(['A', 4])
sage: T.weight_lattice_realization()
Ambient space of the Root system of type ['A', 4]
sage: TP = crystals.TensorProduct(B, T)
sage: TP.weight_lattice_realization()
Ambient space of the Root system of type ['A', 4]
```

class `sage.combinat.crystals.tensor_product.FullTensorProductOfQueerSuperCrystals`(*crystals*,
***options*)

Bases: `sage.combinat.crystals.tensor_product.FullTensorProductOfCrystals`, `sage.combinat.crystals.tensor_product.QueerSuperCrystalsMixin`

Tensor product of queer super crystals.

class Element

Bases: `sage.combinat.crystals.tensor_product_element.TensorProductOfQueerSuperCrystalsElement`

class `sage.combinat.crystals.tensor_product.FullTensorProductOfRegularCrystals`(*crystals*,
***options*)

Bases: `sage.combinat.crystals.tensor_product.FullTensorProductOfCrystals`

Full tensor product of regular crystals.

class Element

Bases: `sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement`

class `sage.combinat.crystals.tensor_product.FullTensorProductOfSuperCrystals`(*crystals*,
***options*)

Bases: `sage.combinat.crystals.tensor_product.FullTensorProductOfCrystals`

Tensor product of super crystals.

EXAMPLES:

```
sage: L = crystals.Letters(['A', [1, 1]])
sage: T = tensor([L, L, L])
sage: T.cardinality()
64
```

class Element

Bases: `sage.combinat.crystals.tensor_product_element.TensorProductOfSuperCrystalsElement`

class sage.combinat.crystals.tensor_product.QueerSuperCrystalsMixin

Bases: object

Mixin class with methods for a finite queer supercrystal.

index_set()

Return the enlarged index set.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q])
sage: T.index_set()
(-4, -3, -2, -1, 1, 2)
```

class sage.combinat.crystals.tensor_product.TensorProductOfCrystals

Bases: `sage.combinat.crystals.tensor_product.CrystalOfWords`

Tensor product of crystals.

Given two crystals B and B' of the same Cartan type, one can form the tensor product $B \otimes B'$. As a set $B \otimes B'$ is the Cartesian product $B \times B'$. The crystal operators f_i and e_i act on $b \otimes b' \in B \otimes B'$ as follows:

$$f_i(b \otimes b') = \begin{cases} f_i(b) \otimes b' & \text{if } \varepsilon_i(b) \geq \varphi_i(b') \\ b \otimes f_i(b') & \text{otherwise} \end{cases}$$

and

$$e_i(b \otimes b') = \begin{cases} e_i(b) \otimes b' & \text{if } \varepsilon_i(b) > \varphi_i(b') \\ b \otimes e_i(b') & \text{otherwise.} \end{cases}$$

We also define:

$$\begin{aligned} \varphi_i(b \otimes b') &= \max(\varphi_i(b), \varphi_i(b') + \langle \alpha_i^\vee, \text{wt}(b) \rangle), \\ \varepsilon_i(b \otimes b') &= \max(\varepsilon_i(b'), \varepsilon_i(b) - \langle \alpha_i^\vee, \text{wt}(b') \rangle). \end{aligned}$$

Note: This is the opposite of Kashiwara's convention for tensor products of crystals.

Since tensor products are associative $(B \otimes C) \otimes D \cong B \otimes (C \otimes D)$ via the natural isomorphism $(b \otimes c) \otimes d \mapsto b \otimes (c \otimes d)$, we can generalize this to arbitrary tensor products. Thus consider $B_N \otimes \cdots \otimes B_1$, where each B_k is an abstract crystal. The underlying set of the tensor product is $B_N \times \cdots \times B_1$, while the crystal structure is given as follows. Let I be the index set, and fix some $i \in I$ and $b_N \otimes \cdots \otimes b_1 \in B_N \otimes \cdots \otimes B_1$. Define

$$a_i(k) := \varepsilon_i(b_k) - \sum_{j=1}^{k-1} \langle \alpha_i^\vee, \text{wt}(b_j) \rangle.$$

Then

$$\begin{aligned} \text{wt}(b_N \otimes \cdots \otimes b_1) &= \text{wt}(b_N) + \cdots + \text{wt}(b_1), \\ \varepsilon_i(b_N \otimes \cdots \otimes b_1) &= \max_{1 \leq k \leq n} \left(\sum_{j=1}^k \varepsilon_i(b_j) - \sum_{j=1}^{k-1} \varphi_i(b_j) \right) \\ &= \max_{1 \leq k \leq N} (a_i(k)), \\ \varphi_i(b_N \otimes \cdots \otimes b_1) &= \max_{1 \leq k \leq N} \left(\varphi_i(b_N) + \sum_{j=k}^{N-1} (\varphi_i(b_j) - \varepsilon_i(b_{j+1})) \right) \\ &= \max_{1 \leq k \leq N} (\lambda_i + a_i(k)) \end{aligned}$$

where $\lambda_i = \langle \alpha_i^\vee, \text{wt}(b_N \otimes \cdots \otimes b_1) \rangle$. Then for $k = 1, \dots, N$ the action of the Kashiwara operators is determined as follows.

- If $a_i(k) > a_i(j)$ for $1 \leq j < k$ and $a_i(k) \geq a_i(j)$ for $k < j \leq N$:

$$e_i(b_N \otimes \cdots \otimes b_1) = b_N \otimes \cdots \otimes e_i b_k \otimes \cdots \otimes b_1.$$

- If $a_i(k) \geq a_i(j)$ for $1 \leq j < k$ and $a_i(k) > a_i(j)$ for $k < j \leq N$:

$$f_i(b_N \otimes \cdots \otimes b_1) = b_N \otimes \cdots \otimes f_i b_k \otimes \cdots \otimes b_1.$$

Note that this is just recursively applying the definition of the tensor product on two crystals. Recall that $\langle \alpha_i^\vee, \text{wt}(b_j) \rangle = \varphi_i(b_j) - \varepsilon_i(b_j)$ by the definition of a crystal.

Regular crystals

Now if all crystals B_k are regular crystals, all ε_i and φ_i are non-negative and we can define tensor product by the *signature rule*. We start by writing a word in $+$ and $-$ as follows:

$$\underbrace{- \cdots -}_{\varphi_i(b_N) \text{ times}} \quad \underbrace{+ \cdots +}_{\varepsilon_i(b_N) \text{ times}} \quad \cdots \quad \underbrace{- \cdots -}_{\varphi_i(b_1) \text{ times}} \quad \underbrace{+ \cdots +}_{\varepsilon_i(b_1) \text{ times}},$$

and then canceling ordered pairs of $+-$ until the word is in the reduced form:

$$\underbrace{- \cdots -}_{\varphi_i \text{ times}} \quad \underbrace{+ \cdots +}_{\varepsilon_i \text{ times}}.$$

Here e_i acts on the factor corresponding to the leftmost $+$ and f_i on the factor corresponding to the rightmost $-$. If there is no $+$ or $-$ respectively, then the result is 0 (None).

EXAMPLES:

We construct the type A_2 -crystal generated by $2 \otimes 1 \otimes 1$:

```
sage: C = crystals.Letters(['A', 2])
sage: T = crystals.TensorProduct(C, C, C, generators=[[C(2), C(1), C(1)]])
```

It has 8 elements:

```
sage: T.list()
[[2, 1, 1], [2, 1, 2], [2, 1, 3], [3, 1, 3],
 [3, 2, 3], [3, 1, 1], [3, 1, 2], [3, 2, 2]]
```

One can also check the Cartan type of the crystal:

```
sage: T.cartan_type()
['A', 2]
```

Other examples include crystals of tableaux (which internally are represented as tensor products obtained by reading the tableaux columnwise):

```
sage: C = crystals.Tableaux(['A', 3], shape=[1, 1, 0])
sage: D = crystals.Tableaux(['A', 3], shape=[1, 0, 0])
sage: T = crystals.TensorProduct(C, D, generators=[[C(rows=[[1], [2]]),
↳D(rows=[[1]])], [C(rows=[[2], [3]]), D(rows=[[1]])]])
sage: T.cardinality()
24
sage: TestSuite(T).run()
sage: T.module_generators
([[1], [2]], [[1]], [[2], [3]], [[1]])
sage: [x.weight() for x in T.module_generators]
[(2, 1, 0, 0), (1, 1, 1, 0)]
```

If no module generators are specified, we obtain the full tensor product:

```
sage: C = crystals.Letters(['A', 2])
sage: T = crystals.TensorProduct(C, C)
sage: T.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
sage: T.cardinality()
9
```

For a tensor product of crystals without module generators, the default implementation of `module_generators` contains all elements in the tensor product of the crystals. If there is a subset of elements in the tensor product that still generates the crystal, this needs to be implemented for the specific crystal separately:

```
sage: T.module_generators.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
```

For classical highest weight crystals, it is also possible to list all highest weight elements:

```
sage: C = crystals.Letters(['A', 2])
sage: T = crystals.TensorProduct(C, C, C, generators=[[C(2), C(1), C(1)], [C(1), C(2),
↳C(1)]])
sage: T.highest_weight_vectors()
([2, 1, 1], [1, 2, 1])
```

Examples with non-regular and infinite crystals (these did not work before [trac ticket #14402](#)):

```
sage: B = crystals.infinity.Tableaux(['D', 10])
sage: T = crystals.TensorProduct(B, B)
sage: T
Full tensor product of the crystals
[The infinity crystal of tableaux of type ['D', 10],
 The infinity crystal of tableaux of type ['D', 10]]

sage: B = crystals.infinity.GeneralizedYoungWalls(15)
```

(continues on next page)

(continued from previous page)

```

sage: T = crystals.TensorProduct(B,B,B)
sage: T
Full tensor product of the crystals
[Crystal of generalized Young walls of type ['A', 15, 1],
 Crystal of generalized Young walls of type ['A', 15, 1],
 Crystal of generalized Young walls of type ['A', 15, 1]]

sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.GeneralizedYoungWalls(2,La[0]+La[1])
sage: C = crystals.GeneralizedYoungWalls(2,2*La[2])
sage: D = crystals.GeneralizedYoungWalls(2,3*La[0]+La[2])
sage: T = crystals.TensorProduct(B,C,D)
sage: T
Full tensor product of the crystals
[Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and
↪highest weight Lambda[0] + Lambda[1],
 Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and
↪highest weight 2*Lambda[2],
 Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and
↪highest weight 3*Lambda[0] + Lambda[2]]

```

There is also a global option for setting the convention (by default Sage uses anti-Kashiwara):

```

sage: C = crystals.Letters(['A', 2])
sage: T = crystals.TensorProduct(C,C)
sage: elt = T(C(1), C(2)); elt
[1, 2]
sage: crystals.TensorProduct.options.convention = "Kashiwara"
sage: elt
[2, 1]
sage: crystals.TensorProduct.options._reset()

```

options(*get_value, **set_value)

Sets the global options for tensor products of crystals. The default is to use the anti-Kashiwara convention.

There are two conventions for how e_i and f_i act on tensor products, and the difference between the two is the order of the tensor factors are reversed. This affects both the input and output. See the example below.

OPTIONS:

- **convention** – (default: antiKashiwara) Sets the convention used for displaying/inputting tensor product of crystals
 - **Kashiwara** – use the Kashiwara convention
 - **anti** – alias for antiKashiwara
 - **antiKashiwara** – use the anti-Kashiwara convention
 - **opposite** – alias for antiKashiwara

Note: Changing the convention also changes how the input is handled.

Warning: Internally, the crystals are always stored using the anti-Kashiwara convention.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: C = crystals.Letters(['A', 2])
sage: T = crystals.TensorProduct(C, C)
sage: elt = T(C(1), C(2)); elt
[1, 2]
sage: crystals.TensorProduct.options.convention = "Kashiwara"
sage: elt
[2, 1]
sage: T(C(1), C(2)) == elt
False
sage: T(C(2), C(1)) == elt
True
sage: crystals.TensorProduct.options._reset()
```

See [GlobalOptions](#) for more features of these options.

```
class sage.combinat.crystals.tensor_product.TensorProductOfCrystalsWithGenerators(crystals,
                                                                                   genera-
                                                                                   tors,
                                                                                   car-
                                                                                   tan_type)
```

Bases: *sage.combinat.crystals.tensor_product.TensorProductOfCrystals*

Tensor product of crystals with a generating set.

Todo: Deprecate this class in favor of using [subcrystal\(\)](#).

```
class sage.combinat.crystals.tensor_product.TensorProductOfRegularCrystalsWithGenerators(crystals,
                                                                                   gen-
                                                                                   er-
                                                                                   a-
                                                                                   tors,
                                                                                   car-
                                                                                   tan_type)
```

Bases: *sage.combinat.crystals.tensor_product.TensorProductOfCrystalsWithGenerators*

Tensor product of regular crystals with a generating set.

class Element

Bases: *sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement*

5.1.67 Tensor Products of Crystal Elements

AUTHORS:

- Anne Schilling, Nicolas Thiery (2007): Initial version
- Ben Salisbury, Travis Scrimshaw (2013): Refactored tensor products to handle non-regular crystals and created new subclass to take advantage of the regularity
- Travis Scrimshaw (2017): Cythonized element classes
- Franco Saliola (2017): Tensor products for crystal of super algebras
- Anne Schilling (2018): Tensor products for crystals of queer super algebras

class `sage.combinat.crystals.tensor_product_element.CrystalOfBKKTTableauxElement`
 Bases: `sage.combinat.crystals.tensor_product_element.TensorProductOfSuperCrystalsElement`
 Element class for the crystal of tableaux for Lie superalgebras of [BKK2000].

pp()

Pretty print self.

EXAMPLES:

```
sage: C = crystals.Tableaux(['A', [1,2]], shape=[1,1])
sage: c = C.an_element()
sage: c.pp()
-2
-1
```

to_tableau()

Return the *Tableau* object corresponding to self.

EXAMPLES:

```
sage: C = crystals.Tableaux(['A', [1,2]], shape=[1,1])
sage: c = C.an_element()
sage: c.to_tableau()
[[-2], [-1]]
sage: type(c.to_tableau())
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
sage: type(c)
<class 'sage.combinat.crystals.bkk_crystals.CrystalOfBKKTTableaux_with_category.
↪element_class'>
```

class `sage.combinat.crystals.tensor_product_element.CrystalOfTableauxElement`
 Bases: `sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement`
 Element in a crystal of tableaux.

pp()

EXAMPLES:

```
sage: T = crystals.Tableaux(['A', 3], shape = [2,2])
sage: t = T(rows=[[1,2],[3,4]])
sage: t.pp()
1 2
3 4
```

promotion()

Return the result of applying promotion on `self`.

Promotion for type A crystals of tableaux of rectangular shape. This method only makes sense in type A with rectangular shapes.

EXAMPLES:

```
sage: C = crystals.Tableaux(["A",3], shape = [3,3,3])
sage: t = C(Tableau([[1,1,1],[2,2,3],[3,4,4]]))
sage: t
[[1, 1, 1], [2, 2, 3], [3, 4, 4]]
sage: t.promotion()
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]
sage: t.promotion().parent()
The crystal of tableaux of type ['A', 3] and shape(s) [[3, 3, 3]]
```

promotion_inverse()

Return the result of applying inverse promotion on `self`.

Inverse promotion for type A crystals of tableaux of rectangular shape. This method only makes sense in type A with rectangular shapes.

EXAMPLES:

```
sage: C = crystals.Tableaux(["A",3], shape = [3,3,3])
sage: t = C(Tableau([[1,1,1],[2,2,3],[3,4,4]]))
sage: t
[[1, 1, 1], [2, 2, 3], [3, 4, 4]]
sage: t.promotion_inverse()
[[1, 1, 2], [2, 3, 3], [4, 4, 4]]
sage: t.promotion_inverse().parent()
The crystal of tableaux of type ['A', 3] and shape(s) [[3, 3, 3]]
```

shape()

Return the shape of the tableau corresponding to `self`.

OUTPUT: an instance of *Partition*

See also:

`to_tableau()`

EXAMPLES:

```
sage: C = crystals.Tableaux(["A", 2], shape=[2,1])
sage: x = C.an_element()
sage: x.to_tableau().shape()
[2, 1]
sage: x.shape()
[2, 1]
```

to_tableau()

Return the *Tableau* object corresponding to `self`.

EXAMPLES:

```

sage: T = crystals.Tableaux(['A',3], shape = [2,2])
sage: t = T(rows=[[1,2],[3,4]]).to_tableau(); t
[[1, 2], [3, 4]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
sage: type(t[0][0])
<class 'int'>
sage: T = crystals.Tableaux(['D',3], shape = [1,1])
sage: t=T(rows=[[-3],[3]]).to_tableau(); t
[[-3], [3]]
sage: t=T(rows=[[3],[-3]]).to_tableau(); t
[[3], [-3]]
sage: T = crystals.Tableaux(['B',2], shape = [1,1])
sage: t = T(rows=[[0],[0]]).to_tableau(); t
[[0], [0]]

```

class sage.combinat.crystals.tensor_product_element.**ImmutableListWithParent**

Bases: [sage.structure.list_clone.ClonableArray](#)

A class for lists having a parent

Specification: any subclass C should implement `__init__` which accepts the following form `C(parent, list=list)`

class sage.combinat.crystals.tensor_product_element.**InfinityCrystalOfTableauxElement**

Bases: [sage.combinat.crystals.tensor_product_element.CrystalOfTableauxElement](#)

e(i)

Return the action of \tilde{e}_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['B',3])
sage: b = B(rows=[[1,1,1,1,1,1,1,2,0,-3,-1,-1,-1,-1],[2,2,2,2,-2,-2],[3,-3,-3]])
sage: b.e(3).pp()
1 1 1 1 1 1 1 2 0 -3 -1 -1 -1 -1
2 2 2 2 -2 -2
3 0 -3
sage: b.e(1).pp()
1 1 1 1 1 1 1 0 -3 -1 -1 -1 -1
2 2 2 2 -2 -2
3 -3 -3

```

f(i)

Return the action of \tilde{f}_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['C',4])
sage: b = B.highest_weight_vector()

```

(continues on next page)

(continued from previous page)

```

sage: b.f(1).pp()
1 1 1 1 2
2 2 2
3 3
4
sage: b.f(3).pp()
1 1 1 1 1
2 2 2 2
3 3 4
4
sage: b.f(3).f(4).pp()
1 1 1 1 1
2 2 2 2
3 3 -4
4

```

class sage.combinat.crystals.tensor_product_element.InfinityCrystalOfTableauxElementTyped
 Bases: sage.combinat.crystals.tensor_product_element.InfinityCrystalOfTableauxElement

e(i)Return the action of \tilde{e}_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['D', 4])
sage: b = B.highest_weight_vector().f_string([1, 4, 3, 1, 2]); b.pp()
1 1 1 1 2 3
2 2 2
3 -3
sage: b.e(2).pp()
1 1 1 1 2 2
2 2 2
3 -3

```

f(i)Return the action of \tilde{f}_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['D', 5])
sage: b = B.highest_weight_vector().f_string([1, 4, 3, 1, 5]); b.pp()
1 1 1 1 1 1 2 2
2 2 2 2 2
3 3 3 -5
4 5
sage: b.f(1).pp()
1 1 1 1 1 1 2 2 2
2 2 2 2 2

```

(continues on next page)

(continued from previous page)

```

3 3 3 -5
4 5
sage: b.f(5).pp()
1 1 1 1 1 1 2 2
2 2 2 2 2
3 3 3 -5
4 -4

```

class sage.combinat.crystals.tensor_product_element.**InfinityQueerCrystalOfTableauxElement**
 Bases: *sage.combinat.crystals.tensor_product_element.TensorProductOfQueerSuperCrystalsElement*

Initialize self.

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,2,1],[3,3,3],[2,2],[1]])
sage: t
[[4, 4, 4, 4, 2, 1], [3, 3, 3], [2, 2], [1]]
sage: TestSuite(t).run()

```

e(*i*)

Return the action of e_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.e(1)
[[4, 4, 4, 4, 4, 4, 2, 1], [3, 3, 3, 3, 3], [2, 2, 1, 1], [1]]
sage: t.e(3)
[[4, 4, 4, 4, 4, 3, 2, 1], [3, 3, 3, 3], [2, 2, 1], [1]]
sage: t.e(-1)

```

epsilon(*i*)

Return ε_i of self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```

sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: [t.epsilon(i) for i in B.index_set()]
[-1, 1, -2, 0]

```

f(*i*)

Return the action of f_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.f(1)
[[4, 4, 4, 4, 4, 2, 2], [3, 3, 3, 3], [2, 2, 1], [1]]
sage: t.f(3)
sage: t.f(-1)
[[4, 4, 4, 4, 4, 2, 2], [3, 3, 3, 3], [2, 2, 1], [1]]
```

rows()

Return the list of rows of self.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.rows()
[[1, 2, 4, 4, 4, 4, 4], [3, 3, 3, 3], [1, 2, 2], [1]]
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.weight()
(4, 2, 2, 0)
```

class sage.combinat.crystals.tensor_product_element.**TensorProductOfCrystalsElement**

Bases: *sage.combinat.crystals.tensor_product_element.ImmutableListWithParent*

A class for elements of tensor products of crystals.

e(i)

Return the action of e_i on self.

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("D4")
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f_string([1,4,3])
sage: b2 = B.highest_weight_vector().f_string([2,2,3,1,4])
sage: t = T(b2, b1)
sage: t.e(1)
[[[1, 1, 1, 1, 1], [2, 2, 3, -3], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
sage: t.e(2)
sage: t.e(3)
[[[1, 1, 1, 1, 1, 2], [2, 2, 3, -4], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
sage: t.e(4)
[[[1, 1, 1, 1, 1, 2], [2, 2, 3, 4], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
```

epsilon(*i*)Return ε_i of self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("G2")
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f(2)
sage: b2 = B.highest_weight_vector().f_string([2,2,1])
sage: t = T(b2, b1)
sage: [t.epsilon(i) for i in B.index_set()]
[0, 3]
```

f(*i*)Return the action of f_i on self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: La = RootSystem(['A',3,1]).weight_lattice(extended=True).fundamental_
↪weights()
sage: B = crystals.GeneralizedYoungWalls(3,La[0])
sage: T = crystals.TensorProduct(B,B,B)
sage: b1 = B.highest_weight_vector().f_string([0,3])
sage: b2 = B.highest_weight_vector().f_string([0])
sage: b3 = B.highest_weight_vector()
sage: t = T(b3, b2, b1)
sage: t.f(0)
[[[0]], [[0]], [[0, 3]]]
sage: t.f(1)
[[], [[0]], [[0, 3], [1]]]
sage: t.f(2)
[[], [[0]], [[0, 3, 2]]]
sage: t.f(3)
[[], [[0, 3]], [[0, 3]]]
```

phi(*i*)Return φ_i of self.

INPUT:

- *i* – an element of the index set

EXAMPLES:

```
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_
↪weights()
sage: B = crystals.GeneralizedYoungWalls(2,La[0]+La[1])
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f_string([1,0])
sage: b2 = B.highest_weight_vector().f_string([0,1])
```

(continues on next page)

(continued from previous page)

```
sage: t = T(b2, b1)
sage: [t.phi(i) for i in B.index_set()]
[1, 1, 4]
```

pp()

Pretty print self.

EXAMPLES:

```
sage: C = crystals.Tableaux(['A', 3], shape=[3, 1])
sage: D = crystals.Tableaux(['A', 3], shape=[1])
sage: E = crystals.Tableaux(['A', 3], shape=[2, 2, 2])
sage: T = crystals.TensorProduct(C, D, E)
sage: T.module_generators[0].pp()
  1  1  1 (X)  1 (X)  1  1
  2
  3  3
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("A3")
sage: T = crystals.TensorProduct(B, B)
sage: b1 = B.highest_weight_vector().f_string([2, 1, 3])
sage: b2 = B.highest_weight_vector().f(1)
sage: t = T(b2, b1)
sage: t
[[[1, 1, 1, 2], [2, 2], [3]], [[1, 1, 1, 1, 2], [2, 2, 4], [3]]]
sage: t.weight()
(-2, 1, 0, 1)
```

```
sage: C = crystals.Letters(['A', 3])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(2)).weight()
(1, 1, 0, 0)
sage: T = crystals.Tableaux(['D', 4], shape=[])
sage: T.list()[0].weight()
(0, 0, 0, 0)
```

class`sage.combinat.crystals.tensor_product_element.TensorProductOfQueerSuperCrystalsElement`Bases: `sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement`

Element class for a tensor product of crystals for queer Lie superalgebras.

This implements the tensor product rule for crystals of Grantcharov et al. [GJK+2014]. Given crystals B_1 and B_2 of type \mathfrak{q}_{n+1} , we define the tensor product $b_1 \otimes b_2 \in B_1 \otimes B_2$, where $b_1 \in B_1$ and $b_2 \in B_2$, as the following:In addition to the tensor product rule for type A_n , the tensor product rule for e_{-1} and f_{-1} on $b_1 \otimes b_2$ are given

by

$$e_{-1}(b_1 \otimes b_2) = \begin{cases} b_1 \otimes e_{-1}b_2 & \text{if } \text{wt}(b_1)_1 = \text{wt}(b_1)_2 = 0, \\ e_{-1}b_1 \otimes b_2 & \text{otherwise,} \end{cases}$$

$$f_{-1}(b_1 \otimes b_2) = \begin{cases} b_1 \otimes f_{-1}b_2 & \text{if } \text{wt}(b_1)_1 = \text{wt}(b_1)_2 = 0, \\ f_{-1}b_1 \otimes b_2 & \text{otherwise.} \end{cases}$$

For $1 < i \leq n$, the operators e_{-i} and f_{-i} are defined as

$$e_{-i} = s_{w_i^{-1}} e_{-1} s_{w_i}, \quad f_{-i} = s_{w_i^{-1}} f_{-1} s_{w_i}.$$

Here, $w_i = s_2 \cdots s_i s_1 \cdots s_{i-1}$ and s_i is the reflection along the i -string in the crystal. Moreover, for $1 < i \leq n$, we define the operators $e_{-i'}$ and $f_{-i'}$ as

$$e_{-i'} = s_{w_0} f_{-(n+1-i)} s_{w_0}, \quad f_{-i'} = s_{w_0} e_{-(n+1-i)} s_{w_0},$$

where w_0 is the longest element in the symmetric group S_{n+1} generated by s_1, \dots, s_n . In this implementation, we use the integers $-2n, \dots, -(n+1)$ to respectively denote the indices $-n', \dots, -1'$.

e(i)

Return e_i on self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q,Q])
sage: t = T(Q(1),Q(1))
sage: t.e(-1)
sage: t = T(Q(2),Q(1))
sage: t.e(-1)
[1, 1]

sage: T = tensor([Q,Q,Q,Q])
sage: t = T(Q(1),Q(3),Q(2),Q(1))
sage: t.e(-2)
[2, 2, 1, 1]
```

epsilon(i)

Return ε_i on self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q, Q, Q])
sage: t = T(Q(1), Q(3), Q(2), Q(1))
sage: t.epsilon(-2)
1
```

f(i)

Return f_i on self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q])
```

(continues on next page)

(continued from previous page)

```
sage: t = T(Q(1), Q(1))
sage: t.f(-1)
[2, 1]
```

phi(i)Return φ_i on self.

EXAMPLES:

```
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q, Q, Q])
sage: t = T(Q(1), Q(3), Q(2), Q(1))
sage: t.phi(-2)
0
sage: t.phi(-1)
1
```

class sage.combinat.crystals.tensor_product_element.**TensorProductOfRegularCrystalsElement**
 Bases: *sage.combinat.crystals.tensor_product_element.TensorProductOfCrystalsElement*

Element class for a tensor product of regular crystals.

e(i)Return the action of e_i on self.

EXAMPLES:

```
sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(2)).e(1) == T(C(1), C(1))
True
sage: T(C(2), C(1)).e(1) is None
True
sage: T(C(2), C(2)).e(1) == T(C(1), C(2))
True
```

epsilon(i)Return ε_i of self.

EXAMPLES:

```
sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(1)).epsilon(1)
0
sage: T(C(1), C(2)).epsilon(1)
1
sage: T(C(2), C(1)).epsilon(1)
0
```

f(i)Return the action of f_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(1)).f(1)
[1, 2]
sage: T(C(1), C(2)).f(1)
[2, 2]
sage: T(C(2), C(1)).f(1) is None
True

```

phi(*i*)

Return φ_i of self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(1)).phi(1)
2
sage: T(C(1), C(2)).phi(1)
1
sage: T(C(2), C(1)).phi(1)
0

```

position_of_first_unmatched_plus(*i*)

Return the position of the first unmatched + or None if there is no unmatched +.

EXAMPLES:

```

sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(2), C(1)).position_of_first_unmatched_plus(1)
sage: T(C(1), C(2)).position_of_first_unmatched_plus(1)
1

```

position_of_last_unmatched_minus(*i*)

Return the position of the last unmatched – or None if there is no unmatched –.

EXAMPLES:

```

sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(2), C(1)).position_of_last_unmatched_minus(1)
sage: T(C(1), C(2)).position_of_last_unmatched_minus(1)
0

```

positions_of_unmatched_minus(*i*, *dual=False*, *reverse=False*)

EXAMPLES:

```

sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(2), C(1)).positions_of_unmatched_minus(1)
[]
sage: T(C(1), C(2)).positions_of_unmatched_minus(1)
[0]

```

positions_of_unmatched_plus(*i*)

EXAMPLES:

```

sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(2),C(1)).positions_of_unmatched_plus(1)
[]
sage: T(C(1),C(2)).positions_of_unmatched_plus(1)
[1]

```

class sage.combinat.crystals.tensor_product_element.**TensorProductOfSuperCrystalsElement**Bases: *sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement*

Element class for a tensor product of crystals for Lie superalgebras.

This implements the tensor product rule for crystals of Lie superalgebras of [BKK2000].

e(*i*)Return e_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.e(0)
[-1, 1]

```

epsilon(*i*)Return ε_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.epsilon(0)
1

```

f(*i*)Return f_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.f(0)
sage: t.f(1)
[1, 2]

```

phi(*i*)Return φ_i on self.

EXAMPLES:

```

sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])

```

(continues on next page)

(continued from previous page)

```
sage: t = T(C(1),C(1))
sage: t.phi(0)
0
```

5.1.68 Cyclic sieving phenomenon

Implementation of the Cyclic Sieving Phenomenon as described by Reiner, Stanton, and White in [RSW2004].

We define the *CyclicSievingPolynomial()* of a finite set S together with cyclic action cyc_act (of order n) to be the unique polynomial $P(q)$ of order $< n$ such that the triple $(S, \text{cyc_act}, P(q))$ exhibits the cyclic sieving phenomenon.

AUTHORS:

- Christian Stump

REFERENCES:

`sage.combinat.cyclic_sieving_phenomenon.CyclicSievingCheck(L, cyc_act, f, order=None)`
Return whether the triple $(L, \text{cyc_act}, f)$ exhibits the cyclic sieving phenomenon.

If cyc_act is `None`, L is expected to contain the orbit lengths.

INPUT:

- L – if cyc_act is `None`: list of orbit sizes, otherwise list of objects
- cyc_act – (default:`None`) bijective function from L to L
- **order** – (default:`None`) if set to an integer, this cyclic order of cyc_act is used (must be an integer multiple of the order of cyc_act) otherwise, the order of cyc_action is used

EXAMPLES:

```
sage: from sage.combinat.cyclic_sieving_phenomenon import *
sage: from sage.combinat.q_analogues import q_binomial
sage: S42 = Subsets([1,2,3,4], 2)
sage: def cyc_act(S): return Set(i.mod(4) + 1 for i in S)
sage: cyc_act([1,3])
{2, 4}
sage: cyc_act([1,4])
{1, 2}
sage: p = q_binomial(4,2); p
q^4 + q^3 + 2*q^2 + q + 1
sage: CyclicSievingPolynomial( S42, cyc_act )
q^3 + 2*q^2 + q + 2
sage: CyclicSievingCheck( S42, cyc_act, p )
True
```

`sage.combinat.cyclic_sieving_phenomenon.CyclicSievingPolynomial(L, cyc_act=None, order=None, get_order=False)`

Return the unique polynomial p of degree smaller than order such that the triple $(L, \text{cyc_act}, p)$ exhibits the Cyclic Sieving Phenomenon.

If cyc_act is `None`, L is expected to contain the orbit lengths.

INPUT:

- L – if cyc_act is `None`: list of orbit sizes, otherwise list of objects

- `cyc_act` – (default:None) bijective function from L to L
- **order** – (default:None) if set to an integer, this cyclic order of `cyc_act` is used (must be an integer multiple of the order of `cyc_act`) otherwise, the order of `cyc_act` is used
- `get_order` – (default:False) if True, a tuple `[p,n]` is returned where `p` is as above, and `n` is the order

EXAMPLES:

```
sage: from sage.combinat.cyclic_sieving_phenomenon import CyclicSievingPolynomial
sage: S42 = Subsets([1,2,3,4], 2)
sage: def cyc_act(S): return Set(i.mod(4) + 1 for i in S)
sage: cyc_act([1,3])
{2, 4}
sage: cyc_act([1,4])
{1, 2}
sage: CyclicSievingPolynomial(S42, cyc_act)
q^3 + 2*q^2 + q + 2
sage: CyclicSievingPolynomial(S42, cyc_act, get_order=True)
[q^3 + 2*q^2 + q + 2, 4]
sage: CyclicSievingPolynomial(S42, cyc_act, order=8)
q^6 + 2*q^4 + q^2 + 2
sage: CyclicSievingPolynomial([4,2])
q^3 + 2*q^2 + q + 2
```

`sage.combinat.cyclic_sieving_phenomenon.orbit_decomposition(L, cyc_act)`
Return the orbit decomposition of L by the action of `cyc_act`.

INPUT:

- L – list
- `cyc_act` – bijective function from L to L

OUTPUT:

- a list of lists, the orbits under the `cyc_act` acting on L

EXAMPLES:

```
sage: from sage.combinat.cyclic_sieving_phenomenon import *
sage: S42 = Subsets([1,2,3,4], 2); S42
Subsets of {1, 2, 3, 4} of size 2
sage: def cyc_act(S): return Set(i.mod(4) + 1 for i in S)
sage: cyc_act([1,3])
{2, 4}
sage: cyc_act([1,4])
{1, 2}
sage: orbits = orbit_decomposition(S42, cyc_act)
sage: sorted([sorted(orb, key=sorted) for orb in orbits], key=len)
[[{1, 3}, {2, 4}], [{1, 2}, {1, 4}, {2, 3}, {3, 4}]]
```

5.1.69 De Bruijn sequences

A De Bruijn sequence is defined as the shortest cyclic sequence that incorporates all substrings of a certain length of an alphabet.

For instance, the $2^3 = 8$ binary strings of length 3 are all included in the following string:

```
sage: DeBruijnSequences(2,3).an_element()
[0, 0, 0, 1, 0, 1, 1, 1]
```

They can be obtained as a subsequence of the *cyclic* De Bruijn sequence of parameters $k = 2$ and $n = 3$:

```
sage: seq = DeBruijnSequences(2,3).an_element()
sage: print(Word(seq).string_rep())
00010111
sage: shift = lambda i: [(i+j)%2**3 for j in range(3)]
sage: for i in range(2**3):
.....:     w = Word([b if j in shift(i) else '*' for j, b in enumerate(seq)])
.....:     print(w.string_rep())
000*****
*001****
**010***
***101**
****011*
*****111
0*****11
00*****1
```

This sequence is of length k^n , which is best possible as it is the number of k -ary strings of length n . One can equivalently define a De Bruijn sequence of parameters k and n as a cyclic sequence of length k^n in which all substring of length n are different.

See also [Wikipedia article De_Bruijn_sequence](#).

AUTHOR:

- Eviatar Bach (2011): initial version
- Nathann Cohen (2011): Some work on the documentation and defined the `__contain__` method

class `sage.combinat.debruijn_sequence.DeBruijnSequences`(k, n)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Represents the De Bruijn sequences of given parameters k and n .

A De Bruijn sequence of parameters k and n is defined as the shortest cyclic sequence that incorporates all substrings of length n a k -ary alphabet.

This class can be used to generate the lexicographically smallest De Bruijn sequence, to count the number of existing De Bruijn sequences or to test whether a given sequence is De Bruijn.

INPUT:

- k – A natural number to define arity. The letters used are the integers $0..k - 1$.
- n – A natural number that defines the length of the substring.

EXAMPLES:

Obtaining a De Bruijn sequence:

```
sage: seq = DeBruijnSequences(2, 3).an_element()
sage: seq
[0, 0, 0, 1, 0, 1, 1, 1]
```

Testing whether it is indeed one:

```
sage: seq in DeBruijnSequences(2, 3)
True
```

The total number for these parameters:

```
sage: DeBruijnSequences(2, 3).cardinality()
2
```

Note: This function only generates one De Bruijn sequence (the smallest lexicographically). Support for generating all possible ones may be added in the future.

an_element()

Returns the lexicographically smallest De Bruijn sequence with the given parameters.

ALGORITHM:

The algorithm is described in the book “Combinatorial Generation” by Frank Ruskey. This program is based on a Ruby implementation by Jonas Elfström, which is based on the C program by Joe Sadawa.

EXAMPLES:

```
sage: DeBruijnSequences(2, 3).an_element()
[0, 0, 0, 1, 0, 1, 1, 1]
```

cardinality()

Returns the number of distinct De Bruijn sequences for the object’s parameters.

EXAMPLES:

```
sage: DeBruijnSequences(2, 5).cardinality()
2048
```

ALGORITHM:

The formula for cardinality is $k!k^{n-1}/k^n$ [Ros2002].

`sage.combinat.debruijn_sequence.debruijn_sequence(k, n)`

The generating function for De Bruijn sequences. This avoids the object creation, so is significantly faster than accessing from `DeBruijnSequence`. For more information, see the documentation there. The algorithm used is from Frank Ruskey’s “Combinatorial Generation”.

INPUT:

- **k** – Arity. Must be an integer.
- **n** – Substring length. Must be an integer.

EXAMPLES:

```
sage: from sage.combinat.debruijn_sequence import debruijn_sequence
sage: debruijn_sequence(3, 1)
[0, 1, 2]
```

`sage.combinat.debruijn_sequence.is_debruijn_sequence(seq, k, n)`

Given a sequence of integer elements in $0..k-1$, tests whether it corresponds to a De Bruijn sequence of parameters k and n .

INPUT:

- `seq` – Sequence of elements in $0..k-1$.
- `n, k` – Integers.

EXAMPLES:

```
sage: from sage.combinat.debruijn_sequence import is_debruijn_sequence
sage: s = DeBruijnSequences(2, 3).an_element()
sage: is_debruijn_sequence(s, 2, 3)
True
sage: is_debruijn_sequence(s + [0], 2, 3)
False
sage: is_debruijn_sequence([1] + s[1:], 2, 3)
False
```

5.1.70 Degree sequences

The present module implements the `DegreeSequences` class, whose instances represent the integer sequences of length n :

```
sage: DegreeSequences(6)
Degree sequences on 6 elements
```

With the object `DegreeSequences(n)`, one can:

- Check whether a sequence is indeed a degree sequence:

```
sage: DS = DegreeSequences(5)
sage: [4, 3, 3, 3, 3] in DS
True
sage: [4, 4, 0, 0, 0] in DS
False
```

- List all the possible degree sequences of length n :

```
sage: for seq in DegreeSequences(4):
.....:     print(seq)
[0, 0, 0, 0]
[1, 1, 0, 0]
[2, 1, 1, 0]
[3, 1, 1, 1]
[1, 1, 1, 1]
[2, 2, 1, 1]
[2, 2, 2, 0]
[3, 2, 2, 1]
[2, 2, 2, 2]
[3, 3, 2, 2]
[3, 3, 3, 3]
```

Note: Given a degree sequence, one can obtain a graph realizing it by using `DegreeSequence()`. For instance:

```
sage: ds = [3, 3, 2, 2, 2, 2, 2, 1, 1, 0]
sage: g = graphs.DegreeSequence(ds)
sage: g.degree_sequence()
[3, 3, 2, 2, 2, 2, 2, 1, 1, 0]
```

Definitions

A sequence of integers d_1, \dots, d_n is said to be a *degree sequence* (or *graphic sequence*) if there exists a graph in which vertex i is of degree d_i . It is often required to be *non-increasing*, i.e. that $d_1 \geq \dots \geq d_n$. Finding a graph with given degree sequence is known as *graph realization problem*.

An integer sequence need not necessarily be a degree sequence. Indeed, in a degree sequence of length n no integer can be larger than $n - 1$ – the degree of a vertex is at most $n - 1$ – and the sum of them is at most $n(n - 1)$.

Degree sequences are completely characterized by a result from Erdos and Gallai:

Erdos and Gallai: *The sequence of integers $d_1 \geq \dots \geq d_n$ is a degree sequence if and only if $\sum_i d_i$ is even and $\forall i$*

$$\sum_{j \leq i} d_j \leq j(j - 1) + \sum_{j > i} \min(d_j, i).$$

Alternatively, a degree sequence can be defined recursively:

Havel and Hakimi: *The sequence of integers $d_1 \geq \dots \geq d_n$ is a degree sequence if and only if $d_2 - 1, \dots, d_{d_1+1} - 1, d_{d_1+2}, \dots, d_n$ is also a degree sequence.*

Or equivalently:

Havel and Hakimi (bis): *If there is a realization of an integer sequence as a graph (i.e. if the sequence is a degree sequence), then it can be realized in such a way that the vertex of maximum degree Δ is adjacent to the Δ vertices of highest degree (except itself, of course).*

Algorithms

Checking whether a given sequence is a degree sequence

This is tested using Erdos and Gallai's criterion. It is also checked that the given sequence is non-increasing and has length n .

Iterating through the sequences of length n

From Havel and Hakimi's recursive definition of a degree sequence, one can build an enumeration algorithm as done in [RCES1994]. It consists in trying to **extend** a current degree sequence on n elements into a degree sequence on $n + 1$ elements by adding a vertex of degree larger than those already present in the sequence. This can be seen as **reversing** the reduction operation described in Havel and Hakimi's characterization. This operation can appear in several different ways:

- Extensions of a degree sequence that do **not** change the value of the maximum element
 - If the maximum element of a given degree sequence is 0, then one can remove it to reduce the sequence, following Havel and Hakimi's rule. Conversely, if the maximum element of the (current) sequence is 0, then one can always extend it by adding a new element of degree 0 to the sequence.

$$0, 0, 0 \xrightarrow{\text{Extension}} 0, 0, 0, 0 \xrightarrow{\text{Extension}} 0, 0, 0, \dots, 0, 0, 0 \xrightarrow{\text{Reduction}} 0, 0, 0, 0 \xrightarrow{\text{Reduction}} 0, 0, 0$$

- If there are at least $\Delta + 1$ elements of (maximum) degree Δ in a given degree sequence, then one can reduce it by removing a vertex of degree Δ and decreasing the values of Δ elements of value Δ to $\Delta - 1$. Conversely, if the maximum element of the (current) sequence is $d > 0$, then one can add a new element of degree d to the sequence if it can be linked to d elements of (current) degree $d - 1$. Those d vertices of degree $d - 1$ hence become vertices of degree d , and so d elements of degree $d - 1$ are removed from the sequence while $d + 1$ elements of degree d are added to it.

$$3, 2, 2, 2, 1 \xrightarrow{\text{Extension}} \mathbf{3}, 3, (2 + 1), (2 + 1), (2 + 1), 1 = \mathbf{3}, 3, 3, 3, 3, 1 \xrightarrow{\text{Reduction}} 3, 2, 2, 2, 1$$

- Extension of a degree sequence that changes the value of the maximum element:

- In the general case, i.e. when the number of elements of value $\Delta, \Delta - 1$ is small compared to Δ (i.e. the maximum element of a given degree sequence), reducing a sequence strictly decreases the value of the maximum element. According to Havel and Hakimi's characterization there is only **one** way to reduce a sequence, but reversing this operation is more complicated than in the previous cases. Indeed, the following extensions are perfectly valid according to the reduction rule.

$$\begin{aligned} 2, 1, 1, 0, 0 &\xrightarrow{\text{Extension}} \mathbf{3}, (2 + 1), (1 + 1), (1 + 1), 0, 0 = 3, 3, 2, 2, 0, 0 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0 \\ 2, 1, 1, 0, 0 &\xrightarrow{\text{Extension}} \mathbf{3}, (2 + 1), (1 + 1), 1, (0 + 1), 0 = 3, 3, 2, 1, 1, 0 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0 \\ 2, 1, 1, 0, 0 &\xrightarrow{\text{Extension}} \mathbf{3}, (2 + 1), 1, 1, (0 + 1), (0 + 1) = 3, 3, 1, 1, 1, 1 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0 \\ &\dots \end{aligned}$$

In order to extend a current degree sequence while strictly increasing its maximum degree, it is equivalent to pick a set I of elements of the degree sequence with $|I| > \Delta$ in such a way that the $(d_i + 1)_{i \in I}$ are the $|I|$ maximum elements of the sequence $(d_i + \begin{smallmatrix} 1 \text{ if } i \in I \\ 0 \text{ if } i \notin I \end{smallmatrix})_{1 \leq i \leq n}$, and to add to this new sequence an element of value $|I|$. The non-increasing sequence containing the elements $|I|$ and $(d_i + \begin{smallmatrix} 1 \text{ if } i \in I \\ 0 \text{ if } i \notin I \end{smallmatrix})_{1 \leq i \leq n}$ can be reduced to $(d_i)_{1 \leq i \leq n}$ by Havel and Hakimi's rule.

$$\dots 1, 1, 2, \mathbf{2}, \mathbf{2}, 2, 2, 3, 3, \mathbf{3}, \mathbf{3}, \mathbf{3}, \mathbf{4}, \mathbf{6}, \dots \xrightarrow{\text{Extension}} \dots 1, 1, 2, 2, 2, 3, 3, \mathbf{3}, \mathbf{3}, \mathbf{3}, \mathbf{4}, \mathbf{4}, \mathbf{5}, \mathbf{7}, \dots$$

The number of possible sets I having this property (i.e. the number of possible extensions of a sequence) is smaller than it seems. Indeed, by definition, if $j \notin I$ then for all $i \in I$ the inequality $d_j \leq d_i + 1$ holds. Hence, each set I is entirely determined by the largest element d_k of the sequence that it does **not** contain (hence I contains $\{1, \dots, k - 1\}$), and by the cardinalities of $\{i \in I : d_i = d_k\}$ and $\{i \in I : d_i = d_k - 1\}$.

$$I = \{i \in I : d_i = d_k\} \cup \{i \in I : d_i = d_k - 1\} \cup \{i : d_i > d_k\}.$$

The number of possible extensions is hence at most cubic, and is easily enumerated.

About the implementation

In the actual implementation of the enumeration algorithm, the degree sequence is stored differently for reasons of efficiency.

Indeed, when enumerating all the degree sequences of length n , Sage first allocates an array `seq` of $n + 1$ integers where `seq[i]` is the number of elements of value i in the current sequence. Obviously, `seq[n]=0` holds in permanence : it is useful to allocate a larger array than necessary to simplify the code. The `seq` array is a global variable.

The recursive function `enum(depth, maximum)` is the one building the list of sequences. It builds the list of degree sequences of length n which *extend* the sequence currently stored in `seq[0] . . . seq[depth-1]`. When it is called, `maximum` must be set to the maximum value of an element in the partial sequence `seq[0] . . . seq[depth-1]`.

If during its run the function `enum` heavily works on the content of the `seq` array, the value of `seq` is the **same** before and after the run of `enum`.

Extending the current partial sequence

The two cases for which the maximum degree of the partial sequence does not change are easy to detect. It is (slightly) harder to enumerate all the sets I corresponding to possible extensions of the partial sequence. As said previously, to each set I one can associate an integer `current_box` such that I contains all the i satisfying $d_i > \text{current_box}$. The variable `taken` represents the number of all such elements i , so that when enumerating all possible sets I in the algorithm we have the equality

$$I = \text{taken} + \text{number of elements of value } \text{current_box} + \text{number of elements of value } \text{current_box} - 1.$$

AUTHORS:

- Nathann Cohen

Warning: For the moment, iterating over all degree sequences involves building the list of them first, then iterate on this list. This is obviously bad, as it requires uselessly a **lot** of memory for large values of n .

This should be changed. Updating the code does not require more than a couple of minutes.

class `sage.combinat.degree_sequences.DegreeSequences`(n)

Bases: `object`

Degree Sequences

An instance of this class represents the degree sequences of graphs on a given number n of vertices. It can be used to list and count them, as well as to test whether a sequence is a degree sequence. For more information, please refer to the documentation of the [DegreeSequence](#) module.

EXAMPLES:

```
sage: DegreeSequences(8)
Degree sequences on 8 elements
sage: [3, 3, 2, 2, 2, 2, 2, 2] in DegreeSequences(8)
True
```

5.1.71 Derangements

AUTHORS:

- Alasdair McAndrew (2010-05): Initial version
- Travis Scrimshaw (2013-03-30): Put derangements into category framework

class `sage.combinat.derangements.Derangement`($parent$, $*args$, $**kws$)

Bases: `sage.combinat.combinat.CombinatorialElement`

A derangement.

A derangement on a set S is a permutation σ such that $\sigma(x) \neq x$ for all $x \in S$, i.e. σ is a permutation of S with no fixed points.

EXAMPLES:

```
sage: D = Derangements(4)
sage: elt = D([4,3,2,1])
sage: TestSuite(elt).run()
```

to_permutation()

Return the permutation corresponding to self.

EXAMPLES:

```
sage: D = Derangements(4)
sage: p = D([4,3,2,1]).to_permutation(); p
[4, 3, 2, 1]
sage: type(p)
<class 'sage.combinat.permutation.StandardPermutations_all_with_category.
↳element_class'>
sage: D = Derangements([1, 3, 3, 4])
sage: D[0].to_permutation()
Traceback (most recent call last):
...
ValueError: Can only convert to a permutation for derangements of [1, 2, ..., n]
```

class sage.combinat.derangements.**Derangements**(*x*)

Bases: [sage.structure.unique_representation.UniqueRepresentation](#), [sage.structure.parent.Parent](#)

The class of all derangements of a set or multiset.

A derangement on a set S is a permutation σ such that $\sigma(x) \neq x$ for all $x \in S$, i.e. σ is a permutation of S with no fixed points.

For an integer, or a list or string with all elements distinct, the derangements are obtained by a standard result described in [BV2004]. For a list or string with repeated elements, the derangements are formed by computing all permutations of the input and discarding all non-derangements.

INPUT:

- x – Can be an integer which corresponds to derangements of $\{1, 2, 3, \dots, x\}$, a list, or a string

REFERENCES:

- [BV2004]
- [Wikipedia article Derangement](#)

EXAMPLES:

```
sage: D1 = Derangements([2,3,4,5])
sage: D1.list()
[[3, 4, 5, 2],
 [5, 4, 2, 3],
 [3, 5, 2, 4],
 [4, 5, 3, 2],
 [4, 2, 5, 3],
 [5, 2, 3, 4],
 [5, 4, 3, 2],
 [4, 5, 2, 3],
 [3, 2, 5, 4]]
sage: D1.cardinality()
```

(continues on next page)

(continued from previous page)

```

9
sage: D1.random_element() # random
[4, 2, 5, 3]
sage: D2 = Derangements([1,2,3,1,2,3])
sage: D2.cardinality()
10
sage: D2.list()
[[2, 1, 1, 3, 3, 2],
 [2, 1, 2, 3, 3, 1],
 [2, 3, 1, 2, 3, 1],
 [2, 3, 1, 3, 1, 2],
 [2, 3, 2, 3, 1, 1],
 [3, 1, 1, 2, 3, 2],
 [3, 1, 2, 2, 3, 1],
 [3, 1, 2, 3, 1, 2],
 [3, 3, 1, 2, 1, 2],
 [3, 3, 2, 2, 1, 1]]
sage: D2.random_element() # random
[2, 3, 1, 3, 1, 2]

```

Elementalias of *Derangement***cardinality()**

Counts the number of derangements of a positive integer, a list, or a string. The list or string may contain repeated elements. If an integer n is given, the value returned is the number of derangements of $[1, 2, 3, \dots, n]$.

For an integer, or a list or string with all elements distinct, the value is obtained by the standard result $D_2 = 1, D_3 = 2, D_n = (n - 1)(D_{n-1} + D_{n-2})$.

For a list or string with repeated elements, the number of derangements is computed by Macmahon's theorem. If the numbers of repeated elements are a_1, a_2, \dots, a_k then the number of derangements is given by the coefficient of $x_1 x_2 \cdots x_k$ in the expansion of $\prod_{i=0}^k (S - s_i)^{a_i}$ where $S = x_1 + x_2 + \cdots + x_k$.

EXAMPLES:

```

sage: D = Derangements(5)
sage: D.cardinality()
44
sage: D = Derangements([1,44,918,67,254])
sage: D.cardinality()
44
sage: D = Derangements(['A', 'AT', 'CAT', 'CATS', 'CATS'])
sage: D.cardinality()
44
sage: D = Derangements('UNCOPYRIGHTABLE')
sage: D.cardinality()
481066515734
sage: D = Derangements([1,1,2,2,3,3])
sage: D.cardinality()
10
sage: D = Derangements('SATTAS')
sage: D.cardinality()

```

(continues on next page)

(continued from previous page)

```

10
sage: D = Derangements([1,1,2,2,2])
sage: D.cardinality()
0

```

random_element()

Produces all derangements of a positive integer, a list, or a string. The list or string may contain repeated elements. If an integer n is given, then a random derangements of $[1, 2, 3, \dots, n]$ is returned

For an integer, or a list or string with all elements distinct, the value is obtained by an algorithm described in [MPP2008]. For a list or string with repeated elements the derangement is formed by choosing an element at random from the list of all possible derangements.

OUTPUT:

A single list or string containing a derangement, or an empty list if there are no derangements.

EXAMPLES:

```

sage: D = Derangements(4)
sage: D.random_element() # random
[2, 3, 4, 1]
sage: D = Derangements(['A', 'AT', 'CAT', 'CATS', 'CARTS', 'CARETS'])
sage: D.random_element() # random
['AT', 'CARTS', 'A', 'CAT', 'CARETS', 'CATS']
sage: D = Derangements('UNCOPYRIGHTABLE')
sage: D.random_element() # random
['C', 'U', 'I', 'H', 'O', 'G', 'N', 'B', 'E', 'L', 'A', 'R', 'P', 'Y', 'T']
sage: D = Derangements([1,1,1,1,2,2,2,3,3,3,3])
sage: D.random_element() # random
[3, 2, 2, 3, 1, 3, 1, 3, 2, 1, 1, 2]
sage: D = Derangements('ESSENCES')
sage: D.random_element() # random
['N', 'E', 'E', 'C', 'S', 'S', 'S', 'E']
sage: D = Derangements([1,1,2,2,2])
sage: D.random_element()
[]

```

5.1.72 Descent Algebras

AUTHORS:

- Travis Scrimshaw (2013-07-28): Initial version

class sage.combinat.descent_algebra.**DescentAlgebra**(R, n)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Solomon's descent algebra.

The descent algebra Σ_n over a ring R is a subalgebra of the symmetric group algebra RS_n . (The product in the latter algebra is defined by $(pq)(i) = q(p(i))$ for any two permutations p and q in S_n and every $i \in \{1, 2, \dots, n\}$. The algebra Σ_n inherits this product.)

There are three bases currently implemented for Σ_n :

- the standard basis D_S of (sums of) descent classes, indexed by subsets S of $\{1, 2, \dots, n-1\}$,

- the subset basis B_p , indexed by compositions p of n ,
- the idempotent basis I_p , indexed by compositions p of n , which is used to construct the mutually orthogonal idempotents of the symmetric group algebra.

The idempotent basis is only defined when R is a \mathbf{Q} -algebra.

We follow the notations and conventions in [GR1989], apart from the order of multiplication being different from the one used in that article. Schocker's exposition [Sch2004], in turn, uses the same order of multiplication as we are, but has different notations for the bases.

INPUT:

- R – the base ring
- n – a nonnegative integer

REFERENCES:

- [GR1989]
- [At1992]
- [MR1995]
- [Sch2004]

EXAMPLES:

```
sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D(); D
Descent algebra of 4 over Rational Field in the standard basis
sage: B = DA.B(); B
Descent algebra of 4 over Rational Field in the subset basis
sage: I = DA.I(); I
Descent algebra of 4 over Rational Field in the idempotent basis
sage: basis_B = B.basis()
sage: elt = basis_B[Composition([1,2,1])] + 4*basis_B[Composition([1,3])]; elt
B[1, 2, 1] + 4*B[1, 3]
sage: D(elt)
5*D{} + 5*D{1} + D{1, 3} + D{3}
sage: I(elt)
7/6*I[1, 1, 1, 1] + 2*I[1, 1, 2] + 3*I[1, 2, 1] + 4*I[1, 3]
```

As syntactic sugar, one can use the notation $D[i, \dots, 1]$ to construct elements of the basis; note that for the empty set one must use $D[[]]$ due to Python's syntax:

```
sage: D[[]] + D[2] + 2*D[1,2]
D{} + 2*D{1, 2} + D{2}
```

The same syntax works for the other bases:

```
sage: I[1,2,1] + 3*I[4] + 2*I[3,1]
I[1, 2, 1] + 2*I[3, 1] + 3*I[4]
```

class `B`(*alg*, *prefix*='B')

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`

The subset basis of a descent algebra (indexed by compositions).

The subset basis $(B_S)_{S \subseteq \{1,2,\dots,n-1\}}$ of Σ_n is formed by

$$B_S = \sum_{T \subseteq S} D_T,$$

where $(D_S)_{S \subseteq \{1,2,\dots,n-1\}}$ is the *standard basis*. However it is more natural to index the subset basis by compositions of n under the bijection $\{i_1, i_2, \dots, i_k\} \mapsto (i_1, i_2 - i_1, i_3 - i_2, \dots, i_k - i_{k-1}, n - i_k)$ (where $i_1 < i_2 < \dots < i_k$), which is what Sage uses to index the basis.

The basis element B_p is denoted Ξ^p in [Sch2004].

By using compositions of n , the product $B_p B_q$ becomes a sum over the non-negative-integer matrices M with row sum p and column sum q . The summand corresponding to M is B_c , where c is the composition obtained by reading M row-by-row from left-to-right and top-to-bottom and removing all zeroes. This multiplication rule is commonly called “Solomon’s Mackey formula”.

EXAMPLES:

```
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: list(B.basis())
[B[1, 1, 1, 1], B[1, 1, 2], B[1, 2, 1], B[1, 3],
 B[2, 1, 1], B[2, 2], B[3, 1], B[4]]
```

one_basis()

Return the identity element which is the composition $[n]$, as per `AlgebrasWithBasis.ParentMethods.one_basis`.

EXAMPLES:

```
sage: DescentAlgebra(QQ, 4).B().one_basis()
[4]
sage: DescentAlgebra(QQ, 0).B().one_basis()
[]

sage: all( U * DescentAlgebra(QQ, 3).B().one() == U
.....:      for U in DescentAlgebra(QQ, 3).B().basis() )
True
```

product_on_basis(p, q)

Return $B_p B_q$, where p and q are compositions of n .

EXAMPLES:

```
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: p = Composition([1,2,1])
sage: q = Composition([3,1])
sage: B.product_on_basis(p, q)
B[1, 1, 1, 1] + 2*B[1, 2, 1]
```

to_D_basis(p)

Return B_p as a linear combination of D -basis elements.

EXAMPLES:

```

sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: D = DA.D()
sage: list(map(D, B.basis())) # indirect doctest
[D{} + D{1} + D{1, 2} + D{1, 2, 3}
 + D{1, 3} + D{2} + D{2, 3} + D{3},
 D{} + D{1} + D{1, 2} + D{2},
 D{} + D{1} + D{1, 3} + D{3},
 D{} + D{1},
 D{} + D{2} + D{2, 3} + D{3},
 D{} + D{2},
 D{} + D{3},
 D{}]

```

to_I_basis(p)

Return B_p as a linear combination of I -basis elements.

This is done using the formula

$$B_p = \sum_{q \leq p} \frac{1}{\mathbf{k}!(q, p)} I_q,$$

where \leq is the refinement order and $\mathbf{k}!(q, p)$ is defined as follows: When $q \leq p$, we can write q as a concatenation $q_{(1)}q_{(2)} \cdots q_{(k)}$ with each $q_{(i)}$ being a composition of the i -th entry of p , and then we set $\mathbf{k}!(q, p)$ to be $l(q_{(1)})!l(q_{(2)})! \cdots l(q_{(k)})!$, where $l(r)$ denotes the number of parts of any composition r .

EXAMPLES:

```

sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: I = DA.I()
sage: list(map(I, B.basis())) # indirect doctest
[I[1, 1, 1, 1],
 1/2*I[1, 1, 1, 1] + I[1, 1, 2],
 1/2*I[1, 1, 1, 1] + I[1, 2, 1],
 1/6*I[1, 1, 1, 1] + 1/2*I[1, 1, 2] + 1/2*I[1, 2, 1] + I[1, 3],
 1/2*I[1, 1, 1, 1] + I[2, 1, 1],
 1/4*I[1, 1, 1, 1] + 1/2*I[1, 1, 2] + 1/2*I[2, 1, 1] + I[2, 2],
 1/6*I[1, 1, 1, 1] + 1/2*I[1, 2, 1] + 1/2*I[2, 1, 1] + I[3, 1],
 1/24*I[1, 1, 1, 1] + 1/6*I[1, 1, 2] + 1/6*I[1, 2, 1]
 + 1/2*I[1, 3] + 1/6*I[2, 1, 1] + 1/2*I[2, 2] + 1/2*I[3, 1] + I[4]]

```

to_nsym(p)

Return B_p as an element in $NSym$, the non-commutative symmetric functions.

This maps B_p to S_p where S denotes the Complete basis of $NSym$.

EXAMPLES:

```

sage: B = DescentAlgebra(QQ, 4).B()
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: list(map(S, B.basis())) # indirect doctest
[S[1, 1, 1, 1],
 S[1, 1, 2],
 S[1, 2, 1],

```

(continues on next page)

(continued from previous page)

```
S[1, 3],
S[2, 1, 1],
S[2, 2],
S[3, 1],
S[4]]
```

class `D`(*alg*, *prefix*='D')

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`

The standard basis of a descent algebra.

This basis is indexed by $S \subseteq \{1, 2, \dots, n-1\}$, and the basis vector indexed by S is the sum of all permutations, taken in the symmetric group algebra RS_n , whose descent set is S . We denote this basis vector by D_S .

Occasionally this basis appears in literature but indexed by compositions of n rather than subsets of $\{1, 2, \dots, n-1\}$. The equivalence between these two indexings is owed to the bijection from the power set of $\{1, 2, \dots, n-1\}$ to the set of all compositions of n which sends every subset $\{i_1, i_2, \dots, i_k\}$ of $\{1, 2, \dots, n-1\}$ (with $i_1 < i_2 < \dots < i_k$) to the composition $(i_1, i_2 - i_1, \dots, i_k - i_{k-1}, n - i_k)$.

The basis element corresponding to a composition p (or to the subset of $\{1, 2, \dots, n-1\}$) is denoted Δ^p in [Sch2004].

EXAMPLES:

```
sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: list(D.basis())
[D{}, D{1}, D{2}, D{3}, D{1, 2}, D{1, 3}, D{2, 3}, D{1, 2, 3}]

sage: DA = DescentAlgebra(QQ, 0)
sage: D = DA.D()
sage: list(D.basis())
[D{}]
```

one_basis()

Return the identity element, as per `AlgebrasWithBasis.ParentMethods.one_basis`.

EXAMPLES:

```
sage: DescentAlgebra(QQ, 4).D().one_basis()
()
sage: DescentAlgebra(QQ, 0).D().one_basis()
()

sage: all( U * DescentAlgebra(QQ, 3).D().one() == U
....:       for U in DescentAlgebra(QQ, 3).D().basis() )
True
```

product_on_basis(S, T)

Return $D_S D_T$, where S and T are subsets of $[n-1]$.

EXAMPLES:

```

sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: D.product_on_basis((1, 3), (2,))
D{} + D{1} + D{1, 2} + 2*D{1, 2, 3} + D{1, 3} + D{2} + D{2, 3} + D{3}

```

to_B_basis(S)

Return D_S as a linear combination of B_p -basis elements.

EXAMPLES:

```

sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: B = DA.B()
sage: list(map(B, D.basis())) # indirect doctest
[B[4],
 B[1, 3] - B[4],
 B[2, 2] - B[4],
 B[3, 1] - B[4],
 B[1, 1, 2] - B[1, 3] - B[2, 2] + B[4],
 B[1, 2, 1] - B[1, 3] - B[3, 1] + B[4],
 B[2, 1, 1] - B[2, 2] - B[3, 1] + B[4],
 B[1, 1, 1, 1] - B[1, 1, 2] - B[1, 2, 1] + B[1, 3]
 - B[2, 1, 1] + B[2, 2] + B[3, 1] - B[4]]

```

to_symmetric_group_algebra_on_basis(S)

Return D_S as a linear combination of basis elements in the symmetric group algebra.

EXAMPLES:

```

sage: D = DescentAlgebra(QQ, 4).D()
sage: [D.to_symmetric_group_algebra_on_basis(tuple(b))
.....: for b in Subsets(3)]
[[1, 2, 3, 4],
 [2, 1, 3, 4] + [3, 1, 2, 4] + [4, 1, 2, 3],
 [1, 3, 2, 4] + [1, 4, 2, 3] + [2, 3, 1, 4]
 + [2, 4, 1, 3] + [3, 4, 1, 2],
 [1, 2, 4, 3] + [1, 3, 4, 2] + [2, 3, 4, 1],
 [3, 2, 1, 4] + [4, 2, 1, 3] + [4, 3, 1, 2],
 [2, 1, 4, 3] + [3, 1, 4, 2] + [3, 2, 4, 1]
 + [4, 1, 3, 2] + [4, 2, 3, 1],
 [1, 4, 3, 2] + [2, 4, 3, 1] + [3, 4, 2, 1],
 [4, 3, 2, 1]]

```

class I(alg, prefix='I')

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`

The idempotent basis of a descent algebra.

The idempotent basis $(I_p)_{p \vdash n}$ is a basis for Σ_n whenever the ground ring is a \mathbf{Q} -algebra. One way to compute it is using the formula (Theorem 3.3 in [GR1989])

$$I_p = \sum_{q \leq p} \frac{(-1)^{l(q)-l(p)}}{k(q,p)} B_q,$$

where \leq is the refinement order and $l(r)$ denotes the number of parts of any composition r , and where

$\mathbf{k}(q, p)$ is defined as follows: When $q \leq p$, we can write q as a concatenation $q_{(1)}q_{(2)} \cdots q_{(k)}$ with each $q_{(i)}$ being a composition of the i -th entry of p , and then we set $\mathbf{k}(q, p)$ to be the product $l(q_{(1)})l(q_{(2)}) \cdots l(q_{(k)})$.

Let $\lambda(p)$ denote the partition obtained from a composition p by sorting. This basis is called the idempotent basis since for any q such that $\lambda(p) = \lambda(q)$, we have:

$$I_p I_q = s(\lambda) I_p$$

where λ denotes $\lambda(p) = \lambda(q)$, and where $s(\lambda)$ is the stabilizer of λ in S_n . (This is part of Theorem 4.2 in [GR1989].)

It is also straightforward to compute the idempotents E_λ for the symmetric group algebra by the formula (Theorem 3.2 in [GR1989]):

$$E_\lambda = \frac{1}{k!} \sum_{\lambda(p)=\lambda} I_p.$$

Note: The basis elements are not orthogonal idempotents.

EXAMPLES:

```
sage: DA = DescentAlgebra(QQ, 4)
sage: I = DA.I()
sage: list(I.basis())
[I[1, 1, 1, 1], I[1, 1, 2], I[1, 2, 1], I[1, 3], I[2, 1, 1], I[2, 2], I[3, 1],
↪ I[4]]
```

idempotent(*la*)

Return the idempotent corresponding to the partition *la* of *n*.

EXAMPLES:

```
sage: I = DescentAlgebra(QQ, 4).I()
sage: E = I.idempotent([3,1]); E
1/2*I[1, 3] + 1/2*I[3, 1]
sage: E*E == E
True
sage: E2 = I.idempotent([2,1,1]); E2
1/6*I[1, 1, 2] + 1/6*I[1, 2, 1] + 1/6*I[2, 1, 1]
sage: E2*E2 == E2
True
sage: E*E2 == I.zero()
True
```

one()

Return the identity element, which is $B_{[n]}$, in the I basis.

EXAMPLES:

```
sage: DescentAlgebra(QQ, 4).I().one()
1/24*I[1, 1, 1, 1] + 1/6*I[1, 1, 2] + 1/6*I[1, 2, 1]
+ 1/2*I[1, 3] + 1/6*I[2, 1, 1] + 1/2*I[2, 2]
+ 1/2*I[3, 1] + I[4]
sage: DescentAlgebra(QQ, 0).I().one()
I[]
```

one_basis()

The element 1 is not (generally) a basis vector in the I basis, thus this returns a `TypeError`.

EXAMPLES:

```
sage: DescentAlgebra(QQ, 4).I().one_basis()
Traceback (most recent call last):
...
TypeError: 1 is not a basis element in the I basis
```

product_on_basis(p, q)

Return $I_p I_q$, where p and q are compositions of n .

EXAMPLES:

```
sage: DA = DescentAlgebra(QQ, 4)
sage: I = DA.I()
sage: p = Composition([1,2,1])
sage: q = Composition([3,1])
sage: I.product_on_basis(p, q)
0
sage: I.product_on_basis(p, p)
2*I[1, 2, 1]
```

to_B_basis(p)

Return I_p as a linear combination of B -basis elements.

This is computed using the formula (Theorem 3.3 in [GR1989])

$$I_p = \sum_{q \leq p} \frac{(-1)^{l(q)-l(p)}}{\mathbf{k}(q,p)} B_q,$$

where \leq is the refinement order and $l(r)$ denotes the number of parts of any composition r , and where $\mathbf{k}(q,p)$ is defined as follows: When $q \leq p$, we can write q as a concatenation $q_{(1)}q_{(2)} \cdots q_{(k)}$ with each $q_{(i)}$ being a composition of the i -th entry of p , and then we set $\mathbf{k}(q,p)$ to be $l(q_{(1)})l(q_{(2)}) \cdots l(q_{(k)})$.

EXAMPLES:

```
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: I = DA.I()
sage: list(map(B, I.basis())) # indirect doctest
[B[1, 1, 1, 1],
 -1/2*B[1, 1, 1, 1] + B[1, 1, 2],
 -1/2*B[1, 1, 1, 1] + B[1, 2, 1],
 1/3*B[1, 1, 1, 1] - 1/2*B[1, 1, 2] - 1/2*B[1, 2, 1] + B[1, 3],
 -1/2*B[1, 1, 1, 1] + B[2, 1, 1],
 1/4*B[1, 1, 1, 1] - 1/2*B[1, 1, 2] - 1/2*B[2, 1, 1] + B[2, 2],
 1/3*B[1, 1, 1, 1] - 1/2*B[1, 2, 1] - 1/2*B[2, 1, 1] + B[3, 1],
 -1/4*B[1, 1, 1, 1] + 1/3*B[1, 1, 2] + 1/3*B[1, 2, 1]
 - 1/2*B[1, 3] + 1/3*B[2, 1, 1] - 1/2*B[2, 2]
 - 1/2*B[3, 1] + B[4]]
```

a_realization()

Return a particular realization of `self` (the B -basis).

EXAMPLES:

```
sage: DA = DescentAlgebra(QQ, 4)
sage: DA.a_realization()
Descent algebra of 4 over Rational Field in the subset basis
```

idempotent

alias of *DescentAlgebra.I*

standard

alias of *DescentAlgebra.D*

subset

alias of *DescentAlgebra.B*

class sage.combinat.descent_algebra.**DescentAlgebraBases**(*base*)

Bases: *sage.categories.realizations.Category_realization_of_parent*

The category of bases of a descent algebra.

class ElementMethods

Bases: object

to_symmetric_group_algebra()

Return self in the symmetric group algebra.

EXAMPLES:

```
sage: B = DescentAlgebra(QQ, 4).B()
sage: B[1,3].to_symmetric_group_algebra()
[1, 2, 3, 4] + [2, 1, 3, 4] + [3, 1, 2, 4] + [4, 1, 2, 3]
sage: I = DescentAlgebra(QQ, 4).I()
sage: elt = I(B[1,3])
sage: elt.to_symmetric_group_algebra()
[1, 2, 3, 4] + [2, 1, 3, 4] + [3, 1, 2, 4] + [4, 1, 2, 3]
```

class ParentMethods

Bases: object

is_commutative()

Return whether this descent algebra is commutative.

EXAMPLES:

```
sage: B = DescentAlgebra(QQ, 4).B()
sage: B.is_commutative()
False
sage: B = DescentAlgebra(QQ, 1).B()
sage: B.is_commutative()
True
```

is_field(*proof=True*)

Return whether this descent algebra is a field.

EXAMPLES:

```
sage: B = DescentAlgebra(QQ, 4).B()
sage: B.is_field()
False
sage: B = DescentAlgebra(QQ, 1).B()
```

(continues on next page)

(continued from previous page)

```
sage: B.is_field()
True
```

to_symmetric_group_algebra()

Morphism from self to the symmetric group algebra.

EXAMPLES:

```
sage: D = DescentAlgebra(QQ, 4).D()
sage: D.to_symmetric_group_algebra(D[1,3])
[2, 1, 4, 3] + [3, 1, 4, 2] + [3, 2, 4, 1] + [4, 1, 3, 2] + [4, 2, 3, 1]
sage: B = DescentAlgebra(QQ, 4).B()
sage: B.to_symmetric_group_algebra(B[1,2,1])
[1, 2, 3, 4] + [1, 2, 4, 3] + [1, 3, 4, 2] + [2, 1, 3, 4]
+ [2, 1, 4, 3] + [2, 3, 4, 1] + [3, 1, 2, 4] + [3, 1, 4, 2]
+ [3, 2, 4, 1] + [4, 1, 2, 3] + [4, 1, 3, 2] + [4, 2, 3, 1]
```

to_symmetric_group_algebra_on_basis(S)

Return the basis element index by S as a linear combination of basis elements in the symmetric group algebra.

EXAMPLES:

```
sage: B = DescentAlgebra(QQ, 3).B()
sage: [B.to_symmetric_group_algebra_on_basis(c)
.....: for c in Compositions(3)]
[[1, 2, 3] + [1, 3, 2] + [2, 1, 3]
+ [2, 3, 1] + [3, 1, 2] + [3, 2, 1],
[1, 2, 3] + [2, 1, 3] + [3, 1, 2],
[1, 2, 3] + [1, 3, 2] + [2, 3, 1],
[1, 2, 3]]
sage: I = DescentAlgebra(QQ, 3).I()
sage: [I.to_symmetric_group_algebra_on_basis(c)
.....: for c in Compositions(3)]
[[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1]
+ [3, 1, 2] + [3, 2, 1],
1/2*[1, 2, 3] - 1/2*[1, 3, 2] + 1/2*[2, 1, 3]
- 1/2*[2, 3, 1] + 1/2*[3, 1, 2] - 1/2*[3, 2, 1],
1/2*[1, 2, 3] + 1/2*[1, 3, 2] - 1/2*[2, 1, 3]
+ 1/2*[2, 3, 1] - 1/2*[3, 1, 2] - 1/2*[3, 2, 1],
1/3*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3]
- 1/6*[2, 3, 1] - 1/6*[3, 1, 2] + 1/3*[3, 2, 1]]
```

super_categories()

The super categories of self.

EXAMPLES:

```
sage: from sage.combinat.descent_algebra import DescentAlgebraBases
sage: DA = DescentAlgebra(QQ, 4)
sage: bases = DescentAlgebraBases(DA)
sage: bases.super_categories()
[Category of finite dimensional algebras with basis over Rational Field,
Category of realizations of Descent algebra of 4 over Rational Field]
```

5.1.73 Combinatorial designs and incidence structures

All designs can be accessed by `designs.<tab>` and are listed in the design catalog:

- *Catalog of designs*

Design-related classes

- *Incidence structures (i.e. hypergraphs, i.e. set systems)*
- *Covering designs: coverings of t -element subsets of a v -set by k -sets*

Constructions

- *Block designs*
- *Balanced Incomplete Block Designs (BIBD)*
- *Resolvable Balanced Incomplete Block Design (RBIBD)*
- *Group-Divisible Designs (GDD)*
- *Mutually Orthogonal Latin Squares (MOLS)*
- *Orthogonal arrays (OA)*
- *Orthogonal arrays (build recursive constructions)*
- *Orthogonal arrays (find recursive constructions)*
- *Difference families*
- *Difference Matrices*
- *Steiner Quadruple Systems*
- *Two-graphs*
- *Database of small combinatorial designs*
- *Database of generalised quadrangles with spread*

Technical things

- *External Representations of Block Designs*
- *Cython functions for combinatorial designs*
- *Hypergraph isomorphic copy search*
- *Evenly distributed sets in finite fields*

5.1.74 Balanced Incomplete Block Designs (BIBD)

This module gathers everything related to Balanced Incomplete Block Designs. One can build a BIBD (or check that it can be built) with `balanced_incomplete_block_design()`:

```
sage: BIBD = designs.balanced_incomplete_block_design(7, 3, 1)
```

In particular, Sage can build a $(v, k, 1)$ -BIBD when one exists for all $k \leq 5$. The following functions are available:

<code>balanced_incomplete_block_design()</code>	Return a BIBD of parameters v, k, λ .
<code>BIBD_from_TD()</code>	Return a BIBD through TD-based constructions.
<code>BIBD_from_difference_family()</code>	Return the BIBD associated to the difference family D on the group G .
<code>BIBD_from_PBD()</code>	Return a $(v, k, 1)$ -BIBD from a (r, K) -PBD where $r = (v - 1)/(k - 1)$.
<code>PBD_from_TD()</code>	Return a $(kt, \{k, t\})$ -PBD if $u = 0$ and a $(kt + u, \{k, k + 1, t, u\})$ -PBD otherwise.
<code>steiner_triple_system()</code>	Return a Steiner Triple System.
<code>v_5_1_BIBD()</code>	Return a $(v, 5, 1)$ -BIBD.
<code>v_4_1_BIBD()</code>	Return a $(v, 4, 1)$ -BIBD.
<code>PBD_4_5_8_9_12()</code>	Return a $(v, \{4, 5, 8, 9, 12\})$ -PBD on v elements.
<code>BIBD_5q_5_for_q_prime_power(q)</code>	Return a $(5q, 5, 1)$ -BIBD with $q \equiv 1 \pmod{4}$ a prime power.

Construction of BIBD when $k = 4$

Decompositions of K_v into K_4 (i.e. $(v, 4, 1)$ -BIBD) are built following Douglas Stinson's construction as presented in [Stinson2004] page 167. It is based upon the construction of $(v\{4, 5, 8, 9, 12\})$ -PBD (see the doc of `PBD_4_5_8_9_12()`), knowing that a $(v\{4, 5, 8, 9, 12\})$ -PBD on v points can always be transformed into a $((k - 1)v + 1, 4, 1)$ -BIBD, which covers all possible cases of $(v, 4, 1)$ -BIBD.

Construction of BIBD when $k = 5$

Decompositions of K_v into K_4 (i.e. $(v, 4, 1)$ -BIBD) are built following Clayton Smith's construction [ClaytonSmith].

Functions

`sage.combinat.designs.bibd.BIBD`

alias of `sage.combinat.designs.bibd.BalancedIncompleteBlockDesign`

`sage.combinat.designs.bibd.BIBD_5q_5_for_q_prime_power(q)`

Return a $(5q, 5, 1)$ -BIBD with $q \equiv 1 \pmod{4}$ a prime power.

See Theorem 24 [ClaytonSmith].

INPUT:

- q (integer) – a prime power such that $q \equiv 1 \pmod{4}$.

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import BIBD_5q_5_for_q_prime_power
sage: for q in [25, 45, 65, 85, 125, 145, 185, 205, 305, 405, 605]: # long time
.....:     _ = BIBD_5q_5_for_q_prime_power(q/5) # long time
```

`sage.combinat.designs.bibd.BIBD_from_PBD(PBD, v, k, check=True, base_cases=None)`

Return a $(v, k, 1)$ -BIBD from a (r, K) -PBD where $r = (v - 1)/(k - 1)$.

This is Theorem 7.20 from [Stinson2004].

INPUT:

- v, k – integers.
- PBD – A PBD on $r = (v - 1)/(k - 1)$ points, such that for any block of PBD of size s there must exist a $((k - 1)s + 1, k, 1)$ -BIBD.
- `check` (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

- `base_cases` – caching system, for internal use.

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import PBD_4_5_8_9_12
sage: from sage.combinat.designs.bibd import BIBD_from_PBD
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: PBD = PBD_4_5_8_9_12(17)
sage: bibd = is_pairwise_balanced_design(BIBD_from_PBD(PBD, 52, 4), 52, [4])
```

`sage.combinat.designs.bibd.BIBD_from_TD(v, k, existence=False)`

Return a BIBD through TD-based constructions.

INPUT:

- `v, k` – (integers) computes a $(v, k, 1)$ -BIBD.
- `existence` – (boolean) instead of building the design, return:
 - `True` – meaning that Sage knows how to build the design
 - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
 - `False` – meaning that the design does not exist

This method implements three constructions:

- If there exists a $TD(k, v)$ and a $(v, k, 1)$ -BIBD then there exists a $(kv, k, 1)$ -BIBD.
The BIBD is obtained from all blocks of the TD , and from the blocks of the $(v, k, 1)$ -BIBDs defined over the k groups of the TD .
- If there exists a $TD(k, v)$ and a $(v + 1, k, 1)$ -BIBD then there exists a $(kv + 1, k, 1)$ -BIBD.
The BIBD is obtained from all blocks of the TD , and from the blocks of the $(v + 1, k, 1)$ -BIBDs defined over the sets $V_1 \cup \infty, \dots, V_k \cup \infty$ where the V_1, \dots, V_k are the groups of the TD .
- If there exists a $TD(k, v)$ and a $(v + k, k, 1)$ -BIBD then there exists a $(kv + k, k, 1)$ -BIBD.
The BIBD is obtained from all blocks of the TD , and from the blocks of the $(v + k, k, 1)$ -BIBDs defined over the sets $V_1 \cup \{\infty_1, \dots, \infty_k\}, \dots, V_k \cup \{\infty_1, \dots, \infty_k\}$ where the V_1, \dots, V_k are the groups of the TD . By making sure that all copies of the $(v + k, k, 1)$ -BIBD contain the block $\{\infty_1, \dots, \infty_k\}$, the result is also a BIBD.

These constructions can be found in <http://www.argilo.net/files/bibd.pdf>.

EXAMPLES:

First construction:

```
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(25, 5, existence=True)
True
sage: _ = BlockDesign(25, BIBD_from_TD(25, 5))
```

Second construction:

```
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(21, 5, existence=True)
True
sage: _ = BlockDesign(21, BIBD_from_TD(21, 5))
```

Third construction:

```
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(85,5,existence=True)
True
sage: _ = BlockDesign(85,BIBD_from_TD(85,5))
```

No idea:

```
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(20,5,existence=True)
Unknown
sage: BIBD_from_TD(20,5)
Traceback (most recent call last):
...
NotImplementedError: I do not know how to build a (20,5,1)-BIBD!
```

`sage.combinat.designs.bibd.BIBD_from_arc_in_desarguesian_projective_plane`(n, k ,
existence=False)

Return a $(n, k, 1)$ -BIBD from a maximal arc in a projective plane.

This function implements a construction from Denniston [Denniston69], who describes a maximal *arc* in a *Desarguesian Projective Plane* of order 2^k . From two powers of two n, q with $n < q$, it produces a $((n-1)(q+1)+1, n, 1)$ -BIBD.

INPUT:

- n, k (integers) – must be powers of two (among other restrictions).
- *existence* (boolean) – whether to return the BIBD obtained through this construction (default), or to merely indicate with a boolean return value whether this method *can* build the requested BIBD.

EXAMPLES:

A $(232, 8, 1)$ -BIBD:

```
sage: from sage.combinat.designs.bibd import BIBD_from_arc_in_desarguesian_
↪projective_plane
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: D = BIBD_from_arc_in_desarguesian_projective_plane(232,8)
sage: BalancedIncompleteBlockDesign(232,D)
(232,8,1)-Balanced Incomplete Block Design
```

A $(120, 8, 1)$ -BIBD:

```
sage: D = BIBD_from_arc_in_desarguesian_projective_plane(120,8)
sage: BalancedIncompleteBlockDesign(120,D)
(120,8,1)-Balanced Incomplete Block Design
```

Other parameters:

```
sage: all(BIBD_from_arc_in_desarguesian_projective_plane(n,k,existence=True)
.....:     for n,k in
.....:         [(120, 8), (232, 8), (456, 8), (904, 8), (496, 16),
.....:          (976, 16), (1936, 16), (2016, 32), (4000, 32), (8128, 64)])
True
```

Of course, not all can be built this way:

```

sage: BIBD_from_arc_in_desarguesian_projective_plane(7,3,existence=True)
False
sage: BIBD_from_arc_in_desarguesian_projective_plane(7,3)
Traceback (most recent call last):
...
ValueError: This function cannot produce a (7,3,1)-BIBD

```

REFERENCE:

```
sage.combinat.designs.bibd.BIBD_from_difference_family(G, D, lambda=None, check=True)
```

Return the BIBD associated to the difference family D on the group G .

Let G be a group. A (G, k, λ) -difference family is a family $B = \{B_1, B_2, \dots, B_b\}$ of k -subsets of G such that for each element of $G \setminus \{0\}$ there exists exactly λ pairs of elements (x, y) , x and y belonging to the same block, such that $x - y = g$ (or $x y^{-1} = g$ in multiplicative notation).

If $\{B_1, B_2, \dots, B_b\}$ is a (G, k, λ) -difference family then its set of translates $\{B_i \cdot g; i \in \{1, \dots, b\}, g \in G\}$ is a (v, k, λ) -BIBD where v is the cardinality of G .

INPUT:

- G - a finite additive Abelian group
- D - a difference family on G (short blocks are allowed).
- λ - the λ parameter (optional, only used if `check` is `True`)
- `check` - whether or not we check the output (default: `True`)

EXAMPLES:

```

sage: G = Zmod(21)
sage: D = [[0, 1, 4, 14, 16]]
sage: sorted(G(x-y) for x in D[0] for y in D[0] if x != y)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]

sage: from sage.combinat.designs.bibd import BIBD_from_difference_family
sage: BIBD_from_difference_family(G, D)
[[0, 1, 4, 14, 16],
 [1, 2, 5, 15, 17],
 [2, 3, 6, 16, 18],
 [3, 4, 7, 17, 19],
 [4, 5, 8, 18, 20],
 [5, 6, 9, 19, 0],
 [6, 7, 10, 20, 1],
 [7, 8, 11, 0, 2],
 [8, 9, 12, 1, 3],
 [9, 10, 13, 2, 4],
 [10, 11, 14, 3, 5],
 [11, 12, 15, 4, 6],
 [12, 13, 16, 5, 7],
 [13, 14, 17, 6, 8],
 [14, 15, 18, 7, 9],
 [15, 16, 19, 8, 10],
 [16, 17, 20, 9, 11],

```
class sage.combinat.designs.bibd.BalancedIncompleteBlockDesign(points, blocks, k=None, lambda=1,
check=True, copy=True, **kwds)
```

Bases: `sage.combinat.designs.bibd.PairwiseBalancedDesign`

Balanced Incomplete Block Design (BIBD)

INPUT:

- `points` – the underlying set. If `points` is an integer v , then the set is considered to be $\{0, \dots, v - 1\}$.
- `blocks` – collection of blocks
- `k` (integer) – size of the blocks. Set to `None` (automatic guess) by default.
- `lambda` (integer) – value of λ , set to 1 by default.
- `check` (boolean) – whether to check that the design is a *PBD* with the right parameters.
- `copy` – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the instance's internal data.

EXAMPLES:

```
sage: b=designs.balanced_incomplete_block_design(9,3); b
(9,3,1)-Balanced Incomplete Block Design
```

```
arc(s, solver=2, verbose=None, integrality_tolerance=0)
```

Return the s -arc with maximum cardinality.

A s -arc is a subset of points in a BIBD that intersects each block on at most s points. It is one possible generalization of independent set for graphs.

A simple counting shows that the cardinality of a s -arc is at most $(s - 1) * r + 1$ where r is the number of blocks incident to any point. A s -arc in a BIBD with cardinality $(s - 1) * r + 1$ is called maximal and is characterized by the following property: it is not empty and each block either contains 0 or s points of this arc. Equivalently, the trace of the BIBD on these points is again a BIBD (with block size s).

For more informations, see [Wikipedia article Arc_\(projective_geometry\)](#).

INPUT:

- `s` - (default to 2) the maximum number of points from the arc in each block
- `solver` – (default: `None`) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – integer (default: `0`). Sets the level of verbosity. Set to 0 by default, which means quiet.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

EXAMPLES:

```
sage: B = designs.balanced_incomplete_block_design(21, 5)
sage: a2 = B.arc()
sage: a2 # random
```

(continues on next page)

(continued from previous page)

```
[5, 9, 10, 12, 15, 20]
sage: len(a2)
6
sage: a4 = B.arc(4)
sage: a4 # random
[0, 1, 2, 5, 6, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 20]
sage: len(a4)
16
```

The 2-arc and 4-arc above are maximal. One can check that they intersect the blocks in either 0 or s points. Or equivalently that the traces are again BIBD:

```
sage: r = (21-1)//(5-1)
sage: 1 + r*1
6
sage: 1 + r*3
16

sage: B.trace(a2).is_t_design(2, return_parameters=True)
(True, (2, 6, 2, 1))
sage: B.trace(a4).is_t_design(2, return_parameters=True)
(True, (2, 16, 4, 1))
```

Some other examples which are not maximal:

```
sage: B = designs.balanced_incomplete_block_design(25, 4)
sage: a2 = B.arc(2)
sage: r = (25-1)//(4-1)
sage: len(a2), 1 + r
(8, 9)
sage: sa2 = set(a2)
sage: set(len(sa2.intersection(b)) for b in B.blocks())
{0, 1, 2}
sage: B.trace(a2).is_t_design(2)
False

sage: a3 = B.arc(3)
sage: len(a3), 1 + 2*r
(15, 17)
sage: sa3 = set(a3)
sage: set(len(sa3.intersection(b)) for b in B.blocks()) == set([0,3])
False
sage: B.trace(a3).is_t_design(3)
False
```

`sage.combinat.designs.bibd.BruckRyserChowla_check(v, k, λ)`

Check whether the parameters passed satisfy the Bruck-Ryser-Chowla theorem.

For more information on the theorem, see the [corresponding Wikipedia entry](#).

INPUT:

- v, k, λ – integers; parameters to check

OUTPUT:

- True – the parameters satisfy the theorem
- False – the theorem fails for the given parameters
- Unknown – the preconditions of the theorem are not met

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check
sage: BruckRyserChowla_check(22,7,2) False
```

Nonexistence of projective planes of order 6 and 14

```
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check
sage: BruckRyserChowla_check(43,7,1) False
sage: BruckRyserChowla_check(211,15,1) False
```

Existence of symmetric BIBDs with parameters (79, 13, 2) and (56, 11, 2)

```
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check
sage: BruckRyserChowla_check(79,13,2) True
sage: BruckRyserChowla_check(56,11,2) True
```

`sage.combinat.designs.bibd.PBD_4_5_8_9_12(v, check=True)`

Return a $(v, \{4, 5, 8, 9, 12\})$ -PBD on v elements.

A $(v, \{4, 5, 8, 9, 12\})$ -PBD exists if and only if $v \equiv 0, 1 \pmod{4}$. The construction implemented here appears page 168 in [Stinson2004].

INPUT:

- v – an integer congruent to 0 or 1 modulo 4.
- `check` (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

EXAMPLES:

```
sage: designs.balanced_incomplete_block_design(40,4).blocks() # indirect doctest
[[0, 1, 2, 12], [0, 3, 6, 9], [0, 4, 8, 10],
 [0, 5, 7, 11], [0, 13, 26, 39], [0, 14, 25, 28],
 [0, 15, 27, 38], [0, 16, 22, 32], [0, 17, 23, 34],
 ...
```

Check that [trac ticket #16476](#) is fixed:

```
sage: from sage.combinat.designs.bibd import PBD_4_5_8_9_12
sage: for v in (0,1,4,5,8,9,12,13,16,17,20,21,24,25):
.....:     _ = PBD_4_5_8_9_12(v)
```

`sage.combinat.designs.bibd.PBD_from_TD(k, t, u)`

Return a $(kt, \{k, t\})$ -PBD if $u = 0$ and a $(kt + u, \{k, k + 1, t, u\})$ -PBD otherwise.

This is theorem 23 from [ClaytonSmith]. The PBD is obtained from the blocks a truncated $TD(k + 1, t)$, to which are added the blocks corresponding to the groups of the TD. When $u = 0$, a $TD(k, t)$ is used instead.

INPUT:

- k, t, u – integers such that $0 \leq u \leq t$.

EXAMPLES:

```

sage: from sage.combinat.designs.bibd import PBD_from_TD
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: PBD = PBD_from_TD(2,2,1); PBD
[[0, 2, 4], [0, 3], [1, 2], [1, 3, 4], [0, 1], [2, 3]]
sage: is_pairwise_balanced_design(PBD,2*2+1,[2,3])
True

```

```

class sage.combinat.designs.bibd.PairwiseBalancedDesign(points, blocks, K=None, lambda=1,
                                                         check=True, copy=True, **kws)

```

Bases: `sage.combinat.designs.group_divisible_designs.GroupDivisibleDesign`

Pairwise Balanced Design (PBD)

A Pairwise Balanced Design, or (v, K, λ) -PBD, is a collection \mathcal{B} of blocks defined on a set X of size v , such that any block pair of points $p_1, p_2 \in X$ occurs in exactly λ blocks of \mathcal{B} . Besides, for every block $B \in \mathcal{B}$ we must have $|B| \in K$.

INPUT:

- `points` – the underlying set. If `points` is an integer v , then the set is considered to be $\{0, \dots, v - 1\}$.
- `blocks` – collection of blocks
- `K` – list of integers of which the sizes of the blocks must be elements. Set to `None` (automatic guess) by default.
- `lambda` (integer) – value of λ , set to 1 by default.
- `check` (boolean) – whether to check that the design is a *PBD* with the right parameters.
- `copy` – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the instance's internal data.

```

sage.combinat.designs.bibd.balanced_incomplete_block_design(v, k, lambda=1, existence=False,
                                                            use_LJCR=False)

```

Return a BIBD of parameters v, k, λ .

A Balanced Incomplete Block Design of parameters v, k, λ is a collection \mathcal{C} of k -subsets of $V = \{0, \dots, v - 1\}$ such that for any two distinct elements $x, y \in V$ there are λ elements $S \in \mathcal{C}$ such that $x, y \in S$.

For more information on BIBD, see the [corresponding Wikipedia entry](#).

INPUT:

- `v, k, lambda` (integers)
- `existence` (boolean) – instead of building the design, return:
 - `True` – meaning that Sage knows how to build the design
 - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
 - `False` – meaning that the design does not exist.
- `use_LJCR` (boolean) – whether to query the La Jolla Covering Repository for the design when Sage does not know how to build it (see `best_known_covering_design_www()`). This requires internet.

See also:

- `steiner_triple_system()`
- `v_4_1_BIBD()`

- `v_5_1_BIBD()`

Todo: Implement other constructions from the Handbook of Combinatorial Designs.

EXAMPLES:

```

sage: designs.balanced_incomplete_block_design(7, 3, 1).blocks()
[[0, 1, 3], [0, 2, 4], [0, 5, 6], [1, 2, 6], [1, 4, 5], [2, 3, 5], [3, 4, 6]]
sage: B = designs.balanced_incomplete_block_design(66, 6, 1, use_LJCR=True) #
↳optional - internet
sage: B # optional -
↳internet
(66,6,1)-Balanced Incomplete Block Design
sage: B.blocks() # optional -
↳internet
[[0, 1, 2, 3, 4, 65], [0, 5, 22, 32, 38, 58], [0, 6, 21, 30, 43, 48], ...
sage: designs.balanced_incomplete_block_design(216, 6, 1)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build a (216,6,1)-BIBD!

```

`sage.combinat.designs.bibd.biplane(n, existence=False)`

Return a biplane of order n .

A biplane of order n is a symmetric $(1 + \frac{(n+1)(n+2)}{2}, n+2, 2)$ -BIBD. A symmetric (or square) (v, k, λ) -BIBD is a (v, k, λ) -BIBD with v blocks.

INPUT:

- n – (integer) order of the biplane
- `existence` (boolean) – instead of building the design, return:
 - True – meaning that Sage knows how to build the design
 - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
 - False – meaning that the design does not exist.

See also:

- `balanced_incomplete_block_design()`

EXAMPLES:

```

sage: designs.biplane(4)
(16,6,2)-Balanced Incomplete Block Design
sage: designs.biplane(7, existence=True)
True
sage: designs.biplane(11)
(79,13,2)-Balanced Incomplete Block Design

```

`sage.combinat.designs.bibd.steiner_triple_system(n)`

Return a Steiner Triple System

A Steiner Triple System (STS) of a set $\{0, \dots, n-1\}$ is a family S of 3-sets such that for any $i \neq j$ there exists exactly one set of S in which they are both contained.

It can alternatively be thought of as a factorization of the complete graph K_n with triangles.

A Steiner Triple System of a n -set exists if and only if $n \equiv 1 \pmod{6}$ or $n \equiv 3 \pmod{6}$, in which case one can be found through Bose's and Skolem's constructions, respectively [AndHonk97].

INPUT:

- `n` return a Steiner Triple System of $\{0, \dots, n-1\}$

EXAMPLES:

A Steiner Triple System on 9 elements

```
sage: sts = designs.steiner_triple_system(9)
sage: sts
(9,3,1)-Balanced Incomplete Block Design
sage: list(sts)
[[0, 1, 5], [0, 2, 4], [0, 3, 6], [0, 7, 8], [1, 2, 3],
 [1, 4, 7], [1, 6, 8], [2, 5, 8], [2, 6, 7], [3, 4, 8],
 [3, 5, 7], [4, 5, 6]]
```

As any pair of vertices is covered once, its parameters are

```
sage: sts.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
```

An exception is raised for invalid values of `n`

```
sage: designs.steiner_triple_system(10)
Traceback (most recent call last):
...
EmptySetError: Steiner triple systems only exist for n = 1 mod 6 or n = 3 mod 6
```

REFERENCE:

`sage.combinat.designs.bibd.v_4_1_BIBD(v, check=True)`
Return a $(v, 4, 1)$ -BIBD.

A $(v, 4, 1)$ -BIBD is an edge-decomposition of the complete graph K_v into copies of K_4 . For more information, see [balanced_incomplete_block_design\(\)](#). It exists if and only if $v \equiv 1, 4 \pmod{12}$.

See page 167 of [Stinson2004] for the construction details.

See also:

- [balanced_incomplete_block_design\(\)](#)

INPUT:

- `v` (integer) – number of points.
- `check` (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import v_4_1_BIBD # long time
sage: for n in range(13,100): # long time
.....:     if n%12 in [1,4]: # long time
.....:         _ = v_4_1_BIBD(n, check = True) # long time
```

`sage.combinat.designs.bibd.v_5_1_BIBD(v, check=True)`

Return a $(v, 5, 1)$ -BIBD.

This method follows the construction from [ClaytonSmith].

INPUT:

- v (integer)

See also:

- `balanced_incomplete_block_design()`

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import v_5_1_BIBD
sage: i = 0
sage: while i < 200:
.....:     i += 20
.....:     _ = v_5_1_BIBD(i+1)
.....:     _ = v_5_1_BIBD(i+5)
```

5.1.75 Resolvable Balanced Incomplete Block Design (RBIBD)

This module contains everything related to resolvable Balanced Incomplete Block Designs. The constructions implemented here can be obtained through the `designs.<tab>` object:

```
designs.resolvable_balanced_incomplete_block_design(15,3)
```

For Balanced Incomplete Block Design (BIBD) see the module `bibd`. A BIBD is said to be *resolvable* if its blocks can be partitioned into parallel classes, i.e. partitions of its ground set.

The main function of this module is `resolvable_balanced_incomplete_block_design()`, which calls all others.

<code>resolvable_balanced_incomplete_block_design(v,k)</code>	Return a resolvable BIBD of parameters v, k .
<code>kirkman_triple_system()</code>	Return a Kirkman Triple System on v points.
<code>v_4_1_rbibd()</code>	Return a $(v, 4, 1)$ -RBIBD
<code>PBD_4_7()</code>	Return a $(v, \{4, 7\})$ -PBD
<code>PBD_4_7_from_Y()</code>	Return a $(3v + 1, \{4, 7\})$ -PBD from a $(v, \{4, 5, 7\}, N - \{3, 6, 10\})$ -GDD.

References:

Functions

`sage.combinat.designs.resolvable_bibd.PBD_4_7(v, check=True, existence=False)`

Return a $(v, \{4, 7\})$ -PBD

For all v such that $v \equiv 1 \pmod{3}$ and $v \neq 10, 19, 31$ there exists a $(v, \{4, 7\})$ -PBD. This is proved in Proposition IX.4.5 from [BJL99], which this method implements.

This construction of PBD is used by the construction of Kirkman Triple Systems.

EXAMPLES:

```
sage: from sage.combinat.designs.resolvable_bibd import PBD_4_7
sage: PBD_4_7(22)
Pairwise Balanced Design on 22 points with sets of sizes in [4, 7]
```

`sage.combinat.designs.resolvable_bibd.PBD_4_7_from_Y(gdd, check=True)`

Return a $(3v + 1, \{4, 7\})$ -PBD from a $(v, \{4, 5, 7\}, \mathbf{N} - \{3, 6, 10\})$ -GDD.

This implements Lemma IX.3.11 from [BJL99] (p.625). All points of the GDD are tripled, and a $+\infty$ point is added to the design.

- A group of size $s \in Y = \mathbf{N} - \{3, 6, 10\}$ becomes a set of size $3s$. Adding ∞ to it gives it size $3s + 1$, and this set is then replaced by a $(3s + 1, \{4, 7\})$ -PBD.
- A block of size $s \in \{4, 5, 7\}$ becomes a $(3s, \{4, 7\}, \{3\})$ -GDD.

This lemma is part of the existence proof of $(v, \{4, 7\})$ -PBD as explained in IX.4.5 from [BJL99]).

INPUT:

- `gdd` – a $(v, \{4, 5, 7\}, Y)$ -GDD where $Y = \mathbf{N} - \{3, 6, 10\}$.
- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

EXAMPLES:

```
sage: from sage.combinat.designs.resolvable_bibd import PBD_4_7_from_Y
sage: PBD_4_7_from_Y(designs.transversal_design(7, 8))
Pairwise Balanced Design on 169 points with sets of sizes in [4, 7]
```

`sage.combinat.designs.resolvable_bibd.kirkman_triple_system(v, existence=False)`

Return a Kirkman Triple System on v points.

A Kirkman Triple System $KTS(v)$ is a resolvable Steiner Triple System. It exists if and only if $v \equiv 3 \pmod{6}$.

INPUT:

- n (integer)
- `existence` (boolean; `False` by default) – whether to build the $KTS(n)$ or only answer whether it exists.

See also:

[`IncidenceStructure.is_resolvable\(\)`](#)

EXAMPLES:

A solution to Kirkman's original problem:

```

sage: kts = designs.kirkman_triple_system(15)
sage: classes = kts.is_resolvable(1)[1]
sage: names = '0123456789abcde'
sage: def to_name(r_s_t):
.....:     r, s, t = r_s_t
.....:     return ' ' + names[r] + names[s] + names[t] + ' '
sage: rows = [' '.join(('Day {}'.format(i) for i in range(1,8)))]
sage: rows.extend(' '.join(map(to_name,row)) for row in zip(*classes))
sage: print('\n'.join(rows))

```

Day 1	Day 2	Day 3	Day 4	Day 5	Day 6	Day 7
07e	18e	29e	3ae	4be	5ce	6de
139	24a	35b	46c	05d	167	028
26b	03c	14d	257	368	049	15a
458	569	06a	01b	12c	23d	347
acd	7bd	78c	89d	79a	8ab	9bc

`sage.combinat.designs.resolvable_bibd.resolvable_balanced_incomplete_block_design($v, k, existence=False$)`

Return a resolvable BIBD of parameters v, k .

A BIBD is said to be *resolvable* if its blocks can be partitioned into parallel classes, i.e. partitions of the ground set.

INPUT:

- v, k (integers)
- *existence* (boolean) – instead of building the design, return:
 - True – meaning that Sage knows how to build the design
 - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
 - False – meaning that the design does not exist.

See also:

- `IncidenceStructure.is_resolvable()`
- `balanced_incomplete_block_design()`

EXAMPLES:

```

sage: KTS15 = designs.resolvable_balanced_incomplete_block_design(15,3); KTS15
(15,3,1)-Balanced Incomplete Block Design
sage: KTS15.is_resolvable()
True

```

`sage.combinat.designs.resolvable_bibd.v_4_1_rbibd($v, existence=False$)`

Return a $(v, 4, 1)$ -RBIBD.

INPUT:

- n (integer)
- *existence* (boolean; False by default) – whether to build the design or only answer whether it exists.

See also:

- `IncidenceStructure.is_resolvable()`
- `resolvable_balanced_incomplete_block_design()`

Note: A resolvable $(v, 4, 1)$ -BIBD exists whenever $1 \equiv 4 \pmod{12}$. This function, however, only implements a construction of $(v, 4, 1)$ -BIBD such that $v = 3q + 1 \equiv 1 \pmod{3}$ where q is a prime power (see VII.7.5.a from [BJL99]).

EXAMPLES:

```
sage: rBIBD = designs.resolvable_balanced_incomplete_block_design(28,4)
sage: rBIBD.is_resolvable()
True
sage: rBIBD.is_t_design(return_parameters=True)
(True, (2, 28, 4, 1))
```

5.1.76 Group-Divisible Designs (GDD)

This module gathers everything related to Group-Divisible Designs. The constructions defined here can be accessed through `designs.<tab>`:

```
sage: designs.group_divisible_design(14, {4}, {2})
Group Divisible Design on 14 points of type 2^7
```

The main function implemented here is `group_divisible_design()` (which calls all others) and the main class is `GroupDivisibleDesign`. The following functions are available:

<code>group_divisible_design()</code>	Return a (v, K, G) -Group Divisible Design.
<code>GDD_4_2()</code>	Return a $(2q, \{4\}, \{2\})$ -GDD for q a prime power with $q \equiv 1 \pmod{6}$.

Functions

```
sage.combinat.designs.group_divisible_designs.GDD_4_2(q, existence=False, check=True)
Return a  $(2q, \{4\}, \{2\})$ -GDD for  $q$  a prime power with  $q \equiv 1 \pmod{6}$ .
```

This method implements Lemma VII.5.17 from [BJL99] (p.495).

INPUT:

- `q` (integer)
- `existence` (boolean) – instead of building the design, return:
 - `True` – meaning that Sage knows how to build the design
 - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
 - `False` – meaning that the design does not exist.
- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

EXAMPLES:

```

sage: from sage.combinat.designs.group_divisible_designs import GDD_4_2
sage: GDD_4_2(7,existence=True)
True
sage: GDD_4_2(7)
Group Divisible Design on 14 points of type 2^7
sage: GDD_4_2(8,existence=True)
Unknown
sage: GDD_4_2(8)
Traceback (most recent call last):
...
NotImplementedError

```

```

class sage.combinat.designs.group_divisible_designs.GroupDivisibleDesign(points, groups,
                                                                           blocks, G=None,
                                                                           K=None, lambda=1,
                                                                           check=True,
                                                                           copy=True, **kws)

```

Bases: `sage.combinat.designs.incidence_structures.IncidenceStructure`

Group Divisible Design (GDD)

Let K and G be sets of positive integers and let λ be a positive integer. A Group Divisible Design of index λ and order v is a triple $(V, \mathcal{G}, \mathcal{B})$ where:

- V is a set of cardinality v
- \mathcal{G} is a partition of V into groups whose size belongs to G
- \mathcal{B} is a family of subsets of V whose size belongs to K such that any two points $p_1, p_2 \in V$ from different groups appear simultaneously in exactly λ elements of \mathcal{B} . Besides, a group and a block intersect on at most one point.

If $K = \{k_1, \dots, k_l\}$ and G has exactly m_i groups of cardinality k_i then G is said to have type $k_1^{m_1} \dots k_l^{m_l}$.

INPUT:

- `points` – the underlying set. If `points` is an integer v , then the set is considered to be $\{0, \dots, v-1\}$.
- `groups` – the groups of the design. Set to `None` for an automatic guess (this triggers `check=True` and can thus cost some time).
- `blocks` – collection of blocks
- `G` – list of integers of which the sizes of the groups must be elements. Set to `None` (automatic guess) by default.
- `K` – list of integers of which the sizes of the blocks must be elements. Set to `None` (automatic guess) by default.
- `lambda` (integer) – value of λ , set to 1 by default.
- `check` (boolean) – whether to check that the design is indeed a *GDD* with the right parameters. Set to `True` by default.
- `copy` – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the instance's internal data.

EXAMPLES:

```
sage: from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
sage: TD = designs.transversal_design(4,10)
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: GDD = GroupDivisibleDesign(40,groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
```

With unspecified groups:

```
sage: D = designs.transversal_design(4,3).relabel(list('abcdefghijklm'),
↳inplace=False).blocks()
sage: GDD = GroupDivisibleDesign('abcdefghijklm',None,D)
sage: sorted(GDD.groups())
[['a', 'b', 'c'], ['d', 'e', 'f'], ['g', 'h', 'i'], ['k', 'l', 'm']]
```

groups()

Return the groups of the Group-Divisible Design.

EXAMPLES:

```
sage: from sage.combinat.designs.group_divisible_designs import_
↳GroupDivisibleDesign
sage: TD = designs.transversal_design(4,10)
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: GDD = GroupDivisibleDesign(40,groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
sage: GDD.groups()
[[0, 1, 2, 3, 4, 5, 6, 7, 8, 9],
 [10, 11, 12, 13, 14, 15, 16, 17, 18, 19],
 [20, 21, 22, 23, 24, 25, 26, 27, 28, 29],
 [30, 31, 32, 33, 34, 35, 36, 37, 38, 39]]
```

`sage.combinat.designs.group_divisible_designs.group_divisible_design(v, K, G, existence=False, check=False)`

Return a (v, K, G) -Group Divisible Design.

A (v, K, G) -GDD is a pair $(\mathcal{G}, \mathcal{B})$ where:

- \mathcal{G} is a partition of $X = \bigcup \mathcal{G}$ where $|X| = v$
- $\forall S \in \mathcal{G}, |S| \in G$
- $\forall S \in \mathcal{B}, |S| \in K$
- $\mathcal{G} \cup \mathcal{B}$ is a $(v, K \cup G)$ -PBD

For more information, see the documentation of `GroupDivisibleDesign` or *PairwiseBalancedDesign*.

INPUT:

- v (integer)
- K, G (sets of integers)
- `existence` (boolean) – instead of building the design, return:
 - `True` – meaning that Sage knows how to build the design
 - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
 - `False` – meaning that the design does not exist.

- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

Note: The GDD returned by this function are defined on `range(v)`, and its groups are sets of consecutive integers.

EXAMPLES:

```
sage: designs.group_divisible_design(14,{4},{2})
Group Divisible Design on 14 points of type 2^7
```

5.1.77 Block designs

A *block design* is a set together with a family of subsets (repeated subsets are allowed) whose members are chosen to satisfy some set of properties that are deemed useful for a particular application. See [Wikipedia article Block design](#).

REFERENCES:

- Block design from wikipedia: [Wikipedia article Block design](#)
- What is a block design?, <http://designtheory.org/library/extrep/extrep-1.1-html/node4.html> (in ‘The External Representation of Block Designs’ by Peter J. Cameron, Peter Dobcsanyi, John P. Morgan, Leonard H. Soicher)

AUTHORS:

- Quentin Honoré (2015): construction of Hughes plane [trac ticket #18527](#)
- Vincent Delecroix (2014): rewrite the part on projective planes [trac ticket #16281](#)
- Peter Dobcsanyi and David Joyner (2007-2008)

This is a significantly modified form of the module `block_design.py` (version 0.6) written by Peter Dobcsanyi peter@designtheory.org. Thanks go to Robert Miller for lots of good design suggestions.

Todo: Implement more finite non-Desarguesian plane as in [We07] and [Wikipedia article Non-Desarguesian plane](#).

Functions and methods

`sage.combinat.designs.block_design.AffineGeometryDesign(n, d, F, point_coordinates=True, check=True)`

Return an affine geometry design.

The affine geometry design $AG_d(n, q)$ is the 2-design whose blocks are the d -vector subspaces in \mathbf{F}_q^n . It has parameters

$$v = q^n, k = q^d, \lambda = \binom{n-1}{d-1}_q$$

where the q -binomial coefficient $\binom{m}{r}_q$ is defined by

$$\binom{m}{r}_q = \frac{(q^m - 1)(q^{m-1} - 1) \cdots (q^{m-r+1} - 1)}{(q^r - 1)(q^{r-1} - 1) \cdots (q - 1)}$$

See also:

[ProjectiveGeometryDesign\(\)](#)

INPUT:

- `n` (integer) – the Euclidean dimension. The number of points of the design is $v = |\mathbb{F}_q^n|$.
- `d` (integer) – the dimension of the (affine) subspaces of \mathbb{F}_q^n which make up the blocks.
- `F` – a finite field or a prime power.
- `point_coordinates` – (optional, default `True`) whether we use coordinates in \mathbb{F}_q^n or plain integers for the points of the design.
- `check` – (optional, default `True`) whether to check the output.

EXAMPLES:

```
sage: BD = designs.AffineGeometryDesign(3, 1, GF(2))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 8, 2, 1))
sage: BD = designs.AffineGeometryDesign(3, 2, GF(4))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))
sage: BD = designs.AffineGeometryDesign(4, 2, GF(3))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 81, 9, 13))
```

With `F` an integer instead of a finite field:

```
sage: BD = designs.AffineGeometryDesign(3, 2, 4)
sage: BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))
```

Testing the option `point_coordinates`:

```
sage: designs.AffineGeometryDesign(3, 1, GF(2), point_coordinates=True).blocks()[0]
[(0, 0, 0), (0, 0, 1)]
sage: designs.AffineGeometryDesign(3, 1, GF(2), point_coordinates=False).blocks()[0]
[0, 1]
```

`sage.combinat.designs.block_design.CremonaRichmondConfiguration()`

Return the Cremona-Richmond configuration

The Cremona-Richmond configuration is a set system whose incidence graph is equal to the [TutteCoxeterGraph\(\)](#). It is a generalized quadrangle of parameters $(2, 2)$.

For more information, see the [Wikipedia article Cremona-Richmond_configuration](#).

EXAMPLES:

```
sage: H = designs.CremonaRichmondConfiguration(); H
Incidence structure with 15 points and 15 blocks
sage: g = graphs.TutteCoxeterGraph()
sage: H.incidence_graph().is_isomorphic(g)
True
```

```
sage.combinat.designs.block_design.DesarguesianProjectivePlaneDesign(n,
                                                                    point_coordinates=True,
                                                                    check=True)
```

Return the Desarguesian projective plane of order n as a 2-design.

The Desarguesian projective plane of order n can also be defined as the projective plane over a field of order n . For more information, have a look at [Wikipedia article Projective_plane](#).

INPUT:

- n – an integer which must be a power of a prime number
- `point_coordinates` (boolean) – whether to label the points with their homogeneous coordinates (default) or with integers.
- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

Traceback (most recent call last):
...
ValueError: the order of a finite field must be a prime power
```

```
sage.combinat.designs.block_design.Hadamard3Design(n)
```

Return the Hadamard 3-design with parameters $3 - (n, \frac{n}{2}, \frac{n}{4} - 1)$.

This is the unique extension of the Hadamard 2-design (see [HadamardDesign\(\)](#)). We implement the description from pp. 12 in [CvL].

INPUT:

- n (integer) – a multiple of 4 such that $n > 4$.

EXAMPLES:

```
sage: designs.Hadamard3Design(12)
Incidence structure with 12 points and 22 blocks
```

We verify that any two blocks of the Hadamard 3-design $3 - (8, 4, 1)$ design meet in 0 or 2 points. More generally, it is true that any two blocks of a Hadamard 3-design meet in 0 or $\frac{n}{4}$ points (for $n > 4$).

```
sage: D = designs.Hadamard3Design(8)
sage: N = D.incidence_matrix()
sage: N.transpose()*N
[4 2 2 2 2 2 2 2 2 2 2 2 0]

[0 2 2 2 2 2 2 2 2 2 2 2 4]
```

REFERENCES:

sage.combinat.designs.block_design.HadamardDesign(*n*)

As described in Section 1, p. 10, in [CvL]. The input *n* must have the property that there is a Hadamard matrix of order $n + 1$ (and that a construction of that Hadamard matrix has been implemented. . .).

EXAMPLES:

```
sage: designs.HadamardDesign(7)
Incidence structure with 7 points and 7 blocks
sage: print(designs.HadamardDesign(7))
Incidence structure with 7 points and 7 blocks
```

For example, the Hadamard 2-design with $n = 11$ is a design whose parameters are 2-(11, 5, 2). We verify that $NJ = 5J$ for this design.

```
sage: D = designs.HadamardDesign(11); N = D.incidence_matrix()
sage: J = matrix(ZZ, 11, 11, [1]*11*11); N*J

- [CvL] P. Cameron, J. H. van Lint, Designs, graphs, codes and their links, London Math. Soc., 1991.

sage.combinat.designs.block_design.HughesPlane(*q2*, *check=True*)

Return the Hughes projective plane of order q^2 .

Let q be an odd prime, the Hughes plane of order q^2 is a finite projective plane of order q^2 introduced by D. Hughes in [Hu57]. Its construction is as follows.

Let $K = GF(q^2)$ be a finite field with q^2 elements and $F = GF(q) \subset K$ be its unique subfield with q elements.

We define a twisted multiplication on K as

$$x \circ y = \begin{cases} x y & \text{if } y \text{ is a square in } K \\ x^q y & \text{otherwise} \end{cases}$$

The points of the Hughes plane are the triples (x, y, z) of points in $K^3 \setminus \{0, 0, 0\}$ up to the equivalence relation $(x, y, z) \sim (x \circ k, y \circ k, z \circ k)$ where $k \in K$.

For $a = 1$ or $a \in (K \setminus F)$ we define a block $L(a)$ as the set of triples (x, y, z) so that $x + a \circ y + z = 0$. The rest of the blocks are obtained by letting act the group $GL(3, F)$ by its standard action.

For more information, see [Wikipedia article Hughes_plane](#) and [We07].

See also:

[DesarguesianProjectivePlaneDesign\(\)](#) to build the Desarguesian projective planes

INPUT:

- `q2` – an even power of an odd prime number
- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

EXAMPLES:

```
sage: H = designs.HughesPlane(9)
sage: H
(91,10,1)-Balanced Incomplete Block Design
```

We prove in the following computations that the Desarguesian plane H is not Desarguesian. Let us consider the two triangles $(0, 1, 10)$ and $(57, 70, 59)$. We show that the intersection points $D_{0,1} \cap D_{57,70}$, $D_{1,10} \cap D_{70,59}$ and $D_{10,0} \cap D_{59,57}$ are on the same line while $D_{0,70}$, $D_{1,59}$ and $D_{10,57}$ are not concurrent:

```
sage: blocks = H.blocks()
sage: line = lambda p,q: next(b for b in blocks if p in b and q in b)

sage: b_0_1 = line(0, 1)
sage: b_1_10 = line(1, 10)
sage: b_10_0 = line(10, 0)
sage: b_57_70 = line(57, 70)
sage: b_70_59 = line(70, 59)
sage: b_59_57 = line(59, 57)

sage: set(b_0_1).intersection(b_57_70)
{2}
sage: set(b_1_10).intersection(b_70_59)
{73}
sage: set(b_10_0).intersection(b_59_57)
{60}

sage: line(2, 73) == line(73, 60)
True

sage: b_0_57 = line(0, 57)
sage: b_1_70 = line(1, 70)
sage: b_10_59 = line(10, 59)
```

(continues on next page)

(continued from previous page)

```
sage: p = set(b_0_57).intersection(b_1_70)
sage: q = set(b_1_70).intersection(b_10_59)
sage: p == q
False
```

```
sage.combinat.designs.block_design.ProjectiveGeometryDesign(n, d, F, algorithm=None,
point_coordinates=True, check=True)
```

Return a projective geometry design.

The projective geometry design $PG_d(n, q)$ has for points the lines of \mathbf{F}_q^{n+1} , and for blocks the $d+1$ -dimensional subspaces of \mathbf{F}_q^{n+1} , each of which contains $\frac{|\mathbf{F}_q|^{d+1}-1}{|\mathbf{F}_q|-1}$ lines. It is a 2-design with parameters

$$v = \binom{n+1}{1}_q, k = \binom{d+1}{1}_q, \lambda = \binom{n-1}{d-1}_q$$

where the q -binomial coefficient $\binom{m}{r}_q$ is defined by

$$\binom{m}{r}_q = \frac{(q^m - 1)(q^{m-1} - 1) \cdots (q^{m-r+1} - 1)}{(q^r - 1)(q^{r-1} - 1) \cdots (q - 1)}$$

See also:

[AffineGeometryDesign\(\)](#)

INPUT:

- n is the projective dimension
- d is the dimension of the subspaces which make up the blocks.
- F – a finite field or a prime power.
- `algorithm` – set to `None` by default, which results in using Sage’s own implementation. In order to use GAP’s implementation instead (i.e. its `PGPointFlatBlockDesign` function) set `algorithm="gap"`. Note that GAP’s “design” package must be available in this case, and that it can be installed with the `gap_packages` spkg.
- `point_coordinates` – `True` by default. Ignored and assumed to be `False` if `algorithm="gap"`. If `True`, the ground set is indexed by coordinates in \mathbf{F}_q^{n+1} . Otherwise the ground set is indexed by integers.
- `check` – (optional, default to `True`) whether to check the output.

EXAMPLES:

The set of d -dimensional subspaces in a n -dimensional projective space forms 2-designs (or balanced incomplete block designs):

```
sage: PG = designs.ProjectiveGeometryDesign(4, 2, GF(2))
sage: PG
Incidence structure with 31 points and 155 blocks
sage: PG.is_t_design(return_parameters=True)
(True, (2, 31, 7, 7))

sage: PG = designs.ProjectiveGeometryDesign(3, 1, GF(4))
sage: PG.is_t_design(return_parameters=True)
(True, (2, 85, 5, 1))
```

Check with F being a prime power:

```
sage: PG = designs.ProjectiveGeometryDesign(3, 2, 4)
sage: PG
Incidence structure with 85 points and 85 blocks
```

Use coordinates:

```
sage: PG = designs.ProjectiveGeometryDesign(2, 1, GF(3))
sage: PG.blocks()[0]
[(1, 0, 0), (1, 0, 1), (1, 0, 2), (0, 0, 1)]
```

Use indexing by integers:

```
sage: PG = designs.ProjectiveGeometryDesign(2,1,GF(3),point_coordinates=0)
sage: PG.blocks()[0]
[0, 1, 2, 12]
```

Check that the constructor using gap also works:

```
sage: BD = designs.ProjectiveGeometryDesign(2, 1, GF(2), algorithm="gap") #_
→ optional - gap_packages (design package)
sage: BD.is_t_design(return_parameters=True) #_
→ optional - gap_packages (design package)
(True, (2, 7, 3, 1))
```

`sage.combinat.designs.block_design.WittDesign(n)`

INPUT:

- n is in 9, 10, 11, 12, 21, 22, 23, 24.

Wraps GAP Design's WittDesign. If $n=24$ then this function returns the large Witt design W_{24} , the unique (up to isomorphism) $5 - (24, 8, 1)$ design. If $n=12$ then this function returns the small Witt design W_{12} , the unique (up to isomorphism) $5 - (12, 6, 1)$ design. The other values of n return a block design derived from these.

Note: Requires GAP's Design package (included in the gap_packages Sage spkg).

EXAMPLES:

```
sage: BD = designs.WittDesign(9) # optional - gap_packages (design_
→package)
sage: BD.is_t_design(return_parameters=True) # optional - gap_packages (design_
→package)
(True, (2, 9, 3, 1))
sage: BD # optional - gap_packages (design package)
Incidence structure with 9 points and 12 blocks
sage: print(BD) # optional - gap_packages (design package)
Incidence structure with 9 points and 12 blocks
```

`sage.combinat.designs.block_design.are_hyperplanes_in_projective_geometry_parameters(v, k,`

`lmbda,`

`re-`

`turn_parameters=False)`

Return True if the parameters $(v, k, lmbda)$ are the one of hyperplanes in a (finite Desarguesian) projective space.

In other words, test whether there exists a prime power q and an integer d greater than two such that:

- $v = (q^{d+1} - 1)/(q - 1) = q^d + q^{d-1} + \dots + 1$
- $k = (q^d - 1)/(q - 1) = q^{d-1} + q^{d-2} + \dots + 1$
- $lmbda = (q^{d-1} - 1)/(q - 1) = q^{d-2} + q^{d-3} + \dots + 1$

If it exists, such a pair (q, d) is unique.

INPUT:

- $v, k, lmbda$ (integers)

OUTPUT:

- a boolean or, if `return_parameters` is set to `True` a pair $(\text{True}, (q, d))$ or $(\text{False}, (\text{None}, \text{None}))$.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import are_hyperplanes_in_projective_
      ↪ geometry_parameters
sage: are_hyperplanes_in_projective_geometry_parameters(40, 13, 4)
True
sage: are_hyperplanes_in_projective_geometry_parameters(40, 13, 4, return_
      ↪ parameters=True)
(True, (3, 3))
sage: PG = designs.ProjectiveGeometryDesign(3, 2, GF(3))
sage: PG.is_t_design(return_parameters=True)
(True, (2, 40, 13, 4))

sage: are_hyperplanes_in_projective_geometry_parameters(15, 3, 1)
False
sage: are_hyperplanes_in_projective_geometry_parameters(15, 3, 1, return_
      ↪ parameters=True)
(False, (None, None))
```

`sage.combinat.designs.block_design.normalize_hughes_plane_point(p, q)`

Return the normalized form of point p as a 3-tuple.

In the Hughes projective plane over the finite field K , all triples (xk, yk, zk) with $k \in K$ represent the same point (where the multiplication is over the nearfield built from K). This function chooses a canonical representative among them.

This function is used in [HughesPlane\(\)](#).

INPUT:

- p - point with the coordinates (x, y, z) (a list, a vector, a tuple...)
- q - cardinality of the underlying finite field

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import normalize_hughes_plane_point
sage: K = FiniteField(9, 'x')
sage: x = K.gen()
sage: normalize_hughes_plane_point((x, x+1, x), 9)
(1, x, 1)
sage: normalize_hughes_plane_point(vector((x, x, x)), 9)
(1, 1, 1)
```

(continues on next page)

sage: one = K.one()
sage: normalize_hughes_plane_point((2*x, one, zero), 9)
(2*x, 1, 0)

```

`sage.combinat.designs.block_design.projective_plane(n, check=True, existence=False)`

Return a projective plane of order *n* as a 2-design.

A finite projective plane is a 2-design with $n^2 + n + 1$ lines (or blocks) and $n^2 + n + 1$ points. For more information on finite projective planes, see the [Wikipedia article Projective_plane#Finite_projective_planes](#).

If no construction is possible, then the function raises a `EmptySetError` whereas if no construction is available the function raises a `NotImplementedError`.

INPUT:

- *n* – the finite projective plane's order

EXAMPLES:

```

sage: designs.projective_plane(2)
(7,3,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(3)
(13,4,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(4)
(21,5,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(5)
(31,6,1)-Balanced Incomplete Block Design

NotImplementedError: If such a projective plane exists, we do not know how to build
↪it.
sage: designs.projective_plane(14)
Traceback (most recent call last):
...
EmptySetError: By the Bruck-Ryser theorem, no projective plane of order 14 exists.

```

`sage.combinat.designs.block_design.projective_plane_to_OA(pplane, pt=None, check=True)`

Return the orthogonal array built from the projective plane *pplane*.

The orthogonal array $OA(n + 1, n, 2)$ is obtained from the projective plane *pplane* by removing the point *pt* and the $n + 1$ lines that pass through it. These $n + 1$ lines form the $n + 1$ groups while the remaining $n^2 + n$ lines form the transversals.

INPUT:

- `pplane` - a projective plane as a 2-design
- `pt` - a point in the projective plane `pplane`. If it is not provided then it is set to $n^2 + n$.
- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import projective_plane_to_OA
sage: p2 = designs.DesarguesianProjectivePlaneDesign(2,point_coordinates=False)
sage: projective_plane_to_OA(p2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]
sage: p3 = designs.DesarguesianProjectivePlaneDesign(3,point_coordinates=False)
sage: projective_plane_to_OA(p3)
[[0, 0, 0, 0],
 [0, 1, 2, 1],
 [0, 2, 1, 2],
 [1, 0, 2, 2],
 [1, 1, 1, 0],
 [1, 2, 0, 1],
 [2, 0, 1, 1],
 [2, 1, 0, 2],
 [2, 2, 2, 0]]

sage: pp = designs.DesarguesianProjectivePlaneDesign(16,point_coordinates=False)
sage: _ = projective_plane_to_OA(pp, pt=0)
sage: _ = projective_plane_to_OA(pp, pt=3)
sage: _ = projective_plane_to_OA(pp, pt=7)
```

`sage.combinat.designs.block_design.q3_minus_one_matrix(K)`

Return a companion matrix in $GL(3, K)$ whose multiplicative order is $q^3 - 1$.

This function is used in [HughesPlane\(\)](#)

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import q3_minus_one_matrix
sage: m = q3_minus_one_matrix(GF(3))
sage: m.multiplicative_order() == 3**3 - 1
True

sage: m = q3_minus_one_matrix(GF(4,'a'))
sage: m.multiplicative_order() == 4**3 - 1
True

sage: m = q3_minus_one_matrix(GF(5))
sage: m.multiplicative_order() == 5**3 - 1
True

sage: m = q3_minus_one_matrix(GF(9,'a'))
sage: m.multiplicative_order() == 9**3 - 1
True
```

`sage.combinat.designs.block_design.tdesign_params(t, v, k, L)`
 Return the design's parameters: (t, v, b, r, k, L) . Note that t must be given.

EXAMPLES:

```
sage: BD = BlockDesign(7, [[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]])
sage: from sage.combinat.designs.block_design import tdesign_params
sage: tdesign_params(2, 7, 3, 1)
(2, 7, 7, 3, 3, 1)
```

5.1.78 Covering designs: coverings of t -element subsets of a v -set by k -sets

A (v, k, t) covering design C is an incidence structure consisting of a set of points P of order v , and a set of blocks B , where each block contains k points of P . Every t -element subset of P must be contained in at least one block.

If every t -set is contained in exactly one block of C , then we have a block design. Following the block design implementation, the standard representation of a covering design uses $P = [0, 1, \dots, v - 1]$.

In addition to the parameters and incidence structure for a covering design from this database, we include extra information:

- Best known lower bound on the size of a (v, k, t) -covering design
- Name of the person(s) who produced the design
- Method of construction used
- Date when the design was added to the database

Classes and methods

class `sage.combinat.designs.covering_design.CoveringDesign`($v=0, k=0, t=0, size=0, points=None, blocks=None, low_bd=0, method="", creator="", timestamp=""$)

Bases: `sage.structure.sage_object.SageObject`

Covering design.

INPUT:

- v, k, t – integer parameters of the covering design
- `size` (integer)
- `points` – list of points (default points are $[0, \dots, v - 1]$)
- `blocks`
- `low_bd` (integer) – lower bound for such a design
- `method, creator, timestamp` – database information

creator()

Return the creator of the covering design

This field is optional, and is used in a database to give attribution for the covering design. It can refer to the person who submitted it, or who originally gave a construction.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6],
.....:      [2, 4, 5]], 0, 'Projective Plane', 'Gino Fano')
sage: C.creator()
'Gino Fano'
```

incidence_structure()

Return the incidence structure of this design, without extra parameters.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....:      [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: D = C.incidence_structure()
sage: D.ground_set()
[0, 1, 2, 3, 4, 5, 6]
sage: D.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5],
 [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

is_covering()

Check all t -sets are in fact covered by the blocks of self.

Note: This is very slow and wasteful of memory.

EXAMPLES:

```
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....:      [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.is_covering()
True
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6],
.....:      [2, 4, 6]], 0, 'not a covering') # last block altered
sage: C.is_covering()
False
```

k()

Return k , the size of blocks of the covering design.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
```

(continues on next page)

(continued from previous page)

```
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.k()
3
```

low_bd()

Return a lower bound for the number of blocks a covering design with these parameters could have.

Typically this is the Schonheim bound, but for some parameters better bounds have been shown.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.low_bd()
7
```

method()

Return the method used to create the covering design.

This field is optional, and is used in a database to give information about how coverings were constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.method()
'Projective Plane'
```

size()

Return the number of blocks in the covering design

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.size()
7
```

t()

Return t , the size of sets which must be covered by the blocks of the covering design

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....: [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.t()
2
```

timestamp()

Return the time that the covering was submitted to the database

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....:      [2, 3, 6], [2, 4, 5]],0, 'Projective Plane',
.....:      'Gino Fano', '1892-01-01 00:00:00')
sage: C.timestamp() # No exact date known; in Fano's 1892 article
'1892-01-01 00:00:00'
```

v()

Return v , the number of points in the covering design.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
.....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
.....:      [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.v()
7
```

`sage.combinat.designs.covering_design.best_known_covering_design_www($v, k, t, verbose=False$)`

Return the best known (v, k, t) covering design from an online database.

This uses the La Jolla Covering Repository, a database available at <https://ljcr.dmgordon.org/cover.html>

INPUT:

- v – integer, the size of the point set for the design
- k – integer, the number of points per block
- t – integer, the size of sets covered by the blocks
- `verbose` – bool (default: `False`), print verbose message

OUTPUT:

A *CoveringDesign* object representing the (v, k, t) -covering design with smallest number of blocks available in the database.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import ( # optional - internet
.....:      best_known_covering_design_www)
sage: C = best_known_covering_design_www(7, 3, 2) # optional - internet
sage: print(C) # optional - internet
C(7, 3, 2) = 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
0 1 2
0 3 4
0 5 6
1 3 5
1 4 6
```

(continues on next page)

(continued from previous page)

```
2 3 6
2 4 5
```

A `ValueError` is raised if the (v, k, t) parameters are not found in the database.

`sage.combinat.designs.covering_design.schonheim(v, k, t)`

Return the Schonheim lower bound for the size of such a covering design.

INPUT:

- v – integer, size of point set
- k – integer, cardinality of each block
- t – integer, cardinality of sets being covered

OUTPUT:

The Schonheim lower bound for such a covering design's size: $C(v, k, t) \leq \lceil \left(\frac{v}{k} \lceil \frac{v-1}{k-1} \dots \lceil \frac{v-t+1}{k-t+1} \rceil \dots \right) \rceil$

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import schonheim
sage: schonheim(10, 3, 2)
17
sage: schonheim(32, 16, 8)
930
```

`sage.combinat.designs.covering_design.trivial_covering_design(v, k, t)`

Construct a trivial covering design.

INPUT:

- v – integer, size of point set
- k – integer, cardinality of each block
- t – integer, cardinality of sets being covered

OUTPUT:

A trivial (v, k, t) covering design

EXAMPLES:

```
sage: C = trivial_covering_design(8, 3, 1)
sage: print(C)
C(8, 3, 1) = 3
Method: Trivial
0 1 2
0 6 7
3 4 5
sage: C = trivial_covering_design(5, 3, 2)
sage: print(C)
4 <= C(5, 3, 2) <= 10
Method: Trivial
0 1 2
0 1 3
0 1 4
0 2 3
```

(continues on next page)

(continued from previous page)

0	2	4
0	3	4
1	2	3
1	2	4
1	3	4
2	3	4

Note: Cases are:

- $t = 0$: This could be empty, but it's a useful convention to have one block (which is empty if $k = 0$).
- $t = 1$: This contains $\lceil v/k \rceil$ blocks: $[0, \dots, k - 1]$, $[k, \dots, 2k - 1]$, The last block wraps around if k does not divide v .
- anything else: Just use every k -subset of $[0, 1, \dots, v - 1]$.

5.1.79 Database of small combinatorial designs

This module implements combinatorial designs that cannot be obtained by more general constructions. Most of them come from the Handbook of Combinatorial Designs [DesignHandbook].

All this would only be a dream without the mathematical knowledge and help of Julian R. Abel.

These functions can all be obtained through the `designs.<tab>` functions.

This module implements:

- $OA(7, 18)$, $OA(9, 40)$, $OA(7, 66)$, $OA(7, 68)$, $OA(8, 69)$, $OA(7, 74)$, $OA(8, 76)$, $OA(11, 80)$, $OA(15, 112)$, $OA(9, 120)$, $OA(9, 135)$, $OA(11, 160)$, $OA(16, 176)$, $OA(11, 185)$, $OA(10, 205)$, $OA(16, 208)$, $OA(15, 224)$, $OA(11, 254)$, $OA(20, 352)$, $OA(20, 416)$, $OA(10, 469)$, $OA(10, 520)$, $OA(12, 522)$, $OA(14, 524)$, $OA(20, 544)$, $OA(17, 560)$, $OA(11, 640)$, $OA(10, 796)$, $OA(15, 896)$, $OA(9, 1078)$, $OA(25, 1262)$, $OA(9, 1612)$, $OA(10, 1620)$
- 2 MOLS of order 10, 5 MOLS of order 12, 4 MOLS of order 14, 4 MOLS of order 15, 3 MOLS of order 18
- $V(m, t)$ vectors:
 - $m = 3$ and $t = 2, 4, 6, 10, 12, 14, 20, 24, 26, 32, 34$
 - $m = 4$ and $t = 3, 7, 9, 13, 15, 25$
 - $m = 5$ and $t = 6, 8, 12, 14, 20, 26$
 - $m = 6$ and $t = 5, 7, 11, 13, 17, 21$
 - $m = 7$ and $t = 6, 10, 16, 18$
 - $m = 8$ and $t = 9, 11, 17, 29, 57$
 - $m = 9$ and $t = 12, 14, 18, 20, 22, 30, 34, 42, 44$
 - $m = 10$ and $t = 13, 15, 19, 21, 25, 27, 31, 33, 43, 49, 81, 97, 103, 181, 187, 259, 273, 319, 391, 409$
 - $m = 11$ and $t = 30, 32, 36, 38, 42, 56, 60, 62, 66, 78, 80, 86, 90, 92, 102, 116, 120, 128, 132, 146, 162, 170, 182, 188, 192, 198, 206, 210, 212, 216, 218, 230, 242, 246, 248, 260, 266, 270, 276, 288, 290, 296, 300, 302, 308, 312, 318, 330, 336, 338, 350, 356, 366, 368, 372, 378, 396, 402, 420, 422, 450, 452$

- $m = 12$ and $t = 33, 35, 45, 51, 55, 59, 61, 63, 69, 71, 73, 83, 85, 89, 91, 93, 101, 103, 115, 119, 121, 129, 133, 135, 139, 141, 145, 149, 155, 161, 169, 171, 185, 189, 191, 195, 199, 203, 213, 223, 229, 233, 243, 253, 255, 259, 265, 269, 271, 275, 281, 289, 293, 295, 301, 303, 309, 311, 321, 323, 335, 341, 355, 363, 379, 383, 385, 399, 401, 405, 409, 411, 413$
- **RBIBD(120, 8, 1)**
- **(v, k, λ) -BIBD:**
 - $\lambda = 1:n$ (66, 6, 1), (76, 6, 1), (96, 6, 1), (106, 6, 1), (111, 6, 1), (120, 8, 1), (126, 6, 1), (136, 6, 1), (141, 6, 1), (171, 6, 1), (196, 6, 1), (201, 6, 1)
 - $\lambda = 2:n$ (56, 11, 2), (79, 13, 2)
 - $\lambda = 8:n$ (45, 9, 8)
 - $\lambda = 14:n$ (176, 50, 14)
- **(v, k, λ) -difference families:**
 - $\lambda = 1:n$ (15, 3, 1), (21, 3, 1), (21, 5, 1), (25, 3, 1), (25, 4, 1), (27, 3, 1), (33, 3, 1), (37, 4, 1), (39, 3, 1), (40, 4, 1), (45, 3, 1), (45, 5, 1), (49, 3, 1), (49, 4, 1), (51, 3, 1), (52, 4, 1), (55, 3, 1), (57, 3, 1), (63, 3, 1), (64, 4, 1), (65, 5, 1), (69, 3, 1), (75, 3, 1), (76, 4, 1), (81, 3, 1), (81, 5, 1), (85, 4, 1), (91, 6, 1), (91, 7, 1), (121, 5, 1), (121, 6, 1), (141, 5, 1), (161, 5, 1), (175, 7, 1), (201, 5, 1), (217, 7, 1), (221, 5, 1), (259, 7, 1)
 - $\lambda = 2:n$ (16, 3, 2), (19, 4, 2), (22, 4, 2), (28, 3, 2), (31, 4, 2), (31, 5, 2), (34, 4, 2), (35, 5, 2), (40, 3, 2), (43, 4, 2), (43, 7, 2), (46, 4, 2), (46, 6, 2), (51, 5, 2), (61, 6, 2), (64, 7, 2), (71, 5, 2), (75, 5, 2), (85, 7, 2), (85, 8, 2), (153, 9, 2), (181, 10, 2)
 - $\lambda = 3:n$ (21, 4, 3), (21, 6, 3), (29, 7, 3), (41, 6, 3), (43, 7, 3), (45, 12, 3), (49, 9, 3), (51, 6, 3), (57, 7, 3), (61, 6, 3), (61, 10, 3), (71, 7, 3), (85, 7, 3), (97, 9, 3), (121, 10, 3)
 - $\lambda = 4:n$ (22, 7, 4), (29, 8, 4), (43, 8, 4), (46, 10, 4), (55, 9, 4), (67, 12, 4), (71, 8, 4)

Functions

`sage.combinat.designs.database.BIBD_106_6_1()`

Return a (106,6,1)-BIBD.

This construction appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_106_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(106, BIBD_106_6_1())
(106,6,1)-Balanced Incomplete Block Design
```

`sage.combinat.designs.database.BIBD_111_6_1()`

Return a (111,6,1)-BIBD.

This construction appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_111_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(111, BIBD_111_6_1())
(111,6,1)-Balanced Incomplete Block Design
```

`sage.combinat.designs.database.BIBD_126_6_1()`

Return a (126,6,1)-BIBD.

This construction appears in VI.16.92 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_126_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(126, BIBD_126_6_1())
(126,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_136_6_1()

Return a (136,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_136_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(136, BIBD_136_6_1())
(136,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_141_6_1()

Return a (141,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_141_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(141, BIBD_141_6_1())
(141,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_171_6_1()

Return a (171,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_171_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(171, BIBD_171_6_1())
(171,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_196_6_1()

Return a (196,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_196_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(196, BIBD_196_6_1())
(196,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_201_6_1()

Return a (201,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_201_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(201, BIBD_201_6_1())
(201,6,1)-Balanced Incomplete Block Design
```

`sage.combinat.designs.database.BIBD_45_9_8(from_code=False)`

Return a (45, 9, 1)-BIBD.

This BIBD is obtained from the codewords of minimal weight in the `ExtendedQuadraticResidueCode()` of length 48. This construction appears in VII.11.2 from [DesignHandbook], which cites [HT95].

INPUT:

- `from_code` (boolean) – whether to build the design from hardcoded data (default) or from the code object (much longer).

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_45_9_8
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: B = BalancedIncompleteBlockDesign(45, BIBD_45_9_8(), lambda=8); B
(45,9,8)-Balanced Incomplete Block Design
```

REFERENCE:

`sage.combinat.designs.database.BIBD_56_11_2()`

Return a symmetric (56, 11, 2)-BIBD.

The construction implemented is given in [Hall71].

Note: A symmetric (v, k, λ) BIBD is a (v, k, λ) BIBD with v blocks.

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_56_11_2 sage: D = IncidenceStructure(BIBD_56_11_2()) sage: D.is_t_design(t=2, v=56, k=11, l=2) True
```

`sage.combinat.designs.database.BIBD_66_6_1()`

Return a (66,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (<https://math.ccrwest.org/cover.html>) where it is attributed to Colin Barker.

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_66_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(66, BIBD_66_6_1())
(66,6,1)-Balanced Incomplete Block Design
```

`sage.combinat.designs.database.BIBD_76_6_1()`

Return a (76,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (<https://math.ccrwest.org/cover.html>) where it is attributed to Colin Barker.

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_76_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(76, BIBD_76_6_1())
(76,6,1)-Balanced Incomplete Block Design
```

`sage.combinat.designs.database.BIBD_79_13_2()`

Return a symmetric $(79, 13, 2)$ -BIBD.

The construction implemented is the one described in [Aschbacher71]. A typo in that paper was corrected in [Hall71].

Note: A symmetric (v, k, λ) BIBD is a (v, k, λ) BIBD with v blocks.

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_79_13_2 sage: D = IncidenceStructure(BIBD_79_13_2()) sage: D.is_t_design(t=2, v=79, k=13, l=2) True
```

`sage.combinat.designs.database.BIBD_96_6_1()`

Return a $(96,6,1)$ -BIBD.

This BIBD was obtained from La Jolla covering repository (<https://math.ccrwest.org/cover.html>) where it is attributed to Colin Barker.

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_96_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(96, BIBD_96_6_1())
(96,6,1)-Balanced Incomplete Block Design
```

`sage.combinat.designs.database.DM_12_6_1()`

Return a $(12, 6, 1)$ -difference matrix as built in [Hanani75].

This design is Lemma 3.21 from [Hanani75].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_12_6_1
sage: G,M = DM_12_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(12,6)
```

REFERENCES:

`sage.combinat.designs.database.DM_21_6_1()`

Return a $(21, 6, 1)$ -difference matrix.

As explained in the Handbook III.3.50 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_21_6_1
sage: G,M = DM_21_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(21,6)
```

`sage.combinat.designs.database.DM_24_8_1()`

Return a (24, 8, 1)-difference matrix.

As explained in the Handbook III.3.52 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_24_8_1
sage: G,M = DM_24_8_1()
sage: is_difference_matrix(M,G,8,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(24,8)
```

`sage.combinat.designs.database.DM_273_17_1()`

Return a (273, 17, 1)-difference matrix.

Given by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_273_17_1
sage: G,M = DM_273_17_1()
sage: is_difference_matrix(M,G,17,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(273,17)
```

`sage.combinat.designs.database.DM_28_6_1()`

Return a (28, 6, 1)-difference matrix.

As explained in the Handbook III.3.54 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_28_6_1
sage: G,M = DM_28_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(28,6)
```

`sage.combinat.designs.database.DM_33_6_1()`

Return a (33, 6, 1)-difference matrix.

As explained in the Handbook III.3.56 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_33_6_1
sage: G,M = DM_33_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(33,6)
```

`sage.combinat.designs.database.DM_35_6_1()`

Return a (35, 6, 1)-difference matrix.

As explained in the Handbook III.3.58 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_35_6_1
sage: G,M = DM_35_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(35,6)
```

`sage.combinat.designs.database.DM_36_9_1()`

Return a (36, 9, 1)-difference matrix.

As explained in the Handbook III.3.59 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_36_9_1
sage: G,M = DM_36_9_1()
sage: is_difference_matrix(M,G,9,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(36,9)
```

`sage.combinat.designs.database.DM_39_6_1()`

Return a (39, 6, 1)-difference matrix.

As explained in the Handbook III.3.61 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_39_6_1
sage: G,M = DM_39_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

The design is available from the general constructor:

```
sage: designs.difference_matrix(39,6,existence=True)
True
```

`sage.combinat.designs.database.DM_44_6_1()`

Return a (44, 6, 1)-difference matrix.

As explained in the Handbook III.3.64 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_44_6_1
sage: G,M = DM_44_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(44,6)
```

`sage.combinat.designs.database.DM_45_7_1()`

Return a (45, 7, 1)-difference matrix.

As explained in the Handbook III.3.65 [DesignHandbook].

... whose description contained a very deadly typo, kindly fixed by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_45_7_1
sage: G,M = DM_45_7_1()
sage: is_difference_matrix(M,G,7,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(45,7)
```

`sage.combinat.designs.database.DM_48_9_1()`

Return a (48, 9, 1)-difference matrix.

As explained in the Handbook III.3.67 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_48_9_1
sage: G,M = DM_48_9_1()
```

(continues on next page)

(continued from previous page)

```
sage: is_difference_matrix(M,G,9,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(48,9)
```

`sage.combinat.designs.database.DM_51_6_1()`

Return a (51, 6, 1)-difference matrix.

As explained in the Handbook III.3.69 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_51_6_1
sage: G,M = DM_51_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(51,6)
```

`sage.combinat.designs.database.DM_52_6_1()`

Return a (52, 6, 1)-difference matrix.

As explained in the Handbook III.3.70 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_52_6_1
sage: G,M = DM_52_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(52,6)
```

`sage.combinat.designs.database.DM_55_7_1()`

Return a (55, 7, 1)-difference matrix.

As explained in the Handbook III.3.72 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_55_7_1
sage: G,M = DM_55_7_1()
sage: is_difference_matrix(M,G,7,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(55,7)
```

`sage.combinat.designs.database.DM_56_8_1()`

Return a (56, 8, 1)-difference matrix.

As explained in the Handbook III.3.73 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_56_8_1
sage: G,M = DM_56_8_1()
sage: is_difference_matrix(M,G,8,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(56,8)
```

`sage.combinat.designs.database.DM_57_8_1()`

Return a (57, 8, 1)-difference matrix.

Given by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_57_8_1
sage: G,M = DM_57_8_1()
sage: is_difference_matrix(M,G,8,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(57,8)
```

`sage.combinat.designs.database.DM_60_6_1()`

Return a (60, 6, 1)-difference matrix.

As explained in [JulianAbel13].

REFERENCES:

<http://onlinelibrary.wiley.com/doi/10.1002/jcd.21384/abstract>

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_60_6_1
sage: G,M = DM_60_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(60,6)
```

`sage.combinat.designs.database.DM_75_8_1()`

Return a (75, 8, 1)-difference matrix.

As explained in the Handbook III.3.75 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_75_8_1
sage: G,M = DM_75_8_1()
sage: is_difference_matrix(M,G,8,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(75,8)
```

`sage.combinat.designs.database.DM_993_32_1()`

Return a (993, 32, 1)-difference matrix.

Given by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_993_32_1
sage: G,M = DM_993_32_1()
sage: is_difference_matrix(M,G,32,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(993,32)
```

`sage.combinat.designs.database.HigmanSimsDesign()`

Return the Higman-Sims designs, which is a (176, 50, 14)-BIBD.

This design is built from a from the *WittDesign* W on 24 points. We define two points a, b , and consider:

- The collection W_a of all blocks of W containing a but not containing b .
- The collection W_b of all blocks of W containing b but not containing a .

The design is then obtained from the incidence structure produced by the blocks $A \in W_a$ and $B \in W_b$ whose intersection has cardinality 2. This construction, due to M.Smith, can be found in [KY04] or in 10.A.(v) of [BL1984].

EXAMPLES:

```
sage: H = designs.HigmanSimsDesign(); H # optional - gap_packages
Incidence structure with 176 points and 176 blocks
sage: H.is_t_design(return_parameters=1) # optional - gap_packages
(True, (2, 176, 50, 14))
```

Make sure that the automorphism group of this designs is isomorphic to the automorphism group of the `HigmanSimsGraph()`. Note that the first of those permutation groups acts on 176 points, while the second acts on 100:

```
sage: gH = H.automorphism_group() # optional - gap_packages
sage: gG = graphs.HigmanSimsGraph().automorphism_group() # optional - gap_packages
sage: gG.is_isomorphic(gG) # long time # optional - gap_packages
True
```

REFERENCE:

`sage.combinat.designs.database.MOLS_10_2()`
Return a pair of MOLS of order 10

Data obtained from <http://www.cecm.sfu.ca/organics/papers/lam/paper/html/POLS10/POLS10.html>

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
      ↪ squares
sage: from sage.combinat.designs.database import MOLS_10_2
sage: MOLS = MOLS_10_2()
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(2,10)
True
```

`sage.combinat.designs.database.MOLS_12_5()`
Return 5 MOLS of order 12

These MOLS have been found by Brendan McKay.

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
      ↪ squares
sage: from sage.combinat.designs.database import MOLS_12_5
sage: MOLS = MOLS_12_5()
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
True
```

`sage.combinat.designs.database.MOLS_14_4()`
Return four MOLS of order 14

These MOLS were shared by Ian Wanless. The first proof of existence was given in [Todorov12].

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
      ↪ squares
sage: from sage.combinat.designs.database import MOLS_14_4
sage: MOLS = MOLS_14_4()
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(4,14)
True
```

REFERENCE:

`sage.combinat.designs.database.MOLS_15_4()`
Return 4 MOLS of order 15.

These MOLS were shared by Ian Wanless.

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
→squares
sage: from sage.combinat.designs.database import MOLS_15_4
sage: MOLS = MOLS_15_4()
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(4,15)
True
```

`sage.combinat.designs.database.MOLS_18_3()`

Return 3 MOLS of order 18.

These MOLS were shared by Ian Wanless.

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
→squares
sage: from sage.combinat.designs.database import MOLS_18_3
sage: MOLS = MOLS_18_3()
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(3,18)
True
```

`sage.combinat.designs.database.OA_10_1620()`

Returns an $OA(10,1620)$

This is obtained through the generalized Brouwer-van Rees construction. Indeed, $1620 = 144.11 + (36 = 4.9)$ and there exists an $OA(10, 153) - OA(10, 9)$.

Note: This function should be removed once *find_brouwer_van_rees_with_one_truncated_column()* can handle all incomplete orthogonal arrays obtained through *incomplete_orthogonal_array()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_1620
sage: OA = OA_10_1620() # not tested -- ~7s
sage: is_orthogonal_array(OA,10,1620,2) # not tested -- ~7s
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10,1620)
True
```

`sage.combinat.designs.database.OA_10_205()`

Return an $OA(10, 205)$.

Julian R. Abel shared the following construction, which originally appeared in Theorem 8.7 of [Greig99], and can in Lemmas 5.14-5.16 of [ColDin01]:

Consider a $PG(2, 4^2)$ containing a Baer subplane (i.e. a $PG(2, 4)$) B and a point $p \in B$. Among the $4^2 + 1 = 17$ lines of $PG(2, 4^2)$ containing p :

- $4 + 1 = 5$ lines intersect B on 5 points
- $4^2 - 4 = 12$ lines intersect B on 1 point

As those lines are disjoint outside of B we can use them as groups to build a GDD on $16^2 + 16 + 1 - (4^4 + 4 + 1) = 252$ points. By keeping only 9 lines of the second kind, however, we obtain a $(204, \{9, 13, 17\})$ -GDD of type $12^5.16^9$.

We complete it into a PBD by adding a block $g \cup \{204\}$ for each group g . We then build an OA from this PBD using the fact that all blocks of size 9 are disjoint.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_from_PBD()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_205
sage: OA = OA_10_205()
sage: is_orthogonal_array(OA, 10, 205, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10, 205)
True
```

`sage.combinat.designs.database.OA_10_469()`

Return an $OA(10, 469)$

This construction appears in [Brouwer80]. It is based on the same technique used in `brouwer_separable_design()`.

Julian R. Abel's instructions:

Brouwer notes that a cyclic $PG(2, 37)$ (or $(1407, 38, 1)$ -BIBD) can be obtained with a base block containing 13, 9, and 16 points in each residue class mod 3. Thus, by reducing the $PG(2, 37)$ to its points congruent to 0 (mod 3) one obtains a $(469, \{9, 13, 16\})$ -PBD which consists in 3 symmetric designs, i.e. 469 blocks of size 9, 469 blocks of size 13, and 469 blocks of size 16.

For each block size s , one can build a matrix with size $s \times 469$ in which each block is a row, and such that each point of the PBD appears once per column. By multiplying a row of an $OA(9, s) - s.OA(9, 1)$ with the rows of the matrix one obtains a parallel class of a resolvable $OA(9, 469)$.

Add to this the parallel class of all blocks $(0, 0, \dots), (1, 1, \dots), \dots$ to obtain a resolvable $OA(9, 469)$ equivalent to an $OA(10, 469)$.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_469
```

(continues on next page)

(continued from previous page)

```
sage: OA = OA_10_469()
sage: is_orthogonal_array(OA, 10, 469, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10, 469)
True
```

```
sage.combinat.designs.database.OA_10_520()
Return an OA(10,520).
```

This design is built by the slightly more general construction *OA_520_plus_x()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_520
sage: OA = OA_10_520()
sage: is_orthogonal_array(OA, 10, 520, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10, 520)
True
```

```
sage.combinat.designs.database.OA_10_796()
Returns an OA(10,796)
```

Construction shared by Julian R. Abel, from [AC07]:

Truncate one block of a $TD(17, 47)$ to size 13, then add an extra point. Form a block on each group plus the extra point: we obtain a $(796, \{13, 16, 17, 47, 48\})$ -PBD in which only the extra point lies in more than one block of size 48 (and each other point lies in exactly 1 such block).

For each block B (of size k say) not containing the extra point, construct a $TD(10, k) - k \cdot TD(k, 1)$ on $I(10)XB$. For each block B (of size $k = 47$ or 48) containing the extra point, construct a $TD(10, k) - TD(k, 1)$ on $I(10)XB$, the size 1 hole being on $I(10)XP$ where P is the extra point. Finally form 1 extra block of size 10 on $I(10)XP$.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_796
sage: OA = OA_10_796()
sage: is_orthogonal_array(OA, 10, 796, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10, 796)
True
```

```
sage.combinat.designs.database.OA_11_160()
Returns an OA(11,160)
```

Published by Julian R. Abel in [Ab1995]. Uses the fact that $160 = 2^5 \times 5$ is a product of a power of 2 and a prime number.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_160
sage: OA = OA_11_160()
sage: is_orthogonal_array(OA, 11, 160, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11, 160)
True
```

`sage.combinat.designs.database.OA_11_185()`

Returns an $OA(11, 185)$

The construction is given in [Greig99]. In Julian R. Abel's words:

Start with a $PG(2, 16)$ with a 7 points Fano subplane; outside this plane there are $7(17 - 3) = 98$ points on a line of the subplane and $273 - 98 - 7 = 168$ other points. Greig notes that the subdesign consisting of these 168 points is a $(168, \{10, 12\}) - PBD$. Now add the 17 points of a line disjoint from this subdesign (e.g. a line of the Fano subplane). This line will intersect every line of the 168 point subdesign in 1 point. Thus the new line sizes are 11 and 13, plus a unique line of size 17, giving a $(185, \{11, 13, 17\}) - PBD$ and an $OA(11, 185)$.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_185
sage: OA = OA_11_185()
sage: is_orthogonal_array(OA, 11, 185, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11, 185)
True
```

`sage.combinat.designs.database.OA_11_254()`

Return an $OA(11, 254)$

This constructions appears in [Greig99].

From a cyclic $PG(2, 19)$ whose base blocks contains 7, 9, and 4 points in the congruence classes mod 3, build a $(254, 11, 13, 16) - PBD$ by ignoring the points of a congruence class. There exist $OA(12, 11)$, $OA(12, 13)$, $OA(12, 16)$, which gives the $OA(11, 254)$.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_from_PBD()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_254
sage: OA = OA_11_254()
sage: is_orthogonal_array(OA, 11, 254, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11, 254)
True
```

`sage.combinat.designs.database.OA_11_640()`

Returns an OA(11,640)

Published by Julian R. Abel in [Ab1995] (uses the fact that $640 = 2^7 \times 5$ is the product of a power of 2 and a prime number).

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_640
sage: OA = OA_11_640() # not tested (too long)
sage: is_orthogonal_array(OA, 11, 640, 2) # not tested (too long)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11, 640)
True
```

`sage.combinat.designs.database.OA_11_80()`

Return an OA(11,80)

As explained in the Handbook III.3.76 [DesignHandbook]. Uses the fact that $80 = 2^4 \times 5$ and that 5 is prime.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_80
sage: OA = OA_11_80()
sage: is_orthogonal_array(OA, 11, 80, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11, 80)
True
```

`sage.combinat.designs.database.OA_12_522()`

Return an OA(12,522)

This design is built by the slightly more general construction *OA_520_plus_x()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_12_522
sage: OA = OA_12_522()
sage: is_orthogonal_array(OA, 12, 522, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(12, 522)
True
```

`sage.combinat.designs.database.OA_14_524()`

Return an OA(14,524)

This design is built by the slightly more general construction *OA_520_plus_x()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_14_524
sage: OA = OA_14_524()
sage: is_orthogonal_array(OA, 14, 524, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(14, 524)
True
```

`sage.combinat.designs.database.OA_15_112()`

Returns an OA(15,112)

Published by Julian R. Abel in [Ab1995]. Uses the fact that $112 = 2^4 \times 7$ and that 7 is prime.

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_112
sage: OA = OA_15_112()
sage: is_orthogonal_array(OA, 15, 112, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(15, 112)
True
```

`sage.combinat.designs.database.OA_15_224()`

Returns an OA(15,224)

Published by Julian R. Abel in [Ab1995] (uses the fact that $224 = 2^5 \times 7$ is a product of a power of 2 and a prime number).

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_224
sage: OA = OA_15_224() # not tested -- too long
sage: is_orthogonal_array(OA,15,224,2) # not tested -- too long
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(15,224)
True
```

`sage.combinat.designs.database.OA_15_896()`

Returns an OA(15,896)

Uses the fact that $896 = 2^7 \times 7$ is the product of a power of 2 and a prime number.

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_896
sage: OA = OA_15_896() # not tested -- too long (~2min)
sage: is_orthogonal_array(OA,15,896,2) # not tested -- too long
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(15,896)
True
```

`sage.combinat.designs.database.OA_16_176()`

Returns an OA(16,176)

Published by Julian R. Abel in [Ab1995]. Uses the fact that $176 = 2^4 \times 11$ is a product of a power of 2 and a prime number.

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_16_176
sage: OA = OA_16_176()
sage: is_orthogonal_array(OA,16,176,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(16,176)
True
```

`sage.combinat.designs.database.OA_16_208()`

Returns an OA(16,208)

Published by Julian R. Abel in [Ab1995]. Uses the fact that $208 = 2^4 \times 13$ is a product of 2 and a prime number.

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_16_208
sage: OA = OA_16_208() # not tested -- too long
sage: is_orthogonal_array(OA,16,208,2) # not tested -- too long
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(16,208)
True
```

`sage.combinat.designs.database.OA_17_560()`

Returns an OA(17,560)

This OA is built in Corollary 2.2 of [Thwarts].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_17_560
sage: OA = OA_17_560()
sage: is_orthogonal_array(OA,17,560,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(17,560)
True
```

`sage.combinat.designs.database.OA_20_352()`

Returns an OA(20,352)

Published by Julian R. Abel in [Ab1995] (uses the fact that $352 = 2^5 \times 11$ is the product of a power of 2 and a prime number).

See also:

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_352
```

(continues on next page)

(continued from previous page)

```
sage: OA = OA_20_352() # not tested (~25s)
sage: is_orthogonal_array(OA,20,352,2) # not tested (~25s)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,352)
True
```

`sage.combinat.designs.database.OA_20_416()`

Returns an OA(20,416)

Published by Julian R. Abel in [Ab1995] (uses the fact that $416 = 2^5 \times 13$ is the product of a power of 2 and a prime number).

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_416
sage: OA = OA_20_416() # not tested (~35s)
sage: is_orthogonal_array(OA,20,416,2) # not tested
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,416)
True
```

`sage.combinat.designs.database.OA_20_544()`

Returns an OA(20,544)

Published by Julian R. Abel in [Ab1995] (uses the fact that $544 = 2^5 \times 17$ is the product of a power of 2 and a prime number).

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_544
sage: OA = OA_20_544() # not tested (too long ~1mn)
sage: is_orthogonal_array(OA,20,544,2) # not tested
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,544)
True
```

`sage.combinat.designs.database.OA_25_1262()`

Returns an OA(25,1262)

The construction is given in [Greig99]. In Julian R. Abel's words:

Start with a cyclic $PG(2, 43)$ or $(1893, 44, 1)$ -BIBD whose base block contains respectively 12, 13 and 19 point in the residue classes mod 3. In the resulting BIBD, remove one of the three classes: the result is a $(1262, \{25, 31, 32\})$ -PBD, from which the $OA(25, 1262)$ is obtained.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_25_1262
sage: OA = OA_25_1262() # not tested -- too long
sage: is_orthogonal_array(OA, 25, 1262, 2) # not tested -- too long
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(25, 1262)
True
```

`sage.combinat.designs.database.OA_520_plus_x(x)`

Return an $OA(10 + x, 520 + x)$.

The construction shared by Julian R. Abel works for $OA(10, 520)$, $OA(12, 522)$, and $OA(14, 524)$.

Let $n = 520 + x$ and $k = 10 + x$. Build a $TD(17, 31)$. Remove $8 - x$ points contained in a common block, add a new point p and create a block $g_i \cup \{p\}$ for every (possibly truncated) group g_i . The result is a $(520 + x, 9 + x, 16, 17, 31, 32) - PBD$. Note that all blocks of size ≥ 30 only intersect on p , and that the unique block B_9 of size 9 intersects all blocks of size 32 on one point. Now:

- Build an $OA(k, 16) - 16.OA(k, 16)$ for each block of size 16
- Build an $OA(k, 17) - 17.OA(k, 17)$ for each block of size 17
- Build an $OA(k, 31) - OA(k, 1)$ for each block of size 31 (with the hole on p).
- Build an $OA(k, 32) - 2.OA(k, 1)$ for each block B of size 32 (with the holes on p and $B \cap B_9$).
- Build an $OA(k, 9)$ on B_9 .

Only a row $[p, p, \dots]$ is missing from the $OA(10 + x, 520 + x)$

This construction is used in $OA(10, 520)$, $OA(12, 522)$, and $OA(14, 524)$.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_520_plus_x
sage: OA = OA_520_plus_x(0) # not tested (already tested in OA_10_
↪ 520)
sage: is_orthogonal_array(OA, 10, 520, 2) # not tested (already tested in OA_10_520)
True
```

`sage.combinat.designs.database.OA_7_18()`

Return an $OA(7, 18)$

Proved in [JulianAbel13].

See also:

`sage.combinat.designs.orthogonal_arrays.OA_from_quasi_difference_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_18
sage: OA = OA_7_18()
sage: is_orthogonal_array(OA,7,18,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(7,18)
True
```

`sage.combinat.designs.database.OA_7_66()`
Return an OA(7,66)

Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_66
sage: OA = OA_7_66()
sage: is_orthogonal_array(OA,7,66,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(7,66)
True
```

`sage.combinat.designs.database.OA_7_68()`
Return an OA(7,68)

Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_68
sage: OA = OA_7_68()
sage: is_orthogonal_array(OA,7,68,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(7,68)
True
```

`sage.combinat.designs.database.OA_7_74()`
Return an OA(7,74)

Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_74
sage: OA = OA_7_74()
sage: is_orthogonal_array(OA,7,74,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(7,74)
True
```

`sage.combinat.designs.database.OA_8_69()`

Return an OA(8,69)

Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_8_69
sage: OA = OA_8_69()
sage: is_orthogonal_array(OA,8,69,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(8,69)
True
```

`sage.combinat.designs.database.OA_8_76()`

Return an OA(8,76)

Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_8_76
sage: OA = OA_8_76()
sage: is_orthogonal_array(OA,8,76,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(8,76)
True
```

`sage.combinat.designs.database.OA_9_1078()`

Returns an $OA(9,1078)$

This is obtained through the generalized Brouwer-van Rees construction. Indeed, $1078 = 89 \cdot 11 + (99 = 9 \cdot 11)$ and there exists an $OA(9, 100) - OA(9, 11)$.

Note: This function should be removed once `find_brouwer_van_rees_with_one_truncated_column()` can handle all incomplete orthogonal arrays obtained through `incomplete_orthogonal_array()`.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_1078
sage: OA = OA_9_1078() # not tested -- ~3s
sage: is_orthogonal_array(OA,9,1078,2) # not tested -- ~3s
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,1078)
True
```

`sage.combinat.designs.database.OA_9_120()`

Return an $OA(9,120)$

Construction shared by Julian R. Abel:

From a resolvable $(120, 8, 1) - BIBD$, one can obtain 7 $MOLS(120)$ or a resolvable $TD(8, 120)$ by forming a resolvable $TD(8, 8) - 8 \cdot TD(8, 1)$ on $I_8 \times B$ for each block B in the BIBD. This gives a $TD(8, 120) - 120TD(8, 1)$ (which is resolvable as the BIBD is resolvable).

See also:

[RBIBD_120_8_1\(\)](#)

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_120
sage: OA = OA_9_120()
sage: is_orthogonal_array(OA,9,120,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,120)
True
```

`sage.combinat.designs.database.OA_9_135()`

Return an $OA(9,135)$

Construction shared by Julian R. Abel:

This design can be built by Wilson's method ($135 = 8 \cdot 16 + 7$) applied to an Orthogonal Array $OA(9 + 7, 16)$ with 7 groups truncated to size 1 in such a way that a block contain 0, 1 or 3 points of the truncated groups.

This is possible, because $PG(2, 2)$ (the projective plane over $GF(2)$) is a subdesign in $PG(2, 16)$ (the projective plane over $GF(16)$); in a cyclic $PG(2, 16)$ or $BIBD(273, 17, 1)$ the points $\equiv 0 \pmod{39}$ form such a subdesign (note that $273 = 16^2 + 16 + 1$ and $273 = 39 \times 7$ and $7 = 2^2 + 2 + 1$).

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_135
sage: OA = OA_9_135()
sage: is_orthogonal_array(OA, 9, 135, 2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9, 135)
True
```

As this orthogonal array requires a $(273, 17, 1)$ cyclic difference set, we check that it is available:

```
sage: G, D = designs.difference_family(273, 17, 1)
sage: G
Ring of integers modulo 273
```

`sage.combinat.designs.database.OA_9_1612()`
Returns an $OA(9, 1612)$

This is obtained through the generalized Brouwer-van Rees construction. Indeed, $1612 = 89 \cdot 17 + (99 = 9 \cdot 11)$ and there exists an $OA(9, 100) - OA(9, 11)$.

Note: This function should be removed once `find_brouwer_van_rees_with_one_truncated_column()` can handle all incomplete orthogonal arrays obtained through `incomplete_orthogonal_array()`.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_1612
sage: OA = OA_9_1612() # not tested -- ~6s
sage: is_orthogonal_array(OA, 9, 1612, 2) # not tested -- ~6s
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9, 1612)
True
```

`sage.combinat.designs.database.OA_9_40()`
Return an $OA(9, 40)$

As explained in the Handbook III.3.62 [DesignHandbook]. Uses the fact that $40 = 2^3 \times 5$ and that 5 is prime.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_40
sage: OA = OA_9_40()
sage: is_orthogonal_array(OA,9,40,2)
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,40)
True
```

`sage.combinat.designs.database.QDM_19_6_1_1_1()`

Return a $(19, 6; 1, 1; 1)$ -quasi-difference matrix.

Used to build an $OA(6, 20)$

Given in the Handbook III.3.49 [[DesignHandbook](#)].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_19_6_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_19_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True
```

`sage.combinat.designs.database.QDM_21_5_1_1_1()`

Return a $(21, 5; 1, 1; 1)$ -quasi-difference matrix.

Used to build an $OA(5, 22)$

Given in the Handbook III.3.51 [[DesignHandbook](#)].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_21_5_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_21_5_1_1_1()
sage: is_quasi_difference_matrix(M,G,5,1,1,1)
True
```

`sage.combinat.designs.database.QDM_21_6_1_1_5()`

Return a $(21, 6; 1, 1; 5)$ -quasi-difference matrix.

Used to build an $OA(6, 26)$

Given in the Handbook III.3.53 [[DesignHandbook](#)].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_21_6_1_1_5
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_21_6_1_1_5()
sage: is_quasi_difference_matrix(M,G,6,1,1,5)
True
```

`sage.combinat.designs.database.QDM_25_6_1_1_5()`

Return a $(25, 6; 1, 1; 5)$ -quasi-difference matrix.

Used to build an $OA(6, 30)$

Given in the Handbook III.3.55 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_25_6_1_1_5
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_25_6_1_1_5()
sage: is_quasi_difference_matrix(M,G,6,1,1,5)
True
```

`sage.combinat.designs.database.QDM_33_6_1_1_1()`

Return a $(33, 6; 1, 1; 1)$ -quasi-difference matrix.

Used to build an $OA(6, 34)$

Given in the Handbook III.3.57 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_33_6_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_33_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True
```

`sage.combinat.designs.database.QDM_35_7_1_1_7()`

Return a $(35, 7; 1, 1; 7)$ -quasi-difference matrix.

Used to build an $OA(7, 42)$

As explained in the Handbook III.3.63 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_35_7_1_1_7
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_35_7_1_1_7()
sage: is_quasi_difference_matrix(M,G,7,1,1,7)
True
```

`sage.combinat.designs.database.QDM_37_6_1_1_1()`

Return a $(37, 6; 1, 1; 1)$ -quasi-difference matrix.

Used to build an $OA(6, 38)$

Given in the Handbook III.3.60 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_37_6_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_37_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True
```

`sage.combinat.designs.database.QDM_45_7_1_1_9()`

Return a $(45, 7; 1, 1; 9)$ -quasi-difference matrix.

Used to build an $OA(7, 54)$

As explained in the Handbook III.3.71 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_45_7_1_1_9
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_45_7_1_1_9()
sage: is_quasi_difference_matrix(M,G,7,1,1,9)
True
```

sage.combinat.designs.database.QDM_54_7_1_1_8()

Return a $(54, 7; 1, 1; 8)$ -quasi-difference matrix.

Used to build an $OA(7, 62)$

As explained in the Handbook III.3.74 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_54_7_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_54_7_1_1_8()
sage: is_quasi_difference_matrix(M,G,7,1,1,8)
True
```

sage.combinat.designs.database.QDM_57_9_1_1_8()

Return a $(57, 9; 1, 1; 8)$ -quasi-difference matrix.

Used to build an $OA(9, 65)$

Construction shared by Julian R. Abel

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_57_9_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_57_9_1_1_8()
sage: is_quasi_difference_matrix(M,G,9,1,1,8)
True
```

sage.combinat.designs.database.RBIBD_120_8_1()

Return a resolvable $BIBD(120, 8, 1)$

This function output a list L of 17×15 blocks such that $L[i*15:(i+1)*15]$ is a partition of 120.

Construction shared by Julian R. Abel:

Seiden's method: Start with a cyclic $(273, 17, 1) - BIBD$ and let B be an hyperoval, i.e. a set of 18 points which intersects any block of the BIBD in either 0 points (153 blocks) or 2 points (120 blocks). Dualise this design and take these last 120 blocks as points in the design; blocks in the design will correspond to the $273 - 18 = 255$ non-hyperoval points.

The design is also resolvable. In the original $PG(2, 16)$ take any point T in the hyperoval and consider a block $B1$ containing T . The 15 points in $B1$ that do not belong to the hyperoval correspond to 15 blocks forming a parallel class in the dualised design. The other 16 parallel classes come in a similar way, by using point T and the other 16 blocks containing T .

See also:

[OA_9_120\(\)](#)

EXAMPLES:

```
sage: from sage.combinat.designs.database import RBIBD_120_8_1
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: RBIBD = RBIBD_120_8_1()
sage: is_pairwise_balanced_design(RBIBD, 120, [8])
True
```

It is indeed resolvable, and the parallel classes are given by 17 slices of consecutive 15 blocks:

```
sage: for i in range(17):
.....:     assert len(set(sum(RBIBD[i*15:(i+1)*15], []))) == 120
```

The BIBD is available from the constructor:

```
sage: _ = designs.balanced_incomplete_block_design(120, 8)
```

`sage.combinat.designs.database.cyclic_shift(l, i)`

`sage.combinat.designs.database.f()`

Return a $(57, 9; 1, 1; 8)$ -quasi-difference matrix.

Used to build an $OA(9, 65)$

Construction shared by Julian R. Abel

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_57_9_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_57_9_1_1_8()
sage: is_quasi_difference_matrix(M, G, 9, 1, 1, 8)
True
```

5.1.80 Catalog of designs

This module gathers all designs that can be reached through `designs.<tab>`. Example with the Witt design on 24 points:

```
sage: designs.WittDesign(24) # optional - gap_packages
Incidence structure with 24 points and 759 blocks
```

Or a Steiner Triple System on 19 points:

```
sage: designs.steiner_triple_system(19)
(19, 3, 1)-Balanced Incomplete Block Design
```

La Jolla Covering Repository

The La Jolla Covering Repository (LJCR, see¹) is an online database of covering designs. As it is frequently updated, it is not included in Sage, but one can query it through `designs.best_known_covering_design_from_LJCR`:

```
sage: C = designs.best_known_covering_design_from_LJCR(7, 3, 2) # optional - internet
sage: C # optional - internet
(7, 3, 2)-covering design of size 7
```

(continues on next page)

¹ La Jolla Covering Repository, <https://math.ccrwest.org/cover.html>

(continued from previous page)

```

Lower bound: 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
sage: C.incidence_structure()      # optional - internet
Incidence structure with 7 points and 7 blocks

```

Design constructors

This module gathers the following designs:

<i>ProjectiveGeometryDesign()</i>
<i>DesarguesianProjectivePlaneDesign()</i>
<i>HughesPlane()</i>
<i>HigmanSimsDesign()</i>
<i>balanced_incomplete_block_design()</i>
<i>resolvable_balanced_incomplete_block_design()</i>
<i>kirkman_triple_system()</i>
<i>AffineGeometryDesign()</i>
<i>CremonaRichmondConfiguration()</i>
<i>WittDesign()</i>
<i>HadamardDesign()</i>
<i>Hadamard3Design()</i>
<i>mutually_orthogonal_latin_squares()</i>
<i>transversal_design()</i>
<i>orthogonal_array()</i>
<i>incomplete_orthogonal_array()</i>
<i>difference_family()</i>
<i>difference_matrix()</i>
<i>steiner_triple_system()</i>
<i>steiner_quadruple_system()</i>
<i>projective_plane()</i>
<i>biplane()</i>
<i>gen_quadrangles_with_spread()</i>

And the *designs.best_known_covering_design_from_LJCR* function which queries the LJCR.

Todo: Implement *DerivedDesign* and *ComplementaryDesign*.

REFERENCES:

5.1.81 Cython functions for combinatorial designs

This module implements the design methods that need to be somewhat efficient.

Functions

`sage.combinat.designs.designs_pyx.is_difference_matrix(M, G, k, lambda=1, verbose=False)`

Test if M is a (G, k, λ) -difference matrix.

A matrix M is a (G, k, λ) -difference matrix if its entries are element of G , and if for any two rows R, R' of M and $x \in G$ there are exactly λ values i such that $R_i - R'_i = x$.

INPUT:

- M – a matrix with entries from G
- G – a group
- k – integer
- λ (integer) – set to 1 by default.
- `verbose` (boolean) – whether to print some information when the answer is `False`.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: q = 3**3
sage: F = GF(q, 'x')
sage: M = [[x*y for y in F] for x in F]
sage: is_difference_matrix(M,F,q,verbose=1)
True

sage: B = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
.....:      [0, 1, 2, 3, 4, 2, 3, 4, 0, 1],
.....:      [0, 2, 4, 1, 3, 3, 0, 2, 4, 1]]
sage: G = GF(5)
sage: B = [[G(b) for b in R] for R in B]
sage: is_difference_matrix(list(zip(*B)),G,3,2)
True
```

Bad input:

```
sage: for R in M: R.append(None)
sage: is_difference_matrix(M,F,q,verbose=1)
The matrix has 28 columns but k=27
False
sage: for R in M: _=R.pop(-1)
sage: M.append([None]*3**3)
sage: is_difference_matrix(M,F,q,verbose=1)
The matrix has 28 rows instead of lambda(|G|-1+2u)+mu=1(27-1+2.0)+1=27
False
sage: _= M.pop(-1)
sage: for R in M: R[-1] = 0
sage: is_difference_matrix(M,F,q,verbose=1)
Columns 0 and 26 generate 0 exactly 27 times instead of the expected mu(=1)
False
sage: for R in M: R[-1] = 1
sage: M[-1][-1] = 0
sage: is_difference_matrix(M,F,q,verbose=1)
```

(continues on next page)

(continued from previous page)

```
Columns 0 and 26 do not generate all elements of G exactly lambda(=1) times. The
↪element x appeared 0 times as a difference.
False
```

```
sage.combinat.designs.designs_pyx.is_group_divisible_design(groups, blocks, v, G=None, K=None,
                                                             lambda=1, verbose=False)
```

Checks that input is a Group Divisible Design on $\{0, \dots, v - 1\}$

For more information on Group Divisible Designs, see [GroupDivisibleDesign](#).

INPUT:

- `groups` – a partition of X . If set to `None` the groups are guessed automatically, and the function returns `(True, guessed_groups)` instead of `True`
- `blocks` – collection of blocks
- `v` (integers) – size of the ground set assumed to be $X = \{0, \dots, v - 1\}$.
- `G` – list of integers of which the sizes of the groups must be elements. Set to `None` (automatic guess) by default.
- `K` – list of integers of which the sizes of the blocks must be elements. Set to `None` (automatic guess) by default.
- `lambda` – value of λ . Set to 1 by default.
- `verbose` (boolean) – whether to display some information when the design is not a GDD.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_group_divisible_design
sage: TD = designs.transversal_design(4,10)
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: is_group_divisible_design(groups,TD,40,lambda=1)
True
```

```
sage.combinat.designs.designs_pyx.is_orthogonal_array(OA, k, n, t=2, verbose=False,
                                                       terminology='OA')
```

Check that the integer matrix OA is an $OA(k, n, t)$.

See [orthogonal_array\(\)](#) for a definition.

INPUT:

- `OA` – the Orthogonal Array to be tested
- `k, n, t` (integers) – only implemented for $t = 2$.
- `verbose` (boolean) – whether to display some information when OA is not an orthogonal array $OA(k, n)$.
- `terminology` (string) – how to phrase the information when `verbose = True`. Possible values are "`OA`", "`MOLS`".

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: OA = designs.orthogonal_arrays.build(8,9)
sage: is_orthogonal_array(OA,8,9)
True
sage: is_orthogonal_array(OA,8,10)
```

(continues on next page)

(continued from previous page)

```

False
sage: OA[4][3] = 1
sage: is_orthogonal_array(OA,8,9)
False
sage: is_orthogonal_array(OA,8,9,verbose=True)
Columns 0 and 3 are not orthogonal
False
sage: is_orthogonal_array(OA,8,9,verbose=True,terminology="MOLS")
Squares 0 and 3 are not orthogonal
False

```

```
sage.combinat.designs.designs_pyx.is_pairwise_balanced_design(blocks, v, K=None, lambda=1,
                                                                verbose=False)
```

Checks that input is a Pairwise Balanced Design (PBD) on $\{0, \dots, v - 1\}$

For more information on Pairwise Balanced Designs (PBD), see [PairwiseBalancedDesign](#).

INPUT:

- `blocks` – collection of blocks
- `v` (integers) – size of the ground set assumed to be $X = \{0, \dots, v - 1\}$.
- `K` – list of integers of which the sizes of the blocks must be elements. Set to `None` (automatic guess) by default.
- `lambda` – value of λ . Set to 1 by default.
- `verbose` (boolean) – whether to display some information when the design is not a PBD.

EXAMPLES:

```

sage: from sage.combinat.designs.designs_pyx import is_pairwise_balanced_design
sage: sts = designs.steiner_triple_system(9)
sage: is_pairwise_balanced_design(sts,9,[3],1)
True
sage: TD = designs.transversal_design(4,10).blocks()
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: is_pairwise_balanced_design(TD+groups,40,[4,10],1,verbose=True)
True

```

```
sage.combinat.designs.designs_pyx.is_projective_plane(blocks, verbose=False)
```

Test whether the blocks form a projective plane on $\{0, \dots, v - 1\}$

A *projective plane* is an incidence structure that has the following properties:

1. Given any two distinct points, there is exactly one line incident with both of them.
2. Given any two distinct lines, there is exactly one point incident with both of them.
3. There are four points such that no line is incident with more than two of them.

For more informations, see [Wikipedia article Projective_plane](#).

`is_t_design()` can also check if an incidence structure is a projective plane with the parameters $v = k^2 + k + 1$, $t = 2$ and $l = 1$.

INPUT:

- `blocks` – collection of blocks

- verbose – whether to print additional information

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_projective_plane
sage: p = designs.projective_plane(4)
sage: b = p.blocks()
sage: is_projective_plane(b, verbose=True)
True

sage: p = designs.projective_plane(2)
sage: b = p.blocks()
sage: is_projective_plane(b)
True
sage: b[0][2] = 5
sage: is_projective_plane(b, verbose=True)
the pair (0,5) has been seen 2 times but lambda=1
False

sage: is_projective_plane([[0,1,2],[1,2,4]], verbose=True)
the pair (0,3) has been seen 0 times but lambda=1
False

sage: is_projective_plane([[1]], verbose=True)
First block has less than 3 points.
False

sage: p = designs.projective_plane(2)
sage: b = p.blocks()
sage: b[2].append(4)
sage: is_projective_plane(b, verbose=True)
a block has size 4 while K=[3]
False
```

`sage.combinat.designs.designs_pyx.is_quasi_difference_matrix(M, G, k, lmbda, mu, u, verbose=False)`

Test if the matrix is a $(G, k; \lambda, \mu; u)$ -quasi-difference matrix

Let G be an abelian group of order n . A $(n, k; \lambda, \mu; u)$ -quasi-difference matrix (QDM) is a matrix Q_{ij} with $\lambda(n - 1 + 2u) + \mu$ rows and k columns, with each entry either equal to None (i.e. the ‘missing entries’) or to an element of G . Each column contains exactly λu empty entries, and each row contains at most one None. Furthermore, for each $1 \leq i < j \leq k$, the multiset

$$\{q_{li} - q_{lj} : 1 \leq l \leq \lambda(n - 1 + 2u) + \mu, \text{ with } q_{li} \text{ and } q_{lj} \text{ not empty}\}$$

contains λ times every nonzero element of G and contains μ times 0.

INPUT:

- M – a matrix with entries from G (or equal to None for missing entries)
- G – a group
- $k, lmbda, mu, u$ – integers
- verbose (boolean) – whether to print some information when the answer is False.

EXAMPLES:

Differences matrices:

```
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: q = 3**3
sage: F = GF(q, 'x')
sage: M = [[x*y for y in F] for x in F]
sage: is_quasi_difference_matrix(M, F, q, 1, 1, 0, verbose=1)
True

sage: B = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
.....:      [0, 1, 2, 3, 4, 2, 3, 4, 0, 1],
.....:      [0, 2, 4, 1, 3, 3, 0, 2, 4, 1]]
sage: G = GF(5)
sage: B = [[G(b) for b in R] for R in B]
sage: is_quasi_difference_matrix(list(zip(*B)), G, 3, 2, 2, 0)
True
```

A quasi-difference matrix from the database:

```
sage: from sage.combinat.designs.database import QDM
sage: G, M = QDM[38, 1][37, 1, 1, 1][1](C)
sage: is_quasi_difference_matrix(M, G, k=6, lmbda=1, mu=1, u=1)
True
```

Bad input:

```
sage: is_quasi_difference_matrix(M, G, k=6, lmbda=1, mu=1, u=3, verbose=1)
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.3)+1=43
False
sage: is_quasi_difference_matrix(M, G, k=6, lmbda=1, mu=2, u=1, verbose=1)
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.1)+2=40
False
sage: M[3][1] = None
sage: is_quasi_difference_matrix(M, G, k=6, lmbda=1, mu=1, u=1, verbose=1)
Row 3 contains more than one empty entry
False
sage: M[3][1] = 1
sage: M[6][1] = None
sage: is_quasi_difference_matrix(M, G, k=6, lmbda=1, mu=1, u=1, verbose=1)
Column 1 contains 2 empty entries instead of the expected lambda.u=1.1=1
False
```

5.1.82 Difference families

This module gathers everything related to difference families. One can build a difference family (or check that it can be built) with `difference_family()`:

```
sage: G, F = designs.difference_family(13, 4, 1)
```

It defines the following functions:

<code>are_hadamard_difference_set_parameters(v, k, lmbda)</code>	Check whether (v, k, lmbda) is of the form $(4N^2, 2N^2 - N, N^2 - N)$.
<code>are_mcfarland_1973_parameters(v, k, lmbda)</code>	Test whether (v, k, lmbda) is a triple that can be obtained from the construction from [McF1973].
<code>block_stabilizer(B)</code>	Compute the left stabilizer of the block B under the action of G .
<code>df_q_6_1(K)</code>	Return a $(q, 6, 1)$ -difference family over the finite field K .
<code>difference_family(v)</code>	Return a $(k, 1)$ -difference family on an Abelian group of cardinality v .
<code>group_law(G)</code>	Return a triple (identity, operation, inverse) that define the operations on the group G .
<code>hadamard_difference_set_product(D1, D2)</code>	Make @product of two Hadamard difference sets.
<code>is_difference_family(D, G)</code>	Check whether D forms a difference family in the group G .
<code>mcfarland_1973_construction(v, k, lmbda)</code>	Return a difference set.
<code>one_cyclic_tiling(G, A)</code>	Given a subset A of the cyclic additive group $G = \mathbb{Z}/n\mathbb{Z}$ return another subset B so that $A + B = G$ and $ A B = n$ (i.e. any element of G is uniquely expressed as a sum $a + b$ with a in A and b in B).
<code>one_radical_difference_family(K)</code>	Search for a radical difference family on K using dancing links algorithm.
<code>radical_difference_family(v, k, l)</code>	Return a $(v, k, 1)$ -radical difference family.
<code>radical_difference_set(K, k, l)</code>	Return a difference set made of a cyclotomic coset in the finite field K and with parameters k and l .
<code>singer_difference_set(d, q)</code>	Return a difference set associated to the set of hyperplanes in a projective space of dimension d over $GF(q)$.
<code>turyn_1965_3x3xK(v, k, lmbda)</code>	Return a difference set in either $C_3 \times C_3 \times C_4$ or $C_3 \times C_3 \times C_2 \times C_2$ with parameters $v = 36, k = 15, \lambda = 6$.
<code>twin_prime_powers_difference_set(p)</code>	Return a difference set on $GF(p) \times GF(p + 2)$.

REFERENCES:

Functions

`sage.combinat.designs.difference_family.are_hadamard_difference_set_parameters(v, k, lmbda)`
 Check whether (v, k, lmbda) is of the form $(4N^2, 2N^2 - N, N^2 - N)$.

INPUT:

- (v, k, lmbda) – parameters of a difference set

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import are_hadamard_difference_
↪set_parameters
sage: are_hadamard_difference_set_parameters(36, 15, 6)
True
sage: are_hadamard_difference_set_parameters(60, 13, 5)
False
```

`sage.combinat.designs.difference_family.are_mcfarland_1973_parameters(v, k, lmbda, return_parameters=False)`
 Test whether (v, k, lmbda) is a triple that can be obtained from the construction from [McF1973].

See `mcfarland_1973_construction()`.

INPUT:

- v, k, lmbda - (integers) parameters of the difference family

- `return_parameters` – (boolean, default `False`) if `True` return a pair (q, s) so that (q, s) can be used in the function `mcfarland_1973_construction()` to actually build a (v, k, λ) -difference family. Or $(False, None)$ if the construction is not possible.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import are_mcfarland_1973_
↳parameters
sage: are_mcfarland_1973_parameters(64, 28, 12)
True
sage: are_mcfarland_1973_parameters(64, 28, 12, return_parameters=True)
(True, (2, 2))
sage: are_mcfarland_1973_parameters(60, 13, 5)
False
sage: are_mcfarland_1973_parameters(98125, 19500, 3875)
True
sage: are_mcfarland_1973_parameters(98125, 19500, 3875, True)
(True, (5, 3))

sage: from sage.combinat.designs.difference_family import are_mcfarland_1973_
↳parameters
sage: for v in range(1, 100):
.....:     for k in range(1, 30):
.....:         for l in range(1, 15):
.....:             if are_mcfarland_1973_parameters(v, k, l):
.....:                 answer, (q, s) = are_mcfarland_1973_parameters(v, k, l, return_
↳parameters=True)
.....:                 print("{} {} {} {} {}".format(v, k, l, q, s))
.....:                 assert answer is True
.....:                 assert designs.difference_family(v, k, l, existence=True) is True
.....:                 G, D = designs.difference_family(v, k, l)
16 6 2 2 1
45 12 3 3 1
64 28 12 2 2
96 20 4 4 1
```

`sage.combinat.designs.difference_family.block_stabilizer(G, B)`

Compute the left stabilizer of the block B under the action of G .

This function return the list of all $x \in G$ such that $x \cdot B = B$ (as a set).

INPUT:

- G – a group (additive or multiplicative).
- B – a subset of G .

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import block_stabilizer

sage: Z8 = Zmod(8)
sage: block_stabilizer(Z8, [Z8(0), Z8(2), Z8(4), Z8(6)])
[0, 2, 4, 6]
sage: block_stabilizer(Z8, [Z8(0), Z8(2)])
[0]
```

(continues on next page)

(continued from previous page)

```

sage: C = cartesian_product([Zmod(4),Zmod(3)])
sage: block_stabilizer(C, [C((0,0)),C((2,0)),C((0,1)),C((2,1))])
[(0, 0), (2, 0)]

sage: b = list(map(Zmod(45),[1, 3, 7, 10, 22, 25, 30, 35, 37, 38, 44]))
sage: block_stabilizer(Zmod(45),b)
[0]

```

`sage.combinat.designs.difference_family.df_q_6_1(K, existence=False, check=True)`
Return a $(q, 6, 1)$ -difference family over the finite field K .

The construction uses Theorem 11 of [Wi72].

EXAMPLES:

```

sage: from sage.combinat.designs.difference_family import is_difference_family, df_
↪q_6_1
sage: prime_powers = [v for v in range(31,500,30) if is_prime_power(v)]
sage: parameters = [v for v in prime_powers if df_q_6_1(GF(v,'a'), existence=True)
↪is True]
sage: parameters
[31, 151, 181, 211, 241, 271, 331, 361, 421]
sage: for v in parameters:
.....:     K = GF(v, 'a')
.....:     df = df_q_6_1(K, check=True)
.....:     assert is_difference_family(K, df, v, 6, 1)

```

Todo: Do improvements due to Zhen and Wu 1999.

`sage.combinat.designs.difference_family.difference_family(v, k, l=1, existence=False, explain_construction=False, check=True)`

Return a $(k, 1)$ -difference family on an Abelian group of cardinality v .

Let G be a finite Abelian group. For a given subset D of G , we define ΔD to be the multi-set of differences $\Delta D = \{x - y; x \in D, y \in D, x \neq y\}$. A (G, k, λ) -difference family is a collection of k -subsets of G , $D = \{D_1, D_2, \dots, D_b\}$ such that the union of the difference sets ΔD_i for $i = 1, \dots, b$, seen as a multi-set, contains each element of $G \setminus \{0\}$ exactly λ -times.

When there is only one block, i.e. $\lambda(v - 1) = k(k - 1)$, then a (G, k, λ) -difference family is also called a *difference set*.

See also [Wikipedia article Difference_set](#).

If there is no such difference family, an `EmptySetError` is raised and if there is no construction at the moment `NotImplementedError` is raised.

INPUT:

- v, k, l – parameters of the difference family. If l is not provided it is assumed to be 1.
- `existence` – if `True`, then return either `True` if Sage knows how to build such design, `Unknown` if it does not and `False` if it knows that the design does not exist.
- `explain_construction` – instead of returning a difference family, returns a string that explains the construction used.

- `check` – boolean (default: `True`). If `True` then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct.

OUTPUT:

A pair (G,D) made of a group G and a difference family D on that group. Or, if `existence` is `True` a boolean or if `explain_construction` is `True` a string.

EXAMPLES:

```
sage: G,D = designs.difference_family(73,4)
sage: G
Finite Field of size 73
sage: D
[[0, 1, 5, 18],
 [0, 3, 15, 54],
 [0, 9, 45, 16],
 [0, 27, 62, 48],
 [0, 8, 40, 71],
 [0, 24, 47, 67]]

sage: print(designs.difference_family(73, 4, explain_construction=True))
The database contains a (73,4)-evenly distributed set

sage: G,D = designs.difference_family(15,7,3)
sage: G
Ring of integers modulo 15
sage: D
[[0, 1, 2, 4, 5, 8, 10]]
sage: print(designs.difference_family(15,7,3,explain_construction=True))
Singer difference set

sage: print(designs.difference_family(91,10,1,explain_construction=True))
Singer difference set
sage: print(designs.difference_family(64,28,12, explain_construction=True))
McFarland 1973 construction
sage: print(designs.difference_family(576, 276, 132, explain_construction=True))
Hadamard difference set product from N1=2 and N2=3
```

For $k = 6, 7$ we look at the set of small prime powers for which a construction is available:

```
sage: def prime_power_mod(r,m):
.....:     k = m+r
.....:     while True:
.....:         if is_prime_power(k):
.....:             yield k
.....:         k += m

sage: from itertools import islice
sage: l6 = {True:[], False:[], Unknown:[]}
sage: for q in islice(prime_power_mod(1,30), int(60)):
.....:     l6[designs.difference_family(q,6,existence=True)].append(q)
sage: l6[True]
[31, 121, 151, 181, 211, ..., 3061, 3121, 3181]
sage: l6[Unknown]
```

(continues on next page)

(continued from previous page)

```
[61]
sage: l6[False]
[]

sage: l7 = {True: [], False: [], Unknown: []}
sage: for q in islice(prime_power_mod(1,42), int(60)):
.....:     l7[designs.difference_family(q,7,existence=True)].append(q)
sage: l7[True]
[169, 337, 379, 421, 463, 547, 631, 673, 757, 841, 883, 967, ..., 4621, 4957, 5167]
sage: l7[Unknown]

Todo: Implement recursive constructions from Buratti “Recursive for difference matrices and relative difference families” (1998) and Jungnickel “Composition theorems for difference families and regular planes” (1978)

`sage.combinat.designs.difference_family.group_law(G)`

Return a triple (identity, operation, inverse) that define the operations on the group G.

EXAMPLES:

```

sage: from sage.combinat.designs.difference_family import group_law
sage: group_law(Zmod(3))

((0, 0, 0), <built-in function add>, <built-in function neg>)

```

`sage.combinat.designs.difference_family.hadamard_difference_set_product(G1, D1, G2, D2)`

Make a product of two Hadamard difference sets.

This product construction appears in [Tu1984].

INPUT:

- G_1, D_1, G_2, D_2 – two Hadamard difference sets

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import hadamard_difference_set_
      ↪product
sage: from sage.combinat.designs.difference_family import is_difference_family

sage: G1,D1 = designs.difference_family(16,6,2)
sage: G2,D2 = designs.difference_family(36,15,6)

sage: G11,D11 = hadamard_difference_set_product(G1,D1,G1,D1)
sage: assert is_difference_family(G11, D11, 256, 120, 56)
sage: assert designs.difference_family(256, 120, 56, existence=True) is True

sage: G12,D12 = hadamard_difference_set_product(G1,D1,G2,D2)
sage: assert is_difference_family(G12, D12, 576, 276, 132)
sage: assert designs.difference_family(576, 276, 132, existence=True) is True
```

`sage.combinat.designs.difference_family.hadamard_difference_set_product_parameters(N)`
Check whether a product construction is available for Hadamard difference set with parameter N .

This function looks for two integers N_1 and N_2 greater than 1 and so that $N = 2N_1N_2$ and there exists Hadamard difference set with parameters $(4N_i^2, 2N_i^2 - N_i, N_i^2 - N_i)$. If such pair exists, the output is the pair (N_1, N_2) otherwise it is None.

INPUT:

- N – positive integer

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import hadamard_difference_set_
      ↪product_parameters
sage: hadamard_difference_set_product_parameters(8)
(2, 2)
```

`sage.combinat.designs.difference_family.is_difference_family(G, D, v=None, k=None, l=None, verbose=False)`

Check whether D forms a difference family in the group G .

INPUT:

- G – group of cardinality v
- D – a set of k -subsets of G
- v, k and l – optional parameters of the difference family
- `verbose` - whether to print additional information

See also:

[`difference_family\(\)`](#)

EXAMPLES:

```

sage: from sage.combinat.designs.difference_family import is_difference_family
sage: G = Zmod(21)
sage: D = [[0,1,4,14,16]]
sage: is_difference_family(G, D, 21, 5)
True

sage: G = Zmod(41)
sage: D = [[0,1,4,11,29],[0,2,8,17,21]]
sage: is_difference_family(G, D, verbose=True)
Too few:
  5 is obtained 0 times in blocks []
 14 is obtained 0 times in blocks []
 27 is obtained 0 times in blocks []
 36 is obtained 0 times in blocks []
Too much:
  4 is obtained 2 times in blocks [0, 1]
 13 is obtained 2 times in blocks [0, 1]
 28 is obtained 2 times in blocks [0, 1]
 37 is obtained 2 times in blocks [0, 1]
False
sage: D = [[0,1,4,11,29],[0,2,8,17,22]]
sage: is_difference_family(G, D)
True

sage: G = Zmod(61)
sage: D = [[0,1,3,13,34],[0,4,9,23,45],[0,6,17,24,32]]
sage: is_difference_family(G, D)
True

sage: G = AdditiveAbelianGroup([3]*4)
sage: a,b,c,d = G.gens()
sage: D = [[d, -a+d, -c+d, a-b-d, b+c+d],
.....:      [c, a+b-d, -b+c, a-b+d, a+b+c],
.....:      [-a-b+c+d, a-b-c-d, -a+c-d, b-c+d, a+b],
.....:      [-b-d, a+b+d, a-b+c-d, a-b+c, -b+c+d]]
sage: is_difference_family(G, D)
True

```

The following example has a third block with a non-trivial stabilizer:

```

sage: G = Zmod(15)
sage: D = [[0,1,4],[0,2,9],[0,5,10]]
sage: is_difference_family(G,D,verbose=True)
It is a (15,3,1)-difference family
True

```

The function also supports multiplicative groups (non necessarily Abelian):

```

sage: G = DihedralGroup(8)
sage: x,y = G.gens()
sage: i = G.one()
sage: D1 = [[i,x,x^4], [i,x^2, y*x], [i,x^5,y], [i,x^6,y*x^2], [i,x^7,y*x^5]]
sage: is_difference_family(G, D1, 16, 3, 2)

```

(continues on next page)

(continued from previous page)

```
True
sage: from sage.combinat.designs.bibd import BIBD_from_difference_family
sage: bibd = BIBD_from_difference_family(G,D1,lambda=2)
```

`sage.combinat.designs.difference_family.mcfarland_1973_construction(q, s)`

Return a difference set.

The difference set returned has the following parameters

$$v = \frac{q^{s+1}(q^{s+1} + q - 2)}{q - 1}, k = \frac{q^s(q^{s+1} - 1)}{q - 1}, \lambda = \frac{q^s(q^s - 1)}{q - 1}$$

This construction is due to [McF1973].

INPUT:

- *q*, *s* - (integers) parameters for the difference set (see the above formulas for the expression of *v*, *k*, *l* in terms of *q* and *s*)

See also:

The function `are_mcfarland_1973_parameters()` makes the translation between the parameters (*q*, *s*) corresponding to a given triple (*v*, *k*, *λ*).

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import (
.....:     mcfarland_1973_construction, is_difference_family)

sage: G,D = mcfarland_1973_construction(3, 1)
sage: assert is_difference_family(G, D, 45, 12, 3)

sage: G,D = mcfarland_1973_construction(2, 2)
sage: assert is_difference_family(G, D, 64, 28, 12)
```

`sage.combinat.designs.difference_family.one_cyclic_tiling(A, n)`

Given a subset *A* of the cyclic additive group $G = \mathbb{Z}/n\mathbb{Z}$ return another subset *B* so that $A + B = G$ and $|A||B| = n$ (i.e. any element of *G* is uniquely expressed as a sum $a + b$ with *a* in *A* and *b* in *B*).

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import one_cyclic_tiling
sage: tile = [0,2,4]
sage: m = one_cyclic_tiling(tile,6); m
[0, 3]
sage: sorted((i+j)%6 for i in tile for j in m)
[0, 1, 2, 3, 4, 5]

sage: def print_tiling(tile, translat, n):
.....:     for x in translat:
.....:         print(''.join('X' if (i-x)%n in tile else '.' for i in range(n)))

sage: tile = [0, 1, 2, 7]
sage: m = one_cyclic_tiling(tile, 12)
sage: print_tiling(tile, m, 12)
```

```

ALGORITHM:

Uses dancing links [sage.combinat.dlx](#)`sage.combinat.designs.difference_family.one_radical_difference_family(K, k)`Search for a radical difference family on K using dancing links algorithm.For the definition of radical difference family, see [radical_difference_family\(\)](#). Here, we consider only radical difference family with $\lambda = 1$.

INPUT:

- K – a finite field of cardinality q .
- k – a positive integer so that $k(k-1)$ divides $q-1$.

OUTPUT:

Either a difference family or None if it does not exist.

ALGORITHM:

The existence of a radical difference family is equivalent to a one dimensional tiling (or packing) problem in a cyclic group. This subsequent problem is solved by a call to the function [one_cyclic_tiling\(\)](#).

Let K^* be the multiplicative group of the finite field K . A radical family has the form $\mathcal{B} = \{x_1B, \dots, x_kB\}$, where $B = \{x : x^k = 1\}$ (for k odd) or $B = \{x : x^{k-1} = 1\} \cup \{0\}$ (for k even). Equivalently, K^* decomposes as:

$$K^* = \Delta(x_1B) \cup \dots \cup \Delta(x_kB) = x_1\Delta B \cup \dots \cup x_k\Delta B.$$

We observe that $C = B \setminus 0$ is a subgroup of the (cyclic) group K^* , that can thus be generated by some element r . Furthermore, we observe that ΔB is always a union of cosets of $\pm C$ (which is twice larger than C).

$$\begin{aligned} (k \text{ odd}) \quad \Delta B &= \{r^i - r^j : r^i \neq r^j\} &= \pm C \cdot \{r^i - 1 : 0 < i \leq m\} \\ (k \text{ even}) \quad \Delta B &= \{r^i - r^j : r^i \neq r^j\} \cup C &= \pm C \cdot \{r^i - 1 : 0 < i < m\} \cup \pm C \end{aligned}$$

where

$$(k \text{ odd}) m = (k - 1)/2 \quad \text{and} \quad (k \text{ even}) m = k/2.$$

Consequently, $\mathcal{B} = \{x_1 B, \dots, x_k B\}$ is a radical difference family if and only if $\{x_1(\Delta B/(\pm C)), \dots, x_k(\Delta B/(\pm C))\}$ is a partition of the cyclic group $K^*/(\pm C)$.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import (
.....:     one_radical_difference_family,
.....:     is_difference_family)

sage: one_radical_difference_family(GF(13), 4)
[[0, 1, 3, 9]]
```

The parameters that appear in [Bu95]:

```
sage: df = one_radical_difference_family(GF(449), 8); df
[[0, 1, 18, 25, 176, 324, 359, 444],
 [0, 9, 88, 162, 222, 225, 237, 404],
 [0, 11, 140, 198, 275, 357, 394, 421],
 [0, 40, 102, 249, 271, 305, 388, 441],
 [0, 49, 80, 93, 161, 204, 327, 433],
 [0, 70, 99, 197, 230, 362, 403, 435],
 [0, 121, 141, 193, 293, 331, 335, 382],
 [0, 191, 285, 295, 321, 371, 390, 392]]
sage: is_difference_family(GF(449), df, 449, 8, 1)
True
```

`sage.combinat.designs.difference_family.radical_difference_family($K, k, l=1, existence=False, check=True$)`

Return a (v, k, l) -radical difference family.

Let fix an integer k and a prime power $q = tk(k - 1) + 1$. Let K be a field of cardinality q . A $(q, k, 1)$ -difference family is *radical* if its base blocks are either: a coset of the k -th root of unity for k odd or a coset of $k - 1$ -th root of unity and 0 if k is even (the number t is the number of blocks of that difference family).

The terminology comes from M. Buratti article [Bu95] but the first constructions go back to R. Wilson [Wi72].

INPUT:

- K - a finite field
- k - positive integer, the size of the blocks
- l - the λ parameter (default to 1)
- `existence` - if `True`, then return either `True` if Sage knows how to build such design, `Unknown` if it does not and `False` if it knows that the design does not exist.
- `check` - boolean (default: `True`). If `True` then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import radical_difference_family

sage: radical_difference_family(GF(73), 9)
```

(continues on next page)

(continued from previous page)

```

```

```
sage.combinat.designs.difference_family.radical_difference_set(K, k, l=1, existence=False,
check=True)
```

Return a difference set made of a cyclotomic coset in the finite field K and with parameters k and l .

Most of these difference sets appear in chapter VI.18.48 of the Handbook of combinatorial designs.

EXAMPLES:

```

sage: from sage.combinat.designs.difference_family import radical_difference_set

sage: D = radical_difference_set(GF(7), 3, 1); D
[[1, 2, 4]]
sage: sorted(x-y for x in D[0] for y in D[0] if x != y)

```

(continues on next page)

(continued from previous page)

`sage.combinat.designs.difference_family.singer_difference_set(q, d)`

Return a difference set associated to the set of hyperplanes in a projective space of dimension d over $GF(q)$.

A Singer difference set has parameters:

$$v = \frac{q^{d+1} - 1}{q - 1}, \quad k = \frac{q^d - 1}{q - 1}, \quad \lambda = \frac{q^{d-1} - 1}{q - 1}.$$

The idea of the construction is as follows. One consider the finite field $GF(q^{d+1})$ as a vector space of dimension $d + 1$ over $GF(q)$. The set of $GF(q)$ -lines in $GF(q^{d+1})$ is a projective plane and its set of hyperplanes form a balanced incomplete block design.

Now, considering a multiplicative generator z of $GF(q^{d+1})$, we get a transitive action of a cyclic group on our projective plane from which it is possible to build a difference set.

The construction is given in details in [Stinson2004], section 3.3.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import singer_difference_set, is_
      ↪difference_family
sage: G,D = singer_difference_set(3,2)
sage: is_difference_family(G,D,verbose=True)
It is a (13,4,1)-difference family
True

sage: G,D = singer_difference_set(4,2)
sage: is_difference_family(G,D,verbose=True)
It is a (21,5,1)-difference family
True

sage: G,D = singer_difference_set(3,3)
sage: is_difference_family(G,D,verbose=True)
It is a (40,13,4)-difference family
True

sage: G,D = singer_difference_set(9,3)
sage: is_difference_family(G,D,verbose=True)
It is a (820,91,10)-difference family
True
```

`sage.combinat.designs.difference_family.turyan_1965_3x3xK(k=4)`

Return a difference set in either $C_3 \times C_3 \times C_4$ or $C_3 \times C_3 \times C_2 \times C_2$ with parameters $v = 36$, $k = 15$, $\lambda = 6$.

This example appears in [Tu1965].

INPUT:

- k – either 2 (to get a difference set in $C_3 \times C_3 \times C_2 \times C_2$) or 4 (to get a difference set in $C_3 \times C_3 \times C_3 \times C_4$).

EXAMPLES:

```

sage: from sage.combinat.designs.difference_family import turyn_1965_3x3xK
sage: from sage.combinat.designs.difference_family import is_difference_family
sage: G,D = turyn_1965_3x3xK(4)
sage: assert is_difference_family(G, D, 36, 15, 6)
sage: G,D = turyn_1965_3x3xK(2)
sage: assert is_difference_family(G, D, 36, 15, 6)

```

`sage.combinat.designs.difference_family.twin_prime_powers_difference_set(p, check=True)`
 Return a difference set on $GF(p) \times GF(p+2)$.

The difference set is built from the following element of the Cartesian product of finite fields $GF(p) \times GF(p+2)$:

- $(x, 0)$ with any x
- (x, y) with x and y squares
- (x, y) with x and y non-squares

For more information see [Wikipedia article Difference_set](#).

INPUT:

- `check` – boolean (default: `True`). If `True` then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct.

EXAMPLES:

```

sage: from sage.combinat.designs.difference_family import twin_prime_powers_
↪difference_set
sage: G,D = twin_prime_powers_difference_set(3)
sage: G
The Cartesian product of (Finite Field of size 3, Finite Field of size 5)
sage: D
[[ (1, 1), (1, 4), (2, 2), (2, 3), (0, 0), (1, 0), (2, 0) ]]

```

5.1.83 Difference Matrices

This module gathers code related to difference matrices. One can build those objects (or know if they can be built) with `difference_matrix()`:

```
sage: G,DM = designs.difference_matrix(9,5,1)
```

Functions

`sage.combinat.designs.difference_matrices.difference_matrix(g, k, lmbda=1, existence=False, check=True)`

Return a (g, k, λ) -difference matrix

A matrix M is a (g, k, λ) -difference matrix if it has size $\lambda g \times k$, its entries belong to the group G of cardinality g , and for any two rows R, R' of M and $x \in G$ there are exactly λ values i such that $R_i - R'_i = x$.

INPUT:

- `k` – (integer) number of columns. If `k=None` it is set to the largest value available.
- `g` – (integer) cardinality of the group G
- `lmbda` – (integer; default: 1) – number of times each element of G appears as a difference.

- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.
- `existence` (boolean) – instead of building the design, return:
 - `True` – meaning that Sage knows how to build the design
 - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
 - `False` – meaning that the design does not exist.

Note: When `k=None` and `existence=True` the function returns an integer, i.e. the largest k such that we can build a (g, k, λ) -DM.

EXAMPLES:

```
sage: G,M = designs.difference_matrix(25,10); G
Finite Field in x of size 5^2
sage: designs.difference_matrix(993,None,existence=1)
32
```

Here we print for each g the maximum possible k for which Sage knows how to build a $(g, k, 1)$ -difference matrix:

```
sage: for g in range(2,30):
.....:     k_max = designs.difference_matrix(g=g,k=None,existence=True)
.....:     print("{:2} {}".format(g, k_max))
.....:     _ = designs.difference_matrix(g,k_max)

```

`sage.combinat.designs.difference_matrices.difference_matrix_product(k, M1, G1, lmbda1, M2, G2, lmbda2, check=True)`

Return the product of the $(G1, k, lmbda1)$ and $(G2, k, lmbda2)$ difference matrices M1 and M2.

The result is a $(G1 \times G2, k, \lambda_1 \lambda_2)$ -difference matrix.

INPUT:

- $k, lmbda1, lmbda2$ – positive integer
- $G1, G2$ – groups
- $M1, M2$ – $(G1, k, lmbda1)$ and $(G, k, lmbda2)$ difference matrices
- `check` (boolean) – if True (default), the output is checked before being returned.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_matrices import (
.....:     difference_matrix_product,
.....:     is_difference_matrix)
sage: G1, M1 = designs.difference_matrix(11, 6)
sage: G2, M2 = designs.difference_matrix(7, 6)
sage: G, M = difference_matrix_product(6, M1, G1, 1, M2, G2, 1)
sage: G1
Finite Field of size 11
sage: G2
Finite Field of size 7
sage: G
The Cartesian product of (Finite Field of size 11, Finite Field of size 7)
sage: is_difference_matrix(M, G, 6, 1)
True
```

`sage.combinat.designs.difference_matrices.find_product_decomposition(g, k, lmbda=1)`

Try to find a product decomposition construction for difference matrices.

INPUT:

- $g, k, lmbda$ – integers, parameters of the difference matrix

OUTPUT:

A pair of pairs $(g1, lmbda), (g2, lmbda2)$ if Sage knows how to build $(g1, k, lmbda1)$ and $(g2, k, lmbda2)$ difference matrices and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_matrices import find_product_
->decomposition
sage: find_product_decomposition(77, 6)
((7, 1), (11, 1))
sage: find_product_decomposition(616, 7)
((7, 1), (88, 1))
sage: find_product_decomposition(24, 10)
False
```

5.1.84 Evenly distributed sets in finite fields

This module consists of a simple class `EvenlyDistributedSetsBacktracker`. Its main purpose is to iterate through the evenly distributed sets of a given finite field.

The naive backtracker implemented here is not directly used to generate difference family as even for small parameters it already takes time to run. Instead, its output has been stored into a database `sage.combinat.designs.database`. If the backtracker is improved, then one might want to update this database with more values.

Classes and methods

class `sage.combinat.designs.evenly_distributed_sets.EvenlyDistributedSetsBacktracker`

Bases: object

Set of evenly distributed subsets in finite fields.

Definition: Let K be a finite field of cardinality q and k an integer so that $k(k-1)$ divides $q-1$. Let $H = K^*$ be the multiplicative group of invertible elements in K . A k -evenly distributed set in K is a set $B = \{b_1, b_2, \dots, b_k\}$ of k elements of K so that the $k(k-1)$ differences $\Delta B = \{b_i - b_j; i \neq j\}$ hit each coset modulo $H^{2(q-1)/(k(k-1))}$ exactly twice.

Evenly distributed sets were introduced by Wilson [Wi72] (see also [BJL99-1], Chapter VII.6). He proved that for any k , and for any prime power q large enough such that $k(k-1)$ divides $q-1$ there exists a k -evenly distributed set in the field of cardinality q . This existence result based on a counting argument (using Dirichlet theorem) does not provide a simple method to generate them.

From a k -evenly distributed set, it is straightforward to build a $(q, k, 1)$ -difference family (see `to_difference_family()`). Another approach to generate a difference family, somehow dual to this one, is via radical difference family (see in particular `radical_difference_family()` from the module `difference_family`).

By default, this backtracker only considers evenly distributed sets up to affine automorphisms, i.e. B is considered equivalent to $sB + t$ for any invertible element s and any element t in the field K . Note that the set of differences is just multiplicatively translated by s as $\Delta(sB + t) = s(\Delta B)$, and so that B is an evenly distributed set if and only if sB is one too. This behaviour can be modified via the argument `up_to_isomorphism` (see the input section and the examples below).

INPUT:

- K – a finite field of cardinality q
- k – a positive integer such that $k(k-1)$ divides $q-1$
- `up_to_isomorphism` - (boolean, default True) whether only consider evenly distributed sets up to automorphisms of the field of the form $x \mapsto ax + b$. If set to False then the iteration is over all evenly distributed sets that contain 0 and 1 .
- `check` – boolean (default is False). Whether you want to check intermediate steps of the iterator. This is mainly intended for debugging purpose. Setting it to True will considerably slow the iteration.

EXAMPLES:

The main part of the code is contained in the iterator. To get one evenly distributed set just do:

```
sage: from sage.combinat.designs.evenly_distributed_sets import _
      ↪ EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(151), 6)
sage: B = E.an_element()
```

(continues on next page)

(continued from previous page)

```
sage: B
[0, 1, 69, 36, 57, 89]
```

The class has a method to convert it to a difference family:

```
sage: E.to_difference_family(B)
[[0, 1, 69, 36, 57, 89],
 [0, 132, 48, 71, 125, 121],
 [0, 59, 145, 10, 41, 117],
 [0, 87, 114, 112, 127, 42],
 [0, 8, 99, 137, 3, 108]]
```

It is also possible to run over all evenly distributed sets:

```
sage: E = EvenlyDistributedSetsBacktracker(Zmod(13), 4, up_to_isomorphism=False)
sage: for B in E: print(B)
[0, 1, 11, 5]
[0, 1, 4, 6]
[0, 1, 9, 3]
[0, 1, 8, 10]

sage: E = EvenlyDistributedSetsBacktracker(Zmod(13), 4, up_to_isomorphism=True)
sage: for B in E: print(B)
[0, 1, 11, 5]
```

Or only count them:

```
sage: for k in range(13, 200, 12):
.....:     if is_prime_power(k):
.....:         K = GF(k, 'a')
.....:         E1 = EvenlyDistributedSetsBacktracker(K, 4, False)
.....:         E2 = EvenlyDistributedSetsBacktracker(K, 4, True)
.....:         print("{:3} {:3} {:3}".format(k, E1.cardinality(), E2.cardinality()))
13  4  1
25 40  4
37 12  1
49 24  2
61 12  1
73 48  4
97 64  6
109 72  6
121 240 20
157 96  8
169 240 20
181 204 17
193 336 28
```

Note that by definition, the number of evenly distributed sets up to isomorphisms is at most $k(k-1)$ times smaller than without isomorphisms. But it might not be exactly $k(k-1)$ as some of them might have symmetries:

```
sage: B = EvenlyDistributedSetsBacktracker(Zmod(13), 4).an_element()
sage: B
[0, 1, 11, 5]
```

(continues on next page)

(continued from previous page)

```
sage: [9*x + 5 for x in B]
[5, 1, 0, 11]
sage: [3*x + 11 for x in B]
[11, 1, 5, 0]
```

an_element()

Return an evenly distributed set.

If there is no such subset raise an `EmptySetError`.

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import _
↳EvenlyDistributedSetsBacktracker

sage: E = EvenlyDistributedSetsBacktracker(Zmod(41),5)
sage: E.an_element()
[0, 1, 13, 38, 31]

sage: E = EvenlyDistributedSetsBacktracker(Zmod(61),6)
sage: E.an_element()
Traceback (most recent call last):
...
EmptySetError: no 6-evenly distributed set in Ring of integers modulo 61
```

cardinality()

Return the number of evenly distributed sets.

Use with precaution as there can be a lot of such sets and this method might be very long to answer!

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import _
↳EvenlyDistributedSetsBacktracker

sage: E = EvenlyDistributedSetsBacktracker(GF(25,'a'),4)
sage: E
4-evenly distributed sets (up to isomorphism) in Finite Field in a of size 5^2
sage: E.cardinality()
4

sage: E = EvenlyDistributedSetsBacktracker(GF(25,'a'), 4, up_to_
↳isomorphism=False)
sage: E.cardinality()
40
```

to_difference_family(B, check=True)

Given an evenly distributed set B convert it to a difference family.

As for any $x \in K^* = H$ we have $|\Delta B \cap xH^{2(q-1)/(k(k-1))}| = 2$ (see *EvenlyDistributedSetsBacktracker*), the difference family is produced as $\{xB : x \in H^{2(q-1)/(k(k-1))}\}$

This method is useful if you want to obtain the difference family from the output of the iterator.

INPUT:

- B – an evenly distributed set
- check – (boolean, default True) whether to check the result

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import _
↳EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(41),5)
sage: B = E.an_element(); B
[0, 1, 13, 38, 31]
sage: D = E.to_difference_family(B); D
[[0, 1, 13, 38, 31], [0, 32, 6, 27, 8]]

sage: from sage.combinat.designs.difference_family import is_difference_family
sage: is_difference_family(Zmod(41),D,41,5,1)
True
```

Setting check to False is much faster:

```
sage: timeit("df = E.to_difference_family(B, check=True)") # random
625 loops, best of 3: 117 µs per loop

sage: timeit("df = E.to_difference_family(B, check=False)") # random
625 loops, best of 3: 1.83 µs per loop
```

5.1.85 External Representations of Block Designs

The “ext_rep” module is an API to the abstract tree represented by an XML document containing the External Representation of a list of block designs. The module also provides the related I/O operations for reading/writing ext_rep files or data. The parsing is based on expat.

This is a modified form of the module ext_rep.py (version 0.8) written by Peter Dobcsanyi [Do2009] peter@designtheory.org.

Todo: The XML data from the designtheory.org database contains a wealth of information about things like automorphism groups, transitivity, cycle type representatives, etc, but none of this data is made available through the current implementation.

Functions

```
class sage.combinat.designs.ext_rep.XTree(node)
```

Bases: object

A lazy class to wrap a rooted tree representing an XML document. The tree’s nodes are tuples of the structure:

(name, {dictionary of attributes}, [list of children])

Methods and services of an XTree object *t*:

- *t*.attribute – attribute named
- *t*.child – first child named
- *t*[*i*] – *i*-th child

- for `child` in `t`: – iterate over `t`'s children
- `len(t)` – number of `t`'s children

If `child` is not an empty subtree, return the subtree as an `XTree` object. If `child` is an empty subtree, return `_name` of the subtree. Otherwise return the child itself.

The lazy tree idea originated from a utility class of the `pyRXP 0.9` package by Robin Becker at ReportLab.

class `sage.combinat.designs.ext_rep.XTreeProcessor`

Bases: `object`

An incremental event-driven parser for ext-rep documents. The processing stages:

- `<list_of_designs ...>` opening element. call-back: `list_of_designs_proc`
- `<list_definition>` subtree. call-back: `list_definition_proc`
- `<info>` subtree. call-back: `info_proc`
- iterating over `<designs>` processing each `<block_design>` separately. call-back: `block_design_proc`
- finishing with closing `</designs>` and `</list_of_designs>`.

parse(`xml_source`)

The main parsing function. Given an XML source (either a file handle or a string), parse the entire XML source.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: proc.save_designs = True
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)
sage: proc.list_of_designs[0]
(2, [[0, 1], [0, 1]])
```

`sage.combinat.designs.ext_rep.check_dtrs_protocols`(`input_name`, `input_pv`)

Check that the XML data is in a valid format. We can currently handle version 2.0. For more information see <http://designtheory.org/library/extrep/>

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: ext_rep.check_dtrs_protocols('source', '2.0')
sage: ext_rep.check_dtrs_protocols('source', '3.0')
Traceback (most recent call last):
...
RuntimeError: Incompatible dtrs_protocols: program: 2.0 source: 3.0
```

`sage.combinat.designs.ext_rep.designs_from_XML`(`fname`)

Return a list of designs contained in an XML file `fname`. The list contains tuples of the form `(v, bs)` where `v` is the number of points of the design and `bs` is the list of blocks.

EXAMPLES:

```

sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: ext_rep.designs_from_XML(file_loc)[0]
(2, [[0, 1], [0, 1]])
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: from sage.combinat.designs.block_design import BlockDesign
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: v, blocks = ext_rep.designs_from_XML(file_loc)[0]
sage: d = BlockDesign(v, blocks)
sage: d.blocks()
[[0, 1], [0, 1]]
sage: d.is_t_design(t=2)
True
sage: d.is_t_design(return_parameters=True)
(True, (2, 2, 2, 2))

```

`sage.combinat.designs.ext_rep.designs_from_XML_url(url)`

Return a list of designs contained in an XML file named by a URL. The list contains tuples of the form (v, bs) where v is the number of points of the design and bs is the list of blocks.

EXAMPLES:

```

sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: ext_rep.designs_from_XML_url("file://" + file_loc)[0]
(2, [[0, 1], [0, 1]])
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.
↳icgsa.txt.bz2") # optional - internet
[(3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 1], [0, 1], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]])]

```

`sage.combinat.designs.ext_rep.dump_to_tmpfile(s)`

Utility function to dump a string to a temporary file.

EXAMPLES:

```

sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile("boo")
sage: os.remove(file_loc)

```

`sage.combinat.designs.ext_rep.open_extrep_file(fname)`

Try to guess the compression type from extension and open the extrep file.

EXAMPLES:

```

sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)

```

`sage.combinat.designs.ext_rep.open_extrep_url(url)`

Try to guess the compression type from extension and open the extrep file pointed to by the url. This function (unlike `open_extrep_file`) returns the uncompressed text contained in the file.

EXAMPLES:

```

sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: s = ext_rep.open_extrep_url("file://" + file_loc)
sage: proc.parse(s)
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: s = ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-
↳b6-k2.icgsa.txt.bz2") # optional - internet

```

5.1.86 Database of generalised quadrangles with spread

This module implements some construction of generalised quadrangles with spread.

EXAMPLES:

```

sage: GQ, S = designs.generalised_quadrangle_with_spread(4, 16, check=False)
sage: GQ
Incidence structure with 325 points and 1105 blocks
sage: GQ2, O = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: GQ2
Incidence structure with 1105 points and 325 blocks
sage: GQ3 = GQ.dual()
sage: set(GQ3._points) == set(GQ2._points)
True
sage: GQ2.is_isomorphic(GQ3) # long time
True

```

REFERENCES:

- [PT2009]
- [TP1994]
- [Wikipedia article Generalized quadrangle](#)

AUTHORS:

- Ivo Maffei (2020-07-26): initial version

`sage.combinat.designs.gen_quadrangles_with_spread.dual_GQ_ovoid(GQ, O)`
 Compute the dual incidence structure of GQ and return the image of O under the dual map

INPUT:

- GQ – IncidenceStructure; the generalised quadrangle we want the dual of
- O – iterable; the iterable of blocks we want to compute the dual

OUTPUT:

A pair (D, S) where D is the dual of GQ and S is the dual of O

EXAMPLES:

```
sage: from sage.combinat.designs.gen_quadrangles_with_spread import \
.....: dual_GQ_ovoid
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(3)
sage: t[0].is_generalized_quadrangle(parameters=True)
(9, 3)
sage: t = dual_GQ_ovoid(*t)
sage: t[0].is_generalized_quadrangle(parameters=True)
(3, 9)
sage: all([x in t[0] for x in t[1]])
True
```

`sage.combinat.designs.gen_quadrangles_with_spread.generalised_quadrangle_hermitian_with_ovoid(q)`
 Construct the generalised quadrangle $H(3, q^2)$ with an ovoid.

The GQ has order (q^2, q) .

INPUT:

- q – integer; a prime power

OUTPUT:

A pair (D, O) where D is an IncidenceStructure representing the generalised quadrangle and O is a list of points of D which constitute an ovoid of D

EXAMPLES:

```
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: t[0]
Incidence structure with 1105 points and 325 blocks
sage: len(t[1])
65
sage: G = t[0].intersection_graph([1]) # line graph
sage: G.is_strongly_regular(True)
(325, 68, 3, 17)
sage: set(t[0].block_sizes())
{17}
```

REFERENCES:

For more on $H(3, q^2)$ and the construction implemented here see [PT2009] or [TP1994].

```
sage.combinat.designs.gen_quadrangles_with_spread.generalised_quadrangle_with_spread(s, t,
                                                                                       existence=False,
                                                                                       check=True)
```

Construct a generalised quadrangle GQ of order (s, t) with a spread S .

INPUT:

- s , t – integers; order of the generalised quadrangle
- `existence` – boolean;
- `check` – boolean; if `True`, then Sage checks that the object built is correct. (default: `True`)

OUTPUT:

A pair (GQ, S) where GQ is a [IncidenceStructure](#) representing the generalised quadrangle and S is a list of blocks of GQ representing the spread of GQ .

EXAMPLES:

```
sage: t = designs.generalised_quadrangle_with_spread(3, 9)
sage: t[0]
Incidence structure with 112 points and 280 blocks
sage: designs.generalised_quadrangle_with_spread(5, 25, existence=True)
True
sage: (designs.generalised_quadrangle_with_spread(4, 16, check=False))[0]
Incidence structure with 325 points and 1105 blocks
sage: designs.generalised_quadrangle_with_spread(0, 2, existence=True)
False
```

REFERENCES:

For more on generalised quadrangles and their spread see [PT2009] or [TP1994].

```
sage.combinat.designs.gen_quadrangles_with_spread.is_GQ_with_spread(GQ, S, s=None, t=None)
```

Check if GQ is a generalised quadrangle of order (s, t) and check that S is a spread of GQ

INPUT:

- GQ – [IncidenceStructure](#); the incidence structure that is supposed to be a generalised quadrangle
- S – iterable; the spread of GQ as an iterable of the blocks of GQ
- s , t – integers (optional); if (s, t) are given, then we check that GQ has order (s, t)

EXAMPLES:

```
sage: from sage.combinat.designs.gen_quadrangles_with_spread import *
sage: t = generalised_quadrangle_hermitian_with_ovoid(3)
sage: is_GQ_with_spread(*t)
Traceback (most recent call last):
...
TypeError: 'int' object is not iterable
sage: t = dual_GQ_ovoid(*t)
sage: is_GQ_with_spread(*t)
True
sage: is_GQ_with_spread(*t, s=3)
True
```

5.1.87 Incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure is specified by a list of points, blocks, or an incidence matrix ^(1,2). *IncidenceStructure* instances have the following methods:

<i>automorphism_group()</i>	Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.
<i>block_sizes()</i>	Return the set of block sizes.
<i>blocks()</i>	Return the list of blocks.
<i>canonical_label()</i>	Return a canonical label for the incidence structure.
<i>coloring()</i>	Compute a (weak) k -coloring of the hypergraph
<i>complement()</i>	Return the complement of the incidence structure.
<i>copy()</i>	Return a copy of the incidence structure.
<i>degree()</i>	Return the degree of a point p (or a set of points).
<i>degrees()</i>	Return the degree of all sets of given size, or the degree of all points.
<i>dual()</i>	Return the dual of the incidence structure.
<i>edge_coloring()</i>	Compute a proper edge-coloring.
<i>ground_set()</i>	Return the ground set (i.e the list of points).
<i>incidence_graph()</i>	Return the incidence graph of the incidence structure
<i>incidence_matrix()</i>	Return the incidence matrix A of the design. A is a $(v \times b)$ matrix defined by: $A[i, j] = 1$ if i is in block B_j and 0 otherwise.
<i>induced_substructure()</i>	Return the substructure induced by a set of points.
<i>intersection_graph()</i>	Return the intersection graph of the incidence structure.
<i>is_berge_cyclic()</i>	Check whether <i>self</i> is a Berge-Cyclic uniform hypergraph.
<i>is_connected()</i>	Test whether the design is connected.
<i>is_generalized_quadrangle()</i>	Test if the incidence structure is a generalized quadrangle.
<i>is_isomorphic()</i>	Return whether the two incidence structures are isomorphic.
<i>is_regular()</i>	Test whether the incidence structure is r -regular.
<i>is_resolvable()</i>	Test whether the hypergraph is resolvable
<i>is_simple()</i>	Test whether this design is simple (i.e. no repeated block).
<i>is_spread()</i>	Check whether the input is a spread for <i>self</i> .
<i>is_t_design()</i>	Test whether <i>self</i> is a $t - (v, k, l)$ design.
<i>is_uniform()</i>	Test whether the incidence structure is k -uniform
<i>isomorphic_substructures_iterates()</i>	Iterates over all copies of H2 contained in <i>self</i> .
<i>num_blocks()</i>	Return the number of blocks.
<i>num_points()</i>	Return the size of the ground set.
<i>packing()</i>	Return a maximum packing
<i>rank()</i>	Return the rank of the hypergraph (the maximum size of a block).
<i>relabel()</i>	Relabel the ground set
<i>trace()</i>	Return the trace of a set of points.

- Vincent Delecroix (2014): major rewrite

¹ Block designs and incidence structures from wikipedia, Wikipedia article [Block_design](#) Wikipedia article [Incidence_structure](#)

² E. Assmus, J. Key, Designs and their codes, CUP, 1992.

Methods

```
class sage.combinat.designs.incidence_structures.IncidenceStructure(points=None, blocks=None,
                                                                    incidence_matrix=None,
                                                                    name=None, check=True,
                                                                    copy=True)
```

Bases: object

A base class for incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure (i.e. hypergraph, i.e. set system) can be defined from a collection of blocks (i.e. sets, i.e. edges), optionally with an explicit ground set (i.e. point set, i.e. vertex set). Alternatively they can be defined from a binary incidence matrix.

INPUT:

- `points` – (i.e. ground set, i.e. vertex set) the underlying set. If `points` is an integer v , then the set is considered to be $\{0, \dots, v - 1\}$.

Note: The following syntax, where `points` is omitted, automatically defines the ground set as the union of the blocks:

```
sage: H = IncidenceStructure([[ 'a', 'b', 'c' ], [ 'c', 'd', 'e' ]])
sage: sorted(H.ground_set())
[ 'a', 'b', 'c', 'd', 'e' ]
```

- `blocks` – (i.e. edges, i.e. sets) the blocks defining the incidence structure. Can be any iterable.
- `incidence_matrix` – a binary incidence matrix. Each column represents a set.
- `name` (a string, such as “Fano plane”).
- `check` – whether to check the input
- `copy` – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the *IncidenceStructure* instance’s internal data.

EXAMPLES:

An incidence structure can be constructed by giving the number of points and the list of blocks:

```
sage: IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,
↪5]])
Incidence structure with 7 points and 7 blocks
```

Only providing the set of blocks is sufficient. In this case, the ground set is defined as the union of the blocks:

```
sage: IncidenceStructure([[1,2,3],[2,3,4]])
Incidence structure with 4 points and 2 blocks
```

Or by its adjacency matrix (a $\{0, 1\}$ -matrix in which rows are indexed by points and columns by blocks):

```
sage: m = matrix([[0,1,0],[0,0,1],[1,0,1],[1,1,1]])
sage: IncidenceStructure(m)
Incidence structure with 4 points and 3 blocks
```

The points can be any (hashable) object:

```

sage: V = [(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]
sage: B = [(V[0], V[1], V[2]), (V[1], V[2]), (V[0], V[2])]
sage: I = IncidenceStructure(V, B)
sage: I.ground_set()
[(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]
sage: I.blocks()
[[ (0, 'a'), (0, 'b'), (1, 'a') ], [ (0, 'a'), (1, 'a') ], [ (0, 'b'), (1, 'a') ]]

```

The order of the points and blocks does not matter as they are sorted on input (see [trac ticket #11333](#)):

```

sage: A = IncidenceStructure([0,1,2], [[0],[0,2]])
sage: B = IncidenceStructure([1,0,2], [[0],[2,0]])
sage: B == A
True

sage: C = BlockDesign(2, [[0], [1,0]])
sage: D = BlockDesign(2, [[0,1], [0]])
sage: C == D
True

```

If you care for speed, you can set `copy` to `False`, but in that case, your input must be a list of lists and the ground set must be $0, \dots, v - 1$:

```

sage: blocks = [[0,1],[2,0],[1,2]] # a list of lists of integers
sage: I = IncidenceStructure(3, blocks, copy=False)
sage: I._blocks is blocks
True

```

automorphism_group()

Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.

EXAMPLES:

```

sage: P = designs.DesarguesianProjectivePlaneDesign(2); P
(7,3,1)-Balanced Incomplete Block Design
sage: G = P.automorphism_group()
sage: G.is_isomorphic(PGL(3,2))
True
sage: G
Permutation Group with generators [...]
sage: G.cardinality()
168

```

A non self-dual example:

```

sage: IS = IncidenceStructure(list(range(4)), [[0,1,2,3],[1,2,3]])
sage: IS.automorphism_group().cardinality()
6
sage: IS.dual().automorphism_group().cardinality()
1

```

Examples with non-integer points:

```

sage: I = IncidenceStructure('abc', ('ab', 'ac', 'bc'))
sage: I.automorphism_group()
Permutation Group with generators [(b', 'c'), ('a', 'b')]
sage: IncidenceStructure([(1,2), (3,4)]).automorphism_group()
Permutation Group with generators [(1,2), (3,4)]

```

block_sizes()

Return the set of block sizes.

EXAMPLES:

```

sage: BD = IncidenceStructure(8, [[0,1,3], [1,4,5,6], [1,2], [5,6,7]])
sage: BD.block_sizes()
[3, 2, 4, 3]
sage: BD = IncidenceStructure(7, [[0,1,2], [0,3,4], [0,5,6], [1,3,5], [1,4,6], [2,3,
↪6], [2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]

```

blocks()

Return the list of blocks.

EXAMPLES:

```

sage: BD = IncidenceStructure(7, [[0,1,2], [0,3,4], [0,5,6], [1,3,5], [1,4,6], [2,3,
↪6], [2,4,5]])
sage: BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]

```

canonical_label()

Return a canonical label for the incidence structure.

A canonical label is relabeling of the points into integers $\{0, \dots, n - 1\}$ such that isomorphic incidence structures are relabelled to equal objects.

EXAMPLES:

```

sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
sage: fano1 == fano2
False
sage: fano1.relabel(fano1.canonical_label())
sage: fano2.relabel(fano2.canonical_label())
sage: fano1 == fano2
True

```

coloring(*k*, solver=None, verbose=None, integrality_tolerance=0)

Compute a (weak) k -coloring of the hypergraph

A weak coloring of a hypergraph \mathcal{H} is an assignment of colors to its vertices such that no set is monochromatic.

INPUT:

- k (integer) – compute a coloring with k colors if an integer is provided, otherwise returns an optimal coloring (i.e. with the minimum possible number of colors).

- `solver` – (default: `None`) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – non-negative integer (default: `0`). Set the level of verbosity you want from the linear program solver. Since the problem is *NP*-complete, its solving may take some time depending on the graph. A value of `0` means that there will be no message printed by the solver.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

EXAMPLES:

The Fano plane has chromatic number 3:

```
sage: len(designs.steiner_triple_system(7).coloring())
3
```

One admissible 3-coloring:

```
sage: designs.steiner_triple_system(7).coloring() # not tested - architecture-
↪dependent
[[0, 2, 5, 1], [4, 3], [6]]
```

The chromatic number of a graph is equal to the chromatic number of its 2-uniform corresponding hypergraph:

```
sage: g = graphs.PetersenGraph()
sage: H = IncidenceStructure(g.edges(sort=True, labels=False))
sage: len(g.coloring())
3
sage: len(H.coloring())
3
```

complement (*uniform=False*)

Return the complement of the incidence structure.

Two different definitions of “complement” are made available, according to the value of `uniform`.

INPUT:

- `uniform` (boolean) –
 - if set to `False` (default), returns the incidence structure whose blocks are the complements of all blocks of the incidence structure.
 - If set to `True` and the incidence structure is k -uniform, returns the incidence structure whose blocks are all k -sets of the ground set that do not appear in `self`.

EXAMPLES:

The complement of a *BalancedIncompleteBlockDesign* is also a 2-design:

```
sage: bibd = designs.balanced_incomplete_block_design(13,4)
sage: bibd.is_t_design(return_parameters=True)
(True, (2, 13, 4, 1))
sage: bibd.complement().is_t_design(return_parameters=True)
(True, (2, 13, 9, 6))
```

The “uniform” complement of a graph is a graph:

```

sage: g = graphs.PetersenGraph()
sage: G = IncidenceStructure(g.edges(sort=True, labels=False))
sage: H = G.complement(uniform=True)
sage: h = Graph(H.blocks())
sage: g == h
False
sage: g == h.complement()
True

```

copy()

Return a copy of the incidence structure.

EXAMPLES:

```

sage: IS = IncidenceStructure([[1,2,3,"e"]],name="Test")
sage: IS
Incidence structure with 4 points and 1 blocks
sage: copy(IS)
Incidence structure with 4 points and 1 blocks
sage: [1, 2, 3, 'e'] in copy(IS)
True
sage: copy(IS)._name
'Test'

```

degree(*p=None, subset=False*)

Return the degree of a point *p* (or a set of points).

The degree of a point (or set of points) is the number of blocks that contain it.

INPUT:

- *p* – a point (or a set of points) of the incidence structure.
- *subset* (boolean) – whether to interpret the argument as a set of point (*subset=True*) or as a point (*subset=False*, default).

EXAMPLES:

```

sage: designs.steiner_triple_system(9).degree(3)
4
sage: designs.steiner_triple_system(9).degree({1,2},subset=True)
1

```

degrees(*size=None*)

Return the degree of all sets of given size, or the degree of all points.

The degree of a point (or set of point) is the number of blocks that contain it.

INPUT:

- *size* (integer) – return the degree of all subsets of points of cardinality *size*. When *size=None*, the function outputs the degree of all points.

Note: When *size=None* the output is indexed by the points. When *size=1* it is indexed by tuples of size 1. This is the same information, stored slightly differently.

OUTPUT:

A dictionary whose values are degrees and keys are either:

- the points of the incidence structure if `size=None` (default)
- the subsets of size `size` of the points stored as tuples

EXAMPLES:

```
sage: IncidenceStructure([[1,2,3],[1,4]]).degrees(2)
{(1, 2): 1, (1, 3): 1, (1, 4): 1, (2, 3): 1, (2, 4): 0, (3, 4): 0}
```

In a Steiner triple system, all pairs have degree 1:

```
sage: S13 = designs.steiner_triple_system(13)
sage: all(v == 1 for v in S13.degrees(2).values())
True
```

dual(*algorithm=None*)

Return the dual of the incidence structure.

INPUT:

- `algorithm` – whether to use Sage’s implementation (`algorithm=None`, default) or use GAP’s (`algorithm="gap"`).

Note: The `algorithm="gap"` option requires GAP’s Design package (included in the `gap_packages Sage spkg`).

EXAMPLES:

The dual of a projective plane is a projective plane:

```
sage: PP = designs.DesarguesianProjectivePlaneDesign(4)
sage: PP.dual().is_t_design(return_parameters=True)
(True, (2, 21, 5, 1))
```

REFERENCE:

- Soicher, Leonard, Design package manual, available at <https://www.gap-system.org/Manuals/pkg/design/htm/CHAP003.htm>

edge_coloring()

Compute a proper edge-coloring.

A proper edge-coloring is an assignment of colors to the sets of the incidence structure such that two sets with non-empty intersection receive different colors. The coloring returned minimizes the number of colors.

OUTPUT:

A partition of the sets into color classes.

EXAMPLES:

```
sage: H = Hypergraph([[1,2,3],[2,3,4],[3,4,5],[4,5,6]]); H
Incidence structure with 6 points and 4 blocks
sage: C = H.edge_coloring()
sage: C # random
[[[3, 4, 5]], [[2, 3, 4]], [[4, 5, 6], [1, 2, 3]]]
```

(continues on next page)

(continued from previous page)

```
sage: Set(map(Set, sum(C, []))) == Set(map(Set, H.blocks()))
True
```

ground_set()

Return the ground set (i.e the list of points).

EXAMPLES:

```
sage: IncidenceStructure(3, [[0,1],[0,2]]) .ground_set()
[0, 1, 2]
```

incidence_graph(labels=False)

Return the incidence graph of the incidence structure

A point and a block are adjacent in this graph whenever they are incident.

INPUT:

- `labels` (boolean) – whether to return a graph whose vertices are integers, or labelled elements.
 - `labels` is `False` (default) – in this case the first vertices of the graphs are the elements of `ground_set()`, and appear in the same order. Similarly, the following vertices represent the elements of `blocks()`, and appear in the same order.
 - `labels` is `True`, the points keep their original labels, and the blocks are `Set` objects.

Note that the labelled incidence graph can be incorrect when blocks are repeated, and on some (rare) occasions when the elements of `ground_set()` mix `Set()` and non-`Set` objects.

EXAMPLES:

```
sage: BD = IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,
↪6],[2,4,5]])
sage: BD.incidence_graph()
Bipartite graph on 14 vertices
sage: A = BD.incidence_matrix()
sage: Graph(block_matrix([[A*0,A],[A.transpose(),A*0]])) == BD.incidence_graph()
True
```

incidence_matrix()

Return the incidence matrix A of the design. A is a $(v \times b)$ matrix defined by: $A[i, j] = 1$ if i is in block B_j and 0 otherwise.

EXAMPLES:

```
sage: BD = IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,
↪6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
sage: BD.incidence_matrix()
[1 1 1 0 0 0 0]
[1 0 0 1 1 0 0]
[1 0 0 0 0 1 1]
[0 1 0 1 0 1 0]
[0 1 0 0 1 0 1]
[0 0 1 1 0 0 1]
[0 0 1 0 1 1 0]
```

(continues on next page)

(continued from previous page)

```

sage: I = IncidenceStructure('abc', ('ab', 'abc', 'ac', 'c'))
sage: I.incidence_matrix()
[1 1 1 0]
[1 1 0 0]
[0 1 1 1]

```

induced_substructure(*points*)

Return the substructure induced by a set of points.

The substructure induced in \mathcal{H} by a set $X \subseteq V(\mathcal{H})$ of points is the incidence structure \mathcal{H}_X defined on X whose sets are all $S \in \mathcal{H}$ such that $S \subseteq X$.

INPUT:

- *points* – a set of points.

Note: This method goes over all sets of *self* before building a new *IncidenceStructure* (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:

A Fano plane with one point removed:

```

sage: F = designs.steiner_triple_system(7)
sage: F.induced_substructure([0..5])
Incidence structure with 6 points and 4 blocks

```

intersection_graph(*sizes=None*)

Return the intersection graph of the incidence structure.

The vertices of this graph are the *blocks()* of the incidence structure. Two of them are adjacent if the size of their intersection belongs to the set *sizes*.

INPUT:

- *sizes* – a list/set of integers. For convenience, setting *sizes* to 5 has the same effect as *sizes*=[5]. When set to *None* (default), behaves as *sizes*=*PositiveIntegers()*.

EXAMPLES:

The intersection graph of a *balanced_incomplete_block_design()* is a *strongly regular graph* (when it is not trivial):

```

sage: BIBD = designs.balanced_incomplete_block_design(19,3)
sage: G = BIBD.intersection_graph(1)
sage: G.is_strongly_regular(parameters=True)
(57, 24, 11, 9)

```

is_berge_cyclic()

Check whether *self* is a Berge-Cyclic uniform hypergraph.

A k -uniform Berge cycle (named after Claude Berge) of length ℓ is a cyclic list of distinct k -sets F_1, \dots, F_ℓ , $\ell > 1$, and distinct vertices $C = \{v_1, \dots, v_\ell\}$ such that for each $1 \leq i \leq \ell$, F_i contains v_i and v_{i+1} (where $v_{\ell+1} = v_1$).

A uniform hypergraph is Berge-cyclic if its incidence graph is cyclic. It is called “Berge-acyclic” otherwise.

For more information, see [Fag1983] and [Wikipedia article Hypergraph](#).

EXAMPLES:

```
sage: Hypergraph(5, [[1, 2, 3], [2, 3, 4]]).is_berge_cyclic()
True
sage: Hypergraph(6, [[1, 2, 3], [3, 4, 5]]).is_berge_cyclic()
False
```

`is_connected()`

Test whether the design is connected.

EXAMPLES:

```
sage: IncidenceStructure(3, [[0, 1], [0, 2]]).is_connected()
True
sage: IncidenceStructure(4, [[0, 1], [2, 3]]).is_connected()
False
```

`is_generalized_quadrangle(verbose=False, parameters=False)`

Test if the incidence structure is a generalized quadrangle.

An incidence structure is a generalized quadrangle iff (see [BH2012], section 9.6):

- two blocks intersect on at most one point.
- For every point p not in a block B , there is a unique block B' intersecting both $\{p\}$ and B

It is a *regular* generalized quadrangle if furthermore:

- it is $s + 1$ -*uniform* for some positive integer s .
- it is $t + 1$ -*regular* for some positive integer t .

For more information, see the [Wikipedia article Generalized_quadrangle](#).

Note: Some references (e.g. [PT2009] or [Wikipedia article Generalized_quadrangle](#)) only allow *regular* generalized quadrangles. To use such a definition, see the `parameters` optional argument described below, or the methods `is_regular()` and `is_uniform()`.

INPUT:

- `verbose` (boolean) – whether to print an explanation when the instance is not a generalized quadrangle.
- `parameters` (boolean; `False`) – if set to `True`, the function returns a pair (s, t) instead of `True` answers. In this case, s and t are the integers defined above if they exist (each can be set to `False` otherwise).

EXAMPLES:

```
sage: h = designs.CremonaRichmondConfiguration()
sage: h.is_generalized_quadrangle()
True
```

This is actually a *regular* generalized quadrangle:

```
sage: h.is_generalized_quadrangle(parameters=True)
(2, 2)
```

is_isomorphic(*other*, *certificate=False*)

Return whether the two incidence structures are isomorphic.

INPUT:

- *other* – an incidence structure.
- *certificate* (boolean) – whether to return an isomorphism from *self* to *other* instead of a boolean answer.

EXAMPLES:

```
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
sage: fano1.is_isomorphic(fano2)
True
sage: fano1.is_isomorphic(fano2,certificate=True)
{0: 0, 1: 1, 2: 2, 3: 6, 4: 4, 5: 3, 6: 5}
```

is_regular(*r=None*)

Test whether the incidence structure is *r*-regular.

An incidence structure is said to be *r*-regular if all its points are incident with exactly *r* blocks.

INPUT:

- *r* (integer)

OUTPUT:

If *r* is defined, a boolean is returned. If *r* is set to *None* (default), the method returns either *False* or the integer *r* such that the incidence structure is *r*-regular.

Warning: In case of 0-regular incidence structure, beware that `if not H.is_regular()` is a satisfied condition.

EXAMPLES:

```
sage: designs.balanced_incomplete_block_design(7,3).is_regular()
3
sage: designs.balanced_incomplete_block_design(7,3).is_regular(r=3)
True
sage: designs.balanced_incomplete_block_design(7,3).is_regular(r=4)
False
```

is_resolvable(*certificate*, *solver=False*, *verbose=None*, *check=0*, *integrality_tolerance=True*)

Test whether the hypergraph is resolvable

A hypergraph is said to be resolvable if its sets can be partitioned into classes, each of which is a partition of the ground set.

Note: This problem is solved using an Integer Linear Program, and GLPK (the default LP solver) has been reported to be very slow on some instances. If you hit this wall, consider installing a more powerful MILP solver (CPLEX, Gurobi, ...).

INPUT:

- `certificate` (boolean) – whether to return the classes along with the binary answer (see examples below).
- `solver` – (default: `None`) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – integer (default: `0`). Sets the level of verbosity. Set to `0` by default, which means quiet.
- `check` (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

EXAMPLES:

Some resolvable designs:

```
sage: TD = designs.transversal_design(2,2,resolvable=True)
sage: TD.is_resolvable()
True

sage: AG = designs.AffineGeometryDesign(3,1,GF(2))
sage: AG.is_resolvable()
True
```

Their classes:

```
sage: b,cls = TD.is_resolvable(True)
sage: b
True
sage: cls # random
[[[0, 3], [1, 2]], [[1, 3], [0, 2]]]

sage: b,cls = AG.is_resolvable(True)
sage: b
True
sage: cls # random
[[[6, 7], [4, 5], [0, 1], [2, 3]],
 [[5, 7], [0, 4], [3, 6], [1, 2]],
 [[0, 2], [4, 7], [1, 3], [5, 6]],
 [[3, 4], [0, 7], [1, 5], [2, 6]],
 [[3, 7], [1, 6], [0, 5], [2, 4]],
 [[0, 6], [2, 7], [1, 4], [3, 5]],
 [[4, 6], [0, 3], [2, 5], [1, 7]]]
```

A non-resolvable design:

```
sage: Fano = designs.balanced_incomplete_block_design(7,3)
sage: Fano.is_resolvable()
False
sage: Fano.is_resolvable(True)
(False, [])
```

`is_simple()`

Test whether this design is simple (i.e. no repeated block).

EXAMPLES:

```
sage: IncidenceStructure(3, [[0,1],[1,2],[0,2]].is_simple()
True
sage: IncidenceStructure(3, [[0],[0]]).is_simple()
False

sage: V = [(0,'a'),(0,'b'),(1,'a'),(1,'b')]
sage: B = [[V[0],V[1]], [V[1],V[2]]]
sage: I = IncidenceStructure(V, B)
sage: I.is_simple()
True
sage: I2 = IncidenceStructure(V, B*2)
sage: I2.is_simple()
False
```

is_spread(*spread*)

Check whether the input is a spread for `self`.

A spread of an incidence structure (P, B) is a subset of B which forms a partition of P .

INPUT:

- `spread` – iterable; defines the spread

EXAMPLES:

```
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[1, 2, 3], [4, 5, 6]])
True
sage: E.is_spread([1, 2, 3, 4, 5, 6])
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
sage: E.is_spread([[1, 2, 3, 4], [5, 6]])
False
```

Order of blocks or of points within each block doesn't matter:

```
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[5, 6, 4], [3, 1, 2]])
True
```

is_t_design(*t=None, v=None, k=None, l=None, return_parameters=False*)

Test whether `self` is a $t - (v, k, l)$ design.

A $t - (v, k, \lambda)$ (sometimes called t -design for short) is a block design in which:

- the underlying set has cardinality v
- the blocks have size k
- each t -subset of points is covered by λ blocks

INPUT:

- t, v, k, l (integers) – their value is set to `None` by default. The function tests whether the design is a $t - (v, k, l)$ design using the provided values and guesses the others. Note that l cannot be specified if t is not.

- `return_parameters` (boolean)– whether to return the parameters of the t -design. If set to `True`, the function returns a pair `(boolean_answer, (t, v, k, l))`.

EXAMPLES:

```
sage: fano_blocks = [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]]
sage: BD = IncidenceStructure(7, fano_blocks)
sage: BD.is_t_design()
True
sage: BD.is_t_design(return_parameters=True)
(True, (2, 7, 3, 1))
sage: BD.is_t_design(2, 7, 3, 1)
True
sage: BD.is_t_design(1, 7, 3, 3)
True
sage: BD.is_t_design(0, 7, 3, 7)
True

sage: BD.is_t_design(0,6,3,7) or BD.is_t_design(0,7,4,7) or BD.is_t_design(0,7,
↪3,8)
False

sage: BD = designs.AffineGeometryDesign(3, 1, GF(2))
sage: BD.is_t_design(1)
True
sage: BD.is_t_design(2)
True
```

Steiner triple and quadruple systems are other names for $2 - (v, 3, 1)$ and $3 - (v, 4, 1)$ designs:

```
sage: S3_9 = designs.steiner_triple_system(9)
sage: S3_9.is_t_design(2,9,3,1)
True

sage: blocks = designs.steiner_quadruple_system(8)
sage: S4_8 = IncidenceStructure(8, blocks)
sage: S4_8.is_t_design(3,8,4,1)
True

sage: blocks = designs.steiner_quadruple_system(14)
sage: S4_14 = IncidenceStructure(14, blocks)
sage: S4_14.is_t_design(3,14,4,1)
True
```

Some examples of Witt designs that need the gap database:

```
sage: BD = designs.WittDesign(9)           # optional - gap_packages
sage: BD.is_t_design(2,9,3,1)           # optional - gap_packages
True

sage: W12 = designs.WittDesign(12)       # optional - gap_packages
sage: W12.is_t_design(5,12,6,1)        # optional - gap_packages
True

sage: W12.is_t_design(4)                 # optional - gap_packages
True
```

Further examples:

```

sage: D = IncidenceStructure(4, [[], []])
sage: D.is_t_design(return_parameters=True)
(True, (0, 4, 0, 2))

sage: D = IncidenceStructure(4, [[0,1],[0,2],[0,3]])
sage: D.is_t_design(return_parameters=True)
(True, (0, 4, 2, 3))

sage: D = IncidenceStructure(4, [[0],[1],[2],[3]])
sage: D.is_t_design(return_parameters=True)
(True, (1, 4, 1, 1))

sage: D = IncidenceStructure(4, [[0,1],[2,3]])
sage: D.is_t_design(return_parameters=True)
(True, (1, 4, 2, 1))

sage: D = IncidenceStructure(4, [list(range(4))])
sage: D.is_t_design(return_parameters=True)
(True, (4, 4, 4, 1))

```

is_uniform(*k=None*)

Test whether the incidence structure is k -uniform

An incidence structure is said to be k -uniform if all its blocks have size k .

INPUT:

- k (integer)

OUTPUT:

If k is defined, a boolean is returned. If k is set to `None` (default), the method returns either `False` or the integer k such that the incidence structure is k -uniform.

Warning: In case of 0-uniform incidence structure, beware that `if not H.is_uniform()` is a satisfied condition.

EXAMPLES:

```

sage: designs.balanced_incomplete_block_design(7,3).is_uniform()
3
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=3)
True
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=4)
False

```

isomorphic_substructures_iterator(H_2 , *induced=False*)

Iterates over all copies of H_2 contained in `self`.

A hypergraph H_1 contains an isomorphic copy of a hypergraph H_2 if there exists an injection $f : V(H_2) \mapsto V(H_1)$ such that for any set $S_2 \in E(H_2)$ the set $S_1 = f(S_2)$ belongs to $E(H_1)$.

It is an *induced* copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{S : S \in E(H_1) \text{ and } f(V(H_2)) \subseteq S\}$.

This function lists all such injections. In particular, the number of copies of H in itself is equal to *the size of its automorphism group*.

See [subhypergraph_search](#) for more information.

INPUT:

- H2 an *IncidenceStructure* object.
- induced (boolean) – whether to require the copies to be induced. Set to False by default.

EXAMPLES:

How many distinct C_5 in Petersen's graph ?

```
sage: P = graphs.PetersenGraph()
sage: C = graphs.CycleGraph(5)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
120
```

As the automorphism group of C_5 has size 10, the number of distinct unlabelled copies is 12. Let us check that all functions returned correspond to an actual C_5 subgraph:

```
sage: for f in IP.isomorphic_substructures_iterator(IC):
.....:     assert all(P.has_edge(f[x],f[y]) for x,y in C.edges(sort=True,
↪ labels=False))
```

The number of induced copies, in this case, is the same:

```
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC, induced=True))
120
```

They begin to differ if we make one vertex universal:

```
sage: P.add_edges([(0,x) for x in P], loops=False)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
420
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC, induced=True))
60
```

The number of copies of H in itself is the size of its automorphism group:

```
sage: H = designs.projective_plane(3)
sage: sum(1 for _ in H.isomorphic_substructures_iterator(H))
5616
sage: H.automorphism_group().cardinality()
5616
```

num_blocks()

Return the number of blocks.

EXAMPLES:

```
sage: designs.DesarguesianProjectivePlaneDesign(2).num_blocks()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2], [1,2,3]])
sage: B.num_blocks()
5
```

num_points()

Return the size of the ground set.

EXAMPLES:

```
sage: designs.DesarguesianProjectivePlaneDesign(2).num_points()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2], [1,2,3]])
sage: B.num_points()
4
```

packing(*solver*, *verbose=None*, *integrality_tolerance=0*)

Return a maximum packing

A maximum packing in a hypergraph is collection of disjoint sets/blocks of maximal cardinality. This problem is NP-complete in general, and in particular on 3-uniform hypergraphs. It is solved here with an Integer Linear Program.

For more information, see the [Wikipedia article Packing_in_a_hypergraph](#).

INPUT:

- *solver* – (default: `None`) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on LP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- *verbose* – integer (default: `0`). Sets the level of verbosity. Set to `0` by default, which means quiet.
- *integrality_tolerance* – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

EXAMPLES:

```
sage: P = IncidenceStructure([[1,2],[3,4],[2,3]])
sage: sorted(sorted(b) for b in P)
[[1, 2], [3, 4]]
sage: len(designs.steiner_triple_system(9).packing())
3
```

rank()

Return the rank of the hypergraph (the maximum size of a block).

EXAMPLES:

```
sage: h = Hypergraph(8, [[0,1,3],[1,4,5,6],[1,2]])
sage: h.rank()
4
```

relabel(*perm=None*, *inplace=True*)

Relabel the ground set

INPUT:

- `perm` – can be one of
 - a dictionary – then each point p (which should be a key of d) is relabeled to $d[p]$
 - a list or a tuple of length n – the first point returned by `ground_set()` is relabeled to $l[0]$, the second to $l[1]$, ...
 - `None` – the incidence structure is relabeled to be on $\{0, 1, \dots, n - 1\}$ in the ordering given by `ground_set()`.
- `inplace` – If `True` then return a relabeled graph and does not touch `self` (default is `False`).

EXAMPLES:

```
sage: TD=designs.transversal_design(5,5)
sage: TD.relabel({i:chr(97+i) for i in range(25)})
sage: TD.ground_set()
['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p',
 ↪ 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y']
sage: TD.blocks()[:3]
[['a', 'f', 'k', 'p', 'u'], ['a', 'g', 'm', 's', 'y'], ['a', 'h', 'o', 'q', 'x
 ↪ ']]
```

Relabel to integer points:

```
sage: TD.relabel()
sage: TD.blocks()[:3]
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23]]
```

trace(*points*, *min_size=1*, *multiset=True*)

Return the trace of a set of points.

Given an hypergraph \mathcal{H} , the *trace* of a set X of points in \mathcal{H} is the hypergraph whose blocks are all non-empty $S \cap X$ where $S \in \mathcal{H}$.

INPUT:

- `points` – a set of points.
- `min_size` (integer; default 1) – minimum size of the sets to keep. By default all empty sets are discarded, i.e. `min_size=1`.
- `multiset` (boolean; default `True`) – whether to keep multiple copies of the same set.

Note: This method goes over all sets of `self` before building a new *IncidenceStructure* (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:

A Baer subplane of order 2 (i.e. a Fano plane) in a projective plane of order 4:

```
sage: P4 = designs.projective_plane(4)
sage: F = designs.projective_plane(2)
sage: for x in Subsets(P4.ground_set(),7):
.....:     if P4.trace(x,min_size=2).is_isomorphic(F):
.....:         break
sage: subplane = P4.trace(x,min_size=2); subplane
Incidence structure with 7 points and 7 blocks
```

(continues on next page)

(continued from previous page)

```
sage: subplane.is_isomorphic(F)
True
```

5.1.88 Mutually Orthogonal Latin Squares (MOLS)

The main function of this module is `mutually_orthogonal_latin_squares()` and can be used to generate MOLS (or check that they exist):

```
sage: MOLS = designs.mutually_orthogonal_latin_squares(4,8)
```

For more information on MOLS, see the [Wikipedia entry on MOLS](#). If you are only interested by latin squares, see [latin](#).

The functions defined here are

<code>mutually_orthogonal_latin_squares()</code>	Return a list of Mutually Orthogonal $n \times n$ Latin Squares.
<code>are_mutually_orthogonal_latin_squares()</code>	Check that the list <code>l</code> of matrices in <code>are</code> are MOLS.
<code>latin_square_product()</code>	Return the product of two (or more) latin squares.
<code>MOLS_table()</code>	Prints the MOLS table.

Table of MOLS

Sage can produce a table of MOLS similar to the one from the Handbook of Combinatorial Designs [[DesignHandbook](#)] (available [here](#)).

```
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(600) # long time
  0  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19
-----
0| +oo +oo  1  2  3  4  1  6  7  8  2 10  5 12  4  4 15 16  5 18
20|  4  5  3 22  7 24  4 26  5 28  4 30 31  5  4  5  8 36  4  5

Functions

`sage.combinat.designs.latin_squares.MOLS_table`(*start*, *stop=None*, *compare=False*, *width=None*)
Prints the MOLS table that Sage can produce.

INPUT:

- *start*, *stop* (integers) – print the table of MOLS for value of n such that $\text{start} \leq n < \text{stop}$. If only one integer is given as input, it is interpreted as the value of *stop* with *start*=0 (same behaviour as `range`).
- *compare* (boolean) – if sets to `True` the MOLS displays with `+` and `-` entries its difference with the table from the Handbook of Combinatorial Designs (2ed).
- *width* (integer) – the width of each column of the table. By default, it is computed from range of values determined by the parameters *start* and *stop*.

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(100)
  0  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19
-----

```

`sage.combinat.designs.latin_squares.are_mutually_orthogonal_latin_squares(l, verbose=False)`
 Check whether the list of matrices in `l` form mutually orthogonal latin squares.

INPUT:

- `verbose` - if `True` then print why the list of matrices provided are not mutually orthogonal latin squares

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
→squares
sage: m1 = matrix([[0,1,2],[2,0,1],[1,2,0]])
sage: m2 = matrix([[0,1,2],[1,2,0],[2,0,1]])
sage: m3 = matrix([[0,1,2],[2,0,1],[1,2,0]])
sage: are_mutually_orthogonal_latin_squares([m1,m2])
True
sage: are_mutually_orthogonal_latin_squares([m1,m3])
False
sage: are_mutually_orthogonal_latin_squares([m2,m3])
True
sage: are_mutually_orthogonal_latin_squares([m1,m2,m3], verbose=True)
Squares 0 and 2 are not orthogonal
False

sage: m = designs.mutually_orthogonal_latin_squares(7,8)
sage: are_mutually_orthogonal_latin_squares(m)
True
```

`sage.combinat.designs.latin_squares.latin_square_product(M, N, *others)`
 Return the product of two (or more) latin squares.

Given two Latin Squares M, N of respective sizes m, n , the direct product $M \times N$ of size mn is defined by $(M \times N)((i_1, i_2), (j_1, j_2)) = (M(i_1, j_1), N(i_2, j_2))$ where $i_1, j_1 \in [m], i_2, j_2 \in [n]$

Each pair of values $(i, j) \in [m] \times [n]$ is then relabeled to $in + j$.

This is Lemma 6.25 of [Stinson2004].

INPUT:

An arbitrary number of latin squares (greater than 2).

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import latin_square_product
sage: m=designs.mutually_orthogonal_latin_squares(3,4)[0]
sage: latin_square_product(m,m,m)
64 x 64 sparse matrix over Integer Ring (use the '.str()' method to see the entries)
```

`sage.combinat.designs.latin_squares.mutually_orthogonal_latin_squares(k, n, partitions=False, check=True)`

Return k Mutually Orthogonal $n \times n$ Latin Squares (MOLS).

For more information on Mutually Orthogonal Latin Squares, see [latin_squares](#).

INPUT:

- `k` (integer) – number of MOLS. If `k=None` it is set to the largest value available.
- `n` (integer) – size of the latin square.

- `partitions` (boolean) – a Latin Square can be seen as 3 partitions of the n^2 cells of the array into n sets of size n , respectively:
 - The partition of rows
 - The partition of columns
 - The partition of number (cells numbered with 0, cells numbered with 1, ...)

These partitions have the additional property that any two sets from different partitions intersect on exactly one element.

When `partitions` is set to `True`, this function returns a list of $k + 2$ partitions satisfying this intersection property instead of the $k + 2$ MOLS (though the data is exactly the same in both cases).

- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

EXAMPLES:

```
sage: designs.mutually_orthogonal_latin_squares(4,5)
[
[0 2 4 1 3] [0 3 1 4 2] [0 4 3 2 1] [0 1 2 3 4]
[4 1 3 0 2] [3 1 4 2 0] [2 1 0 4 3] [4 0 1 2 3]
[3 0 2 4 1] [1 4 2 0 3] [4 3 2 1 0] [3 4 0 1 2]
[2 4 1 3 0] [4 2 0 3 1] [1 0 4 3 2] [2 3 4 0 1]
[1 3 0 2 4], [2 0 3 1 4], [3 2 1 0 4], [1 2 3 4 0]
]

sage: designs.mutually_orthogonal_latin_squares(3,7)
[
[0 2 4 6 1 3 5] [0 3 6 2 5 1 4] [0 4 1 5 2 6 3]
[6 1 3 5 0 2 4] [5 1 4 0 3 6 2] [4 1 5 2 6 3 0]
[5 0 2 4 6 1 3] [3 6 2 5 1 4 0] [1 5 2 6 3 0 4]
[4 6 1 3 5 0 2] [1 4 0 3 6 2 5] [5 2 6 3 0 4 1]
[3 5 0 2 4 6 1] [6 2 5 1 4 0 3] [2 6 3 0 4 1 5]
[2 4 6 1 3 5 0] [4 0 3 6 2 5 1] [6 3 0 4 1 5 2]
[1 3 5 0 2 4 6], [2 5 1 4 0 3 6], [3 0 4 1 5 2 6]
]

sage: designs.mutually_orthogonal_latin_squares(2,5,partitions=True)
[[[0, 1, 2, 3, 4],
  [5, 6, 7, 8, 9],
  [10, 11, 12, 13, 14],

 [3, 7, 11, 15, 24]]]
```

What is the maximum number of MOLS of size 8 that Sage knows how to build?:

```
sage: designs.orthogonal_arrays.largest_available_k(8)-2
7
```

If you only want to know if Sage is able to build a given set of MOLS, query the `orthogonal_arrays.*` functions:

```
sage: designs.orthogonal_arrays.is_available(5+2, 5) # 5 MOLS of order 5
False
sage: designs.orthogonal_arrays.is_available(4+2,6) # 4 MOLS of order 6
False
```

Sage, however, is not able to prove that the second MOLS do not exist:

```
sage: designs.orthogonal_arrays.exists(4+2,6) # 4 MOLS of order 6
Unknown
```

If you ask for such a MOLS then you will respectively get an informative `EmptySetError` or `NotImplementedError`:

```
sage: designs.mutually_orthogonal_latin_squares(5, 5)
Traceback (most recent call last):
...
EmptySetError: there exist at most n-1 MOLS of size n if n>=2
sage: designs.mutually_orthogonal_latin_squares(4,6)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build 4 MOLS of order 6
```

5.1.89 Orthogonal arrays (OA)

This module gathers some construction related to orthogonal arrays (or transversal designs). One can build an $OA(k, n)$ (or check that it can be built) from the Sage console with `designs.orthogonal_arrays.build`:

```
sage: OA = designs.orthogonal_arrays.build(4,8)
```

See also the modules `orthogonal_arrays_build_recursive` or `orthogonal_arrays_find_recursive` for recursive constructions.

This module defines the following functions:

<code>orthogonal_array()</code>	Return an orthogonal array of parameters k, n, t .
<code>transversal_design()</code>	Return a transversal design of parameters k, n .
<code>incomplete_orthogonal_array()</code>	Return an $OA(k, n) - \sum_{1 < i < x} OA(k, s_i)$.

<code>is_transversal_design()</code>	Check that a given set of blocks B is a transversal design.
<code>is_orthogonal_array()</code>	Check that the integer matrix OA is an $OA(k, n, t)$.
<code>wilson_construction()</code>	Return a $OA(k, rm+u)$ from a truncated $OA(k+s, r)$ by Wilson's construction.
<code>TD_product()</code>	Return the product of two transversal designs.
<code>OA_find_disjoint_blocks()</code>	Return x disjoint blocks contained in a given $OA(k, n)$.
<code>OA_relabel()</code>	Return a relabelled version of the OA.
<code>OA_from_quasi_difference_matrix()</code>	Return an Orthogonal Array from a Quasi-Difference matrix
<code>OA_from_Vmt()</code>	Return an Orthogonal Array from a $V(m, t)$
<code>OA_from_PBD()</code>	Return an $OA(k, n)$ from a PBD
<code>OA_n_times_2_pow_c_from_matrix()</code>	Return an $OA(k, G \cdot 2^c)$ from a constrained $(G, k-1, 2)$ -difference matrix.
<code>OA_from_wider_OA()</code>	Return the first k columns of OA .
<code>QDM_from_Vmt()</code>	Return a QDM a $V(m, t)$

– [CD1996]

Functions

class `sage.combinat.designs.orthogonal_arrays.OAMainFunctions(*args, **kwargs)`

Bases: object

Functions related to orthogonal arrays.

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

For more information on orthogonal arrays, see [Wikipedia article Orthogonal_array](#).

From here you have access to:

- `build(k, n, t=2)`: return an orthogonal array with the given parameters.
- `is_available(k, n, t=2)`: answer whether there is a construction available in Sage for a given set of parameters.
- `exists(k, n, t=2)`: answer whether an orthogonal array with these parameters exist.
- `largest_available_k(n, t=2)`: return the largest integer k such that Sage knows how to build an $OA(k, n)$.
- `explain_construction(k, n, t=2)`: return a string that explains the construction that Sage uses to build an $OA(k, n)$.

EXAMPLES:

```
sage: designs.orthogonal_arrays.build(3,2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]

sage: designs.orthogonal_arrays.build(5,5)
[[0, 0, 0, 0, 0], [0, 1, 2, 3, 4], [0, 2, 4, 1, 3],
 [0, 3, 1, 4, 2], [0, 4, 3, 2, 1], [1, 0, 4, 3, 2],
 [1, 1, 1, 1, 1], [1, 2, 3, 4, 0], [1, 3, 0, 2, 4],
 [1, 4, 2, 0, 3], [2, 0, 3, 1, 4], [2, 1, 0, 4, 3],
 [2, 2, 2, 2, 2], [2, 3, 4, 0, 1], [2, 4, 1, 3, 0],
 [3, 0, 2, 4, 1], [3, 1, 4, 2, 0], [3, 2, 1, 0, 4],
 [3, 3, 3, 3, 3], [3, 4, 0, 1, 2], [4, 0, 1, 2, 3],
```

(continues on next page)

(continued from previous page)

```
[4, 1, 3, 0, 2], [4, 2, 0, 3, 1], [4, 3, 2, 1, 0],
[4, 4, 4, 4, 4]]
```

What is the largest value of k for which Sage knows how to compute a $OA(k, 14, 2)$?:

```
sage: designs.orthogonal_arrays.largest_available_k(14)
6
```

If you ask for an orthogonal array that does not exist, then you will either obtain an `EmptySetError` (if it knows that such an orthogonal array does not exist) or a `NotImplementedError`:

```
sage: designs.orthogonal_arrays.build(4,2)
Traceback (most recent call last):
...
EmptySetError: There exists no OA(4,2) as k(=4)>n+t-1=3
sage: designs.orthogonal_arrays.build(12,20)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build an OA(12,20)!
```

static build($k, n, t=2, resolvable=False$)

Return an $OA(k, n)$ of strength t

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

For more information on orthogonal arrays, see [Wikipedia article Orthogonal_array](#).

INPUT:

- k, n, t (integers) – parameters of the orthogonal array.
- `resolvable` (boolean) – set to `True` if you want the design to be resolvable. The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc ... Set to `False` by default.

EXAMPLES:

```
sage: designs.orthogonal_arrays.build(3,3,resolvable=True) # indirect doctest
[[0, 0, 0],
 [1, 2, 1],
 [2, 1, 2],
 [0, 2, 2],
 [1, 1, 0],
 [2, 0, 1],
 [0, 1, 1],
 [1, 0, 2],
 [2, 2, 0]]
sage: OA_7_50 = designs.orthogonal_arrays.build(7,50) # indirect doctest
```

static exists($k, n, t=2$)

Return the existence status of an $OA(k, n)$

INPUT:

- k, n, t (integers) – parameters of the orthogonal array.

Warning: The function does not only return booleans, but True, False, or Unknown.

See also:

`is_available()`

EXAMPLES:

```
sage: designs.orthogonal_arrays.exists(3,6) # indirect doctest
True
sage: designs.orthogonal_arrays.exists(4,6) # indirect doctest
Unknown
sage: designs.orthogonal_arrays.exists(7,6) # indirect doctest
False
```

static explain_construction($k, n, t=2$)

Return a string describing how to builds an $OA(k, n)$

INPUT:

- k, n, t (integers) – parameters of the orthogonal array.

EXAMPLES:

```
sage: designs.orthogonal_arrays.explain_construction(9,565)
"Wilson's construction n=23.24+13 with master design OA(9+1,23)"
sage: designs.orthogonal_arrays.explain_construction(10,154)
'the database contains a (137,10;1,0;17)-quasi difference matrix'
```

static is_available($k, n, t=2$)

Return whether Sage can build an $OA(k, n)$.

INPUT:

- k, n, t (integers) – parameters of the orthogonal array.

See also:

`exists()`

EXAMPLES:

```
sage: designs.orthogonal_arrays.is_available(3,6) # indirect doctest
True
sage: designs.orthogonal_arrays.is_available(4,6) # indirect doctest
False
```

static largest_available_k($n, t=2$)

Return the largest k such that Sage can build an $OA(k, n)$.

INPUT:

- n (integer)
- t – (integer; default: 2) – strength of the array

EXAMPLES:

```

sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0

```

```

sage.combinat.designs.orthogonal_arrays.OA_find_disjoint_blocks(OA, k, n, x, solver,
                                                                integrality_tolerance)

```

Return x disjoint blocks contained in a given $OA(k, n)$.

x blocks of an OA are said to be disjoint if they all have different values for a every given index, i.e. if they correspond to disjoint blocks in the TD associated with the OA .

INPUT:

- OA – an orthogonal array
- k, n, x (integers)
- $solver$ – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- $integrality_tolerance$ – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

See also:

`incomplete_orthogonal_array()`

EXAMPLES:

```

sage: from sage.combinat.designs.orthogonal_arrays import OA_find_disjoint_blocks
sage: k=3;n=4;x=3
sage: Bs = OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,x)
sage: assert len(Bs) == x
sage: for i in range(k):
....:     assert len(set([B[i] for B in Bs])) == x
sage: OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,5)
Traceback (most recent call last):
...
ValueError: There does not exist 5 disjoint blocks in this OA(3,4)

```

```

sage.combinat.designs.orthogonal_arrays.OA_from_PBD(k, n, PBD, check=True)

```

Return an $OA(k, n)$ from a PBD

Construction

Let \mathcal{B} be a $(n, K, 1)$ -PBD. If there exists for every $i \in K$ a $TD(k, i) - i \times TD(k, 1)$ (i.e. if there exist k idempotent MOLS), then one can obtain a $OA(k, n)$ by concatenating:

- A $TD(k, i) - i \times TD(k, 1)$ defined over the elements of B for every $B \in \mathcal{B}$.
- The rows (i, \dots, i) of length k for every $i \in [n]$.

Note: This function raises an exception when Sage is unable to build the necessary designs.

INPUT:

- k, n (integers)
- PBD – a PBD on $0, \dots, n - 1$.

EXAMPLES:

We start from the example VI.1.2 from the [DesignHandbook] to build an $OA(3, 10)$:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_from_PBD
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: pbd = [[0,1,2,3],[0,4,5,6],[0,7,8,9],[1,4,7],[1,5,8],
.....: [1,6,9],[2,4,9],[2,5,7],[2,6,8],[3,4,8],[3,5,9],[3,6,7]]
sage: oa = OA_from_PBD(3,10,pbd)
sage: is_orthogonal_array(oa, 3, 10)
True
```

But we cannot build an $OA(4, 10)$ for this PBD (although there exists an $OA(4, 10)$):

```
sage: OA_from_PBD(4,10,pbd)
Traceback (most recent call last):
...
EmptySetError: There is no  $OA(n+1,n) - 3.OA(n+1,1)$  as all blocks intersect in a
↪projective plane.
```

Or an $OA(3, 6)$ (as the PBD has 10 points):

```
sage: _ = OA_from_PBD(3,6,pbd)
Traceback (most recent call last):
...
RuntimeError: PBD is not a valid Pairwise Balanced Design on [0,...,5]
```

`sage.combinat.designs.orthogonal_arrays.OA_from_Vmt(m, t, V)`

Return an Orthogonal Array from a $V(m, t)$

INPUT:

- m, t (integers)
- V – the vector $V(m, t)$.

See also:

- `QDM_from_Vmt()`
- `OA_from_quasi_difference_matrix()`

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest
```

`sage.combinat.designs.orthogonal_arrays.OA_from_quasi_difference_matrix`($M, G, \text{add_col}=\text{True}, \text{fill_hole}=\text{True}$)

Return an Orthogonal Array from a Quasi-Difference matrix

Difference Matrices

Let G be a group of order g . A *difference matrix* M is a $g \times k$ matrix with entries from G such that for any $1 \leq i < j < k$ the set $\{d_{li} - d_{lj} : 1 \leq l \leq g\}$ is equal to G .

By concatenating the g matrices $M + x$ (where $x \in G$), one obtains a matrix of size $g^2 \times k$ which is also an $OA(k, g)$.

Quasi-difference Matrices

A quasi-difference matrix is a difference matrix with missing entries. The construction above can be applied again in this case, where the missing entries in each column of M are replaced by unique values on which G has a trivial action.

This produces an incomplete orthogonal array with a “hole” (i.e. missing rows) of size ‘ u ’ (i.e. the number of missing values per column of M). If there exists an $OA(k, u)$, then adding the rows of this $OA(k, u)$ to the incomplete orthogonal array should lead to an OA...

Formal definition (from the Handbook of Combinatorial Designs [[DesignHandbook](#)])

Let G be an abelian group of order n . A $(n, k; \lambda, \mu; u)$ -quasi-difference matrix (QDM) is a matrix $Q = (q_{ij})$ with $\lambda(n - 1 + 2u) + \mu$ rows and k columns, with each entry either empty or containing an element of G . Each column contains exactly λu entries, and each row contains at most one empty entry. Furthermore, for each $1 \leq i < j \leq k$ the multiset

$$\{q_{li} - q_{lj} : 1 \leq l \leq \lambda(n - 1 + 2u) + \mu, \text{ with } q_{li} \text{ and } q_{lj} \text{ not empty}\}$$

contains every nonzero element of G exactly λ times, and contains 0 exactly μ times.

Construction

If a $(n, k; \lambda, \mu; u)$ -QDM exists and $\mu \leq \lambda$, then an $ITD_\lambda(k, n + u; u)$ exists. Start with a $(n, k; \lambda, \mu; u)$ -QDM A over the group G . Append $\lambda - \mu$ rows of zeroes. Then select u elements $\infty_1, \dots, \infty_u$ not in G , and replace the empty entries, each by one of these infinite symbols, so that ∞_i appears exactly once in each column. Develop the resulting matrix over the group G (leaving infinite symbols fixed), to obtain a $\lambda(n^2 + 2nu) \times k$ matrix T . Then T is an orthogonal array with k columns and index λ , having $n + u$ symbols and one hole of size u .

Adding to T an $OA(k, u)$ with elements $\infty_1, \dots, \infty_u$ yields the $ITD_\lambda(k, n + u; u)$.

For more information, see the Handbook of Combinatorial Designs [[DesignHandbook](#)] or <http://web.cs.du.edu/~petr/milehigh/2013/Colbourn.pdf>.

INPUT:

- M – the difference matrix whose entries belong to G
- G – a group
- `add_col` (boolean) – whether to add a column to the final OA equal to $(x_1, \dots, x_g, x_1, \dots, x_g, \dots)$ where $G = \{x_1, \dots, x_g\}$.
- `fill_hole` (boolean) – whether to return the incomplete orthogonal array, or complete it with the $OA(k, u)$ (default). When `fill_hole` is `None`, no block of the incomplete OA contains more than one value $\geq |G|$.

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,20) # indirect doctest
```

`sage.combinat.designs.orthogonal_arrays.OA_from_wider_OA(OA, k)`

Return the first k columns of OA .

If OA has k columns, this function returns OA immediately.

INPUT:

- OA – an orthogonal array.
- k (integer)

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_from_wider_OA
sage: OA_from_wider_OA(designs.orthogonal_arrays.build(6,20,2),1)[:5]
[(19,), (19,), (19,), (19,), (19,)]
sage: _ = designs.orthogonal_arrays.build(5,46) # indirect doctest
```

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix(k, c, G, A, Y, check=True)`

Return an $OA(k, |G| \cdot 2^c)$ from a constrained $(G, k - 1, 2)$ -difference matrix.

This construction appears in [AC1994] and [Ab1995].

Let G be an additive Abelian group. We denote by H a $GF(2)$ -hyperplane in $GF(2^c)$.

Let A be a $(k - 1) \times 2|G|$ array with entries in $G \times GF(2^c)$ and Y be a vector with $k - 1$ entries in $GF(2^c)$. Let B and C be respectively the part of the array that belong to G and $GF(2^c)$.

The input A and Y must satisfy the following conditions. For any $i \neq j$ and $g \in G$:

- there are exactly two values of s such that $B_{i,s} - B_{j,s} = g$ (i.e. B is a $(G, k - 1, 2)$ -difference matrix),
- let s_1 and s_2 denote the two values of s given above, then exactly one of $C_{i,s_1} - C_{j,s_1}$ and $C_{i,s_2} - C_{j,s_2}$ belongs to the $GF(2)$ -hyperplane $(Y_i - Y_j) \cdot H$ (we implicitly assumed that $Y_i \neq Y_j$).

Under these conditions, it is easy to check that the array whose $k - 1$ rows of length $|G| \cdot 2^c$ indexed by $1 \leq i \leq k - 1$ given by $A_{i,s} + (0, Y_i \cdot v)$ where $1 \leq s \leq 2|G|, v \in H$ is a $(G \times GF(2^c), k - 1, 1)$ -difference matrix.

INPUT:

- k, c (integers) – integers
- G – an additive Abelian group
- A – a matrix with entries in $G \times GF(2^c)$
- Y – a vector with entries in $GF(2^c)$
- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

Note: By convention, a multiplicative generator w of $GF(2^c)^*$ is fixed (inside the function). The hyperplane H is the one spanned by w^0, w^1, \dots, w^{c-1} . The $GF(2^c)$ part of the input matrix A and vector Y are given in the following form: the integer i corresponds to the element w^i and `None` corresponds to 0.

See also:

Several examples use this construction:

- `OA_9_40()`
- `OA_11_80()`

- `OA_15_112()`
- `OA_11_160()`
- `OA_16_176()`
- `OA_16_208()`
- `OA_15_224()`
- `OA_20_352()`
- `OA_20_416()`
- `OA_20_544()`
- `OA_11_640()`
- `OA_15_896()`

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_n_times_2_pow_c_from_
      ↪matrix
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: A = [
.....: [(0, None), (0, None), (0, None), (0, None), (0, None), (0, None), (0, None), (0,
      ↪None), (0, None)],
.....: [(0, None), (1, None), (2, 2), (3, 2), (4, 2), (2, None), (3, None), (4, None),
      ↪(0, 2), (1, 2)],
.....: [(0, None), (2, 5), (4, 5), (1, 2), (3, 6), (3, 4), (0, 0), (2, 1),

```

`sage.combinat.designs.orthogonal_arrays.OA_relabel(OA, k, n, blocks=(), matrix=None)`

Return a relabelled version of the OA.

INPUT:

- OA – an OA, or rather a list of blocks of length k , each of which contains integers from 0 to $n - 1$.

- k, n (integers)
- `blocks` (list of blocks) – relabels the integers of the OA from $[0..n-1]$ into $[0..n-1]$ in such a way that the i blocks from `block` are respectively relabeled as $[n-i, \dots, n-i], \dots, [n-1, \dots, n-1]$. Thus, the blocks from this list are expected to have disjoint values for each coordinate.

If set to the empty list (default) no such relabelling is performed.

- `matrix` – a matrix of dimensions k, n such that if the i th coordinate of a block is x , this x will be relabelled with `matrix[i][x]`. This is not necessarily an integer between 0 and $n-1$, and it is not necessarily an integer either. This is performed *after* the previous relabelling.

If set to `None` (default) no such relabelling is performed.

Note: A `None` coordinate in one block remains a `None` coordinate in the final block.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_relabel
sage: OA = designs.orthogonal_arrays.build(3,2)
sage: OA_relabel(OA,3,2,matrix=[["A","B"],["C","D"],["E","F"]])
[['A', 'C', 'E'], ['A', 'D', 'F'], ['B', 'C', 'F'], ['B', 'D', 'E']]

sage: TD = OA_relabel(OA,3,2,matrix=[[0,1],[2,3],[4,5]]); TD
[[0, 2, 4], [0, 3, 5], [1, 2, 5], [1, 3, 4]]
sage: from sage.combinat.designs.orthogonal_arrays import is_transversal_design
sage: is_transversal_design(TD,3,2)
True
```

Making sure that $[2, 2, 2, 2]$ is a block of $OA(4, 3)$. We do this by relabelling block $[0, 0, 0, 0]$ which belongs to the design:

```
sage: designs.orthogonal_arrays.build(4,3)
[[0, 0, 0, 0], [0, 1, 2, 1], [0, 2, 1, 2], [1, 0, 2, 2], [1, 1, 1, 0], [1, 2, 0, 1],
↪ [2, 0, 1, 1], [2, 1, 0, 2], [2, 2, 2, 0]]
sage: OA_relabel(designs.orthogonal_arrays.build(4,3),4,3,blocks=[[0,0,0,0]])
[[2, 2, 2, 2], [2, 0, 1, 0], [2, 1, 0, 1], [0, 2, 1, 1], [0, 0, 0, 2], [0, 1, 2, 0],
↪ [1, 2, 0, 0], [1, 0, 2, 1], [1, 1, 1, 2]]
```

`sage.combinat.designs.orthogonal_arrays.QDM_from_Vmt(m, t, V)`

Return a QDM from a $V(m, t)$

Definition

Let q be a prime power and let $q = mt + 1$ for m, t integers. Let ω be a primitive element of \mathbf{F}_q . A $V(m, t)$ vector is a vector (a_1, \dots, a_{m+1}) for which, for each $1 \leq k < m$, the differences

$$\{a_{i+k} - a_i : 1 \leq i \leq m+1, i+k \neq m+2\}$$

represent the m cyclotomic classes of \mathbf{F}_{mt+1} (compute subscripts modulo $m+2$). In other words, for fixed k , is $a_{i+k} - a_i = \omega^{mx+\alpha}$ and $a_{j+k} - a_j = \omega^{my+\beta}$ then $\alpha \not\equiv \beta \pmod{m}$

Construction of a quasi-difference matrix from a $V(m, t)$ vector

Starting with a $V(m, t)$ vector (a_1, \dots, a_{m+1}) , form a single row of length $m+2$ whose first entry is empty, and whose remaining entries are (a_1, \dots, a_{m+1}) . Form t rows by multiplying this row by the t th roots, i.e. the powers of ω^m . From each of these t rows, form $m+2$ rows by taking the $m+2$ cyclic shifts of the row. The result is a $(a, m+2; 1, 0; t) - QDM$.

For more information, refer to the Handbook of Combinatorial Designs [DesignHandbook].

INPUT:

- m, t (integers)
- V – the vector $V(m, t)$.

See also:

[OA_from_quasi_difference_matrix\(\)](#)

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest
```

```
sage.combinat.designs.orthogonal_arrays.TD_product(k, TD1, n1, TD2, n2, check=True)
```

Return the product of two transversal designs.

From a transversal design TD_1 of parameters k, n_1 and a transversal design TD_2 of parameters k, n_2 , this function returns a transversal design of parameters k, n where $n = n_1 \times n_2$.

Formally, if the groups of TD_1 are V_1^1, \dots, V_k^1 and the groups of TD_2 are V_1^2, \dots, V_k^2 , the groups of the product design are $V_1^1 \times V_1^2, \dots, V_k^1 \times V_k^2$ and its blocks are the $\{(x_1^1, x_1^2), \dots, (x_k^1, x_k^2)\}$ where $\{x_1^1, \dots, x_k^1\}$ is a block of TD_1 and $\{x_1^2, \dots, x_k^2\}$ is a block of TD_2 .

INPUT:

- TD_1, TD_2 – transversal designs.
- k, n_1, n_2 (integers) – see above.
- $check$ (boolean) – Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

Note: This function uses transversal designs with $V_1 = \{0, \dots, n-1\}, \dots, V_k = \{(k-1)n, \dots, kn-1\}$ both as input and output.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import TD_product
sage: TD1 = designs.transversal_design(6,7)
sage: TD2 = designs.transversal_design(6,12)
sage: TD6_84 = TD_product(6,TD1,7,TD2,12)
```

```
class sage.combinat.designs.orthogonal_arrays.TransversalDesign(blocks, k=None, n=None,
                                                                check=True, **kws)
```

Bases: [sage.combinat.designs.group_divisible_designs.GroupDivisibleDesign](#)

Class for Transversal Designs

INPUT:

- $blocks$ – collection of blocks
- k, n (integers) – parameters of the transversal design. They can be set to `None` (default) in which case their value is determined by the blocks.
- $check$ (boolean) – whether to check that the design is indeed a transversal design with the right parameters. Set to `True` by default.

EXAMPLES:

```
sage: designs.transversal_design(None, 5)
Transversal Design TD(6, 5)
sage: designs.transversal_design(None, 30)
Transversal Design TD(6, 30)
sage: designs.transversal_design(None, 36)
Transversal Design TD(10, 36)
```

```
sage.combinat.designs.orthogonal_arrays.incomplete_orthogonal_array(k, n, holes,
                                                                    resolvable=False,
                                                                    existence=False)
```

Return an $OA(k, n) - \sum_{1 \leq i \leq x} OA(k, s_i)$.

An $OA(k, n) - \sum_{1 \leq i \leq x} OA(k, s_i)$ is an orthogonal array from which have been removed disjoint $OA(k, s_1), \dots, OA(k, s_x)$. If there exist $OA(k, s_1), \dots, OA(k, s_x)$ they can be used to fill the holes and give rise to an $OA(k, n)$.

A very useful particular case (see e.g. the Wilson construction in [wilson_construction\(\)](#)) is when all $s_i = 1$. In that case the incomplete design is a $OA(k, n) - x.OA(k, 1)$. Such design is equivalent to transversal design $TD(k, n)$ from which has been removed x disjoint blocks.

INPUT:

- **k, n** (integers)
- **holes** (list of integers) – respective sizes of the holes to be found.
- **resolvable** (boolean) – set to True if you want the design to be resolvable. The classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc ... Set to False by default.
- **existence** (boolean) – instead of building the design, return:
 - True – meaning that Sage knows how to build the design
 - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see [sage.misc.unknown](#)).
 - False – meaning that the design does not exist.

Note: By convention, the ground set is always $V = \{0, \dots, n - 1\}$.

If all holes have size 1, in the incomplete orthogonal array returned by this function the holes are $\{n - 1, \dots, n - s_1\}^k$, $\{n - s_1 - 1, \dots, n - s_1 - s_2\}^k$, etc.

More generally, if **holes** is equal to u_1, \dots, u_k , the i -th hole is the set of points $\{n - \sum_{j \geq i} u_j, \dots, n - \sum_{j \geq i+1} u_j\}^k$.

[OA_find_disjoint_blocks\(\)](#)

EXAMPLES:

```
sage: IOA = designs.incomplete_orthogonal_array(3, 3, [1, 1, 1])
sage: IOA
[[0, 1, 2], [0, 2, 1], [1, 0, 2], [1, 2, 0], [2, 0, 1], [2, 1, 0]]
sage: missing_blocks = [[0, 0, 0], [1, 1, 1], [2, 2, 2]]
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
```

(continues on next page)

(continued from previous page)

```
sage: is_orthogonal_array(IOA + missing_blocks,3,3,2)
True
```

`sage.combinat.designs.orthogonal_arrays.is_transversal_design(B, k, n, verbose=False)`
 Check that a given set of blocks B is a transversal design.

See `transversal_design()` for a definition.

INPUT:

- B – the list of blocks
- k, n – integers
- verbose (boolean) – whether to display information about what is going wrong.

Note: The transversal design must have $\{0, \dots, kn - 1\}$ as a ground set, partitioned as k sets of size n : $\{0, \dots, k - 1\} \sqcup \{k, \dots, 2k - 1\} \sqcup \dots \sqcup \{k(n - 1), \dots, kn - 1\}$.

EXAMPLES:

```
sage: TD = designs.transversal_design(5, 5, check=True) # indirect doctest
sage: from sage.combinat.designs.orthogonal_arrays import is_transversal_design
sage: is_transversal_design(TD, 5, 5)
True
sage: is_transversal_design(TD, 4, 4)
False
```

`sage.combinat.designs.orthogonal_arrays.largest_available_k(n, t=2)`
 Return the largest k such that Sage can build an $OA(k, n)$.

INPUT:

- n (integer)
- t – (integer; default: 2) – strength of the array

EXAMPLES:

```
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

```
sage.combinat.designs.orthogonal_arrays.orthogonal_array(k, n, t=2, resolvable=False, check=True,
                                                         existence=False,
                                                         explain_construction=False)
```

Return an orthogonal array of parameters k, n, t .

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

An orthogonal array is said to be *resolvable* if it corresponds to a resolvable transversal design (see [sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable\(\)](#)).

For more information on orthogonal arrays, see [Wikipedia article Orthogonal_array](#).

INPUT:

- **k** – (integer) number of columns. If **k=None** it is set to the largest value available.
- **n** – (integer) number of symbols
- **t** – (integer; default: 2) – strength of the array
- **resolvable** (boolean) – set to **True** if you want the design to be resolvable. The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc ... Set to **False** by default.
- **check** – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to **True** by default.
- **existence** (boolean) – instead of building the design, return:
 - **True** – meaning that Sage knows how to build the design
 - **Unknown** – meaning that Sage does not know how to build the design, but that the design may exist (see [sage.misc.unknown](#)).
 - **False** – meaning that the design does not exist.

Note: When **k=None** and **existence=True** the function returns an integer, i.e. the largest k such that we can build a $OA(k, n)$.

- **explain_construction** (boolean) – return a string describing the construction.

OUTPUT:

The kind of output depends on the input:

- if **existence=False** (the default) then the output is a list of lists that represent an orthogonal array with parameters **k** and **n**
- if **existence=True** and **k** is an integer, then the function returns a troolean: either **True**, **Unknown** or **False**
- if **existence=True** and **k=None** then the output is the largest value of **k** for which Sage knows how to compute a $TD(k, n)$.

Note: This method implements theorems from [\[Stinson2004\]](#). See the code's documentation for details.

See also:

When $t = 2$ an orthogonal array is also a transversal design (see [transversal_design\(\)](#)) and a family of mutually orthogonal latin squares (see [mutually_orthogonal_latin_squares\(\)](#)).

```
sage.combinat.designs.orthogonal_arrays.transversal_design(k, n, resolvable=False, check=True,
                                                           existence=False)
```

Return a transversal design of parameters k, n .

A transversal design of parameters k, n is a collection \mathcal{S} of subsets of $V = V_1 \cup \dots \cup V_k$ (where the groups V_i are disjoint and have cardinality n) such that:

- Any $S \in \mathcal{S}$ has cardinality k and intersects each group on exactly one element.
- Any two elements from distinct groups are contained in exactly one element of \mathcal{S} .

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

For more information on transversal designs, see <http://mathworld.wolfram.com/TransversalDesign.html>.

INPUT:

- n, k – integers. If k is `None` it is set to the largest value available.
- `resolvable` (boolean) – set to `True` if you want the design to be resolvable (see [sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable\(\)](#)). The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc ... Set to `False` by default.
- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.
- `existence` (boolean) – instead of building the design, return:
 - `True` – meaning that Sage knows how to build the design
 - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see [sage.misc.unknown](#)).
 - `False` – meaning that the design does not exist.

Note: When `k=None` and `existence=True` the function returns an integer, i.e. the largest k such that we can build a $TD(k, n)$.

OUTPUT:

The kind of output depends on the input:

- if `existence=False` (the default) then the output is a list of lists that represent a $TD(k, n)$ with $V_1 = \{0, \dots, n-1\}, \dots, V_k = \{(k-1)n, \dots, kn-1\}$
- if `existence=True` and k is an integer, then the function returns a troolean: either `True`, `Unknown` or `False`
- if `existence=True` and `k=None` then the output is the largest value of k for which Sage knows how to compute a $TD(k, n)$.

See also:

[orthogonal_array\(\)](#) – a transversal design $TD(k, n)$ is equivalent to an orthogonal array $OA(k, n, 2)$.

EXAMPLES:

```

sage: TD = designs.transversal_design(5,5); TD
Transversal Design TD(5,5)
sage: TD.blocks()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23],
 [0, 8, 11, 19, 22], [0, 9, 13, 17, 21], [1, 5, 14, 18, 22],
 [1, 6, 11, 16, 21], [1, 7, 13, 19, 20], [1, 8, 10, 17, 24],
 [1, 9, 12, 15, 23], [2, 5, 13, 16, 24], [2, 6, 10, 19, 23],
 [2, 7, 12, 17, 22], [2, 8, 14, 15, 21], [2, 9, 11, 18, 20],
 [3, 5, 12, 19, 21], [3, 6, 14, 17, 20], [3, 7, 11, 15, 24],
 [3, 8, 13, 18, 23], [3, 9, 10, 16, 22], [4, 5, 11, 17, 23],
 [4, 6, 13, 15, 22], [4, 7, 10, 18, 21], [4, 8, 12, 16, 20],
 [4, 9, 14, 19, 24]]

```

Some examples of the maximal number of transversal Sage is able to build:

```

sage: TD_4_10 = designs.transversal_design(4,10)
sage: designs.transversal_design(5,10,existence=True)
Unknown

```

For prime powers, there is an explicit construction which gives a $TD(n+1, n)$:

```

sage: designs.transversal_design(4, 3, existence=True)
True
sage: designs.transversal_design(674, 673, existence=True)
True

```

For other values of n it depends:

```

sage: designs.transversal_design(7, 6, existence=True)
False
sage: designs.transversal_design(4, 6, existence=True)
Unknown
sage: designs.transversal_design(3, 6, existence=True)
True

sage: designs.transversal_design(11, 10, existence=True)
False
sage: designs.transversal_design(4, 10, existence=True)
True
sage: designs.transversal_design(5, 10, existence=True)
Unknown

sage: designs.transversal_design(7, 20, existence=True)
Unknown
sage: designs.transversal_design(6, 12, existence=True)
True
sage: designs.transversal_design(7, 12, existence=True)
True
sage: designs.transversal_design(8, 12, existence=True)
Unknown

sage: designs.transversal_design(6, 20, existence = True)
True

```

(continues on next page)

(continued from previous page)

```
sage: designs.transversal_design(7, 20, existence = True)
Unknown
```

If you ask for a transversal design that Sage is not able to build then an `EmptySetError` or a `NotImplementedError` is raised:

```
sage: designs.transversal_design(47, 100)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build a TD(47,100)!
sage: designs.transversal_design(55, 54)
Traceback (most recent call last):
...
EmptySetError: There exists no TD(55,54)!
```

Those two errors correspond respectively to the cases where Sage answer `Unknown` or `False` when the parameter `existence` is set to `True`:

```
sage: designs.transversal_design(47, 100, existence=True)
Unknown
sage: designs.transversal_design(55, 54, existence=True)
False
```

If for a given n you want to know the largest k for which Sage is able to build a $TD(k, n)$ just call the function with k set to `None` and `existence` set to `True` as follows:

```
sage: designs.transversal_design(None, 6, existence=True)
3
sage: designs.transversal_design(None, 20, existence=True)
6
sage: designs.transversal_design(None, 30, existence=True)
6
sage: designs.transversal_design(None, 120, existence=True)
9
```

`sage.combinat.designs.orthogonal_arrays.wilson_construction(OA, k, r, m, u, check=True, explain_construction=False)`

Returns a $OA(k, rm + \sum_i u_i)$ from a truncated $OA(k + s, r)$ by Wilson's construction.

Simple form:

Let OA be a truncated $OA(k + s, r)$ with s truncated columns of sizes u_1, \dots, u_s , whose blocks have sizes in $\{k + b_1, \dots, k + b_t\}$. If there exist:

- An $OA(k, m + b_i) - b_i \cdot OA(k, 1)$ for every $1 \leq i \leq t$
- An $OA(k, u_i)$ for every $1 \leq i \leq s$

Then there exists an $OA(k, rm + \sum u_i)$. The construction is a generalization of Lemma 3.16 in [HananiBIBD].

Brouwer-Van Rees form:

Let OA be a truncated $OA(k + s, r)$ with s truncated columns of sizes u_1, \dots, u_s . Let the set H_i of the u_i points of column $k + i$ be partitioned into $\sum_j H_{ij}$. Let m_{ij} be integers such that:

- For $0 \leq i < l$ there exists an $OA(k, \sum_j m_{ij} |H_{ij}|)$
- For any block $B \in OA$ intersecting the sets $H_{ij(i)}$ there exists an $OA(k, m + \sum_i m_{ij}) - \sum_i OA(k, m_{ij(j)})$.

Then there exists an $OA(k, rm + \sum_{i,j} m_{ij})$. This construction appears in [BvR1982].

INPUT:

- **OA** – an incomplete orthogonal array with $k + s$ columns. The elements of a column of size c must belong to $\{0, \dots, c\}$. The missing entries of a block are represented by None values. If OA=None, it is defined as a truncated orthogonal arrays with $k + s$ columns.
- **k, r, m** (integers)
- **u** (list) – two cases depending on the form to use:
 - Simple form: a list of length s such that column $k+i$ has size $u[i]$. The untruncated points of column $k+i$ are assumed to be $[0, \dots, u[i]-1]$.
 - Brouwer-Van Rees form: a list of length s such that $u[i]$ is the list of pairs $(m_{i0}, |H_{i0}|), \dots, (m_{ip_i}, |H_{ip_i}|)$. The untruncated points of column $k+i$ are assumed to be $[0, \dots, u_i - 1]$ where $u_i = \sum_j |H_{ip_i}|$. Besides, the first $|H_{i0}|$ points represent H_{i0} , the next $|H_{i1}|$ points represent H_{i1} , etc...
- **explain_construction** (boolean) – return a string describing the construction.
- **check** (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

sage: from sage.combinat.designs.orthogonal_arrays import wilson_construction
```

(continues on next page)

(continued from previous page)

```

sage: OA = designs.orthogonal_arrays.build(6,11)
sage: OA = [[x if (i<5 or x<5) else None for i,x in enumerate(R)] for R in OA]
sage: OAb = wilson_construction(OA,5,11,21,[[5,5]])
sage: is_orthogonal_array(OAb,5,256)
True

```

5.1.90 Orthogonal arrays (build recursive constructions)

This module implements several constructions of *Orthogonal Arrays*. As their input can be complex, they all have a counterpart in the *orthogonal_arrays_find_recursive* module that automatically computes it.

All these constructions are automatically queried when the *orthogonal_array()* function is called.

<i>construction_3_3()</i>	Return an $OA(k, nm + i)$.
<i>construction_3_4()</i>	Return a $OA(k, nm + rs)$.
<i>construction_3_5()</i>	Return an $OA(k, nm + r + s + t)$.
<i>construction_3_6()</i>	Return a $OA(k, nm + i)$.
<i>construction_q_x()</i>	Return an $OA(k, (q - 1) * (q - x) + x + 2)$ using the $q - x$ construction.
<i>OA_and_oval()</i>	Return a $OA(q + 1, q)$ whose blocks contains ≤ 2 zeroes in the last q columns.
<i>thwart_lemma_3_5()</i>	Returns an $OA(k, nm + a + b + c + d)$.
<i>thwart_lemma_4_1()</i>	Returns an $OA(k, nm + 4(n - 2))$.
<i>three_factor_product()</i>	Returns an $OA(k + 1, n_1 n_2 n_3)$.
<i>brouwer_separable_design()</i>	Returns a $OA(k, t(q^2 + q + 1) + x)$ using Brouwer's result on separable designs.

Functions

`sage.combinat.designs.orthogonal_arrays_build_recursive.OA_and_oval(q, solver, integrality_tolerance)`

Return a $OA(q + 1, q)$ whose blocks contains ≤ 2 zeroes in the last q columns.

This OA is build from a projective plane of order q , in which there exists an oval O of size $q + 1$ (i.e. a set of $q + 1$ points no three of which are [colinear/contained in a common set of the projective plane]).

Removing an element $x \in O$ and all sets that contain it, we obtain a $TD(q + 1, q)$ in which O intersects all columns except one. As O is an oval, no block of the TD intersects it more than twice.

INPUT:

- *q* – a prime power
- *solver* – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- *integrality_tolerance* – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

Note: This function is called by `construction_3_6()`, an implementation of Construction 3.6 from [AC07].

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import OA_and_
↪oval
sage: _ = OA_and_oval
```

```
sage.combinat.designs.orthogonal_arrays_build_recursive.brouwer_separable_design(k, t, q, x,
check=False,
ver-
bose=False,
ex-
plain_construction=False)
```

Returns a $OA(k, t(q^2 + q + 1) + x)$ using Brouwer's result on separable designs.

This method is an implementation of Brouwer's construction presented in [Brouwer80]. It consists in a systematic application of the usual transformation from PBD to OA, applied to a specific PBD.

Baer subplanes

When q is a prime power, the projective plane $PG(2, q^2)$ can be partitioned into subplanes $PG(2, q)$ (called Baer subplanes), giving $PG(2, q^2) = B_1 \cup \dots \cup B_{q^2 - q + 1}$. As a result, every line of the $PG(2, q^2)$ intersects one of the subplane on $q + 1$ points and all others on 1 point.

The OA are built by considering $B_1 \cup \dots \cup B_t$, for a total of $t(q^2 + q + 1)$ points (to which x new points are then added). The blocks of this subdesign belong to two categories:

- The blocks of size t : they come from the lines which intersect a B_i on $q + 1$ points for some $i > t$. The blocks of size t can be partitioned into $q^2 - q + t - 1$ parallel classes according to their associated subplane B_i with $i > t$.
- The blocks of size $q + t$: those blocks form a symmetric design, as every point is incident with $q + t$ of them.

Constructions

In the following, we write $N = t(q^2 + q + 1) + x$. The code is also heavily commented, and will clear any doubt.

- i) $x = 0$: in that case we build a resolvable $OA(k - 1, N)$ that will then be completed into an $OA(k, N)$.
 - Sets of size t)

We take the product of each parallel class with the parallel classes of a resolvable $OA(k - 1, t) - t.OA(k - 1, t)$, yielding new parallel classes.
 - Sets of size $q + t$)

A $N \times (q + t)$ array is built whose rows are the sets of size $q + t$ such that every value appears once per column. For each block of a $OA(k - 1, q + t) - (q + t).OA(k - 1, t)$, the product with the rows of the matrix yields a parallel class.
- ii) $x = q + t$
 - Sets of size t)

Each set of size t gives a $OA(k, t) - t.OA(k, 1)$, except if there is only one parallel class in which case a $OA(k, t)$ is sufficient.
 - Sets of size $q + t$)

A $(N - x) \times (q + t)$ array M is built whose $N - x$ rows are the sets of size $q + t$ such that every value appears once per column. For each of the new $x = q + t$ points p_1, \dots, p_{q+t} we build a matrix M_i obtained from M by adding a column equal to $(p_i, p_i, p_i \dots)$. We add to the OA the product of all rows of the M_i with the block of the $x = q + t$ parallel classes of a resolvable $OA(k, t + q + 1) - (t + q + 1).OA(k, 1)$.

- Set of size x) An $OA(k, x)$
- iii) $x = q^2 - q + 1 - t$
 - Sets of size t)

All blocks of the i -th parallel class are extended with the i -th new point. The blocks are then replaced by a $OA(k, t + 1) - (t + 1).OA(k, 1)$ or, if there is only one parallel class (i.e. $x = 1$) by a $OA(k, t + 1) - OA(k, 1)$.
 - Set of size $q + t$)

They are replaced by $OA(k, q + t) - (q + t).OA(k, 1)$.
 - Set of size x) An $OA(k, x)$
- iv) $x = q^2 + 1$
 - Sets of size t)

All blocks of the i -th parallel class are extended with the i -th new point (the other $x - q - t$ new points are not touched at this step). The blocks are then replaced by a $OA(k, t + 1) - (t + 1).OA(k, 1)$ or, if there is only one parallel class (i.e. $x = 1$) by a $OA(k, t + 1) - OA(k, 1)$.
 - Sets of size $q + t$) Same as for ii)
 - Set of size x) An $OA(k, x)$
- v) $0 < x < q^2 - q + 1 - t$
 - Sets of size t)

The blocks of the first x parallel class are extended with the x new points, and replaced with $OA(k, t + 1) - (t + 1).OA(k, 1)$ or, if $x = 1$, by $OA(k, t + 1) - .OA(k, 1)$

The blocks of the other parallel classes are replaced by $OA(k, t) - t.OA(k, t)$ or, if there is only one class left, by $OA(k, t) - OA(k, t)$
 - Sets of size $q + t$)

They are replaced with $OA(k, q + t) - (q + t).OA(k, 1)$.
 - Set of size x) An $OA(k, x)$
- vi) $t + q < x < q^2 + 1$
 - Sets of size t) Same as in v) with an x equal to $x - q + t$.
 - Sets of size t) Same as in vii)
 - Set of size x) An $OA(k, x)$

INPUT:

- **k, t, q, x** (integers)
- **check** – (boolean) Whether to check that output is correct before returning it. Set to `False` by default.
- **verbose** (boolean) – whether to print some information on the construction and parameters being used.
- **explain_construction** (boolean) – return a string describing the construction.

sage: print(designs.orthogonal_arrays.explain_construction(10,189))
Brouwer's separable design construction with t=9,q=4,x=0 from:
  Andries E. Brouwer,
  A series of separable designs with application to pairwise orthogonal Latin_
↳squares
  Vol. 1, n. 1, pp. 39-41,
  European Journal of Combinatorics, 1980
```

`sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_3(k, n, m, i, ex-plain_construction=False)`

Return an $OA(k, nm + i)$.

This is Wilson's construction with i truncated columns of size 1 and such that a block B_0 of the incomplete OA intersects all truncated columns. As a consequence, all other blocks intersect only 0 or 1 of the last i columns. This allow to consider the block B_0 only up to its first k coordinates and then use a $OA(k, i)$ instead of a $OA(k, m + i) - i.OA(k, 1)$.

This is construction 3.3 from [AC07].

INPUT:

- k, n, m, i (integers) such that the following designs are available: $OA(k, n)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, r)$.
- `explain_construction` (boolean) – return a string describing the construction.

  Journal of Combinatorial Designs, 2007
```

`sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_4(k, n, m, r, s, explain_construction=False)`

Return a $OA(k, nm + rs)$.

This is Wilson's construction applied to a truncated $OA(k + r + 1, n)$ with r columns of size 1 and one column of size s .

The unique elements of the r truncated columns are picked so that a block B_0 contains them all.

- If there exists an $OA(k, m + r + 1)$ the column of size s is truncated in order to intersect B_0 .
- Otherwise, if there exists an $OA(k, m + r)$, the last column must not intersect B_0 .

This is construction 3.4 from [AC07].

INPUT:

- k, n, m, r, s (integers) – we assume that $s < n$ and $1 \leq r, s$
- The following designs must be available: $OA(k, n)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, s)$. Additionally, it requires either a $OA(k, m + r)$ or a $OA(k, m + r + 1)$.
- `explain_construction` (boolean) – return a string describing the construction.

  Journal of Combinatorial Designs, 2007

```

`sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_5(k, n, m, r, s, t, explain_construction=False)`

Return an $OA(k, nm + r + s + t)$.

This is exactly Wilson's construction with three truncated groups except we make sure that all blocks have size $> k$, so we don't need a $OA(k, m + 0)$ but only $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$.

This is construction 3.5 from [AC07].

INPUT:

- k, n, m (integers)
- r, s, t (integers) – sizes of the three truncated groups, such that $r \leq s$ and $(q - r - 1)(q - s) \geq (q - s - 1) * (q - r)$.
- `explain_construction` (boolean) – return a string describing the construction.

The following designs must be available : $OA(k, n)$, $OA(k, r)$, $OA(k, s)$, $OA(k, t)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$.

```

`sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_6(k, n, m, i, explain_construction=False)`

Return a $OA(k, nm + i)$

This is Wilson's construction with r columns of order 1, in which each block intersects at most two truncated columns. Such a design exists when n is a prime power and is returned by `OA_and_oval()`.

INPUT:

- `k, n, m, i` (integers) – n must be a prime power. The following designs must be available: $OA(k + r, q)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, m + 2)$.
- `explain_construction` (boolean) – return a string describing the construction.

This is construction 3.6 from [AC07].

See also:

- `find_construction_3_6()`
- `OA_and_oval()`

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
      ↪ construction_3_6
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import_
      ↪ construction_3_6
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: k=8;n=95
sage: is_orthogonal_array(construction_3_6(*find_construction_3_6(k,n)[1]),k,n,2)
True

sage: print(designs.orthogonal_arrays.explain_construction(10,756))
Construction 3.6 with n=16,m=47,i=4 from:
  Julian R. Abel, Nicholas Cavenagh
  Concerning eight mutually orthogonal latin squares,
  Vol. 15, n.3, pp. 255-261,
  Journal of Combinatorial Designs, 2007
```

`sage.combinat.designs.orthogonal_arrays_build_recursive.construction_q_x(k, q, x, check=True, explain_construction=False)`

Return an $OA(k, (q - 1) * (q - x) + x + 2)$ using the $q - x$ construction.

Let $v = (q - 1) * (q - x) + x + 2$. If there exists a projective plane of order q (e.g. when q is a prime power) and $0 < x < q$ then there exists a $(v - 1, \{q - x - 1, q - x + 1\})$ -GDD of type $(q - 1)^{q-x}(x + 1)^1$ (see [Greig99] or Theorem 2.50, section IV.2.3 of [DesignHandbook]). By adding to the ground set one point contained in all groups of the GDD, one obtains a $(v, \{q - x - 1, q - x + 1, q, x + 2\})$ -PBD with exactly one set of size $x + 2$.

Thus, assuming that we have the following:

- $OA(k, q - x - 1) - (q - x - 1).OA(k, 1)$
- $OA(k, q - x + 1) - (q - x + 1).OA(k, 1)$
- $OA(k, q) - q.OA(k, 1)$
- $OA(k, x + 2)$

Then we can build from the PBD an $OA(k, v)$.

Construction of the PBD (shared by Julian R. Abel):

Start with a resolvable $(q^2, q, 1)$ -BIBD and put the points into a $q \times q$ array so that rows form a parallel class and columns form another.

Now delete:

- All $x(q - 1)$ points from the first x columns and not in the first row
- All $q - x$ points in the last $q - x$ columns AND the first row.

Then add a point p_1 to the blocks that are rows. Add a second point p_2 to the $q - x$ blocks that are columns of size $q - 1$, plus the first row of size $x + 1$.

INPUT:

- **k, q, x** – integers such that $0 < x < q$ and such that Sage can build:
 - A projective plane of order q
 - $OA(k, q - x - 1) - (q - x - 1).OA(k, 1)$
 - $OA(k, q - x + 1) - (q - x + 1).OA(k, 1)$
 - $OA(k, q) - q.OA(k, 1)$
 - $OA(k, x + 2)$
- **check** – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- **explain_construction** (boolean) – return a string describing the construction.

REFERENCES:

`sage.combinat.designs.orthogonal_arrays_build_recursive.three_factor_product(k, n1, n2, n3, check=False, ex-plain_construction=False)`

Returns an $OA(k + 1, n_1 n_2 n_3)$

The three factor product construction from [DukesLing14] does the following:

If $n_1 \leq n_2 \leq n_3$ are such that there exists an $OA(k, n_1)$, $OA(k + 1, n_2)$ and $OA(k + 1, n_3)$, then there exists a $OA(k + 1, n_1 n_2 n_3)$.

It works with a modified product of orthogonal arrays ([Rees93], [Rees00]) which keeps track of parallel classes in the OA (the definition is given for transversal designs).

A subset of blocks in an $TD(k, n)$ is called a c -parallel class if every point is covered exactly c times. A 1-parallel class is a parallel class.

The modified product:

If there exists an $OA(k, n_1)$, and if there exists an $OA(k, n_2)$ whose blocks are partitioned into s n_1 -parallel classes and $n_2 - sn_1$ parallel classes, then there exists an $OA(k, n_1 n_2)$ whose blocks can be partitioned into sn_1^2 parallel classes and $(n_1 n_2 - sn_1^2)/n_1 = n_2 - sn_1$ n_1 -parallel classes.

Proof:

- The product of the blocks of a parallel class with an $OA(k, n_1)$ yields an n_1 -parallel class of an $OA(k, n_1 n_2)$.
- The product of the blocks of a n_1 -parallel class of $OA(k, n_2)$ with an $OA(k, n_1)$ can be done in such a way that it yields $n_1 n_2$ parallel classes of $OA(k, n_1 n_2)$. Those classes cover exactly the pairs that would have been covered with the usual product.

This can be achieved by simple cyclic permutations. Let us build the product of the n_1 -parallel class $\mathcal{P} \subseteq OA(k, n_2)$ with $OA(k, n_1)$: when computing the product of $P \in \mathcal{P}$ with $B^1 \in OA(k, n_1)$ the i -th coordinate should not be (B_i^1, P_i) but $(B_i^1 + r, P_i)$ (the sum is mod n_1) where r is the number of blocks of \mathcal{P} we have already processed whose i -th coordinate is equal to P_i (note that $r < n_1$ as \mathcal{P} is n_1 -parallel).

With these tools, one can obtain the designs promised by the three factors construction applied to k, n_1, n_2, n_3 (thanks to Julian R. Abel's help):

- 1) Let s be the largest integer $\leq n_3/n_1$. Apply the product construction to $OA(k, n_1)$ and a resolvable $OA(k, n_3)$ whose blocks are partitioned into s n_1 -parallel classes and $n_3 - sn_1$ parallel classes. It results in a $OA(k, n_1 n_3)$ partitioned into sn_1^2 parallel classes plus $(n_1 n_3 - sn_1^2)/n_1 = n_3 - sn_1$ n_1 -parallel classes.
- 2) Add $n_3 - n_1$ parallel classes to every n_1 -parallel class to turn them into n_3 -parallel classes. Apply the product construction to this partitioned $OA(k, n_1 n_3)$ with a resolvable $OA(k, n_2)$.
- 3) As $OA(k, n_2)$ is resolvable, the n_2 -parallel classes of $OA(k, n_1 n_2 n_3)$ are actually the union of n_2 parallel classes, thus the $OA(k, n_1 n_2 n_3)$ is resolvable and can be turned into an $OA(k + 1, n_1 n_2 n_3)$

INPUT:

- `k, n1, n2, n3` (integers)
- `check` – (boolean) Whether to check that everything is going smoothly while the design is being built. It is disabled by default, as the constructor of orthogonal arrays checks the final design anyway.
- `explain_construction` (boolean) – return a string describing the construction.

```

REFERENCE:

`sage.combinat.designs.orthogonal_arrays_build_recursive.thwart_lemma_3_5(k, n, m, a, b, c, d=0, complement=False, ex-plain_construction=False)`

Returns an $OA(k, nm + a + b + c + d)$

(When $d=0$)

According to [Thwarts] when n is a prime power and $a + b + c \leq n + 1$, one can build an $OA(k + 3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $\leq k + 2$.

(in order to build a $OA(k, nm + a + b + c)$ the following designs must also exist: $OA(k, a), OA(k, b), OA(k, c), OA(k, m + 0), OA(k, m + 1), OA(k, m + 2)$)

Considering the complement of each truncated column, it is also possible to build an $OA(k + 3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $> k$ whenever $(n - a) + (n - b) + (n - c) \leq n + 1$.

(in order to build a $OA(k, nm + a + b + c)$ the following designs must also exist: $OA(k, a), OA(k, b), OA(k, c), OA(k, m + 1), OA(k, m + 2), OA(k, m + 3)$)

Here is the proof of Lemma 3.5 from [Thwarts] enriched with explanations from Julian R. Abel:

For any prime power n one can build $k - 1$ MOLS by associating to every nonzero $x \in \mathbb{F}_n$ the latin

square:

$$M_x(i, j) = i + x * j \text{ where } i, j \in \mathbb{F}_n$$

In particular $M_1(i, j) = i + j$, whose n columns and lines are indexed by the elements of \mathbb{F}_n . If we order the elements of \mathbb{F}_n as $0, 1, \dots, n-1, x+0, \dots, x+n-1, x^2+0, \dots$ and reorder the columns and lines of M_1 accordingly, the top-left $a \times b$ squares contains at most $a + b - 1$ distinct symbols.

(When $d \neq 0$)

If there exists an $OA(k+3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $\leq k+2$, by truncating arbitrarily another column to size d one obtains an OA with 4 truncated columns whose blocks miss at least one value. Thus, following the proof again one can build an $OA(k+4)$ with four truncated columns of sizes a, b, c, d with blocks of size $\leq k+3$.

(in order to build a $OA(k, nm+a+b+c+d)$ the following designs must also exist: $OA(k, a), OA(k, b), OA(k, c), OA(k, d), OA(k, m+0), OA(k, m+1), OA(k, m+2), OA(k, m+3)$)

As before, this also shows that one can build an $OA(k+4, n)$ with four truncated columns of sizes a, b, c, d in such a way that all blocks have size $> k$ whenever $(n-a) + (n-b) + (n-c) \leq n+1$

(in order to build a $OA(k, nm+a+b+c+d)$ the following designs must also exist: $OA(k, n-a), OA(k, n-b), OA(k, n-c), OA(k, d), OA(k, m+1), OA(k, m+2), OA(k, m+3), OA(k, m+4)$)

INPUT:

- k, n, m, a, b, c, d – integers which must satisfy the constraints above. In particular, $a + b + c \leq n + 1$ must hold. By default, $d = 0$.
- complement (boolean) – whether to complement the sets, i.e. follow the $n-a, n-b, n-c$ variant described above.
- explain_construction (boolean) – return a string describing the construction.

```

REFERENCE:

sage.combinat.designs.orthogonal_arrays_build_recursive.thwart_lemma_4_1(*k, n, m, explain_construction=False*)

Returns an $OA(k, nm + 4(n - 2))$.

Implements Lemma 4.1 from [Thwarts].

If $n \equiv 0, 1 \pmod{3}$ is a prime power, then there exists a truncated $OA(n + 1, n)$ whose last four columns have size $n - 2$ and intersect every block on 1, 3 or 4 values. Consequently, if there exists an $OA(k, m + 1)$, $OA(k, m + 3)$, $OA(k, m + 4)$ and a $OA(k, n - 2)$ then there exists an $OA(k, nm + 4(n - 2))$

Proof: form the transversal design by removing one point of the $AG(2, 3)$ (Affine Geometry) contained in the Desarguesian Projective Plane $PG(2, n)$.

The affine geometry on 9 points contained in the projective geometry $PG(2, n)$ is given explicitly in [OS64] (Thanks to Julian R. Abel for finding the reference!).

INPUT:

- *k, n, m* (integers)
- *explain_construction* (boolean) – return a string describing the construction.

5.1.91 Orthogonal arrays (find recursive constructions)

This module implements several functions to find recursive constructions of *Orthogonal Arrays*.

The main function of this module, i.e. `find_recursive_construction()`, queries all implemented recursive constructions of designs implemented in `orthogonal_arrays_build_recursive` in order to obtain an $OA(k, n)$.

`find_recursive_construction()` is called by the `orthogonal_array()` function.

<code>find_recursive_construction()</code>	Find a recursive construction of an $OA(k, n)$ (calls all others <code>find_*</code> functions)
<code>find_product_decomposition()</code>	Find $n_1 n_2 = n$ to obtain an $OA(k, n)$ by the product construction
<code>find_wilson_decomposition()</code>	Find $rm + x_1 + \dots + x_c = n$ to obtain an $OA(k, n)$ by Wilson's construction with one truncated column.
<code>find_wilson_decomposition_2()</code>	Find $rm + x_1 + x_2 + x_3 = n$ to obtain an $OA(k, n)$ by Wilson's construction with two truncated columns.
<code>find_construction_3_3()</code>	Find a decomposition for construction 3.3 from [AC07].
<code>find_construction_3_4()</code>	Find a decomposition for construction 3.4 from [AC07].
<code>find_construction_3_5()</code>	Find a decomposition for construction 3.5 from [AC07].
<code>find_construction_3_6()</code>	Find a decomposition for construction 3.6 from [AC07].
<code>find_q_x()</code>	Find integers q, x such that the $q - x$ construction yields an $OA(k, n)$.
<code>find_thwart_lemma_3_5()</code>	Find the values on which Lemma 3.5 from [Thwarts] applies.
<code>find_thwart_lemma_4_1()</code>	Find a decomposition for Lemma 4.1 from [Thwarts].
<code>find_three_factor_product()</code>	Find $n_1 n_2 n_3 = n$ to obtain an $OA(k, n)$ by the three-factor product from [DukesLing14]
<code>find_brouwer_separable_design()</code>	Find $t(q^2 + q + 1) + x = n$ to obtain an $OA(k, n)$ by Brouwer's separable design construction.
<code>find_brouwer_van_rees_with_one_truncated_column()</code>	Find $rm + x_1 + \dots + x_c = n$ such that the Brouwer-van Rees constructions yields a $OA(k, n)$.

REFERENCES:

Functions

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_brouwer_separable_design(k, n)`

Find $t(q^2 + q + 1) + x = n$ to obtain an $OA(k, n)$ by Brouwer's separable design construction.

INPUT:

- k, n (integers)

The assumptions made on the parameters t, q, x are explained in the documentation of `brouwer_separable_design()`.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
->brouwer_separable_design
sage: find_brouwer_separable_design(5, 13)[1]
(5, 1, 3, 0)
sage: find_brouwer_separable_design(5, 14)
False
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_brouwer_van_rees_with_one_truncated_column()`

Find $rm + x_1 + \dots + x_c = n$ such that the Brouwer-van Rees constructions yields a $OA(k, n)$.

Let $n = rm + \sum_{1 \leq i \leq c} u_i$ such that $c \leq r$. The generalization of Wilson's construction found by Brouwer and van Rees (with one truncated column) ensures that an $OA(k, n)$ exists if the following designs exist: $OA(k+1, r)$, $OA(k, m)$, $OA(k, \sum_{1 \leq i \leq c} u_i)$, $OA(k, m+x_1) - OA(k, x_1), \dots, OA(k, m+x_c) - OA(k, x_c)$.

For more information, see the documentation of `wilson_construction()`.

INPUT:

- k, n (integers)

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
      ↪ brouwer_van_rees_with_one_truncated_column
sage: find_brouwer_van_rees_with_one_truncated_column(5, 53)[1]
(None, 5, 7, 7, [[(2, 1), (2, 1)]])
sage: find_brouwer_van_rees_with_one_truncated_column(6, 96)[1]
(None, 6, 7, 13, [[(3, 1), (1, 1), (1, 1)]])
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_3(k, n)`
Find a decomposition for construction 3.3 from [AC07]

INPUT:

- k, n (integers)

See also:

`construction_3_3()`

OUTPUT:

A pair $f, args$ such that $f(*args)$ returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
      ↪ construction_3_3
sage: find_construction_3_3(11, 177)[1]
(11, 11, 16, 1)
sage: find_construction_3_3(12, 11)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_4(k, n)`
Find a decomposition for construction 3.4 from [AC07]

INPUT:

- k, n (integers)

See also:

`construction_3_4()`

OUTPUT:

A pair $f, args$ such that $f(*args)$ returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
      ↪ construction_3_4
sage: find_construction_3_4(8, 196)[1]
```

(continues on next page)

(continued from previous page)

```
(8, 25, 7, 12, 9)
sage: find_construction_3_4(9, 24)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_5(k, n)`
Find a decomposition for construction 3.5 from [AC07]

INPUT:

- k, n (integers)

See also:

`construction_3_5()`

OUTPUT:

A pair $f, args$ such that $f(*args)$ returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_5
sage: find_construction_3_5(8, 111)[1]
(8, 13, 6, 9, 11, 13)
sage: find_construction_3_5(9, 24)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_6(k, n)`
Find a decomposition for construction 3.6 from [AC07]

INPUT:

- k, n (integers)

See also:

`construction_3_6()`

OUTPUT:

A pair $f, args$ such that $f(*args)$ returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_6
sage: find_construction_3_6(8, 95)[1]
(8, 13, 7, 4)
sage: find_construction_3_6(8, 98)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_product_decomposition(k, n)`
Find $n_1 n_2 = n$ to obtain an $OA(k, n)$ by the product construction.

If Sage can build a $OA(k, n_1)$ and a $OA(k, n_2)$ such that $n = n_1 \times n_2$ then a $OA(k, n)$ can be built by a product construction (which correspond to Wilson's construction with no truncated column). This function look for a pair of integers (n_1, n_2) with $n_1 \leq n_2$, $n_1 \times n_2 = n$ and such that both an $OA(k, n_1)$ and an $OA(k, n_2)$ are available.

INPUT:

- k, n (integers) – see above.

OUTPUT:

A pair `f, args` such that `f(*args)` is an $OA(k, n)$ or `False` if no product decomposition was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
      ↪product_decomposition
sage: f, args = find_product_decomposition(6, 84)
sage: args
(None, 6, 7, 12, (), False)
sage: _ = f(*args)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_q_x(k, n)`

Find integers q, x such that the $q - x$ construction yields an $OA(k, n)$.

See the documentation of `construction_q_x()` to find out what hypotheses the integers q, x must satisfy.

Warning: For efficiency reasons, this function checks that Sage can build an $OA(k + 1, q - x - 1)$ and an $OA(k + 1, q - x + 1)$, which is stronger than checking that Sage can build a $OA(k, q - x - 1) - (q - x - 1).OA(k, 1)$ and a $OA(k, q - x + 1) - (q - x + 1).OA(k, 1)$. The latter would trigger a lot of independent set computations in `sage.combinat.designs.orthogonal_arrays.incomplete_orthogonal_array()`.

INPUT:

- k, n (integers)

See also:

`construction_q_x()`

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_q_x
sage: find_q_x(10, 9)
False
sage: find_q_x(9, 158)[1]
(9, 16, 6)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_recursive_construction(k, n)`

Find a recursive construction of an $OA(k, n)$ (calls all others `find_*` functions)

This determines whether an $OA(k, n)$ can be built through the following constructions:

- `wilson_construction()`
- `construction_3_3()`
- `construction_3_4()`
- `construction_3_5()`
- `construction_3_6()`
- `construction_q_x()`
- `thwart_lemma_3_5()`
- `thwart_lemma_4_1()`
- `three_factor_product()`

- `brouwer_separable_design()`

INPUT:

- `k, n` (integers)

OUTPUT:

Return a pair `f, args` such that `f(*args)` returns the requested OA if possible, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
      ↪recursive_construction
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: count = 0
sage: for n in range(10,150):
.....:     k = designs.orthogonal_arrays.largest_available_k(n)
.....:     if find_recursive_construction(k,n):
.....:         count = count + 1
.....:         f,args = find_recursive_construction(k,n)
.....:         OA = f(*args)
.....:         assert is_orthogonal_array(OA,k,n,2,verbose=True)
sage: count
56
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_three_factor_product(k, n)`
Find $n_1 n_2 n_3 = n$ to obtain an $OA(k, n)$ by the three-factor product from [DukesLing14]

INPUT:

- `k, n` (integers)

See also:

`three_factor_product()`

OUTPUT:

A pair `f, args` such that `f(*args)` returns the requested OA .

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_three_
      ↪factor_product
sage: find_three_factor_product(10,648)[1]
(9, 8, 9, 9)
sage: find_three_factor_product(10,50)
False
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_thwart_lemma_3_5(k, N)`
Find the values on which Lemma 3.5 from [Thwarts] applies.

OUTPUT:

A pair `(f, args)` such that `f(*args)` returns an $OA(k, n)$ or `False` if the construction is not available.

See also:

`thwart_lemma_3_5()`

EXAMPLES:

```

sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↳thwart_lemma_3_5
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array

sage: f,args = find_thwart_lemma_3_5(7,66)
sage: args
(7, 9, 7, 1, 1, 1, 0, False)
sage: OA = f(*args)
sage: is_orthogonal_array(OA,7,66,2)
True

sage: f,args = find_thwart_lemma_3_5(6,100)
sage: args
(6, 8, 10, 8, 7, 5, 0, True)
sage: OA = f(*args)
sage: is_orthogonal_array(OA,6,100,2)
True

```

Some values from [Thwarts]:

```

sage: kn = ((10,1046), (10,1048), (10,1059), (11,1524),
.....:      (11,2164), (12,3362), (12,3992), (12,3994))
sage: for k,n in kn:
.....:     print("{} {} {}".format(k,n,find_thwart_lemma_3_5(k,n)[1]))
10 1046 (10, 13, 79, 9, 1, 0, 9, False)
10 1048 (10, 13, 79, 9, 1, 0, 11, False)
10 1059 (10, 13, 80, 9, 1, 0, 9, False)
11 1524 (11, 19, 78, 16, 13, 13, 0, True)
11 2164 (11, 27, 78, 23, 19, 16, 0, True)
12 3362 (12, 16, 207, 13, 13, 11, 13, True)
12 3992 (12, 19, 207, 16, 13, 11, 19, True)
12 3994 (12, 19, 207, 16, 13, 13, 19, True)

sage: for k,n in kn: # not_
↳tested -- too long
.....:     assert designs.orthogonal_array(k,n,existence=True) is True # not_
↳tested -- too long

```

`sage.combinat.designs.orthogonal_arrays_find_recursive.find_thwart_lemma_4_1(k, n)`

Find a decomposition for Lemma 4.1 from [Thwarts].

INPUT:

- k, n (integers)

See also:

`thwart_lemma_4_1()`

OUTPUT:

A pair $f, args$ such that $f(*args)$ returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↳ thwart_lemma_4_1
sage: find_thwart_lemma_4_1(10,408)[1]
(10, 13, 28)
sage: find_thwart_lemma_4_1(10,50)
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.find_wilson_decomposition_with_one_truncated_group

Find $rm + u = n$ to obtain an $OA(k, n)$ by Wilson's construction with one truncated column.

This function looks for possible integers m, t, u satisfying that $mt + u = n$ and such that Sage knows how to build a $OA(k, m)$, $OA(k, m + 1)$, $OA(k + 1, t)$ and a $OA(k, u)$.

INPUT:

- k, n (integers) – see above

OUTPUT:

A pair $f, args$ such that $f(*args)$ is an $OA(k, n)$ or False if no decomposition with one truncated block was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↳ wilson_decomposition_with_one_truncated_group
sage: f, args = find_wilson_decomposition_with_one_truncated_group(4,38)
sage: args
(None, 4, 5, 7, (3,), False)
sage: _ = f(*args)

sage: find_wilson_decomposition_with_one_truncated_group(4,20)
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.find_wilson_decomposition_with_two_truncated_group

Find $rm + r_1 + r_2 = n$ to obtain an $OA(k, n)$ by Wilson's construction with two truncated columns.

Look for integers r, m, r_1, r_2 satisfying $n = rm + r_1 + r_2$ and $1 \leq r_1, r_2 < r$ and such that the following designs exist: $OA(k + 2, r)$, $OA(k, r_1)$, $OA(k, r_2)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, m + 2)$.

INPUT:

- k, n (integers) – see above

OUTPUT:

A pair $f, args$ such that $f(*args)$ is an $OA(k, n)$ or False if no decomposition with two truncated blocks was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↳ wilson_decomposition_with_two_truncated_groups
sage: f, args = find_wilson_decomposition_with_two_truncated_groups(5,58)
sage: args
(None, 5, 7, 7, (4, 5), False)
sage: _ = f(*args)
```

`sage.combinat.designs.orthogonal_arrays_find_recursive.int_as_sum(value, S, k_max)`

Return a tuple (s_1, s_2, \dots, s_k) of less than k_{max} elements of S such that $value = s_1 + s_2 + \dots + s_k$. If there is no such tuples then the function returns None.

INPUT:

- value (integer)
- S – a list of integers
- k_max (integer)

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import int_as_sum
sage: D = int_as_sum(21, [5, 12], 100)
sage: for k in range(20, 40):
.....:     print("{} {}".format(k, int_as_sum(k, [5, 12], 100)))
20 (5, 5, 5, 5)
21 None
22 (12, 5, 5)
23 None
24 (12, 12)
25 (5, 5, 5, 5, 5)
26 None
27 (12, 5, 5, 5)
28 None
29 (12, 12, 5)
30 (5, 5, 5, 5, 5, 5)
31 None
32 (12, 5, 5, 5, 5)
33 None
34 (12, 12, 5, 5)
35 (5, 5, 5, 5, 5, 5, 5)
36 (12, 12, 12)
37 (12, 5, 5, 5, 5, 5)
38 None
39 (12, 12, 5, 5, 5)
```

5.1.92 Steiner Quadruple Systems

A Steiner Quadruple System on n points is a family $SQS_n \subset \binom{[n]}{4}$ of 4-sets, such that any set $S \subset [n]$ of size three is a subset of exactly one member of SQS_n .

This module implements Haim Hanani's constructive proof that a Steiner Quadruple System exists if and only if $n \equiv 2, 4 \pmod{6}$. Hanani's proof consists in 6 different constructions that build a large Steiner Quadruple System from a smaller one, and though it does not give a very clear understanding of why it works (to say the least)... it does !

The constructions have been implemented while reading two papers simultaneously, for one of them sometimes provides the informations that the other one does not. The first one is Haim Hanani's original paper [Han1960], and the other one is a paper from Horan and Hurlbert which goes through all constructions [HH2012].

It can be used through the designs object:

```
sage: designs.steiner_quadruple_system(8)
Incidence structure with 8 points and 14 blocks
```

AUTHORS:

- Nathann Cohen (May 2013, while listening to “*Le Blues Du Pauvre Delahaye*”)

Index

This module’s main function is the following:

	<code>steiner_quadruple_system</code>	Return a Steiner Quadruple System on n points
--	---------------------------------------	---

This function redistributes its work among 6 constructions:

Construction 1	<code>two_n()</code>	Return a Steiner Quadruple System on $2n$ points
Construction 2	<code>three_n_minus_two()</code>	Return a Steiner Quadruple System on $3n - 2$ points
Construction 3	<code>three_n_minus_eight()</code>	Return a Steiner Quadruple System on $3n - 8$ points
Construction 4	<code>three_n_minus_four()</code>	Return a Steiner Quadruple System on $3n - 4$ points
Construction 5	<code>four_n_minus_six()</code>	Return a Steiner Quadruple System on $4n - 6$ points
Construction 6	<code>twelve_n_minus_ten()</code>	Return a Steiner Quadruple System on $12n - 10$ points

It also defines two specific Steiner Quadruple Systems that the constructions require, i.e. SQS_{14} and SQS_{38} as well as the systems of pairs $P_\alpha(m)$ and $\bar{P}_\alpha(m)$ (see [Han1960]).

Functions

`sage.combinat.designs.steiner_quadruple_systems.P(alpha, m)`

Return the collection of pairs $P_\alpha(m)$

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import P
sage: P(3,4)
[(0, 5), (2, 7), (4, 1), (6, 3)]
```

`sage.combinat.designs.steiner_quadruple_systems.barP(eps, m)`

Return the collection of pairs $\bar{P}_\alpha(m)$

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP
sage: barP(3,4)
[(0, 4), (3, 5), (1, 2)]
```

`sage.combinat.designs.steiner_quadruple_systems.barP_system(m)`

Return the 1-factorization of K_{2m} $\bar{P}(m)$

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP_system
sage: barP_system(3)
[[ (4, 3), (2, 5) ],
 [ (0, 5), (4, 1) ],
 [ (0, 2), (1, 3) ],
 [ (1, 5), (4, 2), (0, 3) ],
 [ (0, 4), (3, 5), (1, 2) ],
 [ (0, 1), (2, 3), (4, 5) ]]
```

`sage.combinat.designs.steiner_quadruple_systems.four_n_minus_six(B)`

Return a Steiner Quadruple System on $4n - 6$ points.

INPUT:

- B – A Steiner Quadruple System on n points.

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import four_n_minus_six
sage: for n in range(4, 20):
.....:     if (n%6) in [2,4]:
.....:         sqs = designs.steiner_quadruple_system(n)
.....:         if not four_n_minus_six(sqs).is_t_design(3,4*n-6,4,1):
.....:             print("Something is wrong !")
```

`sage.combinat.designs.steiner_quadruple_systems.relabel_system(B)`

Relabels the set so that $\{n - 4, n - 3, n - 2, n - 1\}$ is in B .

INPUT:

- B – a list of 4-uples on $0, \dots, n - 1$.

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import relabel_system
sage: SQS8 = designs.steiner_quadruple_system(8)
sage: relabel_system(SQS8)
Incidence structure with 8 points and 14 blocks
```

`sage.combinat.designs.steiner_quadruple_systems.steiner_quadruple_system(n, check=False)`

Return a Steiner Quadruple System on n points.

INPUT:

- n – an integer such that $n \equiv 2, 4 \pmod{6}$
- `check` (boolean) – whether to check that the system is a Steiner Quadruple System before returning it (*False* by default)

EXAMPLES:

```
sage: sqs4 = designs.steiner_quadruple_system(4)
sage: sqs4
Incidence structure with 4 points and 1 blocks
sage: sqs4.is_t_design(3,4,4,1)
```

(continues on next page)

(continued from previous page)

```
True
sage: sqs8 = designs.steiner_quadruple_system(8)
sage: sqs8
Incidence structure with 8 points and 14 blocks
sage: sqs8.is_t_design(3,8,4,1)
True
```

`sage.combinat.designs.steiner_quadruple_systems.three_n_minus_eight(B)`
Return a Steiner Quadruple System on $3n - 8$ points.

INPUT:

- B – A Steiner Quadruple System on n points.

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪eight
sage: for n in range(4, 30):
.....:     if (n%12) == 2:
.....:         sqs = designs.steiner_quadruple_system(n)
.....:         if not three_n_minus_eight(sqs).is_t_design(3,3*n-8,4,1):
.....:             print("Something is wrong !")
```

`sage.combinat.designs.steiner_quadruple_systems.three_n_minus_four(B)`
Return a Steiner Quadruple System on $3n - 4$ points.

INPUT:

- B – A Steiner Quadruple System on n points where $n \equiv 10 \pmod{12}$.

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_four
sage: for n in range(4, 30):
.....:     if n%12 == 10:
.....:         sqs = designs.steiner_quadruple_system(n)
.....:         if not three_n_minus_four(sqs).is_t_design(3,3*n-4,4,1):
.....:             print("Something is wrong !")
```

`sage.combinat.designs.steiner_quadruple_systems.three_n_minus_two(B)`
Return a Steiner Quadruple System on $3n - 2$ points.

INPUT:

- B – A Steiner Quadruple System on n points.

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_two
sage: for n in range(4, 30):
.....:     if (n%6) in [2,4]:
.....:         sqs = designs.steiner_quadruple_system(n)
.....:         if not three_n_minus_two(sqs).is_t_design(3,3*n-2,4,1):
.....:             print("Something is wrong !")
```

`sage.combinat.designs.steiner_quadruple_systems.twelve_n_minus_ten(B)`

Return a Steiner Quadruple System on $12n - 6$ points.

INPUT:

- B – A Steiner Quadruple System on n points.

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import twelve_n_minus_ten
sage: for n in range(4, 15):
.....:     if (n%6) in [2,4]:
.....:         sqs = designs.steiner_quadruple_system(n)
.....:         if not twelve_n_minus_ten(sqs).is_t_design(3,12*n-10,4,1):
.....:             print("Something is wrong !")
```

`sage.combinat.designs.steiner_quadruple_systems.two_n(B)`

Return a Steiner Quadruple System on $2n$ points.

INPUT:

- B – A Steiner Quadruple System on n points.

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import two_n
sage: for n in range(4, 30):
.....:     if (n%6) in [2,4]:
.....:         sqs = designs.steiner_quadruple_system(n)
.....:         if not two_n(sqs).is_t_design(3,2*n,4,1):
.....:             print("Something is wrong !")
```

5.1.93 Hypergraph isomorphic copy search

This module implements a code for the following problem:

INPUT: two hypergraphs H_1, H_2

OUTPUT: a copy of H_2 in H_1

It is also possible to enumerate all such copies, and to require that such copies be induced copies. More formally:

A copy of H_2 in H_1 is an injection $f : V(H_2) \mapsto V(H_1)$ such that for any set $S_2 \in E(H_2)$ we have $f(S_2) \in E(H_1)$.

It is an *induced* copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{S : S \in E(H_1) \text{ and } S \subseteq f(V(H_2))\}$.

The functions implemented here lists all such injections. In particular, the number of copies of H in itself is equal to $|Aut(H)|$.

The feature is available through `IncidenceStructure.isomorphic_substructures_iterator()`.

Implementation

A hypergraph is stored as a list of edges, each of which is a “dense” bitset over $|V(H_1)|$ points. In particular, two sets of distinct cardinalities require the same memory space. A hypergraph is a C struct with the following fields:

- `n,m (int)` – number of points and edges.
- `limbs (int)` – number of 64-bits blocks per set.
- `set_space (uint64_t *)` – address of the memory used to store the sets.
- `sets (uint64_t **)` – `sets[i]` points toward the `limbs` blocks encoding set i . Note also that `sets[i][limbs]` is equal to the cardinality of `set[i]`, so that `sets` has length $m*(limbs+1)*sizeof(uint64_t)$.
- `names (int *)` – associates an integer ‘name’ to each of the n points.

The operations used on this data structure are:

- `void permute(hypergraph * h, int n1, int n2)` – exchanges points $n1$ and $n2$ in the data structure. Note that their names are also exchanged so that we still know which is which.
- `int induced_hypergraph(hypergraph * h1, int n, hypergraph * tmp1)` – stores in `tmp1` the hypergraph induced by the first n points, i.e. all sets S such that $S \subseteq \{0, \dots, n - 1\}$. The function returns the number of such sets.
- `void trace_hypergraph64(hypergraph * h, int n, hypergraph * tmp)` – stores in `tmp1` the trace of h on the first n points, i.e. all sets of the form $S \cap \{0, \dots, n - 1\}$.

Algorithm

We try all possible assignments of a representant $r_i \in H_1$ for every $i \in H_2$. When we have picked a representant for the first $n <$ points $\{0, \dots, n - 1\} \subsetneq V(H_2)$, we check that:

- The hypergraph induced by the (ordered) list $0, \dots, n - 1$ in H_2 is equal to the one induced by r_0, \dots, r_{n-1} in H_1 .
- If $S \subseteq \{0, \dots, n - 1\}$ is contained in c sets of size k in H_2 , then $\{r_i : i \in S\}$ is contained in $\geq c$ sets of size k in H_1 . This is done by comparing the trace of the hypergraphs while remembering the original size of each set.

As we very often need to build the hypergraph obtained by the trace of the first n points (for all possible n), those hypergraphs are cached. The hypergraphs induced by the same points are handled similarly.

Limitations

Number of points For efficiency reason the implementation assumes that H_2 has ≤ 64 points. Making this work for larger values means that calls to `qsort` have to be replaced by calls to `qsort_r` (i.e. to sort the edges you need to know the number of limbs per edge) and that induces a big slowdown for small cases (~50% when this code was implemented). Also, 64 points for H_2 is already very very big considering the problem at hand. Even $|V(H_1)| > 64$ seems too much.

Vertex ordering The order of vertices in H_2 has a huge influence on the performance of the algorithm. If no set of H_2 contains more that one of the first $k < n$ points, then almost all partial assignments of representants are possible for the first k points (though the degree of the vertices is taken into account). For this reason it is best to pick an ordering such that the first vertices are contained in as many sets as possible together. A heuristic is implemented at `relabel_heuristic()`.

AUTHORS:

- Nathann Cohen (November 2014, written in various airports between Nice and Chennai).

Methods

class sage.combinat.designs.subhypergraph_search.SubHypergraphSearch

Bases: object

relabel_heuristic()

Relabels H_2 in order to make the algorithm faster.

Objective: we try to pick an ordering p_1, \dots, p_k of the points of H_2 that maximizes the number of sets involving the first points in the ordering. One way to formalize the problems indicates that it may be NP-Hard (generalizes the max clique problem for graphs) so we do not try to solve it exactly: we just need a sufficiently good heuristic.

Assuming that the first points are p_1, \dots, p_k , we determine p_{k+1} as the point x such that the number of sets S with $x \in S$ and $S \cap \{p_1, \dots, p_k\} \neq \emptyset$ is maximal. In case of ties, we take a point with maximum degree.

This function is called when an instance of *SubHypergraphSearch* is created.

EXAMPLES:

```
sage: d = designs.projective_plane(3)
sage: d.isomorphic_substructures_iterator(d).relabel_heuristic()
```

5.1.94 Two-graphs

A two-graph on n points is a family $T \subset \binom{[n]}{3}$ of 3-sets, such that any 4-set $S \subset [n]$ of size four contains an even number of elements of T . Any graph $([n], E)$ gives rise to a two-graph $T(E) = \{t \in \binom{[n]}{3} : |\binom{t}{2} \cap E| \text{ odd}\}$, and any two graphs with the same two-graph can be obtained one from the other by *Seidel switching*. This defines an equivalence relation on the graphs on $[n]$, called Seidel switching equivalence. Conversely, given a two-graph T , one can construct a graph Γ in the corresponding Seidel switching class with an isolated vertex w . The graph $\Gamma \setminus w$ is called the *descendant* of T w.r.t. v .

T is called regular if each two-subset of $[n]$ is contained in the same number alpha of triples of T .

This module implements a direct construction of a two-graph from a list of triples, construction of descendant graphs, regularity checking, and other things such as constructing the complement two-graph, cf. [BH2012].

AUTHORS:

- Dima Pasechnik (Aug 2015)

Index

This module's methods are the following:

<code>is_regular_twograph()</code>	tests if <code>self</code> is a regular two-graph, i.e. a 2-design
<code>complement()</code>	returns the complement of <code>self</code>
<code>descendant()</code>	returns the descendant graph at w

This module's functions are the following:

<code>taylor_twograph()</code>	constructs Taylor's two-graph for $U_3(q)$
<code>is_twograph()</code>	checks that the incidence system is a two-graph
<code>twograph_descendant()</code>	returns the descendant graph w.r.t. a given vertex of the two-graph of a given graph

Methods

class sage.combinat.designs.twographs.**TwoGraph**(points=None, blocks=None, incidence_matrix=None, name=None, check=False, copy=True)

Bases: *sage.combinat.designs.incidence_structures.IncidenceStructure*

Two-graphs class.

A two-graph on n points is a 3-uniform hypergraph, i.e. a family $T \subset \binom{[n]}{3}$ of 3-sets, such that any 4-set $S \subset [n]$ of size four contains an even number of elements of T . For more information, see the documentation of the *twographs* module.

complement()

The two-graph which is the complement of `self`

That is, the two-graph consisting exactly of triples not in `self`. Note that this is different from *complement* of the *parent class*.

EXAMPLES:

```
sage: p = graphs.CompleteGraph(8).line_graph().twograph()
sage: pc = p.complement(); pc
Incidence structure with 28 points and 1260 blocks
```

descendant(v)

The descendant *graph* at v

The *switching class of graphs* corresponding to `self` contains a graph D with v its own connected component; removing v from D , one obtains the descendant graph of `self` at v , which is constructed by this method.

INPUT:

- v – an element of `ground_set()`

EXAMPLES:

```
sage: p = graphs.PetersenGraph().twograph().descendant(0)
sage: p.is_strongly_regular(parameters=True)
(9, 4, 1, 2)
```

is_regular_twograph(alpha=False)

Test if the *TwoGraph* is regular, i.e. is a 2-design.

Namely, each pair of elements of `ground_set()` is contained in exactly α triples.

INPUT:

- α – (optional, default is `False`) return the value of α , if possible.

EXAMPLES:

```
sage: p=graphs.PetersenGraph().twograph()
sage: p.is_regular_twograph(alpha=True)
4
sage: p.is_regular_twograph()
True
sage: p=graphs.PathGraph(5).twograph()
sage: p.is_regular_twograph(alpha=True)
False
```

(continues on next page)

(continued from previous page)

```
sage: p.is_regular_twograph()
False
```

`sage.combinat.designs.twographs.is_twograph(T)`

Checks that the incidence system T is a two-graph

INPUT:

- T – an incidence structure

EXAMPLES:

a two-graph from a graph:

```
sage: from sage.combinat.designs.twographs import (is_twograph, TwoGraph)
sage: p=graphs.PetersenGraph().twograph()
sage: is_twograph(p)
True
```

a non-regular 2-uniform hypergraph which is a two-graph:

```
sage: is_twograph(TwoGraph([[1,2,3],[1,2,4]]))
True
```

`sage.combinat.designs.twographs.taylor_twograph(q)`

constructing Taylor's two-graph for $U_3(q)$, q odd prime power

The Taylor's two-graph T has the $q^3 + 1$ points of the projective plane over F_{q^2} singular w.r.t. the non-degenerate Hermitian form S preserved by $U_3(q)$ as its ground set; the triples are $\{x, y, z\}$ satisfying the condition that $S(x, y)S(y, z)S(z, x)$ is square (respectively non-square) if $q \cong 1 \pmod{4}$ (respectively if $q \cong 3 \pmod{4}$). See §7E of [BL1984].

There is also a $2 - (q^3 + 1, q + 1, 1)$ -design on these $q^3 + 1$ points, known as the unital of order q , also invariant under $U_3(q)$.

INPUT:

- q – a power of an odd prime

EXAMPLES:

```
sage: from sage.combinat.designs.twographs import taylor_twograph
sage: T=taylor_twograph(3); T
Incidence structure with 28 points and 1260 blocks
```

`sage.combinat.designs.twographs.twograph_descendant(G, v, name=None)`

Return the descendant graph w.r.t. vertex v of the two-graph of G

In the *switching class* of G , construct a graph Δ with v an isolated vertex, and return the subgraph $\Delta \setminus v$. It is equivalent to, although much faster than, computing the `TwoGraph.descendant()` of `two-graph of G` , as the intermediate two-graph is not constructed.

INPUT:

- G – a graph
- v – a vertex of G
- *name* – (optional) `None` - no name, otherwise derive from the construction

EXAMPLES:

one of s.r.g.'s from the database:

```
sage: from sage.combinat.designs.twographs import twograph_descendant
sage: A=graphs.strongly_regular_graph(280,135,70) # optional -L
      ↪gap_packages internet
sage: twograph_descendant(A, 0).is_strongly_regular(parameters=True) # optional -L
      ↪gap_packages internet
(279, 150, 85, 75)
```

5.1.95 Diagram and Partition Algebras

AUTHORS:

- Mike Hansen (2007): Initial version
- Stephen Doty, Aaron Lauve, George H. Seelinger (2012): Implementation of partition, Brauer, Temperley–Lieb, and ideal partition algebras
- Stephen Doty, Aaron Lauve, George H. Seelinger (2015): Implementation of `*Diagram` classes and other methods to improve diagram algebras.
- Mike Zabrocki (2018): Implementation of individual element diagram classes
- Aaron Lauve, Mike Zabrocki (2018): Implementation of orbit basis for Partition algebra.

class `sage.combinat.diagram_algebras.AbstractPartitionDiagram`(*parent, d, check=True*)

Bases: `sage.combinat.set_partition.AbstractSetPartition`

Abstract base class for partition diagrams.

This class represents a single partition diagram, that is used as a basis key for a diagram algebra element. A partition diagram should be a partition of the set $\{1, \dots, k, -1, \dots, -k\}$. Each such set partition is regarded as a graph on nodes $\{1, \dots, k, -1, \dots, -k\}$ arranged in two rows, with nodes $1, \dots, k$ in the top row from left to right and with nodes $-1, \dots, -k$ in the bottom row from left to right, and an edge connecting two nodes if and only if the nodes lie in the same subset of the set partition.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd1 = da.AbstractPartitionDiagram(pd, [[1,2],[-1,-2]])
sage: pd2 = da.AbstractPartitionDiagram(pd, [[1,2],[-1,-2]])
sage: pd1
{{-2, -1}, {1, 2}}
sage: pd1 == pd2
True
sage: pd1 == [[1,2],[-1,-2]]
True
sage: pd1 == ((-2,-1),(2,1))
True
sage: pd1 == SetPartition([[1,2],[-1,-2]])
True
sage: pd3 = da.AbstractPartitionDiagram(pd, [[1,-2],[-1,2]])
sage: pd1 == pd3
False
```

(continues on next page)

(continued from previous page)

```
sage: pd4 = da.AbstractPartitionDiagram(pd, [[1,2],[3,4]])
Traceback (most recent call last):
...
ValueError: {{1, 2}, {3, 4}} does not represent two rows of vertices of order 2
```

base_diagram()

Return the underlying implementation of the diagram.

OUTPUT:

- tuple of tuples of integers

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).base_diagram() == ((-2,-1),(1,2))
True
```

check()

Check the validity of the input for the diagram.

compose(*other*, *check=True*)

Compose *self* with *other*.

The composition of two diagrams *X* and *Y* is given by placing *X* on top of *Y* and removing all loops.

OUTPUT:

A tuple where the first entry is the composite diagram and the second entry is how many loop were removed.

Note: This is not really meant to be called directly, but it works to call it this way if desired.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).compose(pd([[1,2],[-1,-2]]))
({{-2, -1}, {1, 2}}, 1)
```

count_blocks_of_size(*n*)

Count the number of blocks of a given size.

INPUT:

- *n* – a positive integer

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: pd = PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]])
sage: pd.count_blocks_of_size(1)
2
sage: pd.count_blocks_of_size(2)
1
sage: pd.count_blocks_of_size(3)
2
```

diagram()

Return the underlying implementation of the diagram.

OUTPUT:

- tuple of tuples of integers

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).base_diagram() == ((-2,-1),(1,2))
True
```

dual()

Return the dual diagram of `self` by flipping it top-to-bottom.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: D = PartitionDiagram([[1,-1],[2,-2,-3],[3]])
sage: D.dual()
{{-3}, {-2, 2, 3}, {-1, 1}}
```

is_planar()

Test if the diagram `self` is planar.

A diagram element is planar if the graph of the nodes is planar.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import BrauerDiagram
sage: BrauerDiagram([[1,-2],[2,-1]]).is_planar()
False
sage: BrauerDiagram([[1,-1],[2,-2]]).is_planar()
True
```

order()

Return the maximum entry in the diagram element.

A diagram element will be a partition of the set $\{-1, -2, \dots, -k, 1, 2, \dots, k\}$. The order of the diagram element is the value k .

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: PartitionDiagram([[1,-1],[2,-2,-3],[3]]).order()
3
sage: PartitionDiagram([[1,-1]]).order()
1
sage: PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]]).order()
5
```

propagating_number()

Return the propagating number of the diagram.

The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: d1 = pd([[1,-2],[2,-1]])
sage: d1.propagating_number()
2
sage: d2 = pd([[1,2],[-2,-1]])
sage: d2.propagating_number()
0

```

set_partition()

Return the underlying implementation of the diagram as a set of sets.

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: X = pd([[1,2],[-1,-2]]).set_partition(); X
{{-2, -1}, {1, 2}}
sage: X.parent()
Set partitions

```

class `sage.combinat.diagram_algebras.AbstractPartitionDiagrams`(*order*, *category=None*)
 Bases: `sage.structure.parent.Parent`, `sage.structure.unique_representation.UniqueRepresentation`

This is an abstract base class for partition diagrams.

The primary use of this class is to serve as basis keys for diagram algebras, but diagrams also have properties in their own right. Furthermore, this class is meant to be extended to create more efficient contains methods.

INPUT:

- *order* – integer or integer +1/2; the order of the diagrams
- *category* – (default: `FiniteEnumeratedSets()`); the category

All concrete classes should implement attributes

- `_name` – the name of the class
- `_diagram_func` – an iterator function that takes the order as its only input

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(2)
sage: pd
Partition diagrams of order 2
sage: pd.an_element() in pd
True
sage: elm = pd([[1,2],[-1,-2]])
sage: elm in pd
True

```

Element

alias of `AbstractPartitionDiagram`

```
class sage.combinat.diagram_algebras.BrauerAlgebra(k, q, base_ring, prefix)
    Bases: sage.combinat.diagram_algebras.SubPartitionAlgebra, sage.combinat.
           diagram_algebras.UnitDiagramMixin
```

A Brauer algebra.

The Brauer algebra of rank k is an algebra with basis indexed by the collection of set partitions of $\{1, \dots, k, -1, \dots, -k\}$ with block size 2.

This algebra is a subalgebra of the partition algebra. For more information, see [PartitionAlgebra](#).

INPUT:

- k – rank of the algebra
- q – the deformation parameter q

OPTIONAL ARGUMENTS:

- `base_ring` – (default `None`) a ring containing q ; if `None` then just takes the parent of q
- `prefix` – (default `"B"`) a label for the basis elements

EXAMPLES:

We now define the Brauer algebra of rank 2 with parameter x over \mathbf{Z} :

```
sage: R.<x> = ZZ[]
sage: B = BrauerAlgebra(2, x, R)
sage: B
Brauer Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring
sage: B.basis()
Lazy family (Term map from Brauer diagrams of order 2 to Brauer Algebra
of rank 2 with parameter x over Univariate Polynomial Ring in x
over Integer Ring(i))_{i in Brauer diagrams of order 2}
sage: B.basis().keys()
Brauer diagrams of order 2
sage: B.basis().keys()([[ -2, 1], [2, -1]])
[{-2, 1}, {-1, 2}]
sage: b = B.basis().list(); b
[B{{-2, -1}, {1, 2}}, B{{-2, 1}, {-1, 2}}, B{{-2, 2}, {-1, 1}}]
sage: b[0]
B{{-2, -1}, {1, 2}}
sage: b[0]^2
x*B{{-2, -1}, {1, 2}}
sage: b[0]^5
x^4*B{{-2, -1}, {1, 2}}
```

Note, also that since the symmetric group algebra is contained in the Brauer algebra, there is also a conversion between the two.

```
sage: R.<x> = ZZ[]
sage: B = BrauerAlgebra(2, x, R)
sage: S = SymmetricGroupAlgebra(R, 2)
sage: S([2, 1])*B([[1, -1], [2, -2]])
B{{-2, 1}, {-1, 2}}
```

jucys_murphy(j)

Return the j -th generalized Jucys-Murphy element of `self`.

The j -th Jucys-Murphy element of a Brauer algebra is simply the j -th Jucys-Murphy element of the symmetric group algebra with an extra $(z - 1)/2$ term, where z is the parameter of the Brauer algebra.

REFERENCES:

EXAMPLES:

```
sage: z = var('z')
sage: B = BrauerAlgebra(3,z)
sage: B.jucys_murphy(1)
(1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
sage: B.jucys_murphy(3)
-B{{-3, -2}, {-1, 1}, {2, 3}} - B{{-3, -1}, {-2, 2}, {1, 3}}
+ B{{-3, 1}, {-2, 2}, {-1, 3}} + B{{-3, 2}, {-2, 3}, {-1, 1}}
+ (1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
```

options(*get_value, **set_value)

Set and display the global options for Brauer diagram (algebras). If no parameters are set, then the function returns a copy of the options dictionary.

The options to diagram algebras can be accessed as the method `BrauerAlgebra.options` of `BrauerAlgebra` and related classes.

OPTIONS:

- `display` – (default: `normal`) Specifies how the Brauer diagrams should be printed
 - `compact` – Using the compact representation
 - `normal` – Using the normal representation

The compact representation $[A/B;\pi]$ of the Brauer algebra diagram (see [GL1996]) has the following components:

- `A` – is a list of pairs of positive elements (upper row) that are connected,
- `B` – is a list of pairs of negative elements (lower row) that are connected, and
- `pi` – is a permutation that is to be interpreted as the relative order of the remaining elements in the top row and the bottom row.

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: BA = BrauerAlgebra(2, q)
sage: E = BA([[1,2],[-1,-2]])
sage: E
B{{-2, -1}, {1, 2}}
sage: BA8 = BrauerAlgebra(8, q)
sage: BA8([[1,-4],[2,4],[3,8],[-7,-2],[5,7],[6,-1],[-3,-5],[-6,-8]])
B{{-8, -6}, {-7, -2}, {-5, -3}, {-4, 1}, {-1, 6}, {2, 4}, {3, 8}, {5, 7}}
sage: BrauerAlgebra.options.display = "compact"
sage: E
B[12/12;]
sage: BA8([[1,-4],[2,4],[3,8],[-7,-2],[5,7],[6,-1],[-3,-5],[-6,-8]])
B[24.38.57/35.27.68;21]
sage: BrauerAlgebra.options._reset()
```

See `GlobalOptions` for more features of these options.

class sage.combinat.diagram_algebras.**BrauerDiagram**(parent, d, check=True)

Bases: *sage.combinat.diagram_algebras.AbstractPartitionDiagram*

A Brauer diagram.

A Brauer diagram for an integer k is a partition of the set $\{1, \dots, k, -1, \dots, -k\}$ with block size 2.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(2)
sage: bd1 = bd([[1,2],[-1,-2]])
sage: bd2 = bd([[1,2,-1,-2]])
Traceback (most recent call last):
...
ValueError: all blocks of {{-2, -1, 1, 2}} must be of size 2
```

bijection_on_free_nodes(two_line=False)

Return the induced bijection - as a list of $(x, f(x))$ values - from the free nodes on the top at the Brauer diagram to the free nodes at the bottom of self.

OUTPUT:

If two_line is True, then the output is the induced bijection as a two-row list (inputs, outputs).

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.bijection_on_free_nodes()
[[3, -1]]
sage: elm2 = bd([[1,-2],[2,-3],[3,-1]])
sage: elm2.bijection_on_free_nodes(two_line=True)
[[1, 2, 3], [-2, -3, -1]]
```

check()

Check the validity of the input for self.

involution_permutation_triple(curt=True)

Return the involution permutation triple of self.

From Graham-Lehrer (see *BrauerDiagrams*), a Brauer diagram is a triple (D_1, D_2, π) , where:

- D_1 is a partition of the top nodes;
- D_2 is a partition of the bottom nodes;
- π is the induced permutation on the free nodes.

INPUT:

- curt - (default: True) if True, then return bijection on free nodes as a one-line notation (standardized to look like a permutation), else, return the honest mapping, a list of pairs $(i, -j)$ describing the bijection on free nodes

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
```

(continues on next page)

(continued from previous page)

```
sage: elm.involution_permutation_triple()
[[ (1, 2)], [(-3, -2)], [1]]
sage: elm.involution_permutation_triple(curt=False)
[[ (1, 2)], [(-3, -2)], [[3, -1]]]
```

is_elementary_symmetric()

Check if is elementary symmetric.

Let (D_1, D_2, π) be the Graham-Lehrer representation of the Brauer diagram d . We say d is *elementary symmetric* if $D_1 = D_2$ and π is the identity.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-1,-2],[3,-3]])
sage: elm.is_elementary_symmetric()
True
sage: elm2 = bd([[1,2],[-1,-3],[3,-2]])
sage: elm2.is_elementary_symmetric()
False
```

options(*get_value, **set_value)

Set and display the global options for Brauer diagram (algebras). If no parameters are set, then the function returns a copy of the options dictionary.

The options to diagram algebras can be accessed as the method `BrauerAlgebra.options` of `BrauerAlgebra` and related classes.

OPTIONS:

- `display` – (default: `normal`) Specifies how the Brauer diagrams should be printed
 - `compact` – Using the compact representation
 - `normal` – Using the normal representation

The compact representation $[A/B;\pi]$ of the Brauer algebra diagram (see [GL1996]) has the following components:

- A – is a list of pairs of positive elements (upper row) that are connected,
- B – is a list of pairs of negative elements (lower row) that are connected, and
- π – is a permutation that is to be interpreted as the relative order of the remaining elements in the top row and the bottom row.

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: BA = BrauerAlgebra(2, q)
sage: E = BA([[1,2],[-1,-2]])
sage: E
B{{-2, -1}, {1, 2}}
sage: BA8 = BrauerAlgebra(8, q)
sage: BA8([[1,-4],[2,4],[3,8],[-7,-2],[5,7],[6,-1],[-3,-5],[-6,-8]])
B{{-8, -6}, {-7, -2}, {-5, -3}, {-4, 1}, {-1, 6}, {2, 4}, {3, 8}, {5, 7}}
sage: BrauerAlgebra.options.display = "compact"
```

(continues on next page)

(continued from previous page)

```

sage: E
B[12/12;]
sage: BA8([[1,-4],[2,4],[3,8],[-7,-2],[5,7],[6,-1],[-3,-5],[-6,-8]])
B[24.38.57/35.27.68;21]
sage: BrauerAlgebra.options._reset()

```

See [GlobalOptions](#) for more features of these options.

perm()

Return the induced bijection on the free nodes of `self` in one-line notation, re-indexed and treated as a permutation.

See also:

[bijection_on_free_nodes\(\)](#)

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.perm()
[1]

```

class `sage.combinat.diagram_algebras.BrauerDiagrams`(*order, category=None*)

Bases: `sage.combinat.diagram_algebras.AbstractPartitionDiagrams`

This class represents all Brauer diagrams of integer or integer +1/2 order. For more information on Brauer diagrams, see [BrauerAlgebra](#).

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(2); bd
Brauer diagrams of order 2
sage: bd.list()
[{{-2, -1}, {1, 2}}, {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

sage: bd = da.BrauerDiagrams(5/2); bd
Brauer diagrams of order 5/2
sage: bd.list()
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 3}, {-2, 1}, {-1, 2}},
 {{-3, 3}, {-2, 2}, {-1, 1}}]

```

Element

alias of [BrauerDiagram](#)

cardinality()

Return the cardinality of `self`.

The number of Brauer diagrams of integer order k is $(2k - 1)!!$.

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)

```

(continues on next page)

(continued from previous page)

```
sage: bd.cardinality()
15
sage: bd = da.BrauerDiagrams(7/2)
sage: bd.cardinality()
15
```

from_involution_permutation_triple(*D1_D2_pi*)

Construct a Brauer diagram of `self` from an involution permutation triple.

A Brauer diagram can be represented as a triple where the first entry is a list of arcs on the top row of the diagram, the second entry is a list of arcs on the bottom row of the diagram, and the third entry is a permutation on the remaining nodes. This triple is called the *involution permutation triple*. For more information, see [GL1996].

INPUT:

- `D1_D2_pi` – a list or tuple where the first entry is a list of arcs on the top of the diagram, the second entry is a list of arcs on the bottom of the diagram, and the third entry is a permutation on the free nodes.

REFERENCES:

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(4)
sage: bd.from_involution_permutation_triple([[1,2]], [[3,4]], [2,1])
{{-4, -3}, {-2, 3}, {-1, 4}, {1, 2}}
```

options(get_value*, ***set_value*)**

Set and display the global options for Brauer diagram (algebras). If no parameters are set, then the function returns a copy of the options dictionary.

The options to diagram algebras can be accessed as the method `BrauerAlgebra.options` of `BrauerAlgebra` and related classes.

OPTIONS:

- `display` – (default: `normal`) Specifies how the Brauer diagrams should be printed
 - `compact` – Using the compact representation
 - `normal` – Using the normal representation

The compact representation `[A/B;pi]` of the Brauer algebra diagram (see [GL1996]) has the following components:

- `A` – is a list of pairs of positive elements (upper row) that are connected,
- `B` – is a list of pairs of negative elements (lower row) that are connected, and
- `pi` – is a permutation that is to be interpreted as the relative order of the remaining elements in the top row and the bottom row.

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: BA = BrauerAlgebra(2, q)
sage: E = BA([[1,2], [-1,-2]])
```

(continues on next page)

(continued from previous page)

```

sage: E
B{{-2, -1}, {1, 2}}
sage: BA8 = BrauerAlgebra(8, q)
sage: BA8([[1,-4],[2,4],[3,8],[-7,-2],[5,7],[6,-1],[-3,-5],[-6,-8]])
B{{-8, -6}, {-7, -2}, {-5, -3}, {-4, 1}, {-1, 6}, {2, 4}, {3, 8}, {5, 7}}
sage: BrauerAlgebra.options.display = "compact"
sage: E
B[12/12;]
sage: BA8([[1,-4],[2,4],[3,8],[-7,-2],[5,7],[6,-1],[-3,-5],[-6,-8]])
B[24.38.57/35.27.68;21]
sage: BrauerAlgebra.options._reset()

```

See `GlobalOptions` for more features of these options.

symmetric_diagrams(*l=None, perm=None*)

Return the list of Brauer diagrams with symmetric placement of *l* arcs, and with free nodes permuted according to *perm*.

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(4)
sage: bd.symmetric_diagrams(l=1, perm=[2,1])
[{{-4, -2}, {-3, 1}, {-1, 3}, {2, 4}},
 {{-4, -3}, {-2, 1}, {-1, 2}, {3, 4}},
 {{-4, -1}, {-3, 2}, {-2, 3}, {1, 4}},
 {{-4, 2}, {-3, -1}, {-2, 4}, {1, 3}},
 {{-4, 3}, {-3, 4}, {-2, -1}, {1, 2}},
 {{-4, 1}, {-3, -2}, {-1, 4}, {2, 3}}]

```

class `sage.combinat.diagram_algebras.DiagramAlgebra`(*k, q, base_ring, prefix, diagrams, category=None*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

Abstract class for diagram algebras and is not designed to be used directly.

class `Element`

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

An element of a diagram algebra.

This subclass provides a few additional methods for partition algebra elements. Most element methods are already implemented elsewhere.

diagram()

Return the underlying diagram of `self` if `self` is a basis element. Raises an error if `self` is not a basis element.

EXAMPLES:

```

sage: R.<x> = ZZ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = 3*P([[1,2],[-2,-1]])
sage: elt.diagram()
{{-2, -1}, {1, 2}}

```

diagrams()

Return the diagrams in the support of self.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = 3*P([[1,2],[-2,-1]]) + P([[1,2],[-2], [-1]])
sage: sorted(elt.diagrams(), key=str)
[{{-2, -1}, {1, 2}}, {{-2}, {-1}, {1, 2}}]
```

order()

Return the order of self.

The order of a partition algebra is defined as half of the number of nodes in the diagrams.

EXAMPLES:

```
sage: q = var('q')
sage: PA = PartitionAlgebra(2, q)
sage: PA.order()
2
```

set_partitions()

Return the collection of underlying set partitions indexing the basis elements of a given diagram algebra.

Todo: Is this really necessary? deprecate?

class sage.combinat.diagram_algebras.**DiagramBasis**(*k, q, base_ring, prefix, diagrams, category=None*)
 Bases: *sage.combinat.diagram_algebras.DiagramAlgebra*

Abstract base class for diagram algebras in the diagram basis.

product_on_basis(*d1, d2*)

Return the product $D_{d_1}D_{d_2}$ by two basis diagrams.

class sage.combinat.diagram_algebras.**IdealDiagram**(*parent, d, check=True*)

Bases: *sage.combinat.diagram_algebras.AbstractPartitionDiagram*

The element class for a ideal diagram.

An ideal diagram for an integer k is a partition of the set $\{1, \dots, k, -1, \dots, -k\}$ where the propagating number is strictly smaller than the order.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import IdealDiagrams as IDs
sage: IDs(2)
Ideal diagrams of order 2
sage: IDs(2).list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1}, {2}},
```

(continues on next page)

(continued from previous page)

```

[[-2, -1, 2], [1]],
[[-2, 2], [-1], [1]],
[[-2], [-1, 1], [2]],
[[-2], [-1, 2], [1]],
[[-2, -1], [1], [2]],
[[-2], [-1], [1], [2]]]

sage: from sage.combinat.diagram_algebras import PartitionDiagrams as PDs
sage: PDs(4).cardinality() == factorial(4) + IDs(4).cardinality()
True

```

check()

Check the validity of the input for self.

class sage.combinat.diagram_algebras.**IdealDiagrams**(order, category=None)

Bases: *sage.combinat.diagram_algebras.AbstractPartitionDiagrams*

All “ideal” diagrams of integer or integer +1/2 order.

If k is an integer then an ideal diagram of order k is a partition diagram of order k with propagating number less than k .

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: id = da.IdealDiagrams(3)
sage: id.an_element() in id
True
sage: id.cardinality() == len(id.list())
True
sage: da.IdealDiagrams(3/2).list()
[[[-2, -1, 1, 2]],
 [[-2, 1, 2], [-1]],
 [[-2, -1, 2], [1]],
 [[-2, 2], [-1], [1]]]

```

Element

alias of *IdealDiagram*

class sage.combinat.diagram_algebras.**OrbitBasis**(alg)

Bases: *sage.combinat.diagram_algebras.DiagramAlgebra*

The orbit basis of the partition algebra.

Let D_π represent the diagram basis element indexed by the partition π , then (see equations (2.14), (2.17) and (2.18) of [BH2017])

$$D_\pi = \sum_{\tau \geq \pi} O_\tau,$$

where the sum is over all partitions τ which are coarser than π and O_τ is the orbit basis element indexed by the partition τ .

If $\mu_{2k}(\pi, \tau)$ represents the Moebius function of the partition lattice, then

$$O_\pi = \sum_{\tau \geq \pi} \mu_{2k}(\pi, \tau) D_\tau.$$

If τ is a partition of ℓ blocks and the i^{th} block of τ is a union of b_i blocks of π , then

$$\mu_{2k}(\pi, \tau) = \prod_{i=1}^{\ell} (-1)^{b_i-1} (b_i - 1)!$$

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Rational Field
sage: oa = O2([[1],[1],[2,-2]]); ob = O2([[-1,-2,2],[1]]); oa, ob
(O{{-2, 2}, {-1}, {1}}, O{{-2, -1, 2}, {1}})
sage: oa * ob
(x-2)*O{{-2, -1, 2}, {1}}
```

We can convert between the two bases:

```
sage: pa = P2(oa); pa
2*P{{-2, -1, 1, 2}} - P{{-2, -1, 2}, {1}} - P{{-2, 1, 2}, {-1}}
+ P{{-2, 2}, {-1}, {1}} - P{{-2, 2}, {-1, 1}}
sage: pa * ob
(-x+2)*P{{-2, -1, 1, 2}} + (x-2)*P{{-2, -1, 2}, {1}}
sage: _ == pa * P2(ob)
True
sage: O2(pa * ob)
(x-2)*O{{-2, -1, 2}, {1}}
```

Note that the unit in the orbit basis is not a single diagram, in contrast to the natural diagram basis:

```
sage: P2.one()
P{{-2, 2}, {-1, 1}}
sage: O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}
sage: O2.one() == P2.one()
True
```

class Element

Bases: [sage.combinat.diagram_algebras.PartitionAlgebra.Element](#)

to_diagram_basis()

Expand self in the natural diagram basis of the partition algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: O = P.orbit_basis()
sage: elt = O.an_element(); elt
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: elt.to_diagram_basis()
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: pp = P.an_element(); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

(continues on next page)

(continued from previous page)

```

sage: op = pp.to_orbit_basis(); op
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: pp == op.to_diagram_basis()
True

```

diagram_basis()

Return the associated partition algebra of `self` in the diagram basis.

EXAMPLES:

```

sage: R.<x> = QQ[]
sage: O2 = PartitionAlgebra(2, x, R).orbit_basis()
sage: P2 = O2.diagram_basis(); P2
Partition Algebra of rank 2 with parameter x over Univariate
Polynomial Ring in x over Rational Field
sage: o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: P2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}

```

one()

Return the element 1 of the partition algebra in the orbit basis.

EXAMPLES:

```

sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis()
sage: O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}

```

product_on_basis(d1, d2)

Return the product $O_{d_1}O_{d_2}$ of two elements in the orbit basis `self`.

EXAMPLES:

```

sage: R.<x> = QQ[]
sage: OP = PartitionAlgebra(2, x, R).orbit_basis()
sage: SP = OP.basis().keys(); sp = SP([[ -2, -1, 1, 2]])
sage: OP.product_on_basis(sp, sp)
O{{-2, -1, 1, 2}}
sage: o1 = OP.one(); o2 = OP([]); o3 = OP.an_element()
sage: o2 == o1
False
sage: o1 * o1 == o1
True
sage: o3 * o1 == o1 * o3 and o3 * o1 == o3
True
sage: o4 = (3*OP([[ -2, -1, 1], [2]]) + 2*OP([[ -2, -1, 1, 2]])
.....:         + 2*OP([[ -2, -1, 2], [1]]))
sage: o4 * o4
6*O{{-2, -1, 1}, {2}} + 4*O{{-2, -1, 1, 2}} + 4*O{{-2, -1, 2}, {1}}

```

We compute Examples 4.5 in [BH2017]:

```

sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(3,x); O = P.orbit_basis()
sage: O[[1,2,3],[-1,-2,-3]] * O[[1,2,3],[-1,-2,-3]]
(x-2)*O{{-3, -2, -1}, {1, 2, 3}} + (x-1)*O{{-3, -2, -1, 1, 2, 3}}

sage: P = PartitionAlgebra(4,x); O = P.orbit_basis()
sage: O[[1],[2,3],[4,-2],[-3,-4]] * O[[1],[2,-2],[3,4],[-1,-3],[-4]]
(x^2-11*x+30)*O{{-4}, {-3, -1}, {-2, 4}, {1}, {2, 3}}
+ (x^2-9*x+20)*O{{-4}, {-3, -1, 1}, {-2, 4}, {2, 3}}
+ (x^2-9*x+20)*O{{-4}, {-3, -1, 2, 3}, {-2, 4}, {1}}
+ (x^2-9*x+20)*O{{-4, 1}, {-3, -1}, {-2, 4}, {2, 3}}
+ (x^2-7*x+12)*O{{-4, 1}, {-3, -1, 2, 3}, {-2, 4}}
+ (x^2-9*x+20)*O{{-4, 2, 3}, {-3, -1}, {-2, 4}, {1}}
+ (x^2-7*x+12)*O{{-4, 2, 3}, {-3, -1, 1}, {-2, 4}}

sage: O[[1,-1],[2,-2],[3],[4,-3],[-4]] * O[[1,-2],[2],[3,-1],[4],[-3],[-4]]
(x-6)*O{{-4}, {-3}, {-2, 1}, {-1, 4}, {2}, {3}}
+ (x-5)*O{{-4}, {-3, 3}, {-2, 1}, {-1, 4}, {2}}
+ (x-5)*O{{-4, 3}, {-3}, {-2, 1}, {-1, 4}, {2}}

sage: P = PartitionAlgebra(6,x); O = P.orbit_basis()
sage: O[[1,-2,-3],[2,4],[3,5,-6],[6],[-1],[-4,-5]]
..... * O[[1,-2],[2,3],[4],[5],[6,-4,-5,-6],[-1,-3]])
0

sage: O[[1,-2],[2,-3],[3,5],[4,-5],[6,-4],[-1],[-6]]
..... * O[[1,-2],[2,-1],[3,-4],[4,-6],[5,-3],[6,-5]])
O{{-6, 6}, {-5}, {-4, 2}, {-3, 4}, {-2}, {-1, 1}, {3, 5}}

```

REFERENCES:

- [BH2017]

class `sage.combinat.diagram_algebras.PartitionAlgebra`(*k*, *q*, *base_ring*, *prefix*)

Bases: `sage.combinat.diagram_algebras.DiagramBasis`, `sage.combinat.diagram_algebras.UnitDiagramMixin`

A partition algebra.

A partition algebra of rank k over a given ground ring R is an algebra with (R -module) basis indexed by the collection of set partitions of $\{1, \dots, k, -1, \dots, -k\}$. Each such set partition can be represented by a graph on nodes $\{1, \dots, k, -1, \dots, -k\}$ arranged in two rows, with nodes $1, \dots, k$ in the top row from left to right and with nodes $-1, \dots, -k$ in the bottom row from left to right, and edges drawn such that the connected components of the graph are precisely the parts of the set partition. (This choice of edges is often not unique, and so there are often many graphs representing one and the same set partition; the representation nevertheless is useful and vivid. We often speak of “diagrams” to mean graphs up to such equivalence of choices of edges; of course, we could just as well speak of set partitions.)

There is not just one partition algebra of given rank over a given ground ring, but rather a whole family of them, indexed by the elements of R . More precisely, for every $q \in R$, the partition algebra of rank k over R with parameter q is defined to be the R -algebra with basis the collection of all set partitions of $\{1, \dots, k, -1, \dots, -k\}$, where the product of two basis elements is given by the rule

$$a \cdot b = q^N (a \circ b),$$

where $a \circ b$ is the composite set partition obtained by placing the diagram (i.e., graph) of a above the diagram

of b , identifying the bottom row nodes of a with the top row nodes of b , and omitting any closed “loops” in the middle. The number N is the number of connected components formed by the omitted loops.

The parameter q is a deformation parameter. Taking $q = 1$ produces the semigroup algebra (over the base ring) of the partition monoid, in which the product of two set partitions is simply given by their composition.

The partition algebra is regarded as an example of a “diagram algebra” due to the fact that its natural basis is given by certain graphs often called diagrams.

There are a number of predefined elements for the partition algebra. We define the cup/cap pair by $a()$. The simple transpositions are denoted $s()$. Finally, we define elements $e()$, where if $i = (2r + 1)/2$, then $e(i)$ contains the blocks $\{r + 1\}$ and $\{-r - 1\}$ and if $i \in \mathbf{Z}$, then e_i contains the block $\{-i, -i - 1, i, i + 1\}$, with all other blocks being $\{-j, j\}$. So we have:

```
sage: P = PartitionAlgebra(4, 0)
sage: P.a(2)
P{{-4, 4}, {-3, -2}, {-1, 1}, {2, 3}}
sage: P.e(3/2)
P{{-4, 4}, {-3, 3}, {-2}, {-1, 1}, {2}}
sage: P.e(2)
P{{-4, 4}, {-3, -2, 2, 3}, {-1, 1}}
sage: P.e(5/2)
P{{-4, 4}, {-3}, {-2, 2}, {-1, 1}, {3}}
sage: P.s(2)
P{{-4, 4}, {-3, 2}, {-2, 3}, {-1, 1}}
```

An excellent reference for partition algebras and their various subalgebras (Brauer algebra, Temperley–Lieb algebra, etc) is the paper [HR2005].

INPUT:

- k – rank of the algebra
- q – the deformation parameter q

OPTIONAL ARGUMENTS:

- `base_ring` – (default `None`) a ring containing q ; if `None`, then Sage automatically chooses the parent of q
- `prefix` – (default `"P"`) a label for the basis elements

EXAMPLES:

The following shorthand simultaneously defines the univariate polynomial ring over the rationals as well as the variable x :

```
sage: R.<x> = PolynomialRing(QQ)
sage: R
Univariate Polynomial Ring in x over Rational Field
sage: x
x
sage: x.parent() is R
True
```

We now define the partition algebra of rank 2 with parameter x over \mathbf{Z} in the usual (diagram) basis:

```
sage: R.<x> = ZZ[]
sage: A2 = PartitionAlgebra(2, x, R)
sage: A2
```

(continues on next page)

(continued from previous page)

```

Partition Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring
sage: A2.basis().keys()
Partition diagrams of order 2
sage: A2.basis().keys()([[ -2, 1, 2], [-1]])
{{-2, 1, 2}, {-1}}
sage: A2.basis().list()
[P{{-2, -1, 1, 2}}, P{{-2, 1, 2}, {-1}},
 P{{-2}, {-1, 1, 2}}, P{{-2, -1}, {1, 2}},
 P{{-2}, {-1}, {1, 2}}, P{{-2, -1, 1}, {2}},
 P{{-2, 1}, {-1, 2}}, P{{-2, 1}, {-1}, {2}},
 P{{-2, 2}, {-1, 1}}, P{{-2, -1, 2}, {1}},
 P{{-2, 2}, {-1}, {1}}, P{{-2}, {-1, 1}, {2}},
 P{{-2}, {-1, 2}, {1}}, P{{-2, -1}, {1}, {2}},
 P{{-2}, {-1}, {1}, {2}}]
sage: E = A2([[1,2],[-2,-1]]); E
P{{-2, -1}, {1, 2}}
sage: E in A2.basis().list()
True
sage: E^2
x*P{{-2, -1}, {1, 2}}
sage: E^5
x^4*P{{-2, -1}, {1, 2}}
sage: (A2([[2,-2],[-1,1]]) - 2*A2([[1,2],[-1,-2]]))^2
(4*x-4)*P{{-2, -1}, {1, 2}} + P{{-2, 2}, {-1, 1}}

```

Next, we construct an element:

```

sage: a2 = A2.an_element(); a2
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}

```

There is a natural embedding into partition algebras on more elements, by adding identity strands:

```

sage: A4 = PartitionAlgebra(4, x, R)
sage: A4(a2)
3*P{{-4, 4}, {-3, 3}, {-2}, {-1, 1, 2}}
+ 2*P{{-4, 4}, {-3, 3}, {-2, -1, 1, 2}}
+ 2*P{{-4, 4}, {-3, 3}, {-2, 1, 2}, {-1}}

```

Thus, the empty partition corresponds to the identity:

```

sage: A4([])
P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
sage: A4(5)
5*P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}

```

The group algebra of the symmetric group is a subalgebra:

```

sage: S3 = SymmetricGroupAlgebra(ZZ, 3)
sage: s3 = S3.an_element(); s3
[1, 2, 3] + 2*[1, 3, 2] + 3*[2, 1, 3] + [3, 1, 2]
sage: A4(s3)
P{{-4, 4}, {-3, 1}, {-2, 3}, {-1, 2}}

```

(continues on next page)

(continued from previous page)

```

+ 2*P{{-4, 4}, {-3, 2}, {-2, 3}, {-1, 1}}
+ 3*P{{-4, 4}, {-3, 3}, {-2, 1}, {-1, 2}}
+ P{{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}}
sage: A4([2,1])
P{{-4, 4}, {-3, 3}, {-2, 1}, {-1, 2}}

```

Be careful not to confuse the embedding of the group algebra of the symmetric group with the embedding of partial set partitions. The latter are embedded by adding the parts $\{i, -i\}$ if possible, and singletons sets for the remaining parts:

```

sage: A4([[2,1]])
P{{-4, 4}, {-3, 3}, {-2}, {-1}, {1, 2}}
sage: A4([[-1,3],[2,-3,1]])
P{{-4, 4}, {-3, -2, 1}, {-1, 3}, {2}}

```

Another subalgebra is the Brauer algebra, which has perfect matchings as basis elements. The group algebra of the symmetric group is in fact a subalgebra of the Brauer algebra:

```

sage: B3 = BrauerAlgebra(3, x, R)
sage: b3 = B3(s3); b3
B{{-3, 1}, {-2, 3}, {-1, 2}} + 2*B{{-3, 2}, {-2, 3}, {-1, 1}}
+ 3*B{{-3, 3}, {-2, 1}, {-1, 2}} + B{{-3, 3}, {-2, 2}, {-1, 1}}

```

An important basis of the partition algebra is the *orbit basis*:

```

sage: o2 = A2.orbit_basis()
sage: o2 = O2([[1,2],[1,-2]]) + O2([[1,2,-1,-2]]); o2
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}

```

The diagram basis element corresponds to the sum of all orbit basis elements indexed by coarser set partitions:

```

sage: A2(o2)
P{{-2, -1}, {1, 2}}

```

We can convert back from the orbit basis to the diagram basis:

```

sage: o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: A2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}

```

One can work with partition algebras using a symbol for the parameter, leaving the base ring unspecified. This implies that the underlying base ring is Sage's symbolic ring.

```

sage: q = var('q')
sage: PA = PartitionAlgebra(2, q); PA
Partition Algebra of rank 2 with parameter q over Symbolic Ring
sage: PA([[1,2],[2,-1]])^2 == q*PA([[1,2],[2,-1]])
True
sage: (PA([[2, -2], [1, -1]]) - 2*PA([[2, -1], [1, 2]]))^2 == (4*q-4)*PA([[1, 2],
↪[-2, -1]]) + PA([[2, -2], [1, -1]])
True

```

The identity element of the partition algebra is the set partition $\{\{1, -1\}, \{2, -2\}, \dots, \{k, -k\}\}$:

```

sage: P = PA.basis().list()
sage: PA.one()
P{{-2, 2}, {-1, 1}}
sage: PA.one() * P[7] == P[7]
True
sage: P[7] * PA.one() == P[7]
True

```

We now give some further examples of the use of the other arguments. One may wish to “specialize” the parameter to a chosen element of the base ring:

```

sage: R.<q> = RR[]
sage: PA = PartitionAlgebra(2, q, R, prefix='B')
sage: PA
Partition Algebra of rank 2 with parameter q over
Univariate Polynomial Ring in q over Real Field with 53 bits of precision
sage: PA([[1,2],[-1,-2]])
1.0000000000000000*B{{-2, -1}, {1, 2}}
sage: PA = PartitionAlgebra(2, 5, base_ring=ZZ, prefix='B')
sage: PA
Partition Algebra of rank 2 with parameter 5 over Integer Ring
sage: (PA([[2, -2], [1, -1]]) - 2*PA([[2, -1], [1, 2]]))^2 == 16*PA([[2, -1], [1, -2]]) + PA([[2, -2], [1, -1]])
True

```

Symmetric group algebra elements and elements from other subalgebras of the partition algebra (e.g., BrauerAlgebra and TemperleyLiebAlgebra) can also be coerced into the partition algebra:

```

sage: S = SymmetricGroupAlgebra(SR, 2)
sage: B = BrauerAlgebra(2, x, SR)
sage: A = PartitionAlgebra(2, x, SR)
sage: S([2,1])*A([[1,-1],[2,-2]])
P{{-2, 1}, {-1, 2}}
sage: B([[-1,-2],[2,1]]) * A([[1],[-1],[2,-2]])
P{{-2}, {-1}, {1, 2}}
sage: A([[1],[-1],[2,-2]]) * B([[-1,-2],[2,1]])
P{{-2, -1}, {1}, {2}}

```

The same is true if the elements come from a subalgebra of a partition algebra of smaller order, or if they are defined over a different base ring:

```

sage: R = FractionField(ZZ['q']); q = R.gen()
sage: S = SymmetricGroupAlgebra(ZZ, 2)
sage: B = BrauerAlgebra(2, q, ZZ[q])
sage: A = PartitionAlgebra(3, q, R)
sage: S([2,1])*A([[1,-1],[2,-3],[3,-2]])
P{{-3, 1}, {-2, 3}, {-1, 2}}
sage: A(B([[-1,-2],[2,1]]))
P{{-3, 3}, {-2, -1}, {1, 2}}

```

class Element

Bases: `sage.combinat.diagram_algebras.DiagramAlgebra.Element`

`dual()`

Return the dual of self.

The dual of an element in the partition algebra is formed by taking the dual of each diagram in the support.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = P.an_element(); elt
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: elt.dual()
3*P{{-2, -1, 1}, {2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, -1, 2}, {1}}
```

to_orbit_basis()

Return `self` in the orbit basis of the associated partition algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: pp = P.an_element();
sage: pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: pp = (3*P([[ -2], [-1, 1, 2]]) + 2*P([[ -2, -1, 1, 2]])
.....: + 2*P([[ -2, 1, 2], [-1]])); pp
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
```

L(i)

Return the i -th Jucys-Murphy element L_i from [Eny2012].

INPUT:

- i – a half integer between $1/2$ and k

ALGORITHM:

We use the recursive definition for L_{2i} given in [Cre2020]. See also [Eny2012] and [Eny2013].

Note: $L_{1/2}$ and L_1 differs from [HR2005].

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.jucys_murphy_element(1/2)
0
sage: P3.jucys_murphy_element(1)
P{{-3, 3}, {-2, 2}, {-1}, {1}}
sage: P3.jucys_murphy_element(2)
P{{-3, 3}, {-2}, {-1, 1}, {2}} - P{{-3, 3}, {-2}, {-1, 1, 2}}
+ P{{-3, 3}, {-2, -1}, {1, 2}} - P{{-3, 3}, {-2, -1, 1}, {2}}
+ P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.jucys_murphy_element(3/2)
n*P{{-3, 3}, {-2, -1, 1, 2}} - P{{-3, 3}, {-2, -1, 2}, {1}}
- P{{-3, 3}, {-2, 1, 2}, {-1}} + P{{-3, 3}, {-2, 2}, {-1, 1}}
```

(continues on next page)

(continued from previous page)

```
sage: P3.L(3/2) * P3.L(2) == P3.L(2) * P3.L(3/2)
True
```

We test the relations in Lemma 2.2.3(2) in [Cre2020] (v1):

```
sage: k = 4
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x in L for y in L) # long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k)]
sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True
```

Also the relations in Lemma 2.2.3(3) in [Cre2020] (v1):

```
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2)
....:      == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,k))
True
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2))
....:      == (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2)
....:      == n * P.e(i/2) for i in range(1,2*k))
True
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2)
....:      == P.L(2*i/2) * P.e(2*i/2) for i in range(1,k))
True
sage: all(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2)
....:      == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True
sage: all(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2)
....:      == P.L(2*i/2) * P.e(2*i/2) for i in range(1,k))
True
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2)
....:      == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True
```

The same tests for a half integer partition algebra:

```
sage: k = 9/2
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x in L for y in L) # long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k-1/2)]
```

(continues on next page)

(continued from previous page)

```

sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2)
.....:      == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,floor(k))
True
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2))
.....:      == (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2)
.....:      == n * P.e(i/2) for i in range(1,2*k))
True
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2)
.....:      == P.L(2*i/2) * P.e(2*i/2) for i in range(1,ceil(k))
True
sage: all(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2)
.....:      == P.e(2*i/2) * P.L(2*i/2) for i in range(1,ceil(k))
True
sage: all(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2)
.....:      == P.L(2*i/2) * P.e(2*i/2) for i in range(1,floor(k))
True
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2)
.....:      == P.e(2*i/2) * P.L(2*i/2) for i in range(1,floor(k))
True

```

a(i)Return the element a_i in self.

The element a_i is the cap and cup at $(i, i + 1)$, so it contains the blocks $\{i, i + 1\}$, $\{-i, -i - 1\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- i – an integer between 1 and $k - 1$

EXAMPLES:

```

sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1}, {1, 2}}
sage: P3.a(2)
P{{-3, -2}, {-1, 1}, {2, 3}}

sage: P3 = PartitionAlgebra(5/2, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1}, {1, 2}}
sage: P3.a(2)
Traceback (most recent call last):
...
ValueError: i must be an integer between 1 and 1

```

e(i)Return the element e_i in self.

If $i = (2r + 1)/2$, then e_i contains the blocks $\{r + 1\}$ and $\{-r - 1\}$. If $i \in \mathbf{Z}$, then e_i contains the block $\{-i, -i - 1, i, i + 1\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- i – a half integer between $1/2$ and $k - 1/2$

EXAMPLES:

```

sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.e(1)
P{{-3, 3}, {-2, -1, 1, 2}}
sage: P3.e(2)
P{{-3, -2, 2, 3}, {-1, 1}}
sage: P3.e(1/2)

sage: P2h = PartitionAlgebra(5/2,n)
sage: [P2h.e(k/2) for k in range(1,5)]
[P{{-3, 3}, {-2, 2}, {-1}, {1}},
 P{{-3, 3}, {-2, -1, 1, 2}},
 P{{-3, 3}, {-2}, {-1, 1}, {2}},
 P{{-3, -2, 2, 3}, {-1, 1}}]

```

generator_a(i)

Return the element a_i in self.

The element a_i is the cap and cup at $(i, i + 1)$, so it contains the blocks $\{i, i + 1\}$, $\{-i, -i - 1\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- i – an integer between 1 and $k - 1$

EXAMPLES:

```

sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1}, {1, 2}}
sage: P3.a(2)
P{{-3, -2}, {-1, 1}, {2, 3}}

sage: P2h = PartitionAlgebra(5/2, n)
sage: [P2h.e(k/2) for k in range(1, 5)]
[P{{-3, 3}, {-2, 2}, {-1}, {1}},
 P{{-3, 3}, {-2, -1, 1, 2}},
 P{{-3, 3}, {-2}, {-1, 1}, {2}},
 P{{-3, -2, 2, 3}, {-1, 1}}]
```

generator_s(i)

Return the i -th simple transposition s_i in `self`.

Borrowing the notation from the symmetric group, the i -th simple transposition s_i has blocks of the form $\{-i, i + 1\}$, $\{-i - 1, i\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- i – an integer between 1 and $k - 1$

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.s(1)
```

(continues on next page)

(continued from previous page)

```

P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.s(2)
P{{-3, 2}, {-2, 3}, {-1, 1}}

sage: R.<n> = ZZ[]
sage: P2h = PartitionAlgebra(5/2,n)
sage: P2h.s(1)
P{{-3, 3}, {-2, 1}, {-1, 2}}

```

jucys_murphy_element(*i*)

Return the *i*-th Jucys-Murphy element L_i from [Eny2012].

INPUT:

- *i* – a half integer between $1/2$ and k

ALGORITHM:

We use the recursive definition for L_{2i} given in [Cre2020]. See also [Eny2012] and [Eny2013].

Note: $L_{1/2}$ and L_1 differs from [HR2005].

EXAMPLES:

```

sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.jucys_murphy_element(1/2)
0
sage: P3.jucys_murphy_element(1)
P{{-3, 3}, {-2, 2}, {-1}, {1}}
sage: P3.jucys_murphy_element(2)
P{{-3, 3}, {-2}, {-1, 1}, {2}} - P{{-3, 3}, {-2}, {-1, 1, 2}}
+ P{{-3, 3}, {-2, -1}, {1, 2}} - P{{-3, 3}, {-2, -1, 1}, {2}}
+ P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.jucys_murphy_element(3/2)
n*P{{-3, 3}, {-2, -1, 1, 2}} - P{{-3, 3}, {-2, -1, 2}, {1}}
- P{{-3, 3}, {-2, 1, 2}, {-1}} + P{{-3, 3}, {-2, 2}, {-1, 1}}
sage: P3.L(3/2) * P3.L(2) == P3.L(2) * P3.L(3/2)
True

```

We test the relations in Lemma 2.2.3(2) in [Cre2020] (v1):

```

sage: k = 4
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x in L for y in L) # long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k)]
sage: gens += [P.e(i/2) for i in range(1,2*k)]

```

(continues on next page)

(continued from previous page)

```
sage: all(x * Lsum == Lsum * x for x in gens)
True
```

Also the relations in Lemma 2.2.3(3) in [Cre2020] (v1):

```
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2)
.....: == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,k))
True
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2))
.....: == (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2)
.....: == n * P.e(i/2) for i in range(1,2*k))
True
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2)
.....: == P.L(2*i/2) * P.e(2*i/2) for i in range(1,k))
True
sage: all(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2)
.....: == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True
sage: all(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2)
.....: == P.L(2*i/2) * P.e(2*i/2) for i in range(1,k))
True
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2)
.....: == P.e(2*i/2) * P.L(2*i/2) for i in range(1,k))
True
```

The same tests for a half integer partition algebra:

```
sage: k = 9/2
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x in L for y in L) # long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k-1/2)]
sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2)
.....: == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,floor(k)))
True
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2))
.....: == (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2)
.....: == n * P.e(i/2) for i in range(1,2*k))
True
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2)
.....: == P.L(2*i/2) * P.e(2*i/2) for i in range(1,ceil(k)))
True
sage: all(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2)
.....: == P.e(2*i/2) * P.L(2*i/2) for i in range(1,ceil(k)))
```

(continues on next page)

(continued from previous page)

```

True
sage: all(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2)
.....:      == P.L(2*i/2) * P.e(2*i/2) for i in range(1,floor(k)))
True
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2)
.....:      == P.e(2*i/2) * P.L(2*i/2) for i in range(1,floor(k)))
True

```

orbit_basis()

Return the orbit basis of self.

EXAMPLES:

```

sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Rational Field
sage: pp = 7 * P2[{-1}, {-2, 1, 2}] - 2 * P2[{-2}, {-1, 1}, {2}]; pp
-2*P[{-2}, {-1, 1}, {2}] + 7*P[{-2, 1, 2}, {-1}]
sage: op = pp.to_orbit_basis(); op
-2*O[{-2}, {-1, 1}, {2}] - 2*O[{-2}, {-1, 1, 2}]
- 2*O[{-2, -1, 1}, {2}] + 5*O[{-2, -1, 1, 2}]
+ 7*O[{-2, 1, 2}, {-1}] - 2*O[{-2, 2}, {-1, 1}]
sage: op == O2(op)
True
sage: pp * op.leading_term()
4*P[{-2}, {-1, 1}, {2}] - 4*P[{-2, -1, 1}, {2}]
+ 14*P[{-2, -1, 1, 2}] - 14*P[{-2, 1, 2}, {-1}]

```

s(i)Return the i -th simple transposition s_i in self.Borrowing the notation from the symmetric group, the i -th simple transposition s_i has blocks of the form $\{-i, i+1\}$, $\{-i-1, i\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- i – an integer between 1 and $k-1$

EXAMPLES:

```

sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.s(1)
P[{-3, 3}, {-2, 1}, {-1, 2}]
sage: P3.s(2)
P[{-3, 2}, {-2, 3}, {-1, 1}]

sage: R.<n> = ZZ[]
sage: P2h = PartitionAlgebra(5/2, n)
sage: P2h.s(1)
P[{-3, 3}, {-2, 1}, {-1, 2}]

```

sigma(i)Return the element σ_i from [Eny2012] of self.

INPUT:

- i – a half integer between $1/2$ and $k - 1/2$

Note: In [Cre2020] and [Eny2013], these are the elements σ_{2i} .

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.sigma(1)
P{{-3, 3}, {-2, 2}, {-1, 1}}
sage: P3.sigma(3/2)
P{{-3, 3}, {-2, 1}, {-1, 2}}
sage: P3.sigma(2)
-P{{-3, -1, 1, 3}, {-2, 2}} + P{{-3, -1, 3}, {-2, 1, 2}}
+ P{{-3, 1, 3}, {-2, -1, 2}} - P{{-3, 3}, {-2, -1, 1, 2}}
+ P{{-3, 3}, {-2, 2}, {-1, 1}}
sage: P3.sigma(5/2)
-P{{-3, -1, 1, 2}, {-2, 3}} + P{{-3, -1, 2}, {-2, 1, 3}}
+ P{{-3, 1, 2}, {-2, -1, 3}} - P{{-3, 2}, {-2, -1, 1, 3}}
+ P{{-3, 2}, {-2, 3}, {-1, 1}}
```

We test the relations in Lemma 2.2.3(1) in [Cre2020] (v1):

```
sage: k = 4
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(k, x)
sage: all(P.sigma(i/2).dual() == P.sigma(i/2)
.....:     for i in range(1,2*k))
True
sage: all(P.sigma(i)*P.sigma(i+1/2) == P.sigma(i+1/2)*P.sigma(i) == P.s(i)
.....:     for i in range(1,floor(k)))
True
sage: all(P.sigma(i)*P.e(i) == P.e(i)*P.sigma(i) == P.e(i)
.....:     for i in range(1,floor(k)))
True
sage: all(P.sigma(i+1/2)*P.e(i) == P.e(i)*P.sigma(i+1/2) == P.e(i)
.....:     for i in range(1,floor(k)))
True

sage: k = 9/2
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(k, x)
sage: all(P.sigma(i/2).dual() == P.sigma(i/2)
.....:     for i in range(1,2*k-1))

True
```

(continues on next page)

(continued from previous page)

```
sage: all(P.sigma(i+1/2)*P.e(i) == P.e(i)*P.sigma(i+1/2) == P.e(i)
.....:      for i in range(1,floor(k)))
True
```

class sage.combinat.diagram_algebras.PartitionDiagram(*parent, d, check=True*)

Bases: *sage.combinat.diagram_algebras.AbstractPartitionDiagram*

The element class for a partition diagram.

A partition diagram for an integer k is a partition of the set $\{1, \dots, k, -1, \dots, -k\}$

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagram, PartitionDiagrams
sage: PartitionDiagrams(1)
Partition diagrams of order 1
sage: PartitionDiagrams(1).list()
[{{-1, 1}}, {{-1}, {1}}]
sage: PartitionDiagram([[1, -1]])
{{-1, 1}}
sage: PartitionDiagram(((1, -2), (2, -1))).parent()
Partition diagrams of order 2
```

class sage.combinat.diagram_algebras.PartitionDiagrams(*order, category=None*)

Bases: *sage.combinat.diagram_algebras.AbstractPartitionDiagrams*

This class represents all partition diagrams of integer or integer +1/2 order.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(1); pd
Partition diagrams of order 1
sage: pd.list()
[{{-1, 1}}, {{-1}, {1}}]

sage: pd = da.PartitionDiagrams(3/2); pd
Partition diagrams of order 3/2
sage: pd.list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}}]
```

Element

alias of *PartitionDiagram*

cardinality()

The cardinality of partition diagrams of half-integer order n is the $2n$ -th Bell number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(3)
sage: pd.cardinality()
```

(continues on next page)

(continued from previous page)

```

203
sage: pd = da.PartitionDiagrams(7/2)
sage: pd.cardinality()
877

```

class `sage.combinat.diagram_algebras.PlanarAlgebra`(*k*, *q*, *base_ring*, *prefix*)

Bases: `sage.combinat.diagram_algebras.SubPartitionAlgebra`, `sage.combinat.diagram_algebras.UnitDiagramMixin`

A planar algebra.

The planar algebra of rank k is an algebra with basis indexed by the collection of all planar set partitions of $\{1, \dots, k, -1, \dots, -k\}$.

This algebra is thus a subalgebra of the partition algebra. For more information, see [PartitionAlgebra](#).

INPUT:

- k – rank of the algebra
- q – the deformation parameter q

OPTIONAL ARGUMENTS:

- `base_ring` – (default `None`) a ring containing q ; if `None` then just takes the parent of q
- `prefix` – (default "P1") a label for the basis elements

EXAMPLES:

We define the planar algebra of rank 2 with parameter x over \mathbf{Z} :

```

sage: R.<x> = ZZ[]
sage: P1 = PlanarAlgebra(2, x, R); P1
Planar Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over
↳ Integer Ring
sage: P1.basis().keys()
Planar diagrams of order 2
sage: P1.basis().keys()([[ -1, 1], [2, -2]])
{{-2, 2}, {-1, 1}}
sage: P1.basis().list()
[P1{{-2, -1, 1, 2}},
 P1{{-2, 1, 2}, {-1}},
 P1{{-2}, {-1, 1, 2}},
 P1{{-2, -1}, {1, 2}},
 P1{{-2}, {-1}, {1, 2}},
 P1{{-2, -1, 1}, {2}},
 P1{{-2, 1}, {-1}, {2}},
 P1{{-2, 2}, {-1, 1}},
 P1{{-2, -1, 2}, {1}},
 P1{{-2, 2}, {-1}, {1}},
 P1{{-2}, {-1, 1}, {2}},
 P1{{-2}, {-1, 2}, {1}},
 P1{{-2, -1}, {1}, {2}},
 P1{{-2}, {-1}, {1}, {2}}]
sage: E = P1([[1, 2], [-1, -2]])
sage: E^2 == x*E

```

(continues on next page)

(continued from previous page)

```
True
sage: E^5 == x^4*E
True
```

class `sage.combinat.diagram_algebras.PlanarDiagram`(*parent, d, check=True*)

Bases: `sage.combinat.diagram_algebras.AbstractPartitionDiagram`

The element class for a planar diagram.

A planar diagram for an integer k is a partition of the set $\{1, \dots, k, -1, \dots, -k\}$ so that the diagram is non-crossing.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PlanarDiagrams
sage: PlanarDiagrams(2)
Planar diagrams of order 2
sage: PlanarDiagrams(2).list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2, -1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}}]
```

check()

Check the validity of the input for self.

class `sage.combinat.diagram_algebras.PlanarDiagrams`(*order, category=None*)

Bases: `sage.combinat.diagram_algebras.AbstractPartitionDiagrams`

All planar diagrams of integer or integer $+1/2$ order.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: pld = da.PlanarDiagrams(1); pld
Planar diagrams of order 1
sage: pld.list()
[{{-1, 1}}, {{-1}, {1}}]

sage: pld = da.PlanarDiagrams(3/2); pld
Planar diagrams of order 3/2
sage: pld.list()
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
```

(continues on next page)

(continued from previous page)

```

[[-2, -1, 2], [1]],
[[-2, 2], [-1], [1]]]

```

Elementalias of *PlanarDiagram***cardinality()**Return the cardinality of *self*.The number of all planar diagrams of order k is the $2k$ -th Catalan number.

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: pld = da.PlanarDiagrams(3)
sage: pld.cardinality()
132

```

class `sage.combinat.diagram_algebras.PropagatingIdeal`($k, q, base_ring, prefix$)Bases: *sage.combinat.diagram_algebras.SubPartitionAlgebra*

A propagating ideal.

The propagating ideal of rank k is a non-unital algebra with basis indexed by the collection of ideal set partitions of $\{1, \dots, k, -1, \dots, -k\}$. We say a set partition is *ideal* if its propagating number is less than k .This algebra is a non-unital subalgebra and an ideal of the partition algebra. For more information, see *PartitionAlgebra*.

EXAMPLES:

We now define the propagating ideal of rank 2 with parameter x over \mathbf{Z} :

```

sage: R.<x> = QQ[]
sage: I = PropagatingIdeal(2, x, R); I
Propagating Ideal of rank 2 with parameter x
over Univariate Polynomial Ring in x over Rational Field
sage: I.basis().keys()
Ideal diagrams of order 2
sage: I.basis().list()
[I[[-2, -1, 1, 2]],
 I[[-2, 1, 2], [-1]],
 I[[-2], [-1, 1, 2]],
 I[[-2, -1], [1, 2]],
 I[[-2], [-1], [1, 2]],
 I[[-2, -1, 1], [2]],
 I[[-2, 1], [-1], [2]],
 I[[-2, -1, 2], [1]],
 I[[-2, 2], [-1], [1]],
 I[[-2], [-1, 1], [2]],
 I[[-2], [-1, 2], [1]],
 I[[-2, -1], [1], [2]],
 I[[-2], [-1], [1], [2]]]
sage: E = I([[1, 2], [-1, -2]])
sage: E^2 == x*E
True

```

(continues on next page)

(continued from previous page)

```
sage: E^5 == x^4*E
True
```

class ElementBases: *sage.combinat.diagram_algebras.SubPartitionAlgebra.Element*

An element of a propagating ideal.

We need to take care of exponents since we are not unital.

```
class sage.combinat.diagram_algebras.SubPartitionAlgebra(k, q, base_ring, prefix, diagrams,
                                                         category=None)
```

Bases: *sage.combinat.diagram_algebras.DiagramBasis*

A subalgebra of the partition algebra in the diagram basis indexed by a subset of the diagrams.

class ElementBases: *sage.combinat.diagram_algebras.DiagramAlgebra.Element***to_orbit_basis()**Return *self* in the orbit basis of the associated ambient partition algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: B = BrauerAlgebra(2, x, R)
sage: bb = B([[[-2, -1], [1, 2]]]); bb
B{{-2, -1}, {1, 2}}
sage: bb.to_orbit_basis()
0{{-2, -1}, {1, 2}} + 0{{-2, -1, 1, 2}}
```

ambient()Return the partition algebra *self* is a sub-algebra of.

EXAMPLES:

```
sage: x = var('x')
sage: BA = BrauerAlgebra(2, x)
sage: BA.ambient()
Partition Algebra of rank 2 with parameter x over Symbolic Ring
```

lift()

Return the lift map from diagram subalgebra to the ambient space.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: BA = BrauerAlgebra(2, x, R)
sage: E = BA([[1, 2], [-1, -2]])
sage: lifted = BA.lift(E); lifted
B{{-2, -1}, {1, 2}}
sage: lifted.parent() is BA.ambient()
True
```

retract(x)

Retract an appropriate partition algebra element to the corresponding element in the partition subalgebra.

EXAMPLES:

```

sage: R.<x> = QQ[]
sage: BA = BrauerAlgebra(2, x, R)
sage: PA = BA.ambient()
sage: E = PA([[1,2], [-1,-2]])
sage: BA.retract(E) in BA
True

```

`sage.combinat.diagram_algebras.TL_diagram_ascii_art`(*diagram*, *use_unicode=False*, *blobs=[]*)
Return ascii art for a Temperley-Lieb diagram *diagram*.

INPUT:

- *diagram* – a list of pairs of matchings of the set $\{-1, \dots, -n, 1, \dots, n\}$
- *use_unicode* – (default: `False`): whether or not to use unicode art instead of ascii art
- *blobs* – (optional) a list of matchings with blobs on them

EXAMPLES:

```

sage: from sage.combinat.diagram_algebras import TL_diagram_ascii_art
sage: TL = [(-15,-12), (-14,-13), (-11,15), (-10,14), (-9,-6),
.....:      (-8,-7), (-5,-4), (-3,1), (-2,-1), (2,3), (4,5),
.....:      (6,11), (7, 8), (9,10), (12,13)]
sage: TL_diagram_ascii_art(TL, use_unicode=False)
o o o o o o o o o o o o o o o o o
| ` ` ` ` ` | ` ` ` ` ` | ` ` | |

class `sage.combinat.diagram_algebras.TemperleyLiebAlgebra`(*k*, *q*, *base_ring*, *prefix*)

Bases: `sage.combinat.diagram_algebras.SubPartitionAlgebra`, `sage.combinat.diagram_algebras.UnitDiagramMixin`

A Temperley–Lieb algebra.

The Temperley–Lieb algebra of rank k is an algebra with basis indexed by the collection of planar set partitions of $\{1, \dots, k, -1, \dots, -k\}$ with block size 2.

This algebra is thus a subalgebra of the partition algebra. For more information, see [PartitionAlgebra](#).

INPUT:

- k – rank of the algebra
- q – the deformation parameter q

OPTIONAL ARGUMENTS:

- `base_ring` – (default `None`) a ring containing q ; if `None` then just takes the parent of q
- `prefix` – (default `"T"`) a label for the basis elements

EXAMPLES:

We define the Temperley–Lieb algebra of rank 2 with parameter x over \mathbf{Z} :

```

sage: R.<x> = ZZ[]
sage: T = TemperleyLiebAlgebra(2, x, R); T
Temperley-Lieb algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring
sage: T.basis()
Lazy family (Term map from Temperley Lieb diagrams of order 2
to Temperley-Lieb Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Integer
Ring(i))_{i in Temperley Lieb diagrams of order 2}
sage: T.basis().keys()
Temperley Lieb diagrams of order 2
sage: T.basis().keys()([[ -1, 1], [ 2, -2]])
[{-2, 2}, {-1, 1}]
sage: b = T.basis().list(); b
[T{{-2, -1}, {1, 2}}, T{{-2, 2}, {-1, 1}}]

```

(continues on next page)

(continued from previous page)

```

sage: b[0]
T{{-2, -1}, {1, 2}}
sage: b[0]^2 == x*b[0]
True
sage: b[0]^5 == x^4*b[0]
True

```

class `sage.combinat.diagram_algebras.TemperleyLiebDiagram`(*parent, d, check=True*)
 Bases: `sage.combinat.diagram_algebras.AbstractPartitionDiagram`

The element class for a Temperley-Lieb diagram.

A Temperley-Lieb diagram for an integer k is a partition of the set $\{1, \dots, k, -1, \dots, -k\}$ so that the blocks are all of size 2 and the diagram is planar.

EXAMPLES:

```

sage: from sage.combinat.diagram_algebras import TemperleyLiebDiagrams
sage: TemperleyLiebDiagrams(2)
Temperley Lieb diagrams of order 2
sage: TemperleyLiebDiagrams(2).list()
[{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]

```

check()

Check the validity of the input for `self`.

class `sage.combinat.diagram_algebras.TemperleyLiebDiagrams`(*order, category=None*)
 Bases: `sage.combinat.diagram_algebras.AbstractPartitionDiagrams`

All Temperley-Lieb diagrams of integer or integer $+1/2$ order.

For more information on Temperley-Lieb diagrams, see [TemperleyLiebAlgebra](#).

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: td = da.TemperleyLiebDiagrams(3); td
Temperley Lieb diagrams of order 3
sage: td.list()
[{{-3, 3}, {-2, -1}, {1, 2}},
 {{-3, 1}, {-2, -1}, {2, 3}},
 {{-3, -2}, {-1, 1}, {2, 3}},
 {{-3, -2}, {-1, 3}, {1, 2}},
 {{-3, 3}, {-2, 2}, {-1, 1}}]

sage: td = da.TemperleyLiebDiagrams(5/2); td
Temperley Lieb diagrams of order 5/2
sage: td.list()
[{{-3, 3}, {-2, -1}, {1, 2}}, {{-3, 3}, {-2, 2}, {-1, 1}}]

```

Element

alias of `TemperleyLiebDiagram`

cardinality()

Return the cardinality of `self`.

The number of Temperley-Lieb diagrams of integer order k is the k -th Catalan number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: td = da.TemperleyLiebDiagrams(3)
sage: td.cardinality()
5
```

class `sage.combinat.diagram_algebras.UnitDiagramMixin`

Bases: `object`

Mixin class for diagram algebras that have the unit indexed by the `identity_set_partition()`.

one_basis()

The following constructs the identity element of `self`.

It is not called directly; instead one should use `DA.one()` if `DA` is a defined diagram algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: P.one_basis()
[[-2, 2], [-1, 1]]
```

`sage.combinat.diagram_algebras.brauer_diagrams(k)`

Return a generator of all Brauer diagrams of order `k`.

A Brauer diagram of order `k` is a partition diagram of order `k` with block size 2.

INPUT:

- `k` – the order of the Brauer diagrams

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.brauer_diagrams(2)]
[[-2, -1], {1, 2}], [-2, 1], {-1, 2}], [-2, 2], {-1, 1}]
sage: [SetPartition(p) for p in da.brauer_diagrams(5/2)]
[[-3, 3], {-2, -1}, {1, 2}],
[[-3, 3], {-2, 1}, {-1, 2}],
[[-3, 3], {-2, 2}, {-1, 1}]
```

`sage.combinat.diagram_algebras.diagram_latex(diagram, fill=False, edge_options=None, edge_additions=None)`

Return latex code for the diagram `diagram` using `tikz`.

EXAMPLES:

```
sage: from sage.combinat.diagram_algebras import PartitionDiagrams, diagram_latex
sage: P = PartitionDiagrams(2)
sage: D = P([[1,2],[-2,-1]])
sage: print(diagram_latex(D)) # indirect doctest
\begin{tikzpicture}[scale = 0.5,thick, baseline={(0,-1ex/2)}]
\tikzstyle{vertex} = [shape = circle, minimum size = 7pt, inner sep = 1pt]
\node[vertex] (G--2) at (1.5, -1) [shape = circle, draw] {};
\node[vertex] (G--1) at (0.0, -1) [shape = circle, draw] {};
\node[vertex] (G-1) at (0.0, 1) [shape = circle, draw] {};
```

(continues on next page)

(continued from previous page)

```
\node[vertex] (G-2) at (1.5, 1) [shape = circle, draw] {};
\draw[] (G--2) .. controls +(-0.5, 0.5) and +(0.5, 0.5) .. (G--1);
\draw[] (G-1) .. controls +(0.5, -0.5) and +(-0.5, -0.5) .. (G-2);
\end{tikzpicture}
```

`sage.combinat.diagram_algebras.ideal_diagrams(k)`

Return a generator of all “ideal” diagrams of order k .

An ideal diagram of order k is a partition diagram of order k with propagating number less than k .

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: all_diagrams = da.partition_diagrams(2)
sage: [SetPartition(p) for p in all_diagrams if p not in da.ideal_diagrams(2)]
[{{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

sage: all_diagrams = da.partition_diagrams(3/2)
sage: [SetPartition(p) for p in all_diagrams if p not in da.ideal_diagrams(3/2)]
[{{-2, 2}, {-1, 1}}]
```

`sage.combinat.diagram_algebras.identity_set_partition(k)`

Return the identity set partition $\{\{1, -1\}, \dots, \{k, -k\}\}$.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: SetPartition(da.identity_set_partition(2))
{{-2, 2}, {-1, 1}}
```

`sage.combinat.diagram_algebras.is_planar(sp)`

Return True if the diagram corresponding to the set partition sp is planar; otherwise, return False.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: da.is_planar( da.to_set_partition([[1, -2], [2, -1]]))
False
sage: da.is_planar( da.to_set_partition([[1, -1], [2, -2]]))
True
```

`sage.combinat.diagram_algebras.pair_to_graph(sp1, sp2)`

Return a graph consisting of the disjoint union of the graphs of set partitions $sp1$ and $sp2$ along with edges joining the bottom row (negative numbers) of $sp1$ to the top row (positive numbers) of $sp2$.

The vertices of the graph $sp1$ appear in the result as pairs $(k, 1)$, whereas the vertices of the graph $sp2$ appear as pairs $(k, 2)$.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: sp1 = da.to_set_partition([[1, -2], [2, -1]])
sage: sp2 = da.to_set_partition([[1, -2], [2, -1]])
sage: g = da.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices
```

(continues on next page)

(continued from previous page)

```

sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
[((-2, 1), (1, 1), None), ((-2, 1), (2, 2), None),
 ((-2, 2), (1, 2), None), ((-1, 1), (1, 2), None),
 ((-1, 1), (2, 1), None), ((-1, 2), (2, 2), None)]

```

Another example which used to be wrong until [trac ticket #15958](#):

```

sage: sp3 = da.to_set_partition([[1, -1], [2], [-2]])
sage: sp4 = da.to_set_partition([[1], [-1], [2], [-2]])
sage: g = da.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices

sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
 ((-1, 1), (1, 2), None)]

```

`sage.combinat.diagram_algebras.partition_diagrams(k)`

Return a generator of all partition diagrams of order k .

A partition diagram of order $k \in \mathbf{Z}$ is a set partition of $\{1, \dots, k, -1, \dots, -k\}$. If we have $k - 1/2 \in \mathbf{Z}$, then a partition diagram of order $k \in 1/2\mathbf{Z}$ is a set partition of $\{1, \dots, k + 1/2, -1, \dots, -(k + 1/2)\}$ with $k + 1/2$ and $-(k + 1/2)$ in the same block. See [HR2005].

INPUT:

- k – the order of the partition diagrams

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.partition_diagrams(2)]
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1, 2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2, -1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}}]
sage: [SetPartition(p) for p in da.partition_diagrams(3/2)]
[{{-2, -1, 1, 2}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},

```

(continues on next page)

(continued from previous page)

```

[{-2, -1, 2}, {1}],
[{-2, 2}, {-1}, {1}]

```

`sage.combinat.diagram_algebras.planar_diagrams(k)`

Return a generator of all planar diagrams of order k .

A planar diagram of order k is a partition diagram of order k that has no crossings.

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: all_diagrams = da.partition_diagrams(2)
sage: [SetPartition(p) for p in all_diagrams if p not in da.planar_diagrams(2)]
[{-2, 1}, {-1, 2}]
sage: all_diagrams = da.partition_diagrams(5/2)
sage: [SetPartition(p) for p in all_diagrams if p not in da.planar_diagrams(5/2)]
[{-3, -1, 3}, {-2, 1, 2}],
[{-3, -2, 1, 3}, {-1, 2}],
[{-3, -1, 1, 3}, {-2, 2}],
[{-3, 1, 3}, {-2, -1, 2}],
[{-3, 1, 3}, {-2, 2}, {-1}],
[{-3, 1, 3}, {-2}, {-1, 2}],
[{-3, -1, 2, 3}, {-2, 1}],
[{-3, 3}, {-2, 1}, {-1, 2}],
[{-3, -1, 3}, {-2, 1}, {2}],
[{-3, -1, 3}, {-2, 2}, {1}]

```

`sage.combinat.diagram_algebras.propagating_number(sp)`

Return the propagating number of the set partition sp .

The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: sp1 = da.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = da.to_set_partition([[1,2],[-2,-1]])
sage: da.propagating_number(sp1)
2
sage: da.propagating_number(sp2)
0

```

`sage.combinat.diagram_algebras.temperley_lieb_diagrams(k)`

Return a generator of all Temperley–Lieb diagrams of order k .

A Temperley–Lieb diagram of order k is a partition diagram of order k with block size 2 and is planar.

INPUT:

- k – the order of the Temperley–Lieb diagrams

EXAMPLES:

```

sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.temperley_lieb_diagrams(2)]
[{-2, -1}, {1, 2}], [{-2, 2}, {-1, 1}]

```

(continues on next page)

(continued from previous page)

```
sage: [SetPartition(p) for p in da.temperley_lieb_diagrams(5/2)]
[{{-3, 3}, {-2, -1}, {1, 2}}, {{-3, 3}, {-2, 2}, {-1, 1}}]
```

`sage.combinat.diagram_algebras.to_Brauer_partition(l, k=None)`

Same as `to_set_partition()` but assumes omitted elements are connected straight through.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: f = lambda sp: SetPartition(da.to_Brauer_partition(sp))
sage: f([[1,2],[-1,-2]]) == SetPartition([[1,2],[-1,-2]])
True
sage: f([[1,3],[-1,-3]]) == SetPartition([[1,3],[-3,-1],[2,-2]])
True
sage: f([[1,-4],[-3,-1],[3,4]]) == SetPartition([[3,-1],[2,-2],[1,-4],[3,4]])
True
sage: p = SetPartition([[1,2],[-1,-2],[3,-3],[4,-4]])
sage: SetPartition(da.to_Brauer_partition([[1,2],[-1,-2]], k=4)) == p
True
```

`sage.combinat.diagram_algebras.to_graph(sp)`

Return a graph representing the set partition *sp*.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: g = da.to_graph( da.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices

sage: g.vertices(sort=True)
[-2, -1, 1, 2]
sage: g.edges(sort=True)
[(-2, 1, None), (-1, 2, None)]
```

`sage.combinat.diagram_algebras.to_set_partition(l, k=None)`

Convert input to a set partition of $\{1, \dots, k, -1, \dots, -k\}$

Convert a list of a list of numbers to a set partitions. Each list of numbers in the outer list specifies the numbers contained in one of the blocks in the set partition.

If *k* is specified, then the set partition will be a set partition of $\{1, \dots, k, -1, \dots, -k\}$. Otherwise, *k* will default to the minimum number needed to contain all of the specified numbers.

INPUT:

- *l* - a list of lists of integers
- *k* - integer (optional, default None)

OUTPUT:

- a list of sets

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: f = lambda sp: SetPartition(da.to_set_partition(sp))
```

(continues on next page)

(continued from previous page)

```

sage: f([[1,-1],[2,-2]]) == SetPartition(da.identity_set_partition(2))
True
sage: da.to_set_partition([[1]])
[{1}, {-1}]
sage: da.to_set_partition([[1,-1],[-2,3]],9/2)
[{-1, 1}, {-2, 3}, {2}, {-4, 4}, {-5, 5}, {-3}]

```

5.1.96 Exact Cover Problem via Dancing Links

`sage.combinat.dlx.AllExactCovers(M)`

Use A. Ajanki's DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```

sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]]) #no exact covers
sage: for cover in AllExactCovers(M):
.....:     print(cover)
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) #two exact covers
sage: for cover in AllExactCovers(M):
.....:     print(cover)
[(1, 1, 0), (0, 0, 1)]
[(1, 0, 1), (0, 1, 0)]

```

class `sage.combinat.dlx.DLXMatrix(ones, initialsolution=None)`

Bases: `object`

Solve the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix M with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1's.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form: (note the 1-index!):

```

[
  [1, [i_11,i_12,...,i_1r]]
  ...
  [m, [i_m1,i_m2,...,i_ms]]
]

```

where $M[j][i_{jk}] = 1$.

The first example below corresponds to the matrix:

```

1110
1010
0100
0001

```

which is exactly covered by:

```

1110
0001

```

and

```
1010
0100
0001
```

EXAMPLES:

```
sage: from sage.combinat.dlx import *
sage: ones = [[1, [1, 2, 3]]]
sage: ones += [[2, [1, 3]]]
sage: ones += [[3, [2]]]
sage: ones += [[4, [4]]]
sage: DLXM = DLXMatrix(ones, [4])
sage: for C in DLXM:
.....:     print(C)
[4, 1]
[4, 2, 3]
```

Note: The 0 entry is reserved internally for headers in the sparse representation, so rows and columns begin their indexing with 1. Apologies for any heartache this causes. Blame the original author, or fix it yourself.

next()

Search for the first solution we can find, and return it.

Knuth describes the Dancing Links algorithm recursively, though actually implementing it as a recursive algorithm is permissible only for highly restricted problems. (for example, the original author implemented this for Sudoku, and it works beautifully there)

What follows is an iterative description of DLX:

```
stack <- [(NULL)]
level <- 0
while level >= 0:
    cur <- stack[level]
    if cur = NULL:
        if R[h] = h:
            level <- level - 1
            yield solution
        else:
            cover(best_column)
            stack[level] = best_column
    else if D[cur] != C[cur]:
        if cur != C[cur]:
            delete solution[level]
            for j in L[cur], L[L[cur]], ... , while j != cur:
                uncover(C[j])
        cur <- D[cur]
        solution[level] <- cur
        stack[level] <- cur
        for j in R[cur], R[R[cur]], ... , while j != cur:
            cover(C[j])
        level <- level + 1
```

(continues on next page)

(continued from previous page)

```

    stack[level] <- (NULL)
  else:
    if C[cur] != cur:
      delete solution[level]
      for j in L[cur], L[L[cur]], ... , while j != cur:
        uncover(C[j])
    uncover(cur)
    level <- level - 1

```

`sage.combinat.dlx.OneExactCover(M)`

Use A. Ajanki's DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```

sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]]) # no exact covers
sage: OneExactCover(M)

sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) # two exact covers
sage: OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]

```

5.1.97 Dyck Words

A class of an object enumerated by the *Catalan numbers*, see [Sta-EC2], [StaCat98] for details.

AUTHORS:

- Mike Hansen
- Dan Drake (2008-05-30): DyckWordBacktracker support
- Florent Hivert (2009-02-01): Bijections with NonDecreasingParkingFunctions
- Christian Stump (2011-12): added combinatorial maps and statistics
- Mike Zabrocki:
 - (2012-10): added pretty print, characteristic function, more functions
 - (2013-01): added inverse of area/dinv, bounce/area map
- Jean-Baptiste Priez, Travis Scrimshaw (2013-05-17): Added ASCII art
- Travis Scrimshaw (2013-07-09): Removed CombinatorialClass and added global options.

REFERENCES:

class `sage.combinat.dyck_word.CompleteDyckWords`

Bases: `sage.combinat.dyck_word.DyckWords`

Abstract base class for all complete Dyck words.

Element

alias of `DyckWord_complete`

from_Catalan_code(code)

Return the Dyck word associated to the given Catalan code code.

A Catalan code of length n is a sequence (a_1, a_2, \dots, a_n) of n integers a_i such that:

- $0 \leq a_i \leq n - i$ for every i ;
- if $i < j$ and $a_i > 0$ and $a_j > 0$ and $a_{i+1} = a_{i+2} = \dots = a_{j-1} = 0$, then $a_i - a_j < j - i$.

It turns out that the Catalan codes of length n are in bijection with Dyck words.

The Catalan code of a Dyck word is example (x) in Richard Stanley's exercises on combinatorial interpretations for Catalan objects. The code in this example is the reverse of the description provided there. See [Sta-EC2] and [StaCat98].

EXAMPLES:

```
sage: DyckWords().from_Catalan_code([])
[]
sage: DyckWords().from_Catalan_code([0])
[1, 0]
sage: DyckWords().from_Catalan_code([0, 1])
[1, 1, 0, 0]
sage: DyckWords().from_Catalan_code([0, 0])
[1, 0, 1, 0]
```

from_area_sequence(code)

Return the Dyck word associated to the given area sequence code.

See [to_area_sequence\(\)](#) for a definition of the area sequence of a Dyck word.

See also:

[area\(\)](#), [to_area_sequence\(\)](#).

INPUT:

- code – a list of integers satisfying $\text{code}[0] == 0$ and $0 \leq \text{code}[i+1] \leq \text{code}[i]+1$.

EXAMPLES:

```
sage: DyckWords().from_area_sequence([])
[]
sage: DyckWords().from_area_sequence([0])
[1, 0]
sage: DyckWords().from_area_sequence([0, 1])
[1, 1, 0, 0]
sage: DyckWords().from_area_sequence([0, 0])
[1, 0, 1, 0]
```

from_non_decreasing_parking_function(pf)

Bijection from *non-decreasing parking functions*.

See there the method [to_dyck_word\(\)](#) for more information.

EXAMPLES:

```
sage: D = DyckWords()
sage: D.from_non_decreasing_parking_function([])
[]
sage: D.from_non_decreasing_parking_function([1])
[1, 0]
sage: D.from_non_decreasing_parking_function([1, 1])
[1, 1, 0, 0]
sage: D.from_non_decreasing_parking_function([1, 2])
```

(continues on next page)

(continued from previous page)

```
[1, 0, 1, 0]
sage: D.from_non_decreasing_parking_function([1,1,1])
[1, 1, 1, 0, 0, 0]
sage: D.from_non_decreasing_parking_function([1,2,3])
[1, 0, 1, 0, 1, 0]
sage: D.from_non_decreasing_parking_function([1,1,3,3,4,6,6])
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```

from_noncrossing_partition(ncp)

Convert a noncrossing partition ncp to a Dyck word.

EXAMPLES:

```
sage: DyckWord(noncrossing_partition=[[1,2]]) # indirect doctest
[1, 1, 0, 0]
sage: DyckWord(noncrossing_partition=[[1],[2]])
[1, 0, 1, 0]

sage: dws = DyckWords(5).list()
sage: ncps = [x.to_noncrossing_partition() for x in dws]
sage: dws2 = [DyckWord(noncrossing_partition=x) for x in ncps]
sage: dws == dws2
True
```

class sage.combinat.dyck_word.CompleteDyckWords_allBases: *sage.combinat.dyck_word.CompleteDyckWords*, *sage.combinat.dyck_word.DyckWords_all*

All complete Dyck words.

class height_posetBases: *sage.structure.unique_representation.UniqueRepresentation*, *sage.structure.parent.Parent*

The poset of complete Dyck words compared componentwise by heights.

This is, D is smaller than or equal to D' if it is weakly below D' .

This is implemented by comparison of area sequences.

le(dw1, dw2)

Compare two Dyck words of equal size, and return True if all of the heights of dw1 are less than or equal to the respective heights of dw2.

See also:*to_area_sequence()*

EXAMPLES:

```
sage: poset = DyckWords().height_poset()
sage: poset.le(DyckWord([]), DyckWord([]))
True
sage: poset.le(DyckWord([1,0]), DyckWord([1,0]))
True
sage: poset.le(DyckWord([1,0,1,0]), DyckWord([1,1,0,0]))
True
sage: poset.le(DyckWord([1,1,0,0]), DyckWord([1,0,1,0]))
```

(continues on next page)

(continued from previous page)

```
False
sage: [poset.le(dw1, dw2)
.....:      for dw1 in DyckWords(3) for dw2 in DyckWords(3)]
[True, True, True, True, True, False, True, False, True, True,
False, False, True, True, True, False, False, False, True,
True, False, False, False, False, True]
```

class sage.combinat.dyck_word.CompleteDyckWords_size(*k*)

Bases: [sage.combinat.dyck_word.CompleteDyckWords](#), [sage.combinat.dyck_word.DyckWords_size](#)

All complete Dyck words of a given size.

cardinality()

Return the number of complete Dyck words of semilength *n*, i.e. the *n*-th *Catalan number*.

EXAMPLES:

```
sage: DyckWords(4).cardinality()
14
sage: ns = list(range(9))
sage: dws = [DyckWords(n) for n in ns]
sage: all(dw.cardinality() == len(dw.list()) for dw in dws)
True
```

random_element()

Return a random complete Dyck word of semilength *n*.

The algorithm is based on a classical combinatorial fact. One chooses at random a word with *n* 0's and *n* + 1 1's. One then considers every 1 as an ascending step and every 0 as a descending step, and one finds the lowest point of the path (with respect to a slightly tilted slope). One then cuts the path at this point and builds a Dyck word by exchanging the two parts of the word and removing the initial step.

Todo: extend this to m-Dyck words

EXAMPLES:

```
sage: dw = DyckWords(8)
sage: dw.random_element() # random
[1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 1, 0, 1, 0, 1, 0]

sage: D = DyckWords(8)
sage: D.random_element() in D
True
```

class sage.combinat.dyck_word.DyckWord(*parent, l, latex_options={}*)

Bases: [sage.combinat.combinat.CombinatorialElement](#)

A Dyck word.

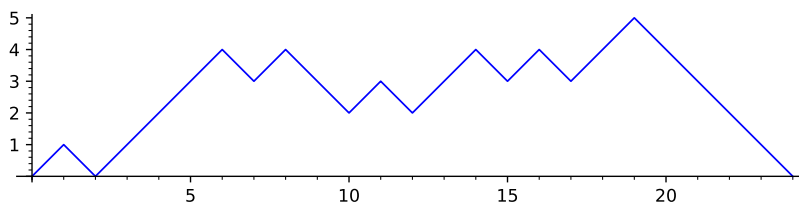

A Dyck word is a sequence of open and close symbols such that every close symbol has a corresponding open symbol preceding it. That is to say, a Dyck word of length *n* is a list with *k* entries 1 and *n* - *k* entries 0 such that the first *i* entries always have at least as many 1s among them as 0s. (Here, the 1 serves as the open symbol and the 0 as the close symbol.) Alternatively, the alphabet 1 and 0 can be replaced by other characters such as '(' and ')'.

A Dyck word is *complete* if every open symbol moreover has a corresponding close symbol.

A Dyck word may also be specified by either a noncrossing partition or by an area sequence or the sequence of heights.

A Dyck word may also be thought of as a lattice path in the \mathbf{Z}^2 grid, starting at the origin $(0, 0)$, and with steps in the North $N = (0, 1)$ and east $E = (1, 0)$ directions such that it does not pass below the $x = y$ diagonal. The diagonal is referred to as the “main diagonal” in the documentation. A North step is represented by a 1 in the list and an East step is represented by a 0.

Equivalently, the path may be represented with steps in the $NE = (1, 1)$ and the $SE = (1, -1)$ direction such that it does not pass below the horizontal axis.

A path representing a Dyck word (either using N and E steps, or using NE and SE steps) is called a Dyck path.

EXAMPLES:

```
sage: dw = DyckWord([1, 0, 1, 0]); dw
[1, 0, 1, 0]
sage: print(dw)
()()
sage: dw.height()
1
sage: dw.to_noncrossing_partition()
{{1}, {2}}
```

```
sage: DyckWord('()()')
[1, 0, 1, 0]
sage: DyckWord('(())')
[1, 1, 0, 0]
sage: DyckWord('(('')
[1, 1]
sage: DyckWord('')
[]
```

```
sage: DyckWord(noncrossing_partition=[[1],[2]])
[1, 0, 1, 0]
sage: DyckWord(noncrossing_partition=[[1,2]])
[1, 1, 0, 0]
sage: DyckWord(noncrossing_partition=[])
[]
```

```
sage: DyckWord(area_sequence=[0,0])
[1, 0, 1, 0]
sage: DyckWord(area_sequence=[0,1])
[1, 1, 0, 0]
sage: DyckWord(area_sequence=[0,1,2,2,0,1,1,2])
[1, 1, 1, 0, 1, 0, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0]
sage: DyckWord(area_sequence=[])
[]
```

```
sage: DyckWord(heights_sequence=(0,1,0,1,0))
[1, 0, 1, 0]
sage: DyckWord(heights_sequence=(0,1,2,1,0))
[1, 1, 0, 0]
sage: DyckWord(heights_sequence=(0,))
[]
```

```
sage: print(DyckWord([1,0,1,1,0,0]).to_path_string())
  ^
 ^\  \
sage: DyckWord([1,0,1,1,0,0]).pretty_print()
  ---
  | x
  -| .
  | . .
```

ascent_prime_decomposition()

Decompose this Dyck word into a sequence of ascents and prime Dyck paths.

A Dyck word is *prime* if it is complete and has precisely one return - the final step. In particular, the empty Dyck path is not prime. Thus, the factorization is unique.

This decomposition yields a sequence of odd length: the words with even indices consist of up steps only, the words with odd indices are prime Dyck paths. The concatenation of the result is the original word.

EXAMPLES:

```
sage: D = DyckWord([1,1,1,0,1,0,1,1,1,1,0,1])
sage: D.ascent_prime_decomposition()
[[1, 1], [1, 0], [], [1, 0], [1, 1, 1], [1, 0], [1]]

sage: DyckWord([]).ascent_prime_decomposition()
[]

sage: DyckWord([1,1]).ascent_prime_decomposition()
[[1, 1]]
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1,0,1,0]).ascent_prime_decomposition()
[[], [1, 0], [], [1, 0], []]
```

associated_parenthesis(*pos*)

Report the position for the parenthesis in `self` that matches the one at position `pos`.

The positions in `self` are counted from 0.

INPUT:

- `pos` – the index of the parenthesis in the list

OUTPUT:

- Integer representing the index of the matching parenthesis. If no parenthesis matches, return `None`.

EXAMPLES:

```
sage: DyckWord([1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(1)
0
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(2)
3
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(3)
2
sage: DyckWord([1, 1, 0, 0]).associated_parenthesis(0)
3
sage: DyckWord([1, 1, 0, 0]).associated_parenthesis(2)
1
sage: DyckWord([1, 1, 0]).associated_parenthesis(1)
2
sage: DyckWord([1, 1]).associated_parenthesis(0)
```

catalan_factorization()

Decompose this Dyck word into a sequence of complete Dyck words.

Each element of the list returned is a (possibly empty) complete Dyck word. The original word is obtained by placing an up step between each of these complete Dyck words. Thus, the number of words returned is one more than the final height.

See Section 1.2 of [CC1982] or Lemma 9.1.1 of [Lot2005].

EXAMPLES:

```
sage: D = DyckWord([1,1,1,0,1,0,1,1,1,0,1])
sage: D.catalan_factorization()
[[], [], [1, 0, 1, 0], [], [], [1, 0], []]

sage: DyckWord([]).catalan_factorization()
[[]]

sage: DyckWord([1,1]).catalan_factorization()
[[], [], []]
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1,0,1,0]).catalan_factorization()
[[1, 0, 1, 0]]
```

height()

Return the height of `self`.

We view the Dyck word as a Dyck path from $(0, 0)$ to $(2n, 0)$ in the first quadrant by letting 1's represent steps in the direction $(1, 1)$ and 0's represent steps in the direction $(1, -1)$.

The height is the maximum y -coordinate reached.

See also:

[*heights\(\)*](#)

EXAMPLES:

```
sage: DyckWord([]).height()
0
sage: DyckWord([1,0]).height()
1
sage: DyckWord([1, 1, 0, 0]).height()
2
sage: DyckWord([1, 1, 0, 1, 0]).height()
2
sage: DyckWord([1, 1, 0, 0, 1, 0]).height()
2
sage: DyckWord([1, 0, 1, 0]).height()
1
sage: DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]).height()
3
```

heights()

Return the heights of `self`.

We view the Dyck word as a Dyck path from $(0, 0)$ to $(2n, 0)$ in the first quadrant by letting 1's represent steps in the direction $(1, 1)$ and 0's represent steps in the direction $(1, -1)$.

The heights is the sequence of the y -coordinates of all $2n + 1$ lattice points along the path.

See also:

[*from_heights\(\)*](#), [*min_from_heights\(\)*](#)

EXAMPLES:

```
sage: DyckWord([]).heights()
(0,)
sage: DyckWord([1,0]).heights()
(0, 1, 0)
sage: DyckWord([1, 1, 0, 0]).heights()
(0, 1, 2, 1, 0)
sage: DyckWord([1, 1, 0, 1, 0]).heights()
(0, 1, 2, 1, 2, 1)
sage: DyckWord([1, 1, 0, 0, 1, 0]).heights()
(0, 1, 2, 1, 0, 1, 0)
sage: DyckWord([1, 0, 1, 0]).heights()
(0, 1, 0, 1, 0)
```

(continues on next page)

(continued from previous page)

```
(0, 1, 0, 1, 0)
sage: DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]).heights()
(0, 1, 2, 1, 0, 1, 2, 3, 2, 1, 0)
```

is_complete()

Return True if self is complete.

A Dyck word d is complete if d contains as many closers as openers.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).is_complete()
True
sage: DyckWord([1, 0, 1, 1, 0]).is_complete()
False
```

latex_options()

Return the latex options for use in the `_latex_` function as a dictionary.

The default values are set using the options.

- `tikz_scale` – (default: 1) scale for use with the tikz package.
- `diagonal` – (default: False) boolean value to draw the diagonal or not.
- `line width` – (default: $2 \cdot \text{tikz_scale}$) value representing the line width.
- `color` – (default: black) the line color.
- `bounce path` – (default: False) boolean value to indicate if the bounce path should be drawn.
- `peaks` – (default: False) boolean value to indicate if the peaks should be displayed.
- `valleys` – (default: False) boolean value to indicate if the valleys should be displayed.

EXAMPLES:

```
sage: D = DyckWord([1,0,1,0,1,0])
sage: D.latex_options()
{'bounce path': False,
 'color': black,
 'diagonal': False,
 'line width': 2,
 'peaks': False,
 'tikz_scale': 1,
 'valleys': False}
```

Todo: This should probably be merged into `DyckWord.options`.

length()

Return the length of self.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).length()
4
```

(continues on next page)

(continued from previous page)

```
sage: DyckWord([1, 0, 1, 1, 0]).length()
5
```

number_of_close_symbols()

Return the number of close symbols in `self`.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_close_symbols()
2
sage: DyckWord([1, 0, 1, 1, 0]).number_of_close_symbols()
2
```

number_of_double_rises()

Return a the number of positions in `self` where there are two consecutive 1's.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).number_of_double_
↪rises()
2
sage: DyckWord([1, 1, 0, 0]).number_of_double_rises()
1
sage: DyckWord([1, 0, 1, 0]).number_of_double_rises()
0
```

number_of_initial_rises()

Return the length of the initial run of `self`.

OUTPUT:

- a non-negative integer indicating the length of the initial rise

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_initial_rises()
1
sage: DyckWord([1, 1, 0, 0]).number_of_initial_rises()
2
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_initial_rises()
2
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_initial_rises()
1
```

number_of_open_symbols()

Return the number of open symbols in `self`.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_open_symbols()
2
sage: DyckWord([1, 0, 1, 1, 0]).number_of_open_symbols()
3
```

number_of_peaks()

Return the number of peaks of the Dyck path associated to `self`.

See also:*peaks()*, *number_of_valleys()*

EXAMPLES:

```

sage: DyckWord([1, 0, 1, 0]).number_of_peaks()
2
sage: DyckWord([1, 1, 0, 0]).number_of_peaks()
1
sage: DyckWord([1, 1, 0, 1, 0, 1, 0, 0]).number_of_peaks()
3
sage: DyckWord([]).number_of_peaks()
0

```

number_of_touch_points()Return the number of touches of *self* at the main diagonal.

OUTPUT:

- a non-negative integer

EXAMPLES:

```

sage: DyckWord([1, 0, 1, 0]).number_of_touch_points()
2
sage: DyckWord([1, 1, 0, 0]).number_of_touch_points()
1
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_touch_points()
2
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_touch_points()
2

```

number_of_valleys()Return the number of valleys of *self*.**See also:***number_of_peaks()*, *valleys()*

EXAMPLES:

```

sage: DyckWord([1, 0, 1, 0]).number_of_valleys()
1
sage: DyckWord([1, 1, 0, 0]).number_of_valleys()
0
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_valleys()
1
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_valleys()
1

```

peaks()

Return a list of the positions of the peaks of a Dyck word.

A peak is 1 followed by a 0. Note that this does not agree with the definition given in [Hag2008].

See also:*valleys()*, *number_of_peaks()*

EXAMPLES:

```

sage: DyckWord([1, 0, 1, 0]).peaks()
[0, 2]
sage: DyckWord([1, 1, 0, 0]).peaks()
[1]
sage: DyckWord([1,1,0,1,0,1,0,0]).peaks() # Haglund's def gives 2
[1, 3, 5]

```

plot(***kws*)

Plot a Dyck word as a continuous path.

EXAMPLES:

```

sage: w = DyckWords(100).random_element()
sage: w.plot()
Graphics object consisting of 1 graphics primitive

```

position_of_first_return()

Return the number of vertical steps before the Dyck path returns to the main diagonal.

EXAMPLES:

```

sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).position_of_first_
↪return()
1
sage: DyckWord([1, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0, 0]).position_of_first_
↪return()
7
sage: DyckWord([1, 1, 0, 0]).position_of_first_return()
2
sage: DyckWord([1, 0, 1, 0]).position_of_first_return()
1
sage: DyckWord([]).position_of_first_return()
0

```

positions_of_double_rises()

Return a list of positions in *self* where there are two consecutive 1's.

EXAMPLES:

```

sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).positions_of_double_
↪rises()
[2, 5]
sage: DyckWord([1, 1, 0, 0]).positions_of_double_rises()
[0]
sage: DyckWord([1, 0, 1, 0]).positions_of_double_rises()
[]

```

pp(*type=None, labelling=None, underpath=True*)

Display a DyckWord as a lattice path in the \mathbb{Z}^2 grid.

If the *type* is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

If the *type* is “NE-SE”, then the path is simply printed as up steps and down steps.

INPUT:

- `type` – (default: `None`) can either be:
 - `None` to use the option default
 - “N-E” to show `self` as a path of north and east steps, or
 - “NE-SE” to show `self` as a path of north-east and south-east steps.
- `labelling` – (if `type` is “N-E”) a list of labels assigned to the up steps in `self`.
- `underpath` – (if `type` is “N-E”, default: `True`) If `True`, the labelling is shown under the path; otherwise, it is shown to the right of the path.

EXAMPLES:

```
sage: for D in DyckWords(3): D.pretty_print()

  -
  -|
-| .
| . .
  ---
  | x
-| .
| . .

  -
---|
| x .
| . .

  ---
-| x
| x .
| . .

-----
| x x
| x .
| . .
```

```
sage: for D in DyckWords(3): D.pretty_print(type="NE-SE")

/\ /\
 ^
/\  \
 ^
 /  \
/\  \
 ^\
 /  \
 ^
 /  \
 /  \
```

```
sage: D = DyckWord([1,1,1,0,1,0,0,1,1])

sage: DyckWord([]).pretty_print()
.

```

pretty_print(*type=None, labelling=None, underpath=True*)

Display a DyckWord as a lattice path in the \mathbf{Z}^2 grid.

If the *type* is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

If the *type* is “NE-SE”, then the path is simply printed as up steps and down steps.

INPUT:

- *type* – (default: None) can either be:
 - None to use the option default
 - “N-E” to show `self` as a path of north and east steps, or
 - “NE-SE” to show `self` as a path of north-east and south-east steps.
- *labelling* – (if *type* is “N-E”) a list of labels assigned to the up steps in `self`.
- *underpath* – (if *type* is “N-E”, default:True) If True, the labelling is shown under the path; otherwise, it is shown to the right of the path.

EXAMPLES:

```

sage: for D in DyckWords(3): D.pretty_print()

```

```
sage: DyckWord([]).pretty_print()
```

```
.
```

returns_to_zero()

Return a list of positions where `self` has height 0, excluding the position 0.

EXAMPLES:

```
sage: DyckWord([]).returns_to_zero()
[]
sage: DyckWord([1, 0]).returns_to_zero()
[2]
sage: DyckWord([1, 0, 1, 0]).returns_to_zero()
[2, 4]
sage: DyckWord([1, 1, 0, 0]).returns_to_zero()
[4]
```

rise_composition()

The sequences of lengths of runs of 1's in `self`. Also equal to the sequence of lengths of vertical segments in the Dyck path.

EXAMPLES:

```
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).pretty_print()
          | x
        -----| .
      | x x x . .
      | x x . . .
    _ | x . . . .
    | x . . . . .
    | . . . . .

sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).rise_composition()
[2, 3, 2]
sage: DyckWord([1, 1, 0, 0]).rise_composition()
[2]
sage: DyckWord([1, 0, 1, 0]).rise_composition()
[1, 1]
```

set_latex_options(D)

Set the latex options for use in the `_latex_` function.

The default values are set in the `__init__` function.

- `tikz_scale` – (default: 1) scale for use with the `tikz` package.
- `diagonal` – (default: `False`) boolean value to draw the diagonal or not.
- `line_width` – (default: `2*tikz_scale`) value representing the line width.
- `color` – (default: `black`) the line color.
- `bounce_path` – (default: `False`) boolean value to indicate if the bounce path should be drawn.
- `peaks` – (default: `False`) boolean value to indicate if the peaks should be displayed.
- `valleys` – (default: `False`) boolean value to indicate if the valleys should be displayed.

INPUT:

- `D` – a dictionary with a list of latex parameters to change

EXAMPLES:

```
sage: D = DyckWord([1,0,1,0,1,0])
sage: D.set_latex_options({"tikz_scale":2})
sage: D.set_latex_options({"valleys":True, "color":"blue"})
```

Todo: This should probably be merged into `DyckWord.options`.

`tamari_interval` (*other*)

Return the Tamari interval between `self` and `other` as a *TamariIntervalPoset*.

A “Tamari interval” means an interval in the Tamari order. The Tamari order on the set of Dyck words of size n is the partial order obtained from the Tamari order on the set of binary trees of size n (see `tamari_lequal()`) by means of the Tamari bijection between Dyck words and binary trees (`to_dyck_word_tamari()`).

INPUT:

- `other` – a Dyck word greater or equal to `self` in the Tamari order

EXAMPLES:

```
sage: dw = DyckWord([1, 1, 0, 1, 0, 0, 1, 0])
sage: ip = dw.tamari_interval(DyckWord([1, 1, 1, 0, 0, 1, 0, 0])); ip
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)
↔1])
sage: ip.lower_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]
sage: ip.upper_dyck_word()
[1, 1, 1, 0, 0, 1, 0, 0]
sage: ip.interval_cardinality()
4
sage: ip.number_of_tamari_inversions()
2
sage: list(ip.dyck_words())
[[1, 1, 1, 0, 0, 1, 0, 0],
 [1, 1, 1, 0, 0, 0, 1, 0],
 [1, 1, 0, 1, 0, 1, 0, 0],
 [1, 1, 0, 1, 0, 0, 1, 0]]
```

(continues on next page)

(continued from previous page)

```
sage: dw.tamari_interval(DyckWord([1,1,0,0,1,1,0,0]))
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice
```

to_area_sequence()

Return the area sequence of the Dyck word `self`.

The area sequence of a Dyck word w is defined as follows: Representing the Dyck word w as a Dyck path from $(0, 0)$ to (n, n) using N and E steps (this involves padding w by E steps until w reaches the main diagonal if w is not already a complete Dyck path), the area sequence of w is the sequence (a_1, a_2, \dots, a_n) , where a_i is the number of full cells in the i -th row of the rectangle $[0, n] \times [0, n]$ which lie completely above the diagonal. (The cells are the regions into which the rectangle is subdivided by the lines $x = i$ with i integer and the lines $y = j$ with j integer. The i -th row consists of all the cells between the lines $y = i - 1$ and $y = i$.)

An alternative definition: Representing the Dyck word w as a Dyck path consisting of NE and SE steps, the area sequence is the sequence of ordinates of all lattice points on the path which are starting points of NE steps.

A list of integers l is the area sequence of some Dyck path if and only if it satisfies $l_0 = 0$ and $0 \leq l_{i+1} \leq l_i + 1$ for $i > 0$.

EXAMPLES:

```
sage: DyckWord([]).to_area_sequence()
[]
sage: DyckWord([1, 0]).to_area_sequence()
[0]
sage: DyckWord([1, 1, 0, 0]).to_area_sequence()
[0, 1]
sage: DyckWord([1, 0, 1, 0]).to_area_sequence()
[0, 0]
sage: all(dw ==
.....:     DyckWords().from_area_sequence(dw.to_area_sequence())
.....:     for i in range(6) for dw in DyckWords(i))
True
sage: DyckWord([1,0,1,0,1,0,1,0,1,0]).to_area_sequence()
[0, 0, 0, 0, 0]
sage: DyckWord([1,1,1,1,1,0,0,0,0,0]).to_area_sequence()
[0, 1, 2, 3, 4]
sage: DyckWord([1,1,1,1,0,1,0,0,0,0]).to_area_sequence()
[0, 1, 2, 3, 3]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_area_sequence()
[0, 1, 1, 0, 1, 1, 1]
```

to_binary_tree(usemap='1LOR')

Return a binary tree recursively constructed from the Dyck path `self` by the map `usemap`. The default `usemap` is '1LOR' which means:

- an empty Dyck word is a leaf,
- a non empty Dyck word reads 1LOR where L and R correspond to respectively its left and right subtrees.

INPUT:

- `usemap` – a string, either '1L0R', '1R0L', 'L1R0', 'R1L0'

Other valid `usemap` are '1R0L', 'L1R0', and 'R1L0'. These correspond to different maps from Dyck paths to binary trees, whose recursive definitions are hopefully clear from the names.

EXAMPLES:

```
sage: dw = DyckWord([1,0])
sage: dw.to_binary_tree()
[., .]
sage: dw = DyckWord([])
sage: dw.to_binary_tree()
.
sage: dw = DyckWord([1,0,1,1,0,0])
sage: dw.to_binary_tree()
[., [[., .], .]]
sage: dw.to_binary_tree("L1R0")
[[., .], [., .]]
sage: dw = DyckWord([1,0,1,1,0,0,1,1,1,0,1,0,0,0])
sage: dw.to_binary_tree() == dw.to_binary_tree("1R0L").left_right_symmetry()
True
sage: dw.to_binary_tree() == dw.to_binary_tree("L1R0").left_border_symmetry()
False
sage: dw.to_binary_tree("1R0L") == dw.to_binary_tree("L1R0").left_border_
↳symmetry()
True
sage: dw.to_binary_tree("R1L0") == dw.to_binary_tree("L1R0").left_right_
↳symmetry()
True
sage: dw.to_binary_tree("R10L")
Traceback (most recent call last):
...
ValueError: R10L is not a correct map
```

`to_binary_tree_tamari()`

Return the binary tree corresponding to `self` in a way which is consistent with the Tamari orders on the set of Dyck paths and on the set of binary trees.

This is the 'L1R0' map documented in `to_binary_tree()`.

EXAMPLES:

```
sage: DyckWord([1,0]).to_binary_tree_tamari()
[., .]
sage: DyckWord([1,0,1,1,0,0]).to_binary_tree_tamari()
[[., .], [., .]]
sage: DyckWord([1,0,1,0,1,0]).to_binary_tree_tamari()
[[[., .], .], .]
```

`to_path_string(unicode=False)`

Return a path representation of the Dyck word consisting of steps / and \ .

INPUT:

- `unicode` – boolean (default `False`) whether to use unicode

EXAMPLES:

```

sage: print(DyckWord([1, 0, 1, 0]).to_path_string())
/\
sage: print(DyckWord([1, 1, 0, 0]).to_path_string())
  ^
 / \
sage: print(DyckWord([1, 1, 0, 1, 1, 0, 0, 1, 0, 1, 0, 0]).to_path_string())
  ^
 / \
/\  \  /\  \
/   \ /   \

```

to_standard_tableau()

Return a standard tableau of shape (a, b) where a is the number of open symbols and b is the number of close symbols in self.

EXAMPLES:

```

sage: DyckWord([]).to_standard_tableau()
[]
sage: DyckWord([1, 0]).to_standard_tableau()
[[1], [2]]
sage: DyckWord([1, 1, 0, 0]).to_standard_tableau()
[[1, 2], [3, 4]]
sage: DyckWord([1, 0, 1, 0]).to_standard_tableau()
[[1, 3], [2, 4]]
sage: DyckWord([1]).to_standard_tableau()
[[1]]
sage: DyckWord([1, 0, 1]).to_standard_tableau()
[[1, 3], [2]]

```

to_tamari_sorting_tuple()

Convert a Dyck word to a Tamari sorting tuple.

The result is a list of integers, one for every up-step from left to right. To each up-step is associated the distance to the corresponding down step in the Dyck word.

This is useful for a faster conversion to binary trees.

EXAMPLES:

```

sage: DyckWord([]).to_tamari_sorting_tuple()
[]
sage: DyckWord([1, 0]).to_tamari_sorting_tuple()
[0]
sage: DyckWord([1, 1, 0, 0]).to_tamari_sorting_tuple()
[1, 0]
sage: DyckWord([1, 0, 1, 0]).to_tamari_sorting_tuple()
[0, 0]
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_tamari_sorting_tuple()
[2, 0, 0]

```

See also:

[`to_Catalan_code\(\)`](#)

touch_composition()

Return a composition which indicates the positions where self returns to the diagonal.

This assumes `self` to be a complete Dyck word.

OUTPUT:

- a composition of length equal to the length of the Dyck word.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).touch_composition()
[1, 1]
sage: DyckWord([1, 1, 0, 0]).touch_composition()
[2]
sage: DyckWord([1, 1, 0, 0, 1, 0]).touch_composition()
[2, 1]
sage: DyckWord([1, 0, 1, 1, 0, 0]).touch_composition()
[1, 2]
sage: DyckWord([]).touch_composition()
[]
```

`touch_points()`

Return the abscissae (or, equivalently, ordinates) of the points where the Dyck path corresponding to `self` (comprising *NE* and *SE* steps) touches the main diagonal. This includes the last point (if it is on the main diagonal) but excludes the beginning point.

Note that these abscissae are precisely the entries of `returns_to_zero()` divided by 2.

OUTPUT:

- a list of integers indicating where the path touches the diagonal

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).touch_points()
[1, 2]
sage: DyckWord([1, 1, 0, 0]).touch_points()
[2]
sage: DyckWord([1, 1, 0, 0, 1, 0]).touch_points()
[2, 3]
sage: DyckWord([1, 0, 1, 1, 0, 0]).touch_points()
[1, 3]
```

`valleys()`

Return a list of the positions of the valleys of a Dyck word.

A valley is 0 followed by a 1.

See also:

`peaks()`, `number_of_valleys()`

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).valleys()
[1]
sage: DyckWord([1, 1, 0, 0]).valleys()
[]
sage: DyckWord([1, 1, 0, 1, 0, 1, 0, 0]).valleys()
[2, 4]
```

class sage.combinat.dyck_word.DyckWordBacktracker(*k1*, *k2*)

Bases: [sage.combinat.backtrack.GenericBacktracker](#)

This class is an iterator for all Dyck words with n opening parentheses and $n - k$ closing parentheses using the backtracker class. It is used by the [DyckWords_size](#) class.

This is not really meant to be called directly, partially because it fails in a couple corner cases: `DWB(0)` yields `[0]`, not the empty word, and `DWB(k, k+1)` yields something (it shouldn't yield anything). This could be fixed with a sanity check in `_rec()`, but then we'd be doing the sanity check *every time* we generate new objects; instead, we do *one* sanity check in [DyckWords](#) and assume here that the sanity check has already been made.

AUTHOR:

- Dan Drake (2008-05-30)

class sage.combinat.dyck_word.DyckWord_complete(*parent*, *l*, *latex_options*={})

Bases: [sage.combinat.dyck_word.DyckWord](#)

The class of complete [Dyck words](#). A Dyck word is complete, if it contains as many closers as openers.

For further information on Dyck words, see [DyckWords_class](#).

area()

Return the area for `self` corresponding to the area of the Dyck path.

One can view a balanced Dyck word as a lattice path from $(0, 0)$ to (n, n) in the first quadrant by letting '1's represent steps in the direction $(1, 0)$ and '0's represent steps in the direction $(0, 1)$. The resulting path will remain weakly above the diagonal $y = x$.

The area statistic is the number of complete squares in the integer lattice which are below the path and above the line $y = x$. The 'half-squares' directly above the line $y = x$ do not contribute to this statistic.

EXAMPLES:

```
sage: dw = DyckWord([1,0,1,0])
sage: dw.area() # 2 half-squares, 0 complete squares
0
```

```
sage: dw = DyckWord([1,1,1,0,1,1,1,0,0,0,1,1,0,0,1,0,0,0])
sage: dw.area()
19
```

```
sage: DyckWord([1,1,1,1,0,0,0,0]).area()
6
sage: DyckWord([1,1,1,0,1,0,0,0]).area()
5
sage: DyckWord([1,1,1,0,0,1,0,0]).area()
4
sage: DyckWord([1,1,1,0,0,0,1,0]).area()
3
sage: DyckWord([1,0,1,1,0,1,0,0]).area()
2
sage: DyckWord([1,1,0,1,1,0,0,0]).area()
4
sage: DyckWord([1,1,0,0,1,1,0,0]).area()
2
sage: DyckWord([1,0,1,1,1,0,0,0]).area()
3
```

(continues on next page)

(continued from previous page)

```

sage: DyckWord([1,0,1,1,0,0,1,0]).area()
1
sage: DyckWord([1,0,1,0,1,1,0,0]).area()
1
sage: DyckWord([1,1,0,0,1,0,1,0]).area()
1
sage: DyckWord([1,1,0,1,0,0,1,0]).area()
2
sage: DyckWord([1,1,0,1,0,1,0,0]).area()
3
sage: DyckWord([1,0,1,0,1,0,1,0]).area()
0

```

area_dinv_to_bounce_area_map()

Return the image of `self` under the map which sends a Dyck word with area equal to r and `dinv` equal to s to a Dyck word with bounce equal to r and area equal to s .

The inverse of this map is `bounce_area_to_area_dinv_map()`.

For a definition of this map, see [Hag2008] p. 50 where it is called ζ . However, this map differs from Haglund's map by an application of `reverse()` (as does the definition of the `bounce()` statistic).

EXAMPLES:

```

sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area_dinv_to_bounce_area_map()
[1, 1, 1, 1, 1, 0, 0, 0, 1, 0, 0, 1, 0, 0]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv()
13
sage: DyckWord([1,1,1,1,1,0,0,0,1,0,0,1,0,0]).area()
13
sage: DyckWord([1,1,1,1,1,0,0,0,1,0,0,1,0,0]).bounce()
5
sage: DyckWord([1,1,1,1,1,0,0,0,1,0,0,1,0,0]).area_dinv_to_bounce_area_map()
[1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]
sage: DyckWord([1,1,0,0]).area_dinv_to_bounce_area_map()
[1, 0, 1, 0]
sage: DyckWord([1,0,1,0]).area_dinv_to_bounce_area_map()
[1, 1, 0, 0]

```

bounce()

Return the bounce statistic of `self` due to J. Haglund, see [Hag2008].

One can view a balanced Dyck word as a lattice path from $(0, 0)$ to (n, n) in the first quadrant by letting '1's represent steps in the direction $(0, 1)$ and '0's represent steps in the direction $(1, 0)$. The resulting path will remain weakly above the diagonal $y = x$.

We describe the bounce statistic of such a path in terms of what is known as the "bounce path".

We can think of our bounce path as describing the trail of a billiard ball shot West from (n, n) , which "bounces" down whenever it encounters a vertical step and "bounces" left when it encounters the line $y = x$.

The bouncing ball will strike the diagonal at the places

$$(0, 0), (j_1, j_1), (j_2, j_2), \dots, (j_r - 1, j_r - 1), (j_r, j_r) = (n, n).$$

We define the bounce to be the sum $\sum_{i=1}^{r-1} j_i$.

EXAMPLES:

```
sage: DyckWord([1,1,1,0,1,1,1,0,0,0,1,1,0,0,1,0,0,0]).bounce()
7
sage: DyckWord([1,1,1,1,0,0,0,0]).bounce()
0
sage: DyckWord([1,1,1,0,1,0,0,0]).bounce()
1
sage: DyckWord([1,1,1,0,0,1,0,0]).bounce()
2
sage: DyckWord([1,1,1,0,0,0,1,0]).bounce()
3
sage: DyckWord([1,0,1,1,0,1,0,0]).bounce()
3
sage: DyckWord([1,1,0,1,1,0,0,0]).bounce()
1
sage: DyckWord([1,1,0,0,1,1,0,0]).bounce()
2
sage: DyckWord([1,0,1,1,1,0,0,0]).bounce()
1
sage: DyckWord([1,0,1,1,0,0,1,0]).bounce()
4
sage: DyckWord([1,0,1,0,1,1,0,0]).bounce()
3
sage: DyckWord([1,1,0,0,1,0,1,0]).bounce()
5
sage: DyckWord([1,1,0,1,0,0,1,0]).bounce()
4
sage: DyckWord([1,1,0,1,0,1,0,0]).bounce()
2
sage: DyckWord([1,0,1,0,1,0,1,0]).bounce()
6
```

`bounce_area_to_area_dinv_map()`

Return the image of the Dyck word under the map which sends a Dyck word with bounce equal to r and area equal to s to a Dyck word with area equal to r and `dinv` equal to s .

This implementation uses a recursive method by saying that the last entry in the area sequence of the Dyck word `self` is equal to the number of touch points of the Dyck path minus 1 of the image of this map.

The inverse of this map is `area_dinv_to_bounce_area_map()`.

For a definition of this map, see [Hag2008] p. 50 where it is called ζ^{-1} . However, this map differs from Haglund's map by an application of `reverse()` (as does the definition of the `bounce()` statistic).

EXAMPLES:

```
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).bounce_area_to_area_dinv_map()
[1, 1, 0, 0, 1, 1, 1, 1, 0, 0, 1, 0, 0, 0]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).bounce()
9
sage: DyckWord([1,1,0,0,1,1,1,1,0,0,1,0,0,0]).area()

```

(continues on next page)

(continued from previous page)

```

9
sage: DyckWord([1,1,0,0,1,1,1,1,0,0,1,0,0,0]).dinv()
5
sage: all(D==D.bounce_area_to_area_dinv_map().area_dinv_to_bounce_area_map()
↳ for D in DyckWords(6))
True
sage: DyckWord([1,1,0,0]).bounce_area_to_area_dinv_map()
[1, 0, 1, 0]
sage: DyckWord([1,0,1,0]).bounce_area_to_area_dinv_map()
[1, 1, 0, 0]

```

bounce_path()

Return the bounce path of `self` formed by starting at (n, n) and traveling West until encountering the first vertical step of `self`, then South until encountering the diagonal, then West again to hit the path, etc. until the $(0, 0)$ point is reached. The path followed by this walk is the bounce path.

See also:[bounce\(\)](#)

EXAMPLES:

```

sage: DyckWord([1,1,0,1,0,0]).bounce_path()
[1, 0, 1, 1, 0, 0]
sage: DyckWord([1,1,1,0,0,0]).bounce_path()
[1, 1, 1, 0, 0, 0]
sage: DyckWord([1,0,1,0,1,0]).bounce_path()
[1, 0, 1, 0, 1, 0]
sage: DyckWord([1,1,1,1,0,0,1,0,0,0]).bounce_path()
[1, 1, 0, 0, 1, 1, 1, 0, 0, 0]

```

characteristic_symmetric_function($q=None$, $R=$ *Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field*)

The characteristic function of `self` is the sum of $q^{\text{dinv}(D,F)} Q_{\text{ides}(\text{read}(D,F))}$ over all permutation fillings of the Dyck path representing `self`, where $\text{ides}(\text{read}(D, F))$ is the descent composition of the inverse of the reading word of the filling.

INPUT:

- q – (default: $q = R('q')$) a parameter for the generating function power
- R – (default: $R = \text{QQ}['q', 't'].fraction_field()$) the base ring to do the calculations over

OUTPUT:

- an element of the symmetric functions over the ring R (in the Schur basis).

EXAMPLES:

```

sage: R = QQ['q', 't'].fraction_field()
sage: (q,t) = R.gens()
sage: f = sum(t**D.area()*D.characteristic_symmetric_function() for D in
↳ DyckWords(3)); f
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: f.nabla(power=-1)
s[1, 1, 1]

```

decomposition_reverse()

Return the involution of `self` with a recursive definition.

If a Dyck word D decomposes as $1D_10D_2$ where D_1 and D_2 are complete Dyck words then the decomposition reverse is $1\phi(D_2)0\phi(D_1)$.

EXAMPLES:

```
sage: DyckWord([1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]).decomposition_
↪reverse()
[1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).decomposition_
↪reverse()
[1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]
sage: DyckWord([1,1,0,0]).decomposition_reverse()
[1, 0, 1, 0]
sage: DyckWord([1,0,1,0]).decomposition_reverse()
[1, 1, 0, 0]
```

dinv(*labeling=None*)

Return the `dinv` statistic of `self` due to M. Haiman, see [Hag2008].

If a `labeling` is provided then this function returns the `dinv` of the labeled Dyck word.

INPUT:

- `labeling` – an optional argument to be viewed as the labelings of the vertical edges of the Dyck path

OUTPUT:

- an integer representing the `dinv` statistic of the Dyck path or the labelled Dyck path.

EXAMPLES:

```
sage: DyckWord([1,0,1,0,1,0,1,0,1,0]).dinv()
10
sage: DyckWord([1,1,1,1,1,0,0,0,0,0]).dinv()
0
sage: DyckWord([1,1,1,1,0,1,0,0,0,0]).dinv()
1
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv()
13
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv([1,2,3,4,5,6,7])
11
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv([6,7,5,3,4,2,1])
2
```

first_return_decomposition()

Decompose a Dyck word into a pair of Dyck words (potentially empty) where the first word consists of the word after the first up step and the corresponding matching closing parenthesis.

EXAMPLES:

```
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).first_return_decomposition()
([1, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0])
sage: DyckWord([1,1,0,0]).first_return_decomposition()
([1, 0], [])
sage: DyckWord([1,0,1,0]).first_return_decomposition()
([], [1, 0])
```

list_parking_functions()

Return all parking functions whose supporting Dyck path is `self`.

EXAMPLES:

```
sage: DyckWord([1,1,0,0,1,0]).list_parking_functions()
Permutations of the multi-set [1, 1, 3]
sage: DyckWord([1,1,1,0,0,0]).list_parking_functions()
Permutations of the multi-set [1, 1, 1]
sage: DyckWord([1,0,1,0,1,0]).list_parking_functions()
Standard permutations of 3
```

major_index()

Return the major index of `self`.

The major index of a Dyck word D is the sum of the positions of the valleys of D (when started counting at position 1).

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).major_index()
2
sage: DyckWord([1, 1, 0, 0]).major_index()
0
sage: DyckWord([1, 1, 0, 0, 1, 0]).major_index()
4
sage: DyckWord([1, 0, 1, 1, 0, 0]).major_index()
2
```

number_of_parking_functions()

Return the number of parking functions with `self` as the supporting Dyck path.

One representation of a parking function is as a pair consisting of a Dyck path and a permutation π such that if $[a_0, a_1, \dots, a_{n-1}]$ is the `area_sequence` of the Dyck path (see [to_area_sequence](#)) then the permutation π satisfies $\pi_i < \pi_{i+1}$ whenever $a_i < a_{i+1}$. This function counts the number of permutations π which satisfy this condition.

EXAMPLES:

```
sage: DyckWord(area_sequence=[0,1,2]).number_of_parking_functions()
1
sage: DyckWord(area_sequence=[0,1,1]).number_of_parking_functions()
3
sage: DyckWord(area_sequence=[0,1,0]).number_of_parking_functions()
3
sage: DyckWord(area_sequence=[0,0,0]).number_of_parking_functions()
6
```

number_of_tunnels(*tunnel_type*='centered')

Return the number of tunnels of `self` of type `tunnel_type`.

A tunnel is a pair (a, b) where a is the position of an open parenthesis and b is the position of the matching close parenthesis. If $a + b = n$ then the tunnel is called *centered*. If $a + b < n$ then the tunnel is called *left* and if $a + b > n$, then the tunnel is called *right*.

INPUT:

- `tunnel_type` – (default: 'centered') can be one of the following: 'left', 'right', 'centered', or 'all'.

EXAMPLES:

```

sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels()
0
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(
↪'left')
5
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(
↪'right')
2
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(
↪'all')
7
sage: DyckWord([1, 1, 0, 0]).number_of_tunnels('centered')
2

```

pyramid_weight()Return the pyramid weight of `self`.

A pyramid of `self` is a subsequence of the form $1^h 0^h$. A pyramid is maximal if it is neither preceded by a 1 nor followed by a 0.

The pyramid weight of a Dyck path is the sum of the lengths of the maximal pyramids and was defined in [DS1992].

EXAMPLES:

```

sage: DyckWord([1,1,0,1,1,1,0,0,1,0,0,0,1,1,0,0]).pyramid_weight()
6
sage: DyckWord([1,1,1,0,0,0]).pyramid_weight()
3
sage: DyckWord([1,0,1,0,1,0]).pyramid_weight()
3
sage: DyckWord([1,1,0,1,0,0]).pyramid_weight()
2

```

reading_permutation()Return the reading permutation of `self`.

This is the permutation formed by taking the reading word of the Dyck path representing `self` (with N and E steps) if the vertical edges of the Dyck path are labeled from bottom to top with 1 through n and the diagonals are read from top to bottom starting with the diagonal furthest from the main diagonal.

EXAMPLES:

```

sage: DyckWord([1,0,1,0]).reading_permutation()
[2, 1]
sage: DyckWord([1,1,0,0]).reading_permutation()
[2, 1]
sage: DyckWord([1,1,0,1,0,0]).reading_permutation()
[3, 2, 1]
sage: DyckWord([1,1,0,0,1,0]).reading_permutation()
[2, 3, 1]
sage: DyckWord([1,0,1,1,0,0,1,0]).reading_permutation()
[3, 4, 2, 1]

```

reverse()

Return the reverse and complement of `self`.

This operation corresponds to flipping the Dyck path across the $y = -x$ line.

EXAMPLES:

```
sage: DyckWord([1,1,0,0,1,0]).reverse()
[1, 0, 1, 1, 0, 0]
sage: DyckWord([1,1,1,0,0,0]).reverse()
[1, 1, 1, 0, 0, 0]
sage: len([D for D in DyckWords(5) if D.reverse() == D])
10
```

semilength()

Return the semilength of `self`.

The semilength of a complete Dyck word d is the number of openers and the number of closers.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).semilength()
2
```

to_132_avoiding_permutation()

Use the bijection by C. Krattenthaler in [Kra2001] to send `self` to a 132-avoiding permutation.

EXAMPLES:

```
sage: DyckWord([1,1,0,0]).to_132_avoiding_permutation()
[1, 2]
sage: DyckWord([1,0,1,0]).to_132_avoiding_permutation()
[2, 1]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_132_avoiding_permutation()
[6, 5, 4, 7, 2, 1, 3]
```

to_312_avoiding_permutation()

Convert `self` to a 312-avoiding permutation using the bijection by Bandlow and Killpatrick in [BK2001].

This sends the area to the inversion number.

EXAMPLES:

```
sage: DyckWord([1,1,0,0]).to_312_avoiding_permutation()
[2, 1]
sage: DyckWord([1,0,1,0]).to_312_avoiding_permutation()
[1, 2]
sage: p = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_312_avoiding_permutation();
↪ p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: p.length()
5
```

to_321_avoiding_permutation()

Use the bijection (pp. 60-61 of [Knu1973] or section 3.1 of [CK2008]) to send `self` to a 321-avoiding permutation.

It is shown in [EP2004] that it sends the number of centered tunnels to the number of fixed points, the number of right tunnels to the number of excedences, and the semilength plus the height of the middle point to 2 times the length of the longest increasing subsequence.

EXAMPLES:

```
sage: DyckWord([1,0,1,0]).to_321_avoiding_permutation()
[2, 1]
sage: DyckWord([1,1,0,0]).to_321_avoiding_permutation()
[1, 2]
sage: D = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0])
sage: p = D.to_321_avoiding_permutation()
sage: p
[3, 5, 1, 6, 2, 7, 4]
sage: D.number_of_tunnels()
0
sage: p.number_of_fixed_points()
0
sage: D.number_of_tunnels('right')
4
sage: len(p.weak_excedences())-p.number_of_fixed_points()
4
sage: n = D.semilength()
sage: D.heights()[n] + n
8
sage: 2*p.longest_increasing_subsequence_length()
8
```

to_Catalan_code()

Return the Catalan code associated to self.

A Catalan code of length n is a sequence (a_1, a_2, \dots, a_n) of n integers a_i such that:

- $0 \leq a_i \leq n - i$ for every i ;
- if $i < j$ and $a_i > 0$ and $a_j > 0$ and $a_{i+1} = a_{i+2} = \dots = a_{j-1} = 0$, then $a_i - a_j < j - i$.

It turns out that the Catalan codes of length n are in bijection with Dyck words.

The Catalan code of a Dyck word is example (x) in Richard Stanley's exercises on combinatorial interpretations for Catalan objects. The code in this example is the reverse of the description provided there. See [Sta-EC2] and [StaCat98].

EXAMPLES:

```
sage: DyckWord([]).to_Catalan_code()
[]
sage: DyckWord([1, 0]).to_Catalan_code()
[0]
sage: DyckWord([1, 1, 0, 0]).to_Catalan_code()
[0, 1]
sage: DyckWord([1, 0, 1, 0]).to_Catalan_code()
[0, 0]
sage: all(dw ==
.....:     DyckWords().from_Catalan_code(dw.to_Catalan_code())
.....:     for i in range(6) for dw in DyckWords(i))
True
```

See also:

`to_tamari_sorting_tuple()`

`to_alternating_sign_matrix()`

Return self as an alternating sign matrix.

This is an inclusion map from Dyck words of length $2n$ to certain $n \times n$ alternating sign matrices.

EXAMPLES:

```
sage: DyckWord([1,1,1,0,1,0,0,0]).to_alternating_sign_matrix()
[ 0  0  1  0]
[ 1  0 -1  1]
[ 0  1  0  0]
[ 0  0  1  0]
sage: DyckWord([1,0,1,0,1,1,0,0]).to_alternating_sign_matrix()
[1  0  0  0]
[0  1  0  0]
[0  0  0  1]
[0  0  1  0]
```

`to_non_decreasing_parking_function()`

Bijection to *non-decreasing parking functions*.

See there the method `to_dyck_word()` for more information.

EXAMPLES:

```
sage: DyckWord([]).to_non_decreasing_parking_function()
[]
sage: DyckWord([1,0]).to_non_decreasing_parking_function()
[1]
sage: DyckWord([1,1,0,0]).to_non_decreasing_parking_function()
[1, 1]
sage: DyckWord([1,0,1,0]).to_non_decreasing_parking_function()
[1, 2]
sage: DyckWord([1,0,1,1,0,1,0,0,1,0]).to_non_decreasing_parking_function()
[1, 2, 2, 3, 5]
```

`to_noncrossing_partition(bijection=None)`

Bijection of Biane from self to a noncrossing partition.

There is an optional parameter `bijection` that indicates if a different bijection from Dyck words to noncrossing partitions should be used (since there are potentially many).

If the parameter `bijection` is “Stump” then the bijection used is from [Stu2008], see also the method `to_noncrossing_permutation()`.

Thanks to Mathieu Dutour for describing the bijection. See also `from_noncrossing_partition()`.

EXAMPLES:

```
sage: DyckWord([]).to_noncrossing_partition()
{}
sage: DyckWord([1, 0]).to_noncrossing_partition()
{{1}}
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition()
{{1, 2}}
```

(continues on next page)

(continued from previous page)

```

sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition()
{{1, 2, 3}}
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition()
{{1}, {2}, {3}}
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition()
{{1, 3}, {2}}
sage: DyckWord([]).to_noncrossing_partition("Stump")
{}
sage: DyckWord([1, 0]).to_noncrossing_partition("Stump")
{{1}}
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition("Stump")
{{1, 2}}
sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition("Stump")
{{1, 3}, {2}}
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition("Stump")
{{1}, {2}, {3}}
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition("Stump")
{{1, 2, 3}}

```

to_noncrossing_permutation()

Use the bijection by C. Stump in [Stu2008] to send `self` to a non-crossing permutation.

A non-crossing permutation when written in cyclic notation has cycles which are strictly increasing. Sends the area to the inversion number and `self.major_index()` to $n(n-1) - maj(\sigma) - maj(\sigma^{-1})$. Uses the function `pealing()`

EXAMPLES:

```

sage: DyckWord([1,1,0,0]).to_noncrossing_permutation()
[2, 1]
sage: DyckWord([1,0,1,0]).to_noncrossing_permutation()
[1, 2]
sage: p = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_noncrossing_permutation(); L
↪p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: p.length()
5

```

to_ordered_tree()

Return the ordered tree corresponding to `self` where the depth of the tree is the maximal height of `self`.

EXAMPLES:

```

sage: D = DyckWord([1,1,0,0])
sage: D.to_ordered_tree()
[[[]]]
sage: D = DyckWord([1,0,1,0])
sage: D.to_ordered_tree()
[[], []]
sage: D = DyckWord([1, 0, 1, 1, 0, 0])
sage: D.to_ordered_tree()
[[], [[]]]

```

(continues on next page)

(continued from previous page)

```

sage: D = DyckWord([1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0])
sage: D.to_ordered_tree()
[[[], [[[], []], [[], [[]]]]]

```

to_pair_of_standard_tableaux()

Convert `self` to a pair of standard tableaux of the same shape and of length less than or equal to two.

EXAMPLES:

```

sage: DyckWord([1,0,1,0]).to_pair_of_standard_tableaux()
([[1], [2]], [[1], [2]])
sage: DyckWord([1,1,0,0]).to_pair_of_standard_tableaux()
([[1, 2], [1, 2]])
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_pair_of_standard_tableaux()
([[1, 2, 4, 7], [3, 5, 6]], [[1, 2, 4, 6], [3, 5, 7]])

```

to_partition()

Return the partition associated to `self`.

This partition is determined by thinking of `self` as a lattice path and considering the cells which are above the path but within the $n \times n$ grid and the partition is formed by reading the sequence of the number of cells in this collection in each row.

OUTPUT:

- a partition representing the rows of cells in the square lattice and above the path

EXAMPLES:

```

sage: DyckWord([]).to_partition()
[]
sage: DyckWord([1,0]).to_partition()
[]
sage: DyckWord([1,1,0,0]).to_partition()
[]
sage: DyckWord([1,0,1,0]).to_partition()
[1]
sage: DyckWord([1,0,1,0,1,0]).to_partition()
[2, 1]
sage: DyckWord([1,1,0,0,1,0]).to_partition()
[2]
sage: DyckWord([1,0,1,1,0,0]).to_partition()
[1, 1]

```

to_permutation(*map*)

This is simply a method collecting all implemented maps from Dyck words to permutations.

INPUT:

- `map` – defines the map from Dyck words to permutations. These are currently:
 - Bandlow-Killpatrick: `to_312_avoiding_permutation()`
 - Knuth: `to_321_avoiding_permutation()`
 - Krattenthaler: `to_132_avoiding_permutation()`
 - Stump: `to_noncrossing_permutation()`

EXAMPLES:

```
sage: D = DyckWord([1,1,1,0,1,0,0,0])
sage: D.pretty_print()
  -----
  _| x x
  | x x .
  | x . .
  | . . .

sage: D.to_permutation(map="Bandlow-Killpatrick")
[3, 4, 2, 1]
sage: D.to_permutation(map="Stump")
[4, 2, 3, 1]
sage: D.to_permutation(map="Knuth")
[1, 2, 4, 3]
sage: D.to_permutation(map="Krattenthaler")
[2, 1, 3, 4]
```

to_triangulation()

Map `self` to a triangulation.

The map from complete Dyck words of length $2n$ to triangulations of $n + 2$ -gon given by this function is a bijection that can be described as follows.

Consider the Dyck word as a path from $(0, 0)$ to (n, n) staying above the diagonal, where 1 is an up step and 0 is a right step. Then each horizontal step has a co-height (0 at the top and $n - 1$ at most at the bottom). One reads the Dyck word from left to right. At the beginning, all vertices from 0 to $n + 1$ are available. For each horizontal step, one creates an edge from the vertex indexed by the co-height to the next available vertex. This chops out a triangle from the polygon and one removes the middle vertex of this triangle from the list of available vertices.

This bijection has the property that the set of smallest vertices of the edges in a triangulation is an encoding of the co-heights, from which the Dyck word can be easily recovered.

OUTPUT:

a list of pairs (i, j) that are the edges of the triangulations.

EXAMPLES:

```
sage: DyckWord([1, 1, 0, 0]).to_triangulation()
[(0, 2)]

sage: [t.to_triangulation() for t in DyckWords(3)]
[[ (2, 4), (1, 4) ],
 [ (2, 4), (0, 2) ],
 [ (1, 3), (1, 4) ],
 [ (1, 3), (0, 3) ],
 [ (0, 2), (0, 3) ]]
```

REFERENCES:

- [Cha2005]

to_triangulation_as_graph()

Map `self` to a triangulation and return the result as a graph.

See `to_triangulation()` for the bijection used to map complete Dyck words to triangulations.

OUTPUT:

- a graph containing both the perimeter edges and the inner edges of a triangulation of a regular polygon.

EXAMPLES:

```
sage: g = DyckWord([1, 1, 0, 0, 1, 0]).to_triangulation_as_graph()
sage: g
Graph on 5 vertices
sage: g.edges(sort=True, labels=False)
[(0, 1), (0, 4), (1, 2), (1, 3), (1, 4), (2, 3), (3, 4)]
sage: g.show()           # not tested
```

tunnels()

Return an iterator of ranges of the matching parentheses in the Dyck word `self`.

That is, if (a, b) is in `self.tunnels()`, then the matching parenthesis to `self[a]` is `self[b-1]`.

EXAMPLES:

```
sage: list(DyckWord([1, 1, 0, 1, 1, 0, 0, 1, 0, 0]).tunnels())
[(0, 10), (1, 3), (3, 7), (4, 6), (7, 9)]
```

class `sage.combinat.dyck_word.DyckWords`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Dyck words.

A Dyck word is a sequence (w_1, \dots, w_n) consisting of 1 s and 0 s, with the property that for any i with $1 \leq i \leq n$, the sequence (w_1, \dots, w_i) contains at least as many 1 s as 0 s.

A Dyck word is balanced if the total number of 1 s is equal to the total number of 0 s. The number of balanced Dyck words of length $2k$ is given by the *Catalan number* C_k .

EXAMPLES:

This class can be called with three keyword parameters `k1`, `k2` and `complete`.

If neither `k1` nor `k2` are specified, then `DyckWords` returns the combinatorial class of all balanced (=complete) Dyck words, unless the keyword `complete` is set to `False` (in which case it returns the class of all Dyck words).

```
sage: DW = DyckWords(); DW
Complete Dyck words
sage: [] in DW
True
sage: [1, 0, 1, 0] in DW
True
sage: [1, 1, 0] in DW
False
sage: ADW = DyckWords(complete=False); ADW
Dyck words
sage: [] in ADW
True
sage: [1, 0, 1, 0] in ADW
True
sage: [1, 1, 0] in ADW
True
```

(continues on next page)

(continued from previous page)

```
sage: [1, 0, 0] in ADW
False
```

If just k_1 is specified, then it returns the balanced Dyck words with k_1 opening parentheses and k_1 closing parentheses.

```
sage: DW2 = DyckWords(2); DW2
Dyck words with 2 opening parentheses and 2 closing parentheses
sage: DW2.first()
[1, 0, 1, 0]
sage: DW2.last()
[1, 1, 0, 0]
sage: DW2.cardinality()
2
sage: DyckWords(100).cardinality() == catalan_number(100)
True
```

If k_2 is specified in addition to k_1 , then it returns the Dyck words with k_1 opening parentheses and k_2 closing parentheses.

```
sage: DW32 = DyckWords(3,2); DW32
Dyck words with 3 opening parentheses and 2 closing parentheses
sage: DW32.list()
[[1, 0, 1, 0, 1],
 [1, 0, 1, 1, 0],
 [1, 1, 0, 0, 1],
 [1, 1, 0, 1, 0],
 [1, 1, 1, 0, 0]]
```

Element

alias of *DyckWord*

from_heights(heights)

Compute a Dyck word knowing its heights.

We view the Dyck word as a Dyck path from $(0, 0)$ to $(2n, 0)$ in the first quadrant by letting 1's represent steps in the direction $(1, 1)$ and 0's represent steps in the direction $(1, -1)$.

The *heights()* is the sequence of the y -coordinates of the $2n + 1$ lattice points along this path.

EXAMPLES:

```
sage: from sage.combinat.dyck_word import DyckWord
sage: D = DyckWords(complete=False)
sage: D.from_heights((0,))
[]
sage: D.from_heights((0, 1, 0))
[1, 0]
sage: D.from_heights((0, 1, 2, 1, 0))
[1, 1, 0, 0]
```

This also works for incomplete Dyck words:

```
sage: D.from_heights((0, 1, 2, 1, 2, 1))
[1, 1, 0, 1, 0]
```

(continues on next page)

(continued from previous page)

```
sage: D.from_heights((0, 1, 2, 1))
[1, 1, 0]
```

See also:[heights\(\)](#), [min_from_heights\(\)](#)**min_from_heights**(*heights*)

Compute the smallest Dyck word which achieves or surpasses a given sequence of heights.

INPUT:

- *heights* – a nonempty list or iterable consisting of nonnegative integers, the first of which is 0

OUTPUT:

- The smallest Dyck word whose sequence of heights is componentwise higher-or-equal to *heights*. Here, “smaller” can be understood both in the sense of lexicographic order on the Dyck words, and in the sense of every vertex of the path having the smallest possible height.

See also:

- [heights\(\)](#)
- [from_heights\(\)](#)

EXAMPLES:

```
sage: D = DyckWords(complete=False)
sage: D.min_from_heights((0,))
[]
sage: D.min_from_heights((0, 1, 0))
[1, 0]
sage: D.min_from_heights((0, 0, 2, 0, 0))
[1, 1, 0, 0]
sage: D.min_from_heights((0, 0, 2, 0, 2, 0))
[1, 1, 0, 1, 0]
sage: D.min_from_heights((0, 0, 1, 0, 1, 0))
[1, 1, 0, 1, 0]
```

options(**get_value*, ***set_value*)

Set and display the options for Dyck words. If no parameters are set, then the function returns a copy of the options dictionary.

The options to Dyck words can be accessed as the method [DyckWords.options\(\)](#) of [DyckWords](#) and related parent classes.

@OPTIONS

EXAMPLES:

```
sage: D = DyckWord([1, 1, 0, 1, 0, 0])
sage: D
[1, 1, 0, 1, 0, 0]
sage: DyckWords.options.display="lattice"
sage: D
  ---
_ | x
```

(continues on next page)

(continued from previous page)

```

| x .
| . .
sage: DyckWords.options(diagram_style="line")
sage: D
  /\
 /  \
sage: DyckWords.options._reset()

```

See `GlobalOptions` for more features of these options.

class `sage.combinat.dyck_word.DyckWords_all`

Bases: `sage.combinat.dyck_word.DyckWords`

All Dyck words.

class `sage.combinat.dyck_word.DyckWords_size(k1, k2)`

Bases: `sage.combinat.dyck_word.DyckWords`

Dyck words with k_1 openers and k_2 closers.

cardinality()

Return the number of Dyck words with k_1 openers and k_2 closers.

This number is

$$\frac{k_1 - k_2 + 1}{k_1 + 1} \binom{k_1 + k_2}{k_2} = \binom{k_1 + k_2}{k_2} - \binom{k_1 + k_2}{k_2 - 1}$$

if $k_2 \leq k_1 + 1$, and 0 if $k_2 > k_1 + 1$ (these numbers are the same if $k_2 = k_1 + 1$).

EXAMPLES:

```

sage: DyckWords(3, 2).cardinality()
5
sage: all(all(DyckWords(p, q).cardinality()
.....:      == len(DyckWords(p, q).list()) for q in range(p + 1))
.....:      for p in range(7))
True

```

`sage.combinat.dyck_word.is_a(obj, k1=None, k2=None)`

Test if `obj` is a Dyck word with exactly k_1 open symbols and exactly k_2 close symbols.

If k_1 is not specified, then the number of open symbols can be arbitrary. If k_1 is specified but k_2 is not, then k_2 is set to be k_1 .

EXAMPLES:

```

sage: from sage.combinat.dyck_word import is_a
sage: is_a([1,1,0,0])
True
sage: is_a([1,0,1,0])
True
sage: is_a([1,1,0,0], 2)
True
sage: is_a([1,1,0,0], 3)
False
sage: is_a([1,1,0,0], 3, 2)
False

```

(continues on next page)

(continued from previous page)

```

sage: is_a([1,1,0])
True
sage: is_a([0,1,0])
False
sage: is_a([1,0,0])
False
sage: is_a([1,1,0],2,1)
True
sage: is_a([1,1,0],2)
False
sage: is_a([1,1,0],1,1)
False

```

`sage.combinat.dyck_word.is_area_sequence(seq)`

Test if a sequence l of integers satisfies $l_0 = 0$ and $0 \leq l_{i+1} \leq l_i + 1$ for $i > 0$.

EXAMPLES:

```

sage: from sage.combinat.dyck_word import is_area_sequence
sage: is_area_sequence([0,2,0])
False
sage: is_area_sequence([1,2,3])
False
sage: is_area_sequence([0,1,0])
True
sage: is_area_sequence([0,1,2])
True
sage: is_area_sequence([])
True

```

`sage.combinat.dyck_word.pealing(D, return_touches=False)`

A helper function for computing the bijection from a Dyck word to a 231-avoiding permutation using the bijection “Stump”. For details see [Stu2008].

See also:

[`to_noncrossing_partition\(\)`](#)

EXAMPLES:

```

sage: from sage.combinat.dyck_word import pealing
sage: pealing(DyckWord([1,1,0,0]))
[1, 0, 1, 0]
sage: pealing(DyckWord([1,0,1,0]))
[1, 0, 1, 0]
sage: pealing(DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]))
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: pealing(DyckWord([1,1,0,0]),return_touches=True)
([1, 0, 1, 0], [[1, 2]])
sage: pealing(DyckWord([1,0,1,0]),return_touches=True)
([1, 0, 1, 0], [])
sage: pealing(DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]),return_touches=True)
([1, 0, 1, 0, 1, 0, 1, 0, 1, 0], [[1, 2], [3, 5]])

```

`sage.combinat.dyck_word.replace_parens(x)`

A map sending '(' to `open_symbol` and ')' to `close_symbol`, and raising an error on any input other than '(' and ')'. The values of the constants `open_symbol` and `close_symbol` are subject to change.

This is the inverse map of `replace_symbols()`.

INPUT:

- `x` – either an opening or closing parenthesis

OUTPUT:

- If `x` is an opening parenthesis, replace `x` with the constant `open_symbol`.
- If `x` is a closing parenthesis, replace `x` with the constant `close_symbol`.
- Raise a `ValueError` if `x` is neither an opening nor a closing parenthesis.

See also:

`replace_symbols()`

EXAMPLES:

```
sage: from sage.combinat.dyck_word import replace_parens
sage: replace_parens('(')
1
sage: replace_parens(')')
0
sage: replace_parens(1)
Traceback (most recent call last):
...
ValueError
```

`sage.combinat.dyck_word.replace_symbols(x)`

A map sending `open_symbol` to '(' and `close_symbol` to ')', and raising an error on any input other than `open_symbol` and `close_symbol`. The values of the constants `open_symbol` and `close_symbol` are subject to change.

This is the inverse map of `replace_parens()`.

INPUT:

- `x` – either `open_symbol` or `close_symbol`.

OUTPUT:

- If `x` is `open_symbol`, replace `x` with '('.
- If `x` is `close_symbol`, replace `x` with ')
- If `x` is neither `open_symbol` nor `close_symbol`, a `ValueError` is raised.

See also:

`replace_parens()`

EXAMPLES:

```
sage: from sage.combinat.dyck_word import replace_symbols
sage: replace_symbols(1)
 '('
sage: replace_symbols(0)
 ')'

```

(continues on next page)

(continued from previous page)

```

')'
sage: replace_symbols(3)
Traceback (most recent call last):
...
ValueError

```

5.1.98 Substitutions over unit cube faces (Rauzy fractals)

This module implements the $E_1^*(\sigma)$ substitution associated with a one-dimensional substitution σ , that acts on unit faces of dimension $(d - 1)$ in \mathbf{R}^d .

This module defines the following classes and functions:

- `Face` - a class to model a face
- `Patch` - a class to model a finite set of faces
- `E1Star` - a class to model the $E_1^*(\sigma)$ application defined by the substitution `sigma`

See the documentation of these objects for more information.

The convention for the choice of the unit faces and the definition of $E_1^*(\sigma)$ varies from article to article. Here, unit faces are defined by

$$\begin{aligned} [x, 1]^* &= \{x + \lambda e_2 + \mu e_3 : \lambda, \mu \in [0, 1]\} \\ [x, 2]^* &= \{x + \lambda e_1 + \mu e_3 : \lambda, \mu \in [0, 1]\} \\ [x, 3]^* &= \{x + \lambda e_1 + \mu e_2 : \lambda, \mu \in [0, 1]\} \end{aligned}$$

and the dual substitution $E_1^*(\sigma)$ is defined by

$$E_1^*(\sigma)([x, i]^*) = \bigcup_{k=1,2,3} \bigcup_{s \mid \sigma(k)=pis} [M^{-1}(x + \ell(s)), k]^*,$$

where $\ell(s)$ is the abelianized of s , and M is the matrix of σ .

- Franco Saliola (2009): initial version
- Vincent Delecroix, Timo Jolivet, Stepan Starosta, Sebastien Labbe (2010-05): redesign
- Timo Jolivet (2010-08, 2010-09, 2011): redesign

REFERENCES:

EXAMPLES:

We start by drawing a simple three-face patch:

```

sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: x = [Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)]
sage: P = Patch(x)
sage: P
Patch: [[(0, 0, 0), 1]^*, [(0, 0, 0), 2]^*, [(0, 0, 0), 3]^*]
sage: P.plot()
#not tested

```

We apply a substitution to this patch, and draw the result:

```

sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -1),
↪ 1]*]
sage: E(P).plot()           #not tested

```

Note:

- The type of a face is given by an integer in $[1, \dots, d]$ where d is the length of the vector of the face.
- The alphabet of the domain and the codomain of σ must be equal, and they must be of the form $[1, \dots, d]$, where d is a positive integer corresponding to the length of the vectors of the faces on which $E_1^*(\sigma)$ will act.

```

sage: P = Patch([Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -1),
↪ 1]*]

```

The application of an `E1Star` substitution assigns to each new face the color of its preimage. The `repaint` method allows us to repaint the faces of a patch. A single color can also be assigned to every face, by specifying a list of a single color:

```

sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.repaint(['green'])
sage: P.plot()           #not tested

```

A list of colors allows us to color the faces sequentially:

```

sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P)
sage: P.repaint(['red', 'yellow', 'green', 'blue', 'black'])
sage: P = E(P, 3)
sage: P.plot()           #not tested

```

All the color schemes from `list(matplotlib.cm.datad)` can be used:

```

sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.repaint(cmap='summer')
sage: P = E(P, 3)
sage: P.plot()           #not tested
sage: P.repaint(cmap='hsv')
sage: P = E(P, 2)
sage: P.plot()           #not tested

```

It is also possible to specify a dictionary to color the faces according to their type:

```

sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.repaint({1:(0.7, 0.7, 0.7), 2:(0.5,0.5,0.5), 3:(0.3,0.3,0.3)})

```

(continues on next page)

(continued from previous page)

```
sage: P.plot()           #not tested
sage: P.repaint({1:'red', 2:'yellow', 3:'green'})
sage: P.plot()           #not tested
```

Let us look at a nice big patch in 3D:

```
sage: sigma = WordMorphism({1:[1,2], 2:[3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = P + P.translate([-1,1,0])
sage: P = E(P, 11)
sage: P.plot3d()         #not tested
```

Plotting with TikZ pictures is possible:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: s = P.plot_tikz()
sage: print(s)           #not tested
\begin{tikzpicture}
[x={(-0.216506cm,-0.125000cm)}, y={(0.216506cm,-0.125000cm)}, z={(0.000000cm,0.250000cm)}
↪]
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\end{tikzpicture}
```

Plotting patches made of unit segments instead of unit faces:

```
sage: P = Patch([Face([0,0], 1), Face([0,0], 2)])
sage: E = E1Star(WordMorphism({1:[1,2],2:[1]}))
sage: F = E1Star(WordMorphism({1:[1,1,2],2:[2,1]}))
sage: E(P,5).plot()
Graphics object consisting of 21 graphics primitives
sage: F(P,3).plot()
Graphics object consisting of 34 graphics primitives
```

Everything works in any dimension (except for the plotting features which only work in dimension two or three):

```
sage: P = Patch([Face((0,0,0,0),1), Face((0,0,0,0),4)])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1]}))
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -1), 2]*,
↪ [(1, 0, 0, -1), 1]*]
```

```
sage: sigma = WordMorphism({1:[1,2],2:[1,3],3:[1,4],4:[1,5],5:[1,6],6:[1,7],7:[1,8],8:[1,
↪9],9:[1,10],10:[1,11],11:[1,12],12:[1]}))
```

(continues on next page)

(continued from previous page)

```

sage: E = E1Star(sigma)
sage: E
E_1^*(1->12, 10->1,11, 11->1,12, 12->1, 2->13, 3->14, 4->15, 5->16, 6->17, 7->18, 8->19,
↪9->1,10)
sage: P = Patch([Face((0,0,0,0,0,0,0,0,0,0,0,0),t) for t in [1,2,3]])
sage: for x in sorted(E(P), key=lambda x : (x.vector(),x.type())): print(x)
[(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0), 1]*
[(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0), 2]*
[(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0), 12]*
[(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, -1), 11]*
[(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, -1), 10]*
[(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, -1), 9]*

```

```
class sage.combinat.e_one_star.E1Star(sigma, method='suffix')
```

```
Bases: sage.structure.sage_object.SageObject
```

A class to model the $E_1^*(\sigma)$ map associated with a unimodular substitution σ .

INPUT:

- `sigma` - unimodular `WordMorphism`, i.e. such that its incidence matrix has determinant ± 1 .
- `method` - 'prefix' or 'suffix' (optional, default: 'suffix') Enables to use an alternative definition $E_1^*(\sigma)$ substitutions, where the abelianized of the prefix` is used instead of the suffix.

Note: The alphabet of the domain and the codomain of σ must be equal, and they must be of the form $[1, \dots, d]$, where d is a positive integer corresponding to the length of the vectors of the faces on which $E_1^*(\sigma)$ will act.

EXAMPLES:

```

sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0,
↪ -1), 1]*]

```

```

sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma, method='prefix')
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 0, 1), 1]*, [(0, 0,
↪ -1), 2]*]

```

```

sage: x = [Face((0,0,0,0),1), Face((0,0,0,0),4)]
sage: P = Patch(x)
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -1),
↪ 2]*, [(1, 0, 0, -1), 1]*]

```

inverse_matrix()

Return the inverse of the matrix associated with self.

EXAMPLES:

```

sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.inverse_matrix()
[ 0  1  0]
[ 0  0  1]
[ 1 -1 -1]

```

matrix()

Return the matrix associated with self.

EXAMPLES:

```

sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.matrix()
[1 1 1]
[1 0 0]
[0 1 0]

```

sigma()

Return the WordMorphism associated with self.

EXAMPLES:

```

sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.sigma()
WordMorphism: 1->12, 2->13, 3->1

```

class `sage.combinat.e_one_star.Face`(*v*, *t*, *color=None*)

Bases: `sage.structure.sage_object.SageObject`

A class to model a unit face of arbitrary dimension.

A unit face in dimension d is represented by a d -dimensional vector v and a type t in $\{1, \dots, d\}$. The type of the face corresponds to the canonical unit vector to which the face is orthogonal. The optional `color` argument is used in plotting functions.

INPUT:

- v - tuple of integers

- t - integer in $[1, \dots, \text{len}(v)]$, type of the face. The face of type i is orthogonal to the canonical vector e_i .
- `color` - color (optional, default: `None`) color of the face, used for plotting only. If `None`, its value is guessed from the face type.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.vector()
(0, 2, 0)
sage: f.type()
3
```

```
sage: f = Face((0,2,0), 3, color=(0.5, 0.5, 0.5))
sage: f.color()
RGB color (0.5, 0.5, 0.5)
```

color(*color=None*)

Return or change the color of the face.

INPUT:

- `color` - string, rgb tuple, color (optional, default: `None`) the new color to assign to the face. If `None`, it returns the color of the face.

OUTPUT:

color or `None`

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.color()
RGB color (0.0, 0.0, 1.0)
sage: f.color('red')
sage: f.color()
RGB color (1.0, 0.0, 0.0)
```

type()

Return the type of the face.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.type()
3
```

```
sage: f = Face((0,2,0), 3)
sage: f.type()
3
```

vector()

Return the vector of the face.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.vector()
(0, 2, 0)
```

class `sage.combinat.e_one_star.Patch`(*faces*, *face_contour*=None)

Bases: `sage.structure.sage_object.SageObject`

A class to model a collection of faces. A patch is represented by an immutable set of Faces.

Note: The dimension of a patch is the length of the vectors of the faces in the patch, which is assumed to be the same for every face in the patch.

Note: Since version 4.7.1, Patches are immutable, except for the colors of the faces, which are not taken into account for equality tests and hash functions.

INPUT:

- *faces* - finite iterable of faces
- *face_contour* - dict (optional, default:None) maps the face type to vectors describing the contour of unit faces. If None, defaults contour are assumed for faces of type 1, 2, 3 or 1, 2, 3. Used in plotting methods only.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
```

```
sage: face_contour = {}
sage: face_contour[1] = map(vector, [(0,0,0),(0,1,0),(0,1,1),(0,0,1)])
sage: face_contour[2] = map(vector, [(0,0,0),(0,0,1),(1,0,1),(1,0,0)])
sage: face_contour[3] = map(vector, [(0,0,0),(1,0,0),(1,1,0),(0,1,0)])
sage: Patch([Face((0,0,0),t) for t in [1,2,3]], face_contour=face_contour)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
```

difference(*other*)

Return the difference of self and other.

INPUT:

- *other* - a finite iterable of faces or a single face

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.difference(Face([0,0,0],2))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 3]*]
sage: P.difference(P)
Patch: []
```

dimension()

Return the dimension of the vectors of the faces of self

It returns None if self is the empty patch.

The dimension of a patch is the length of the vectors of the faces in the patch, which is assumed to be the same for every face in the patch.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.dimension()
3
```

faces_of_color(*color*)

Return a list of the faces that have the given color.

INPUT:

- *color* - color

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1, 'red'), Face((1,2,0),3, 'blue'), Face((1,2,0),
↪1, 'red')])
sage: sorted(P.faces_of_color('red'))
[[ (0, 0, 0), 1]*, [(1, 2, 0), 1]*]
```

faces_of_type(*t*)

Return a list of the faces that have type *t*.

INPUT:

- *t* - integer or any other type

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: sorted(P.faces_of_type(1))
[[ (0, 0, 0), 1]*, [(1, 2, 0), 1]*]
```

faces_of_vector(*v*)

Return a list of the faces whose vector is *v*.

INPUT:

- *v* - a vector

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: sorted(P.faces_of_vector([1,2,0]))
[[ (1, 2, 0), 1]*, [(1, 2, 0), 3]*]
```

occurrences_of(*other*)

Return all positions at which *other* appears in self, that is, all vectors *v* such that `set(other.translate(v)) <= set(self)`.

INPUT:

- other - a Patch

OUTPUT:

a list of vectors

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch, E1Star
sage: P = Patch([Face([0,0,0], 1), Face([0,0,0], 2), Face([0,0,0], 3)])
sage: Q = Patch([Face([0,0,0], 1), Face([0,0,0], 2)])
sage: P.occurrences_of(Q)
[(0, 0, 0)]
sage: Q = Q.translate([1,2,3])
sage: P.occurrences_of(Q)
[(-1, -2, -3)]
```

```
sage: E = E1Star(WordMorphism({1:[1,2], 2:[1,3], 3:[1]}))
sage: P = Patch([Face([0,0,0], 1), Face([0,0,0], 2), Face([0,0,0], 3)])
sage: P = E(P,4)
sage: Q = Patch([Face([0,0,0], 1), Face([0,0,0], 2)])
sage: L = P.occurrences_of(Q)
sage: sorted(L)
[(0, 0, 0), (0, 0, 1), (0, 1, -1), (1, 0, -1), (1, 1, -3), (1, 1, -2)]
```

plot(*projmat=None, opacity=0.75*)

Return a 2D graphic object depicting the patch.

INPUT:

- *projmat* - matrix (optional, default: *None*) the projection matrix. Its number of lines must be two. Its number of columns must equal the dimension of the ambient space of the faces. If *None*, the isometric projection is used by default.
- *opacity* - float between 0 and 1 (optional, default: 0.75) opacity of the face

Warning: Plotting is implemented only for patches in two or three dimensions.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.plot()
Graphics object consisting of 3 graphics primitives
```

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.plot()
Graphics object consisting of 57 graphics primitives
```

Plot with a different projection matrix:

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: M = matrix(2, 3, [1,0,-1,0.3,1,-3])
sage: P = E(P, 3)
sage: P.plot(projmat=M)
Graphics object consisting of 17 graphics primitives
```

Plot patches made of unit segments:

```
sage: P = Patch([Face([0,0], 1), Face([0,0], 2)])
sage: E = E1Star(WordMorphism({1:[1,2], 2:[1]})
sage: F = E1Star(WordMorphism({1:[1,1,2], 2:[2,1]})
sage: E(P,5).plot()
Graphics object consisting of 21 graphics primitives
sage: F(P,3).plot()
Graphics object consisting of 34 graphics primitives
```

plot3d()

Return a 3D graphics object depicting the patch.

Warning: 3D plotting is implemented only for patches in three dimensions.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.plot3d() #not tested
```

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.repaint()
sage: P.plot3d() #not tested
```

plot_tikz(*projmat=None, print_tikz_env=True, edgcolor='black', scale=0.25, drawzero=False, extra_code_before="", extra_code_after=""*)

Return a string containing some TikZ code to be included into a LaTeX document, depicting the patch.

Warning: Tikz Plotting is implemented only for patches in three dimensions.

INPUT:

- *projmat* - matrix (optional, default: None) the projection matrix. Its number of lines must be two. Its number of columns must equal the dimension of the ambient space of the faces. If None, the isometric projection is used by default.
- *print_tikz_env* - bool (optional, default: True) if True, the tikzpicture environment are printed
- *edgcolor* - string (optional, default: 'black') either 'black' or 'facecolor' (color of unit face edges)

- `scale` - real number (optional, default: 0.25) scaling constant for the whole figure
- `drawzero` - bool (optional, default: False) if True, mark the origin by a black dot
- `extra_code_before` - string (optional, default: '') extra code to include in the tikz picture
- `extra_code_after` - string (optional, default: '') extra code to include in the tikz picture

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: s = P.plot_tikz()
sage: len(s)
602
sage: print(s)          #not tested
\begin{tikzpicture}
[x={(-0.216506cm,-0.125000cm)}, y={(0.216506cm,-0.125000cm)}, z={(0.000000cm,0.
↪250000cm)}]
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\end{tikzpicture}
```

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 4)
sage: from sage.misc.latex import latex          #not tested
sage: latex.add_to_preamble('\usepackage{tikz}') #not tested
sage: view(P)                                   #not tested
```

Plot using shades of gray (useful for article figures):

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.repaint([(0.9, 0.9, 0.9), (0.65,0.65,0.65), (0.4,0.4,0.4)])
sage: P = E(P, 4)
sage: s = P.plot_tikz()
```

Plotting with various options:

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: M = matrix(2,3,[float(u) for u in [1,0,-0.7071,0,1,-0.7071]])
sage: P = E(P, 3)
sage: s = P.plot_tikz(projmat=M, edgecolor='facecolor', scale=0.6,
↪drawzero=True)
```

Adding X, Y, Z axes using the extra code feature:

```
sage: length = 1.5
sage: space = 0.3
sage: axes = ''
sage: axes += "\\draw[->, thick, black] (0,0,0) -- (%s, 0, 0);\\n" % length
sage: axes += "\\draw[->, thick, black] (0,0,0) -- (0, %s, 0);\\n" % length
sage: axes += "\\node at (%s,0,0) {$x$};\\n" % (length + space)
sage: axes += "\\node at (0,%s,0) {$y$};\\n" % (length + space)
sage: axes += "\\node at (0,0,%s) {$z$};\\n" % (length + space)
sage: axes += "\\draw[->, thick, black] (0,0,0) -- (0, 0, %s);\\n" % length
sage: cube = Patch([Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)])
sage: options = dict(scale=0.5,drawzero=True,extra_code_before=axes)
sage: s = cube.plot_tikz(**options)
sage: len(s)
986
sage: print(s) #not tested
\\begin{tikzpicture}
[x={{(-0.433013cm,-0.250000cm)}, y={{(0.433013cm,-0.250000cm)}, z={{(0.000000cm,0.
↪500000cm)}}}
\\draw[->, thick, black] (0,0,0) -- (1.5000000000000000, 0, 0);
\\draw[->, thick, black] (0,0,0) -- (0, 1.5000000000000000, 0);
\\node at (1.8000000000000000,0,0) {$x$};
\\node at (0,1.8000000000000000,0) {$y$};
\\node at (0,0,1.8000000000000000) {$z$};
\\draw[->, thick, black] (0,0,0) -- (0, 0, 1.5000000000000000);
\\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\\node[circle,fill=black,draw=black,minimum size=1.5mm,inner sep=0pt] at (0,0,0)
↪{};
\\end{tikzpicture}
```

repaint (cmap='Set1')

Repaint all the faces of self from the given color map.

This only changes the colors of the faces of self.

INPUT:

- cmap - color map (default: 'Set1'). It can be one of the following:
 - string – A coloring map. For available coloring map names type: `sorted(colormaps)`
 - list – a list of colors to assign cyclically to the faces. A list of a single color colors all the faces with the same color.
 - dict – a dict of face types mapped to colors, to color the faces according to their type.
 - {}, the empty dict - shortcut for {1: 'red', 2: 'green', 3: 'blue'}.

EXAMPLES:

Using a color map:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: color = (0, 0, 0)
sage: P = Patch([Face((0,0,0),t,color) for t in [1,2,3]])
sage: for f in P: f.color()
RGB color (0.0, 0.0, 0.0)
RGB color (0.0, 0.0, 0.0)
RGB color (0.0, 0.0, 0.0)
sage: P.repaint()
sage: next(iter(P)).color() #random
RGB color (0.498..., 0.432..., 0.522...)
```

Using a list of colors:

```
sage: P = Patch([Face((0,0,0),t,color) for t in [1,2,3]])
sage: P.repaint([(0.9, 0.9, 0.9), (0.65,0.65,0.65), (0.4,0.4,0.4)])
sage: for f in P: f.color()
RGB color (0.9, 0.9, 0.9)
RGB color (0.65, 0.65, 0.65)
RGB color (0.4, 0.4, 0.4)
```

Using a dictionary to color faces according to their type:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.repaint({1:'black', 2:'yellow', 3:'green'})
sage: P.plot() #not tested
sage: P.repaint({})
sage: P.plot() #not tested
```

translate(*v*)

Return a translated copy of self by vector *v*.

INPUT:

- *v* - vector or tuple

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: P.translate([-1,-2,0])
Patch: [[(-1, -2, 0), 1]*, [(0, 0, 0), 1]*, [(0, 0, 0), 3]*]
```

union(*other*)

Return a Patch consisting of the union of self and other.

INPUT:

- *other* - a Patch or a Face or a finite iterable of faces

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((0,0,0),2)])
sage: P.union(Face((1,2,3), 3))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*]
```

5.1.100 Tools for enumeration modulo the action of a permutation group

`sage.combinat.enumeration_mod_permgroup.all_children(v, max_part)`

Returns all the children of an integer vector (`ClonableIntArray`) v in the tree of enumeration by lexicographic order. The children of an integer vector v whose entries have the sum n are all integer vectors of sum $n + 1$ which follow v in the lexicographic order.

That means this function adds 1 on the last non zero entries and the following ones. For an integer vector v such that

$$v = [\dots, a, 0, 0] \text{ with } a \neq 0,$$

then, the list of children is

$$[[\dots, a + 1, 0, 0], [\dots, a, 1, 0], [\dots, a, 0, 1]].$$

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import all_children
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: v = IncreasingIntArrays([1,2,3,4])
sage: all_children(v, -1)
[[1, 2, 3, 5]]
```

`sage.combinat.enumeration_mod_permgroup.canonical_children(sgs, v, max_part)`

Returns the canonical children of the integer vector v . This function computes all children of the integer vector v via the function `all_children()` and returns from this list only these which are canonicals identified via the function `is_canonical()`.

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import canonical_children
sage: G = PermutationGroup([[1,2,3,4]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: canonical_children(sgs, IA([1,2,3,5]), -1)
[]
```

`sage.combinat.enumeration_mod_permgroup.canonical_representative_of_orbit_of(sgs, v)`

Returns the maximal vector for the lexicographic order living in the orbit of v under the action of the permutation group whose strong generating system is sgs . The maximal vector is also called “canonical”. Hence, this method returns the canonical vector inside the orbit of v . If v is already canonical, the method returns v .

Let G to be the permutation group which admits sgs as a strong generating system. An integer vector v is said to be canonical under the action of G if and only if:

$$v = \max_{\text{lex order}} \{g \cdot v \mid g \in G\}$$

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import canonical_representative_
      ↪_of_orbit_of
sage: G = PermutationGroup([[1,2,3,4]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArray
sage: IA = IncreasingIntArray()
sage: canonical_representative_of_orbit_of(sgs, IA([1,2,3,5]))
[5, 1, 2, 3]
```

`sage.combinat.enumeration_mod_permgroup.is_canonical(sgs, v)`

Returns True if the integer vector v is maximal with respect to the lexicographic order in its orbit under the action of the permutation group whose strong generating system is sgs . Such vectors are said to be canonical.

Let G to be the permutation group which admit sgs as a strong generating system. An integer vector v is said to be canonical under the action of G if and only if:

$$v = \max_{\text{lex order}} \{g \cdot v \mid g \in G\}$$

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import is_canonical
sage: G = PermutationGroup([[1,2,3,4]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArray
sage: IA = IncreasingIntArray()
sage: is_canonical(sgs, IA([1,2,3,6]))
False
```

`sage.combinat.enumeration_mod_permgroup.lex_cmp(v1, v2)`

Lexicographic comparison of `ClonableIntArray`.

INPUT:

Two instances v_1, v_2 of `ClonableIntArray`

OUTPUT:

-1, 0, 1, depending on whether v_1 is lexicographically smaller, equal, or greater than v_2 .

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(SymmetricGroup(5), 5)
sage: I = IntegerVectorsModPermutationGroup(SymmetricGroup(5))
sage: J = IntegerVectorsModPermutationGroup(SymmetricGroup(6))
sage: v1 = I([2,3,1,2,3], check=False)
sage: v2 = I([2,3,2,3,2], check=False)
```

(continues on next page)

(continued from previous page)

```

sage: v3 = J([2,3,1,2,3,1], check=False)
sage: from sage.combinat.enumeration_mod_permgroup import lex_cmp
sage: lex_cmp(v1, v1)
0
sage: lex_cmp(v1, v2)
-1
sage: lex_cmp(v2, v1)
1
sage: lex_cmp(v1, v3)
-1
sage: lex_cmp(v3, v1)
1

```

`sage.combinat.enumeration_mod_permgroup.lex_cmp_partial(v1, v2, step)`

Partial comparison of the two lists according to the lexicographic order. It compares the *step*-th first entries.

EXAMPLES:

```

sage: from sage.combinat.enumeration_mod_permgroup import lex_cmp_partial
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: lex_cmp_partial(IA([0,1,2,3]), IA([0,1,2,4]), 3)
0
sage: lex_cmp_partial(IA([0,1,2,3]), IA([0,1,2,4]), 4)
-1

```

`sage.combinat.enumeration_mod_permgroup.orbit(sgs, v)`

Returns the orbit of the integer vector *v* under the action of the permutation group whose strong generating system is *sgs*.

NOTE:

The returned orbit is a set. In the doctests, we convert it into a sorted list.

EXAMPLES:

```

sage: from sage.combinat.enumeration_mod_permgroup import orbit
sage: G = PermutationGroup([[1,2,3,4]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: sorted(orbit(sgs, IA([1,2,3,4])))
[[1, 2, 3, 4], [2, 3, 4, 1], [3, 4, 1, 2], [4, 1, 2, 3]]

```

5.1.101 Compute Bell and Uppuluri-Carpenter numbers

AUTHORS:

- Nick Alexander

`sage.combinat.expnnums.expnnums(n, aa)`

Compute the first *n* exponential numbers around *aa*, starting with the zero-th.

INPUT:

- *n* - C machine int

- aa - C machine int

OUTPUT: A list of length n .

ALGORITHM: We use the same integer addition algorithm as GAP. This is an extension of Bell's triangle to the general case of exponential numbers. The recursion performs $O(n^2)$ additions, but the running time is dominated by the cost of the last integer addition, because the growth of the integer results of partial computations is exponential in n . The algorithm stores $O(n)$ integers, but each is exponential in n .

EXAMPLES:

```
sage: expnums(10, 1)
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
```

```
sage: expnums(10, -1)
[1, -1, 0, 1, 1, -2, -9, -9, 50, 267]
```

```
sage: expnums(1, 1)
[1]
sage: expnums(0, 1)
[]
sage: expnums(-1, 0)
[]
```

AUTHORS:

- Nick Alexander

sage.combinat.expnums.**expnums2**(n , aa)

A vanilla python (but compiled via Cython) implementation of expnums.

We Compute the first n exponential numbers around aa , starting with the zero-th.

EXAMPLES:

```
sage: from sage.combinat.expnums import expnums2
sage: expnums2(10, 1)
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
```

5.1.102 Families

This is a backward compatibility stub. Use `sage.sets.family` instead.

5.1.103 Brent Yorgey's fast algorithm for integer vector (multiset) partitions.

ALGORITHM:

Brent Yorgey, Generating Multiset Partitions, The Monad Reader, Issue 8, September 2007, p. 5.

https://wiki.haskell.org/The_Monad.Reader/Previous_issues

AUTHORS:

- D. K. Sunko (2020-02-19): initial version
- F. Chapoton (2020-02-22): conversion to iterators and shorter doctests and doc tweaks
- T. Scrimshaw (2020-03-06): Cython optimizations and doc tweaks

`sage.combinat.fast_vector_partitions.fast_vector_partitions(v, min_vals=None)`

Brent Yorgey's fast algorithm for integer vector (multiset) partitions.

INPUT:

- `v` – list of non-negative integers, understood as the vector to be partitioned
- `min_vals` – optional list of non-negative integers, of same length as `v`

OUTPUT:

A list of lists, each representing a vector partition of `v`.

If `min_vals` is given, only partitions with parts `p >= min_vals` in the lexicographic ordering will appear.

If `min_vals` is given and `len(min_vals) != len(v)`, an error is raised.

EXAMPLES:

The older the computer, the more impressive the comparison:

```
sage: from sage.combinat.fast_vector_partitions import fast_vector_partitions
sage: fastvparts = list(fast_vector_partitions([3, 3, 3]))
sage: vparts = list(VectorPartitions([3, 3, 3]))
sage: vparts == fastvparts[::-1]
True
sage: len(fastvparts)
686
sage: list(fast_vector_partitions([1, 2, 3], min_vals=[0, 1, 1]))
[[[1, 2, 3],
 [[0, 2, 3], [1, 0, 0]],
 [[0, 2, 2], [1, 0, 1]],
 [[0, 2, 1], [1, 0, 2]],
 [[0, 2, 0], [1, 0, 3]],
 [[0, 1, 3], [1, 1, 0]],
 [[0, 1, 2], [1, 1, 1]],
 [[0, 1, 1], [1, 1, 2]],
 [[0, 1, 1], [0, 1, 2], [1, 0, 0]],
 [[0, 1, 1], [0, 1, 1], [1, 0, 1]]]
sage: L1 = list(fast_vector_partitions([5, 7, 6], min_vals=[1, 3, 2]))
sage: L1 == list(VectorPartitions([5, 7, 6], min=[1, 3, 2]))[::-1]
True
```

Note: The partitions are returned as an iterator.

In this documentation, $a \leq b$ means $a[i] \leq b[i]$ for all i (notation following B. Yorgey's paper). It is the monomial partial ordering in Dickson's lemma: $a \leq b$ iff x^a divides x^b as monomials.

Warning: The ordering of the partitions is reversed with respect to the output of Sage class `VectorPartitions`.

`sage.combinat.fast_vector_partitions.recursive_vector_partitions(v, vL)`

Iterate over a lexicographically ordered list of lists, each list representing a vector partition of `v`, such that no part of any partition is lexicographically smaller than `vL`.

Internal part of `fast_vector_partitions()`.

INPUT:

- v – list of non-negative integers, understood as a vector
- vL – list of non-negative integers, understood as a vector

EXAMPLES:

```
sage: from sage.combinat.fast_vector_partitions import recursive_vector_partitions
sage: list(recursive_vector_partitions([2, 2, 2],[1, 1, 1]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]]]
sage: list(recursive_vector_partitions([2, 2, 2],[1, 1, 0]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]], [[1, 1, 0], [1, 1, 2]]]
sage: list(recursive_vector_partitions([2, 2, 2],[1, 0, 1]))
[[[2, 2, 2]],
 [[1, 1, 1], [1, 1, 1]],
 [[1, 1, 0], [1, 1, 2]],
 [[1, 0, 2], [1, 2, 0]],
 [[1, 0, 1], [1, 2, 1]]]
```

`sage.combinat.fast_vector_partitions.recursive_within_from_to($m, s, e, useS, useE$)`
Iterate over a lexicographically ordered list of lists v satisfying $e \leq v \leq s$ and $v \leq m$ as vectors.

Internal part of `fast_vector_partitions()`.

INPUT:

- m – list of non-negative integers, understood as a vector
- s – list of non-negative integers, understood as a vector
- e – list of non-negative integers, understood as a vector
- `useS` – boolean
- `useE` – boolean

EXAMPLES:

```
sage: from sage.combinat.fast_vector_partitions import recursive_within_from_to
sage: list(recursive_within_from_to([1, 2, 3],[1, 2, 2],[1, 1, 1],True,True))
[[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]]
```

Note: The flags `useS` and `useE` are used to implement the condition efficiently. Because testing it loops over the vector, re-testing at each step as the vector is parsed is inefficient: all but the last comparison have been done cumulatively already. This code tests only for the last one, using the flags to accumulate information from previous calls.

Warning: Expects to be called with $s \leq m$.

Expects to be called first with `useS == useE == True`.

`sage.combinat.fast_vector_partitions.within_from_to(m, s, e)`
Iterate over a lexicographically ordered list of lists v satisfying $e \leq v \leq s$ and $v \leq m$ as vectors.

Internal part of `fast_vector_partitions()`.

INPUT:

- m – list of non-negative integers, understood as a vector
- s – list of non-negative integers, understood as a vector
- e – list of non-negative integers, understood as a vector

EXAMPLES:

```
sage: from sage.combinat.fast_vector_partitions import within_from_to
sage: list(within_from_to([1, 2, 3], [1, 2, 2], [1, 1, 1]))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

Note: The input s will be “clipped” internally if it does not satisfy the condition $s \leq m$.

To understand the input check, some line art is helpful. Assume that (a, b) are the two least significant coordinates of some vector. Say:

```
e = (2,3), s = (7,6), m = (9,8).
```

In the figure, these values are denoted by E , S , and M , while the letter X stands for all other allowed values of $v = (a, b)$:

If S moves horizontally, the full-height columns fill the box in until S reaches M , at which point it remains the limit in the b -direction as it moves out of the box, while M takes over as the limit in the a -direction, so the M -column remains filled only up to S , no matter how much S moves further to the right.

If S moves vertically, its column will be filled to the top of the box, but it remains the relevant limit in the a -direction, while M takes over in the b -direction as S goes out of the box upwards.

Both behaviors are captured by using the smaller coordinate of S and M , whenever S is outside the box defined by M . The input will be “clipped” accordingly in that case.

Warning: The “clipping” behavior is transparent to the user, but may be puzzling when comparing outputs with the function `recursive_within_from_to()` which has no input protection.

5.1.104 Fully commutative elements of Coxeter groups

An element w in a Coxeter system (W,S) is fully commutative (FC) if every two reduced words of w can be related by a sequence of only commutation relations, i.e., relations of the form $st = ts$ where s, t are commuting generators in S . See [Ste1996].

Authors:

- Chase Meadors, Tianyuan Xu (2020): Initial version

Acknowledgements

A draft of this code was written during an REU project at University of Colorado Boulder. We thank Rachel Castro, Joel Courtney, Thomas Magnuson and Natalie Schoenhals for their contribution to the project and the code.

class `sage.combinat.fully_commutative_elements.FullyCommutativeElement`

Bases: `sage.structure.list_clone.NormalizedClonableList`

A fully commutative (FC) element in a Coxeter system.

An element w in a Coxeter system (W,S) is fully commutative (FC) if every two reduced word of w can be related by a sequence of only commutation relations, i.e., relations of the form $st = ts$ where s, t are commuting generators in S .

Every FC element has a canonical reduced word called its Cartier–Foata form. See [Gre2006]. We will normalize each FC element to this form.

check()

Called automatically when an element is created.

EXAMPLES:

```
sage: CoxeterGroup(['A', 3]).fully_commutative_elements()([1, 2]) # indirect_
↳doctest
[1, 2]
sage: CoxeterGroup(['A', 3]).fully_commutative_elements()([1, 2, 1]) # indirect_
↳doctest
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
```

coset_decomposition(J , $side='left'$)

Return the coset decomposition of `self` with respect to the parabolic subgroup generated by J .

INPUT:

- J – subset of the generating set S of the Coxeter system
- $side$ – string (default: 'left'); if the value is set to 'right', then the function returns the tuple (w^J, w'_J) from the coset decomposition $w = w^J \cdot w'_J$ of w with respect to J

OUTPUT:

The tuple of elements (w_J, w^J) such that $w = w_J \cdot w^J$, w_J is generated by the elements in J , and w^J has no left descent from J . This tuple is unique and satisfies the equation $\ell(w) = \ell(w_J) + \ell(w^J)$, where ℓ denotes Coxeter length, by general theory; see Proposition 2.4.4 of [BB2005].

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 6]).fully_commutative_elements()
sage: w = FC([1, 6, 2, 5, 4, 6, 5])
sage: w.coset_decomposition({1})
([1], [6, 2, 5, 4, 6, 5])
sage: w.coset_decomposition({1}, side = 'right')
([1, 6, 2, 5, 4, 6, 5], [])
sage: w.coset_decomposition({5, 6})
([6, 5, 6], [1, 2, 4, 5])
sage: w.coset_decomposition({5, 6}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

Note: The factor w_J of the coset decomposition $w = w_J \cdot w^J$ can be obtained by greedily “pulling left descents of w that are in J to the left”; see the proof of [BB2005]. This greedy algorithm works for all elements in Coxeter group, but it becomes especially simple for FC elements because descents are easier to find for FC elements.

descents(*side='left'*)

Obtain the set of descents on the appropriate side of `self`.

INPUT:

- `side` – string (default: 'left'); if set to 'right', find the right descents

A generator s is called a left or right descent of an element w if $\ell(sw)$ or $\ell(ws)$ is smaller than $\ell(w)$, respectively. If w is FC, then s is a left descent of w if and only if s appears to in the word and every generator to the left of the leftmost s in the word commutes with s . A similar characterization exists for right descents of FC elements.

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: sorted(w.descents())
[1, 4]
sage: w.descents(side='right')
{3}
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: sorted(FC([1, 4, 3, 5, 2, 4, 3]).descents())
[1, 4]
```

See also:

[*find_descent\(\)*](#)

find_descent(*s, side='left'*)

Check if s is a descent of `self` and find its position if so.

A generator s is called a left or right descent of an element w if $\ell(sw)$ or $\ell(ws)$ is smaller than $\ell(w)$, respectively. If w is FC, then s is a left descent of w if and only if s appears to in the word and every generator to the left of the leftmost s in the word commutes with s . A similar characterization exists for right descents of FC elements.

INPUT:

- `s` – integer representing a generator of the Coxeter system
- `side` – string (default: `'left'`); if the argument is set to `'right'`, the function checks if `s` is a right descent of `self` and finds the index of the rightmost occurrence of `s` if so

OUTPUT:

Determine if the generator `s` is a left descent of `self`; return the index of the leftmost occurrence of `s` in `self` if so and return `None` if not.

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: w.find_descent(1)
0
sage: w.find_descent(1, side='right')

sage: w.find_descent(4)
1
sage: w.find_descent(4, side='right')

sage: w.find_descent(3)
```

group_element()

Get the actual element of the Coxeter group associated with `self.parent()` corresponding to `self`.

EXAMPLES:

```
sage: W = CoxeterGroup(['A', 3])
sage: FC = W.fully_commutative_elements()
sage: x = FC([1, 2])
sage: x.group_element()
[ 0 -1  1]
[ 1 -1  1]
[ 0  0  1]
sage: x.group_element() in W
True
```

has_descent(*s*, *side*='left')

Determine if `s` is a descent on the appropriate side of `self`.

INPUT:

- `side` – string (default: `'left'`); if set to `'right'`, determine if `self` has `s` as a right descent

OUTPUT: a boolean value

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: w.has_descent(1)
True
sage: w.has_descent(1, side='right')
False
sage: w.has_descent(4)
```

(continues on next page)

(continued from previous page)

```
True
sage: w.has_descent(4, side='right')
False
```

See also:[*find_descent\(\)*](#)**heap(**kargs)**Create the heap poset of `self`.

The heap of an FC element w is a labeled poset that can be defined from any reduced word of w . Different reduced words yield isomorphic labeled posets, so the heap is well defined.

Heaps are very useful for visualizing and studying FC elements; see, for example, [Ste1996] and [GX2020].

INPUT:

- `self` – list, a reduced word $w = s_0 \dots s_{k-1}$ of an FC element
- `one_index` – boolean (default: False). Setting the value to True will change the underlying set of the poset to $\{1, 2, \dots, n\}$
- `display_labeling` – boolean (default: False). Setting the value to True will display the label s_i for each element i of the poset

OUTPUT: A labeled poset where the underlying set is $\{0, 1, \dots, k-1\}$ and where each element i carries s_i as its label. The partial order \prec on the poset is defined by declaring $i \prec j$ if $i < j$ and $m(s_i, s_j) \neq 2$.

EXAMPLES:

```
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: FC([1, 4, 3, 5, 2, 4]).heap().cover_relations()
[[1, 2], [1, 3], [2, 5], [2, 4], [3, 5], [0, 4]]
sage: FC([1, 4, 3, 5, 4, 2]).heap(one_index=True).cover_relations()
[[2, 3], [2, 4], [3, 6], [3, 5], [4, 6], [1, 5]]
```

is_fully_commutative()Check if `self` is the reduced word of an FC element.

To check if `self` is FC, we use the well-known characterization that an element w in a Coxeter system (W, S) is FC if and only if for every pair of generators $s, t \in S$ for which $m(s, t) > 2$, no reduced word of w contains the ‘braid’ word $sts\dots$ of length $m(s, t)$ as a contiguous subword. See [Ste1996].

[*check\(\)*](#) is an alias of this method, and is called automatically when an element is created.

EXAMPLES:

```
sage: FC = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: x = FC([1, 2]); x.is_fully_commutative()
True
sage: x = FC.element_class(FC, [1, 2, 1], check=False); x.is_fully_commutative()
False
```

n_value()Calculate the n -value of `self`.

The n -value of a fully commutative element is the *width* (length of any longest antichain) of its heap. The n -value is important as it coincides with Lusztig’s a -value for FC elements in all Weyl and affine Weyl groups as well as so-called star-reducible groups; see [GX2020].

EXAMPLES:

```
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: FC([1,3]).n_value()
2
sage: FC([1,2,3]).n_value()
1
sage: FC([1,3,2]).n_value()
2
sage: FC([1,3,2,5]).n_value()
3
```

normalize()

Mutate `self` into Cartier-Foata normal form.

EXAMPLES:

The following reduced words express the same FC elements in B_5 :

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: FC([1, 4, 3, 5, 2, 4, 3]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
sage: FC([4, 1, 3, 5, 2, 4, 3]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
sage: FC([4, 3, 1, 5, 4, 2, 3]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
```

Note: The Cartier–Foata form of a reduced word of an FC element w can be found recursively by repeatedly moving left descents of elements to the left and ordering the left descents from small to large. In the above example, the left descents of the element are 4 and 1, therefore the Cartier–Foata form of the element is the concatenation of [1,4] with the Cartier–Foata form of the remaining part of the word. See [Gre2006].

See also:

[`descents\(\)`](#)

plot_heap()

Display the Hasse diagram of the heap of `self`.

The Hasse diagram is rendered in the lattice $S \times \mathbb{N}$, with every element i in the poset drawn as a point labelled by its label s_i . Every point is placed in the column for its label at a certain level. The levels start at 0 and the level k of an element i is the maximal number k such that the heap contains a chain $i_0 \prec i_1 \prec \dots \prec i_k = i$ where $i_k = i$. See [Ste1996] and [GX2020].

OUTPUT: GraphicsObject

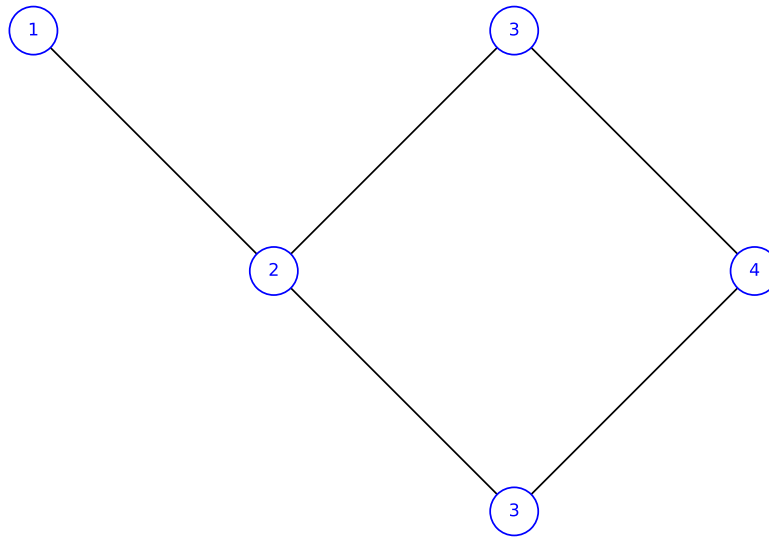

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: FC([3,2,4,3,1]).plot_heap()
Graphics object consisting of 15 graphics primitives
```

star_operation(J , $direction$, $side='left'$)

Apply a star operation on `self` relative to two noncommuting generators.

Star operations were first defined on elements of Coxeter groups by Kazhdan and Lusztig in [KL1979] with respect to pair of generators s, t such that $m(s, t) = 3$. Later, Lusztig generalized the definition in

[Lus1985], via coset decompositions, to allow star operations with respect to any pair of generators s, t such that $m(s, t) \geq 3$. Given such a pair, we can potentially perform four types of star operations corresponding to all combinations of a ‘direction’ and a ‘side’: upper left, lower left, upper right and lower right; see [Gre2006].

Let w be an element in W and let J be any pair $\{s, t\}$ of noncommuting generators in S . Consider the coset decomposition $w = w_J \cdot {}^J w$ of w relative to J . Then an upper left star operation is defined on w if and only if $1 \leq l(w_J) \leq m(s, t) - 2$; when this is the case, the operation returns $x \cdot w_J \cdot w^J$ where x is the letter J different from the leftmost letter of w_J . A lower left star operation is defined on w if and only if $2 \leq l(w_J) \leq m(s, t) - 1$; when this is the case, the operation removes the leftmost letter of w_J from w . Similar facts hold for right star operations. See [Gre2006].

The facts of the previous paragraph hold in general, even if w is not FC. Note that if f is a star operation of any kind, then for every element $w \in W$, the elements w and $f(w)$ are either both FC or both not FC.

INPUT:

- J – a set of two integers representing two noncommuting generators of the Coxeter system
- `direction` – string, ‘upper’ or ‘lower’; the function performs an upper or lower star operation according to `direction`
- `side` – string (default: ‘left’); if this is set to ‘right’, the function performs a right star operation

OUTPUT:

The Cartier–Foata form of the result of the star operation if the operation is defined on `self`, `None` otherwise.

EXAMPLES:

We will compute all star operations on the following FC element in type B_6 relative to $J = \{5, 6\}$:

```

sage: FC = CoxeterGroup(['B', 6]).fully_commutative_elements()
sage: w = FC([1, 6, 2, 5, 4, 6, 5])

```

Whether and how a left star operations can be applied depend on the coset decomposition $w = w_J \cdot w^J$:

```
sage: w.coset_decomposition({5, 6})
([6, 5, 6], [1, 2, 4, 5])
```

Only the lower star operation is defined on the left on w :

```
sage: w.star_operation({5,6}, 'upper')
sage: w.star_operation({5,6}, 'lower')
[1, 5, 2, 4, 6, 5]
```

Whether and how a right star operations can be applied depend on the coset decomposition $w = w^J \cdot w_J$:

```
sage: w.coset_decomposition({5, 6}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

Both types of right star operations on defined for this example:

```
sage: w.star_operation({5, 6}, 'upper', side='right')
[1, 6, 2, 5, 4, 6, 5, 6]
sage: w.star_operation({5, 6}, 'lower', side='right')
[1, 6, 2, 5, 4, 6]
```

```
class sage.combinat.fully_commutative_elements.FullyCommutativeElements(coxeter_group)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent
```

Class for the set of fully commutative (FC) elements of a Coxeter system.

Coxeter systems with finitely many FC elements, or *FC-finite* Coxeter systems, are classified by Stembridge in [Ste1996]. They fall into seven families, namely the groups of types $A_n, B_n, D_n, E_n, F_n, H_n$ and $I_2(m)$.

INPUT:

- `data` – CoxeterMatrix, CartanType, or the usual datum that can be taken in the constructors for these classes (see `sage.combinat.root_system.coxeter_group.CoxeterGroup()`)

OUTPUT:

The class of fully commutative elements in the Coxeter group constructed from `data`. This will belong to the category of enumerated sets. If the Coxeter data corresponds to a Cartan type, the category is further refined to either finite enumerated sets or infinite enumerated sets depending on whether the Coxeter group is FC-finite; the refinement is not carried out if `data` is a Coxeter matrix not corresponding to a Cartan type.

Todo: It would be ideal to implement the aforementioned refinement to finite and infinite enumerated sets for all possible `data`, regardless of whether it corresponds to a Cartan type. Doing so requires determining if an arbitrary Coxeter matrix corresponds to a Cartan type. It may be best to address this issue in `sage.combinat.root_system`. On the other hand, the refinement in the general case may be unnecessary in light of the fact that Stembridge's classification of FC-finite groups contains a very small number of easily-recognizable families.

EXAMPLES:

Create the enumerated set of fully commutative elements in B_3 :

```
sage: FC = CoxeterGroup(['B', 3]).fully_commutative_elements(); FC
Fully commutative elements of Finite Coxeter group over Number Field in a with_
defining polynomial x^2 - 2 with a = 1.414213562373095? with Coxeter matrix:
(continues on next page)
```

(continued from previous page)

```
[1 3 2]
[3 1 4]
[2 4 1]
```

Construct elements:

```
sage: FC([])
[]
sage: FC([1,2])
[1, 2]
sage: FC([2,3,2])
[2, 3, 2]
sage: FC([3,2,3])
[3, 2, 3]
```

Elements are normalized to Cartier–Foata normal form upon construction:

```
sage: FC([3,1])
[1, 3]
sage: FC([2,3,1])
[2, 1, 3]
sage: FC([1,3]) == FC([3,1])
True
```

Attempting to create an element from an input that is not the reduced word of a fully commutative element throws a `ValueError`:

```
sage: FC([1,2,1])
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
sage: FC([2,3,2,3])
Traceback (most recent call last):
...
ValueError: the input is not a reduced word of a fully commutative element
```

Enumerate the FC elements in A_3 :

```
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: FCA3.category()
Category of finite enumerated sets
sage: FCA3.list()
[[],
 [1],
 [2],
 [3],
 [2, 1],
 [1, 3],
 [1, 2],
 [3, 2],
 [2, 3],
 [3, 2, 1],
 [2, 1, 3],
```

(continues on next page)

(continued from previous page)

```
[1, 3, 2],
[1, 2, 3],
[2, 1, 3, 2]]
```

Count the FC elements in B_3 :

```
sage: FCB8 = CoxeterGroup(['B', 8]).fully_commutative_elements()
sage: len(FCB8) # long time (7 seconds)
14299
```

Iterate through the FC elements of length up to 2 in the non-FC-finite group affine A_2 :

```
sage: FCAffineA2 = CoxeterGroup(['A', 2, 1]).fully_commutative_elements()
sage: FCAffineA2.category()
Category of infinite enumerated sets
sage: list(FCAffineA2.iterate_to_length(2))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2], [1, 2]]
```

The cardinality of the set is determined from the classification of FC-finite Coxeter groups:

```
sage: CoxeterGroup('A2').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('B7').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('A3~').fully_commutative_elements().category()
Category of infinite enumerated sets
sage: CoxeterGroup('F4~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('E8~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('F4~xE8~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('B4~xE8~').fully_commutative_elements().category()
Category of infinite enumerated sets
```

Element

alias of *FullyCommutativeElement*

coxeter_group()

Obtain the Coxeter group associated with self.

EXAMPLES:

```
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: FCA3.coxeter_group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2]
[3 1 3]
[2 3 1]
```

iterate_to_length(*length*)

Iterate through the elements of this class up to a maximum length.

INPUT:

- *length* – integer; maximum length of element to generate

OUTPUT: generator for elements of `self` of length up to `length`

EXAMPLES:

The following example produces all FC elements of length up to 2 in the group A_3 :

```
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: list(FCA3.iterate_to_length(2))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3]]
```

The lists for length 4 and 5 are the same since 4 is the maximum length of an FC element in A_3 :

```
sage: list(FCA3.iterate_to_length(4))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3],
 [3, 2, 1], [2, 1, 3], [1, 3, 2], [1, 2, 3], [2, 1, 3, 2]]
sage: list(FCA3.iterate_to_length(5))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3],
 [3, 2, 1], [2, 1, 3], [1, 3, 2], [1, 2, 3], [2, 1, 3, 2]]
sage: list(FCA3.iterate_to_length(4)) == list(FCA3)
True
```

The following example produces all FC elements of length up to 4 in the affine Weyl group \tilde{A}_2 :

```
sage: FCAffineA2 = CoxeterGroup(['A', 2, 1]).fully_commutative_elements()
sage: FCAffineA2.category()
Category of infinite enumerated sets
sage: list(FCAffineA2.iterate_to_length(4))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2],
 [1, 2], [2, 1, 0], [1, 2, 0], [2, 0, 1], [0, 2, 1], [1, 0, 2],
 [0, 1, 2], [0, 2, 1, 0], [0, 1, 2, 0], [1, 2, 0, 1],
 [1, 0, 2, 1], [2, 1, 0, 2], [2, 0, 1, 2]]
```

5.1.105 Finite state machines, automata, transducers

This module adds support for finite state machines, automata and transducers.

For creating automata and transducers you can use classes

- *Automaton* and *Transducer* (or the more general class *FiniteStateMachine*)

or the generators

- *automata* and *transducers*

which contain *preconstructed and commonly used automata and transducers*. See also the *examples* below.

Contents

FiniteStateMachine and derived classes Transducer and Automaton

Accessing parts of a finite state machine

<code>state()</code>	Get a state by its label
<code>states()</code>	List of states
<code>iter_states()</code>	Iterator over the states
<code>initial_states()</code>	List of initial states
<code>iter_initial_states()</code>	Iterator over initial states
<code>final_states()</code>	List of final states
<code>iter_final_states()</code>	Iterator over final states
<code>transition()</code>	Get a transition by its states and labels
<code>transitions()</code>	List of transitions
<code>iter_transitions()</code>	Iterator over the transitions
<code>predecessors()</code>	List of predecessors of a state
<code>induced_sub_finite_state_machine()</code>	Induced sub-machine
<code>accessible_components()</code>	Accessible components
<code>coaccessible_components()</code>	Coaccessible components
<code>final_components()</code>	Final components (connected components which cannot be left again)

(Modified) Copies

<code>empty_copy()</code>	Returns an empty deep copy
<code>deepcopy()</code>	Returns a deep copy
<code>reabeled()</code>	Returns a relabeled deep copy
<code>Automaton.with_output()</code>	Extends an automaton to a transducer

Manipulation

<code>add_state()</code>	Add a state
<code>add_states()</code>	Add states
<code>delete_state()</code>	Delete a state
<code>add_transition()</code>	Add a transition
<code>add_transitions_from_function()</code>	Add transitions
<code>input_alphabet</code>	Input alphabet
<code>output_alphabet</code>	Output alphabet
<code>on_duplicate_transition</code>	Hook for handling duplicate transitions
<code>add_from_transition_function()</code>	Add transitions by a transition function
<code>delete_transition()</code>	Delete a transition
<code>remove_epsilon_transitions()</code>	Remove epsilon transitions (not implemented)
<code>split_transitions()</code>	Split transitions with input words of length > 1
<code>determine_alphabets()</code>	Determine input and output alphabets
<code>determine_input_alphabet()</code>	Determine input alphabet
<code>determine_output_alphabet()</code>	Determine output alphabet
<code>construct_final_word_out()</code>	Construct final output by implicitly reading trailing letters; cf. <code>with_final_word_out()</code>

Properties

<i>has_state()</i>	Checks for a state
<i>has_initial_state()</i>	Checks for an initial state
<i>has_initial_states()</i>	Checks for initial states
<i>has_final_state()</i>	Checks for an final state
<i>has_final_states()</i>	Checks for final states
<i>has_transition()</i>	Checks for a transition
<i>is_deterministic()</i>	Checks for a deterministic machine
<i>is_complete()</i>	Checks for a complete machine
<i>is_connected()</i>	Checks for a connected machine
<i>Automaton.is_equivalent()</i>	Checks for equivalent automata
<i>is_Markov_chain()</i>	Checks for a Markov chain
<i>is_monochromatic()</i>	Checks whether the colors of all states are equal
<i>number_of_words()</i>	Determine the number of successful paths
<i>asymptotic_moments()</i>	Main terms of expectation and variance of sums of labels
<i>moments_waiting_time()</i>	Moments of the waiting time for first true output
<i>epsilon_successors()</i>	Epsilon successors of a state
<i>Automaton.shannon_parry_markov_chain()</i>	Compute Markov chain with Parry measure

Operations

<code>disjoint_union()</code>	Disjoint union
<code>concatenation()</code>	Concatenation
<code>kleene_star()</code>	Kleene star
<code>Automaton.complement()</code>	Complement of an automaton
<code>Automaton.intersection()</code>	Intersection of automata
<code>Transducer.intersection()</code>	Intersection of transducers
<code>Transducer.cartesian_product()</code>	Cartesian product of a transducer with another finite state machine
<code>product_FiniteStateMachine()</code>	Product of finite state machines
<code>composition()</code>	Composition (output of other is input of self)
<code>input_projection()</code>	Input projection (output is deleted)
<code>output_projection()</code>	Output projection (old output is new input)
<code>projection()</code>	Input or output projection
<code>transposition()</code>	Transposition (all transitions are reversed)
<code>with_final_word_out()</code>	Machine with final output constructed by implicitly reading trailing letters, cf. <code>construct_final_word_out()</code> for inplace version
<code>Automaton.determinisation()</code>	Determinisation of an automaton
<code>completion()</code>	Completion of a finite state machine
<code>process()</code>	Process input
<code>__call__()</code>	Process input with shortened output
<code>Automaton.process()</code>	Process input of an automaton (output differs from general case)
<code>Transducer.process()</code>	Process input of a transducer (output differs from general case)
<code>iter_process()</code>	Return process iterator
<code>language()</code>	Return all possible output words
<code>Automaton.language()</code>	Return all possible accepted words

Simplification

<code>prepone_output()</code>	Prepone output where possible
<code>equivalence_classes()</code>	List of equivalent states
<code>quotient()</code>	Quotient with respect to equivalence classes
<code>merged_transitions()</code>	Merge transitions while adding input
<code>markov_chain_simplification()</code>	Simplification of a Markov chain
<code>Automaton.minimization()</code>	Minimization of an automaton
<code>Transducer.simplification()</code>	Simplification of a transducer

Conversion

<code>adjacency_matrix()</code>	(Weighted) <code>adjacency matrix()</code>
<code>graph()</code>	Underlying <code>DiGraph</code>
<code>plot()</code>	Plot

LaTeX output

<code>latex_options()</code>	Set options
<code>set_coordinates()</code>	Set coordinates of the states
<code>default_format_transition_label()</code>	Default formatting of words in transition labels
<code>format_letter_negative()</code>	Format negative numbers as overlined number
<code>format_transition_label_reversed()</code>	Format words in transition labels in reversed order

See also:

LaTeX output

FSMState

<code>final_word_out</code>	Final output of a state
<code>is_final</code>	Describes whether a state is final or not
<code>is_initial</code>	Describes whether a state is initial or not
<code>initial_probability</code>	Probability of starting in this state as part of a Markov chain
<code>label()</code>	Label of a state
<code>reabeled()</code>	Returns a relabeled deep copy of a state
<code>fully_equal()</code>	Checks whether two states are fully equal (including all attributes)

FSMTransition

<code>from_state</code>	State in which transition starts
<code>to_state</code>	State in which transition ends
<code>word_in</code>	Input word of the transition
<code>word_out</code>	Output word of the transition
<code>deepcopy()</code>	Returns a deep copy of the transition

FSMProcessIterator

<code>next()</code>	Makes one step in processing the input tape
<code>preview_word()</code>	Reads a word from the input tape
<code>result()</code>	Returns the finished branches during process

Helper Functions

<code>equal()</code>	Checks whether all elements of <code>iterator</code> are equal
<code>full_group_by()</code>	Group iterable by values of some key
<code>startswith()</code>	Determine whether list starts with the given prefix
<code>FSMLetterSymbol()</code>	Returns a string associated to the input letter
<code>FSMWordSymbol()</code>	Returns a string associated to a word
<code>is_FSMState()</code>	Tests whether an object inherits from <code>FSMState</code>
<code>is_FSMTransition()</code>	Tests whether an object inherits from <code>FSMTransition</code>
<code>is_FiniteStateMachine()</code>	Tests whether an object inherits from <code>FiniteStateMachine</code>
<code>duplicate_transition_ignore</code>	Default function for handling duplicate transitions
<code>duplicate_transition_raise</code>	Raises <code>ValueError</code> for when inserting a duplicate transition
<code>duplicate_transition_add_input</code>	Adds input when inserting a duplicate transition

Examples

We start with a general `FiniteStateMachine`. Later there will be also an `Automaton` and a `Transducer`.

A simple finite state machine

We can easily create a finite state machine by

```
sage: fsm = FiniteStateMachine()
sage: fsm
Empty finite state machine
```

By default this is the empty finite state machine, so not very interesting. Let's create and add some states and transitions:

```
sage: day = fsm.add_state('day')
sage: night = fsm.add_state('night')
sage: sunrise = fsm.add_transition(night, day)
sage: sunset = fsm.add_transition(day, night)
```

Let us look at `sunset` more closely:

```
sage: sunset
Transition from 'day' to 'night': -|-
```

Note that could also have created and added the transitions directly by:

```
sage: fsm.add_transition('day', 'night')
Transition from 'day' to 'night': -|-
```

This would have had added the states automatically, since they are present in the transitions.

Anyhow, we got the following finite state machine:

```
sage: fsm
Finite state machine with 2 states
```

We can also obtain the underlying `directed graph` by

```
sage: fsm.graph()
Looped multi-digraph on 2 vertices
```

To visualize a finite state machine, we can use `latex()` and run the result through LaTeX, see the section on *LaTeX output* below.

Alternatively, we could have created the finite state machine above simply by

```
sage: FiniteStateMachine([('night', 'day'), ('day', 'night')])
Finite state machine with 2 states
```

See *FiniteStateMachine* for a lot of possibilities to create finite state machines.

A simple Automaton (recognizing NAFs)

We want to build an automaton which recognizes non-adjacent forms (NAFs), i.e., sequences which have no adjacent non-zeros. We use 0, 1, and -1 as digits:

```
sage: NAF = Automaton(
....:     {'A': [('A', 0), ('B', 1), ('B', -1)], 'B': [('A', 0)]})
sage: NAF.state('A').is_initial = True
sage: NAF.state('A').is_final = True
sage: NAF.state('B').is_final = True
sage: NAF
Automaton with 2 states
```

Of course, we could have specified the initial and final states directly in the definition of NAF by `initial_states=['A']` and `final_states=['A', 'B']`.

So let's test the automaton with some input:

```
sage: NAF([0])
True
sage: NAF([0, 1])
True
sage: NAF([1, -1])
False
sage: NAF([0, -1, 0, 1])
True
sage: NAF([0, -1, -1, -1, 0])
False
sage: NAF([-1, 0, 0, 1, 1])
False
```

Alternatively, we could call that by

```
sage: NAF.process([0, -1, 0, 1])
(True, 'B')
```

which gives additionally the state in which we arrived.

We can also let an automaton act on a *word*:

```
sage: W = Words([-1, 0, 1]); W
Finite and infinite words over {-1, 0, 1}
sage: w = W([1, 0, 1, 0, -1]); w
word: 1,0,1,0,-1
sage: NAF(w)
True
```

Recognizing NAFs via Automata Operations

Alternatively, we can use automata operations to recognize NAFs; for simplicity, we only use the input alphabet $[0, 1]$. On the one hand, we can construct such an automaton by forbidding the word 11:

```
sage: forbidden = automata.ContainsWord([1, 1], input_alphabet=[0, 1])
sage: NAF_negative = forbidden.complement()
sage: NAF_negative([1, 1, 0, 1])
False
sage: NAF_negative([1, 0, 1, 0, 1])
True
```

On the other hand, we can write this as a regular expression and translate that into automata operations:

```
sage: zero = automata.Word([0])
sage: one = automata.Word([1])
sage: epsilon = automata.EmptyWord(input_alphabet=[0, 1])
sage: NAF_positive = (zero + one*zero).kleene_star() * (epsilon + one)
```

We check that the two approaches are equivalent:

```
sage: NAF_negative.is_equivalent(NAF_positive)
True
```

See also:

[*ContainsWord\(\)*](#), [*Word\(\)*](#), [*complement\(\)*](#), [*kleene_star\(\)*](#), [*EmptyWord\(\)*](#), [*is_equivalent\(\)*](#).

LaTeX output

We can visualize a finite state machine by converting it to LaTeX by using the usual function `latex()`. Within LaTeX, TikZ is used for typesetting the graphics, see the [Wikipedia article PGF/TikZ](#).

```
sage: print(latex(NAF)) # abs tol 1e-3
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state, accepting, initial] (v0) at (3.000000, 0.000000) {$\text{\texttt{A}}$};
\node[state, accepting] (v1) at (-3.000000, 0.000000) {$\text{\texttt{B}}$};
\path[->] (v0) edge[loop above] node {$0$} ();
\path[->] (v0.185.00) edge node[rotate=360.00, anchor=north] {$1, -1$} (v1.355.00);
\path[->] (v1.5.00) edge node[rotate=0.00, anchor=south] {$0$} (v0.175.00);
\end{tikzpicture}
```

We can turn this into a graphical representation.

```
sage: view(NAF) # not tested
```

To actually see this, use the live documentation in the Sage notebook and execute the cells in this and the previous section.

Several options can be set to customize the output, see `latex_options()` for details. In particular, we use `format_letter_negative()` to format -1 as $\bar{1}$.

```
sage: NAF.latex_options(
.....:     coordinates={'A': (0, 0),
.....:                   'B': (6, 0)},
.....:     initial_where={'A': 'below'},
.....:     format_letter=NAF.format_letter_negative,
.....:     format_state_label=lambda x:
.....:         r'\mathcal{%s}' % x.label()
.....: )
sage: print(latex(NAF))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state, accepting, initial, initial where=below] (v0) at (0.000000, 0.000000) {$\mathcal{A}$};
\node[state, accepting] (v1) at (6.000000, 0.000000) {$\mathcal{B}$};
\path[->] (v0) edge[loop above] node {$0$} ();
\path[->] (v0.5.00) edge node[rotate=0.00, anchor=south] {$1, \overline{1}$} (v1.175.00);
\path[->] (v1.185.00) edge node[rotate=360.00, anchor=north] {$0$} (v0.355.00);
\end{tikzpicture}
sage: view(NAF) # not tested
```

To use the output of `latex()` in your own \LaTeX file, you have to include

```
\usepackage{tikz}
\usetikzlibrary{automata}
```

into the preamble of your file.

A simple transducer (binary inverter)

Let's build a simple transducer, which rewrites a binary word by inverting each bit:

```
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
.....:     initial_states=['A'], final_states=['A'])
```

We can look at the states and transitions:

```
sage: inverter.states()
['A']
sage: for t in inverter.transitions():
.....:     print(t)
Transition from 'A' to 'A': 0|1
Transition from 'A' to 'A': 1|0
```

Now we apply a word to it and see what the transducer does:

```
sage: inverter([0, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 1])
[1, 0, 1, 1, 0, 0, 1, 1, 1, 0, 0, 0]
```

True means, that we landed in a final state, that state is labeled 'A', and we also got an output.

Transducers and (in)finite Words

A transducer can also act on everything iterable, in particular, on Sage's *words*.

```
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
```

Let us take the inverter from the previous section and feed some finite word into it:

```
sage: w = W([1, 1, 0, 1]); w
word: 1101
sage: inverter(w)
word: 0010
```

We see that the output is again a word (this is a consequence of calling *process()* with *automatic_output_type*).

We can even input something infinite like an infinite word:

```
sage: tm = words.ThueMorseWord(); tm
word: 0110100110010110100101100110100110010110...
sage: inverter(tm)
word: 1001011001101001011010011001011001101001...
```

A transducer which performs division by 3 in binary

Now we build a transducer, which divides a binary number by 3. The labels of the states are the remainder of the division. The transition function is

```
sage: def f(state_from, read):
.....:     if state_from + read <= 1:
.....:         state_to = 2*state_from + read
.....:         write = 0
.....:     else:
.....:         state_to = 2*state_from + read - 3
.....:         write = 1
.....:     return (state_to, write)
```

which assumes reading a binary number from left to right. We get the transducer with

```
sage: D = Transducer(f, initial_states=[0], final_states=[0],
.....:                 input_alphabet=[0, 1])
```

Let us try to divide 12 by 3:

```
sage: D([1, 1, 0, 0])
[0, 1, 0, 0]
```

Now we want to divide 13 by 3:

```
sage: D([1, 1, 0, 1])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

The raised `ValueError` means 13 is not divisible by 3.

Gray Code

The Gray code is a binary numeral system where two successive values differ in only one bit, cf. the [Wikipedia article Gray_code](#). The Gray code of an integer n is obtained by a bitwise xor between the binary expansion of n and the binary expansion of $\lfloor n/2 \rfloor$; the latter corresponds to a shift by one position in binary.

The purpose of this example is to construct a transducer converting the standard binary expansion to the Gray code by translating this construction into operations with transducers.

For this construction, the least significant digit is at the left-most position. Note that it is easier to shift everything to the right first, i.e., multiply by 2 instead of building $\lfloor n/2 \rfloor$. Then, we take the input xor with the right shift of the input and forget the first letter.

We first construct a transducer shifting the binary expansion to the right. This requires storing the previously read digit in a state.

```
sage: def shift_right_transition(state, digit):
.....:     if state == 'I':
.....:         return (digit, None)
.....:     else:
.....:         return (digit, state)
sage: shift_right_transducer = Transducer(
.....:     shift_right_transition,
.....:     initial_states=['I'],
.....:     input_alphabet=[0, 1],
.....:     final_states=[0])
sage: shift_right_transducer.transitions()
[Transition from 'I' to 0: 0|-,
Transition from 'I' to 1: 1|-,
Transition from 0 to 0: 0|0,
Transition from 0 to 1: 1|0,
Transition from 1 to 0: 0|1,
Transition from 1 to 1: 1|1]
sage: shift_right_transducer([0, 1, 1, 0])
[0, 1, 1]
sage: shift_right_transducer([1, 0, 0])
[1, 0]
```

The output of the shifts above look a bit weird (from a right-shift transducer, we would expect, for example, that $[1, 0, 0]$ was mapped to $[0, 1, 0]$), since we write `None` instead of the zero at the left. Further, note that only 0 is listed as a final state as we have to enforce that a most significant zero is read as the last input letter in order to flush the last digit:

```
sage: shift_right_transducer([0, 1, 0, 1])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

Next, we construct the transducer performing the xor operation. We also have to take None into account as our `shift_right_transducer` waits one iteration until it starts writing output. This corresponds with our intention to forget the first letter.

```
sage: def xor_transition(state, digits):
.....:     if digits[0] is None or digits[1] is None:
.....:         return (0, None)
.....:     else:
.....:         return (0, digits[0].__xor__(digits[1]))
sage: from itertools import product
sage: xor_transducer = Transducer(
.....:     xor_transition,
.....:     initial_states=[0],
.....:     final_states=[0],
.....:     input_alphabet=list(product([None, 0, 1], [0, 1])))
sage: xor_transducer.transitions()
[Transition from 0 to 0: (None, 0)|-,
 Transition from 0 to 0: (None, 1)|-,
 Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|0]
sage: xor_transducer([(None, 0), (None, 1), (0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 0]
sage: xor_transducer([(0, None)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

The transducer computing the Gray code is then constructed as a *Cartesian product* between the shifted version and the original input (represented here by the `shift_right_transducer` and the *identity transducer*, respectively). This Cartesian product is then fed into the `xor_transducer` as a *composition* of transducers.

```
sage: product_transducer = shift_right_transducer.cartesian_product(transducers.
↳ Identity([0, 1]))
sage: Gray_transducer = xor_transducer(product_transducer)
```

We use `construct_final_word_out()` to make sure that all output is written; otherwise, we would have to make sure that a sufficient number of trailing zeros is read.

```
sage: Gray_transducer.construct_final_word_out([0])
sage: Gray_transducer.transitions()
[Transition from (('I', 0), 0) to ((0, 0), 0): 0|-,
 Transition from (('I', 0), 0) to ((1, 0), 0): 1|-,
 Transition from ((0, 0), 0) to ((0, 0), 0): 0|0,
 Transition from ((0, 0), 0) to ((1, 0), 0): 1|1,
 Transition from ((1, 0), 0) to ((0, 0), 0): 0|1,
 Transition from ((1, 0), 0) to ((1, 0), 0): 1|0]
```

There is a *prepackaged transducer* for Gray code, let's see whether they agree. We have to use `relabelled()` to relabel our states with integers.

```
sage: constructed = Gray_transducer.relabelled()
sage: packaged = transducers.GrayCode()
```

(continues on next page)

(continued from previous page)

```
sage: constructed == packaged
True
```

Finally, we check that this indeed computes the Gray code of the first 10 non-negative integers.

```
sage: for n in xrange(10):
.....:     Gray_transducer(n.bits())
[]
[1]
[1, 1]
[0, 1]
[0, 1, 1]
[1, 1, 1]
[1, 0, 1]
[0, 0, 1]
[0, 0, 1, 1]
[1, 0, 1, 1]
```

Using the hook-functions

Let's use the *previous example* "division by 3" to demonstrate the optional state and transition parameters hook.

First, we define what those functions should do. In our case, this is just saying in which state we are and which transition we take

```
sage: def state_hook(process, state, output):
.....:     print("We are now in State %s." % (state.label(),))
sage: from sage.combinat.finite_state_machine import FSMWordSymbol
sage: def transition_hook(transition, process):
.....:     print("Currently we go from %s to %s, "
.....:           "reading %s and writing %s." % (
.....:               transition.from_state, transition.to_state,
.....:               FSMWordSymbol(transition.word_in),
.....:               FSMWordSymbol(transition.word_out)))
```

Now, let's add these hook-functions to the existing transducer:

```
sage: for s in D.iter_states():
.....:     s.hook = state_hook
sage: for t in D.iter_transitions():
.....:     t.hook = transition_hook
```

Rerunning the process again now gives the following output:

```
sage: D.process([1, 1, 0, 1], check_epsilon_transitions=False)
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
Currently we go from 1 to 0, reading 1 and writing 1.
We are now in State 0.
Currently we go from 0 to 0, reading 0 and writing 0.
We are now in State 0.
```

(continues on next page)

(continued from previous page)

```
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
(False, 1, [0, 1, 0, 0])
```

The example above just explains the basic idea of using hook-functions. In the following, we will use those hooks more seriously.

Warning: The hooks of the states are also called while exploring the epsilon successors of a state (during processing). In the example above, we used `check_epsilon_transitions=False` to avoid this (and also therefore got a cleaner output).

Warning: The arguments used when calling a hook have changed in [trac ticket #16538](#) from `hook(state, process)` to `hook(process, state, output)`.

Detecting sequences with same number of 0 and 1

Suppose we have a binary input and want to accept all sequences with the same number of 0 and 1. This cannot be done with a finite automaton. Anyhow, we can make usage of the hook functions to extend our finite automaton by a counter:

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: C = FiniteStateMachine()
sage: def update_counter(process, state, output):
.....:     try:
.....:         l = process.preview_word()
.....:     except RuntimeError:
.....:         raise StopIteration
.....:     process.fsm.counter += 1 if l == 1 else -1
.....:     if process.fsm.counter > 0:
.....:         next_state = 'positive'
.....:     elif process.fsm.counter < 0:
.....:         next_state = 'negative'
.....:     else:
.....:         next_state = 'zero'
.....:     return FSMTransition(state, process.fsm.state(next_state),
.....:                          1, process.fsm.counter)
sage: C.add_state(FSMState('zero', hook=update_counter,
.....:                       is_initial=True, is_final=True))
'zero'
sage: C.add_state(FSMState('positive', hook=update_counter))
'positive'
sage: C.add_state(FSMState('negative', hook=update_counter))
'negative'
```

Now, let's input some sequence:

```
sage: C.counter = 0; C([1, 1, 1, 1, 0, 0])
(False, 'positive', [1, 2, 3, 4, 3, 2])
```

The result is False, since there are four 1 but only two 0. We land in the state `positive` and we can also see the values of the counter in each step.

Let's try some other examples:

```
sage: C.counter = 0; C([1, 1, 0, 0])
(True, 'zero', [1, 2, 1, 0])
sage: C.counter = 0; C([0, 1, 0, 0])
(False, 'negative', [-1, 0, -1, -2])
```

See also methods `Automaton.process()` and `Transducer.process()` (or even `FiniteStateMachine.process()`), the explanation of the parameter `hook` and the examples in `FSMState` and `FSMTransition`, and the description and examples in `FSMProcessIterator` for more information on processing and hooks.

Methods

class `sage.combinat.finite_state_machine.Automaton(*args, **kwargs)`

Bases: `sage.combinat.finite_state_machine.FiniteStateMachine`

This creates an automaton, which is a finite state machine, whose transitions have input labels.

An automaton has additional features like creating a deterministic and a minimized automaton.

See class `FiniteStateMachine` for more information.

EXAMPLES:

We can create an automaton recognizing even numbers (given in binary and read from left to right) in the following way:

```
sage: A = Automaton([('P', 'Q', 0), ('P', 'P', 1),
.....:              ('Q', 'P', 1), ('Q', 'Q', 0)],
.....:              initial_states=['P'], final_states=['Q'])
sage: A
Automaton with 2 states
sage: A([0])
True
sage: A([1, 1, 0])
True
sage: A([1, 0, 1])
False
```

Note that the full output of the commands can be obtained by calling `process()` and looks like this:

```
sage: A.process([1, 0, 1])
(False, 'P')
```

cartesian_product(*other*, *only_accessible_components=True*)

Return a new automaton which accepts an input if it is accepted by both given automata.

INPUT:

- *other* – an automaton
- *only_accessible_components* – If True (default), then the result is piped through `accessible_components()`. If no *new_input_alphabet* is given, it is determined by `determine_alphabets()`.

OUTPUT:

A new automaton which computes the intersection (see below) of the languages of *self* and *other*.

The set of states of the new automaton is the Cartesian product of the set of states of both given automata. There is a transition $((A, B), (C, D), a)$ in the new automaton if there are transitions (A, C, a) and (B, D, a) in the old automata.

The methods `intersection()` and `cartesian_product()` are the same (for automata).

EXAMPLES:

```

sage: aut1 = Automaton([('1', '2', 1),
.....:                  ('2', '2', 1),
.....:                  ('2', '2', 0)],
.....:                  initial_states=['1'],
.....:                  final_states=['2'],
.....:                  determine_alphabets=True)
sage: aut2 = Automaton([('A', 'A', 1),
.....:                  ('A', 'B', 0),
.....:                  ('B', 'B', 0),
.....:                  ('B', 'A', 1)],
.....:                  initial_states=['A'],
.....:                  final_states=['B'],
.....:                  determine_alphabets=True)
sage: res = aut1.intersection(aut2)
sage: (aut1([1, 1]), aut2([1, 1]), res([1, 1]))
(True, False, False)
sage: (aut1([1, 0]), aut2([1, 0]), res([1, 0]))
(True, True, True)
sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
Transition from ('2', 'A') to ('2', 'B'): 0|-,
Transition from ('2', 'A') to ('2', 'A'): 1|-,
Transition from ('2', 'B') to ('2', 'B'): 0|-,
Transition from ('2', 'B') to ('2', 'A'): 1|-]

```

For automata with epsilon-transitions, intersection is not well defined. But for any finite state machine, epsilon-transitions can be removed by `remove_epsilon_transitions()`.

```

sage: a1 = Automaton([(0, 0, 0),
.....:                (0, 1, None),
.....:                (1, 1, 1),
.....:                (1, 2, 1)],
.....:                initial_states=[0],
.....:                final_states=[1],
.....:                determine_alphabets=True)
sage: a2 = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 1)],
.....:                initial_states=[0],
.....:                final_states=[1],
.....:                determine_alphabets=True)
sage: a1.intersection(a2)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input)
was found.
sage: a1.remove_epsilon_transitions() # not tested (since not implemented yet)
sage: a1.intersection(a2) # not tested

```

`complement()`

Return the complement of this automaton.

OUTPUT:

An *Automaton*.

If this automaton recognizes language \mathcal{L} over an input alphabet \mathcal{A} , then the complement recognizes $\mathcal{A} \setminus \mathcal{L}$.

EXAMPLES:

```
sage: A = automata.Word([0, 1])
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1])
.....: if A(w)]
[[0, 1]]
sage: Ac = A.complement()
sage: Ac.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 0 to 3: 1|-,
 Transition from 2 to 3: 0|-,
 Transition from 2 to 3: 1|-,
 Transition from 1 to 2: 1|-,
 Transition from 1 to 3: 0|-,
 Transition from 3 to 3: 0|-,
 Transition from 3 to 3: 1|-]
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1])
.....: if Ac(w)]
[[], [0], [1], [0, 0], [1, 0], [1, 1]]
```

The automaton must be deterministic:

```
sage: A = automata.Word([0]) * automata.Word([1])
sage: A.complement()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
sage: Ac = A.determinisation().complement()
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1])
.....: if Ac(w)]
[[], [0], [1], [0, 0], [1, 0], [1, 1]]
```

determinisation()

Return a deterministic automaton which accepts the same input words as the original one.

OUTPUT:

A new automaton, which is deterministic.

The labels of the states of the new automaton are frozensets of states of `self`. The color of a new state is the frozenset of colors of the constituent states of `self`. Therefore, the colors of the constituent states have to be hashable. However, if all constituent states have color `None`, then the resulting color is `None`, too.

The input alphabet must be specified.

EXAMPLES:

```
sage: aut = Automaton([('A', 'A', 0), ('A', 'B', 1), ('B', 'B', 1)],
.....:                 initial_states=['A'], final_states=['B'])
sage: aut.determinisation().transitions()
[Transition from frozenset({'A'}) to frozenset({'A'}): 0|-,
 Transition from frozenset({'A'}) to frozenset({'B'}): 1|-,
 Transition from frozenset({'B'}) to frozenset(): 0|-,
 Transition from frozenset({'B'}) to frozenset({'B'}): 1|-,
 Transition from frozenset() to frozenset(): 0|-,
 Transition from frozenset() to frozenset(): 1|-]
```

```

sage: A = Automaton([('A', 'A', 1), ('A', 'A', 0), ('A', 'B', 1),
.....:              ('B', 'C', 0), ('C', 'C', 1), ('C', 'C', 0)],
.....:              initial_states=['A'], final_states=['C'])
sage: A.determinisation().states()
[frozenset({'A'}),
 frozenset({'A', 'B'}),
 frozenset({'A', 'C'}),
 frozenset({'A', 'B', 'C'})]

```

```

sage: A = Automaton([(0, 1, 1), (0, 2, [1, 1]), (0, 3, [1, 1, 1]),
.....:              (1, 0, -1), (2, 0, -2), (3, 0, -3)],
.....:              initial_states=[0], final_states=[0, 1, 2, 3])
sage: B = A.determinisation().reabeled().coaccessible_components()
sage: sorted(B.transitions())
[Transition from 0 to 1: 1|-,
 Transition from 1 to 0: -1|-,
 Transition from 1 to 3: 1|-,
 Transition from 3 to 0: -2|-,
 Transition from 3 to 4: 1|-,
 Transition from 4 to 0: -3|-]

```

Note that colors of states have to be hashable:

```

sage: A = Automaton([(0, 0, 0)], initial_states=[0])
sage: A.state(0).color = []
sage: A.determinisation()
Traceback (most recent call last):
...
TypeError: unhashable type: 'list'
sage: A.state(0).color = ()
sage: A.determinisation()
Automaton with 1 state

```

If the colors of all constituent states are None, the resulting color is None, too ([trac ticket #19199](#)):

```

sage: A = Automaton([(0, 0, 0)],
.....:              initial_states=[0],
.....:              final_states=[0])
sage: [s.color for s in A.determinisation().iter_states()]
[None]

```

intersection(*other*, *only_accessible_components=True*)

Return a new automaton which accepts an input if it is accepted by both given automata.

INPUT:

- *other* – an automaton
- *only_accessible_components* – If True (default), then the result is piped through `accessible_components()`. If no *new_input_alphabet* is given, it is determined by `determine_alphabets()`.

OUTPUT:

A new automaton which computes the intersection (see below) of the languages of *self* and *other*.

The set of states of the new automaton is the Cartesian product of the set of states of both given automata. There is a transition $((A, B), (C, D), a)$ in the new automaton if there are transitions (A, C, a) and (B, D, a) in the old automata.

The methods `intersection()` and `cartesian_product()` are the same (for automata).

EXAMPLES:

```
sage: aut1 = Automaton([('1', '2', 1),
.....:                  ('2', '2', 1),
.....:                  ('2', '2', 0)],
.....:                  initial_states=['1'],
.....:                  final_states=['2'],
.....:                  determine_alphabets=True)
sage: aut2 = Automaton([('A', 'A', 1),
.....:                  ('A', 'B', 0),
.....:                  ('B', 'B', 0),
.....:                  ('B', 'A', 1)],
.....:                  initial_states=['A'],
.....:                  final_states=['B'],
.....:                  determine_alphabets=True)
sage: res = aut1.intersection(aut2)
sage: (aut1([1, 1]), aut2([1, 1]), res([1, 1]))
(True, False, False)
sage: (aut1([1, 0]), aut2([1, 0]), res([1, 0]))
(True, True, True)
sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
Transition from ('2', 'A') to ('2', 'B'): 0|-,
Transition from ('2', 'A') to ('2', 'A'): 1|-,
Transition from ('2', 'B') to ('2', 'B'): 0|-,
Transition from ('2', 'B') to ('2', 'A'): 1|-]
```

For automata with epsilon-transitions, intersection is not well defined. But for any finite state machine, epsilon-transitions can be removed by `remove_epsilon_transitions()`.

```
sage: a1 = Automaton([(0, 0, 0),
.....:                  (0, 1, None),
.....:                  (1, 1, 1),
.....:                  (1, 2, 1)],
.....:                  initial_states=[0],
.....:                  final_states=[1],
.....:                  determine_alphabets=True)
sage: a2 = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 1)],
.....:                  initial_states=[0],
.....:                  final_states=[1],
.....:                  determine_alphabets=True)
sage: a1.intersection(a2)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input)
was found.
sage: a1.remove_epsilon_transitions() # not tested (since not implemented yet)
sage: a1.intersection(a2) # not tested
```

is_equivalent(*other*)

Test whether two automata are equivalent, i.e., accept the same language.

INPUT:

- *other* – an *Automaton*.

EXAMPLES:

```
sage: A = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 1)],
.....:               initial_states=[0],
.....:               final_states=[0])
sage: B = Automaton([('a', 'a', 0), ('a', 'b', 1), ('b', 'a', 1)],
.....:               initial_states=['a'],
.....:               final_states=['a'])
sage: A.is_equivalent(B)
True
sage: B.add_transition('b', 'a', 0)
Transition from 'b' to 'a': 0|-
sage: A.is_equivalent(B)
False
```

language(*max_length=None, **kwargs*)

Return all words accepted by this automaton.

INPUT:

- *max_length* – an integer or None (default). Only inputs of length at most *max_length* will be considered. If None, then this iterates over all possible words without length restrictions.
- *kwargs* – will be passed on to the *process iterator*. See *process()* for a description.

OUTPUT:

An iterator.

EXAMPLES:

```
sage: NAF = Automaton(
.....:   {'A': [('A', 0), ('B', 1), ('B', -1)],
.....:    'B': [('A', 0)]},
.....:   initial_states=['A'], final_states=['A', 'B'])
sage: list(NAF.language(3))
[[],
 [0], [-1], [1],
 [-1, 0], [0, 0], [1, 0], [0, -1], [0, 1],
 [-1, 0, 0], [0, -1, 0], [0, 0, 0], [0, 1, 0], [1, 0, 0],
 [-1, 0, -1], [-1, 0, 1], [0, 0, -1],
 [0, 0, 1], [1, 0, -1], [1, 0, 1]]
```

See also:

FiniteStateMachine.language(), *process()*.

minimization(*algorithm=None*)

Return the minimization of the input automaton as a new automaton.

INPUT:

- `algorithm` – Either Moore’s algorithm (by `algorithm='Moore'` or as default for deterministic automata) or Brzozowski’s algorithm (when `algorithm='Brzozowski'` or when the automaton is not deterministic) is used.

OUTPUT:

A new automaton.

The resulting automaton is deterministic and has a minimal number of states.

EXAMPLES:

```
sage: A = Automaton([('A', 'A', 1), ('A', 'A', 0), ('A', 'B', 1),
.....:              ('B', 'C', 0), ('C', 'C', 1), ('C', 'C', 0)],
.....:              initial_states=['A'], final_states=['C'])
sage: B = A.minimization(algorithm='Brzozowski')
sage: B_trans = B.transitions(B.states()[1])
sage: B_trans # random
[Transition from frozenset({frozenset({'B', 'C'})},
.....:                  frozenset({'A', 'C'})},
.....:                  frozenset({'A', 'B', 'C'}))
.....: to frozenset({frozenset({'C'})},
.....:                  frozenset({'B', 'C'})},
.....:                  frozenset({'A', 'C'})},
.....:                  frozenset({'A', 'B', 'C'}))):
.....: 0|- ,
.....: Transition from frozenset({frozenset({'B', 'C'})},
.....:                  frozenset({'A', 'C'})},
.....:                  frozenset({'A', 'B', 'C'}))
.....: to frozenset({frozenset({'B', 'C'})},
.....:                  frozenset({'A', 'C'})},
.....:                  frozenset({'A', 'B', 'C'}))):
.....: 1|-]
sage: len(B.states())
3
sage: C = A.minimization(algorithm='Brzozowski')
sage: C_trans = C.transitions(C.states()[1])
sage: B_trans == C_trans
True
sage: len(C.states())
3
```

```
sage: aut = Automaton([('1', '2', 'a'), ('2', '3', 'b'),
.....:                  ('3', '2', 'a'), ('2', '1', 'b'),
.....:                  ('3', '4', 'a'), ('4', '3', 'b')],
.....:                  initial_states=['1'], final_states=['1'])
sage: min = aut.minimization(algorithm='Brzozowski')
sage: [len(min.states()), len(aut.states())]
[3, 4]
sage: min = aut.minimization(algorithm='Moore')
Traceback (most recent call last):
...
NotImplementedError: Minimization via Moore's Algorithm is only
implemented for deterministic finite state machines
```

process(*args, **kwargs)

Return whether the automaton accepts the input and the state where the computation stops.

INPUT:

- `input_tape` – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- `initial_state` or `initial_states` – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- `list_of_outputs` – (default: `None`) a boolean or `None`. If `True`, then the outputs are given in list form (even if we have no or only one single output). If `False`, then the result is never a list (an exception is raised if the result cannot be returned). If `list_of_outputs=None` the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).
- `only_accepted` – (default: `False`) a boolean. If set, then the first argument in the output is guaranteed to be `True` (if the output is a list, then the first argument of each element will be `True`).
- `full_output` – (default: `True`) a boolean. If set, then the full output is given, otherwise only whether the sequence is accepted or not (the first entry below only).
- `always_include_output` – if set (not by default), always return a triple containing the (non-existing) output. This is in order to obtain output compatible with that of `FiniteStateMachine.process()`. If this parameter is set, `full_output` has no effect.
- `format_output` – a function that translates the written output (which is in form of a list) to something more readable. By default (`None`) identity is used here.
- `check_epsilon_transitions` – (default: `True`) a boolean. If `False`, then epsilon transitions are not taken into consideration during process.
- `write_final_word_out` – (default: `True`) a boolean specifying whether the final output words should be written or not.
- `use_multitape_input` – (default: `False`) a boolean. If `True`, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- `process_all_prefixes_of_input` – (default: `False`) a boolean. If `True`, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.
- `process_iterator_class` – (default: `None`) a class inherited from `FSMProcessIterator`. If `None`, then `FSMProcessIterator` is taken. An instance of this class is created and is used during the processing.

OUTPUT:

The full output is a pair (or a list of pairs, cf. parameter `list_of_outputs`), where

- the first entry is `True` if the input string is accepted and
- the second gives the state reached after processing the input tape (This is a state with label `None` if the input could not be processed, i.e., if at one point no transition to go on could be found.).

If `full_output` is `False`, then only the first entry is returned.

If `always_include_output` is set, an additional third entry `[]` is included.

Note that in the case the automaton is not deterministic, all possible paths are taken into account. You can use `determinisation()` to get a deterministic automaton machine.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see `__call__()` for a version of `process()` with shortened output.

Internally this function creates and works with an instance of `FSMProcessIterator`. This iterator can also be obtained with `iter_process()`.

If working with multi-tape finite state machines, all input words of transitions are words of k -tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

Warning: Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

In the following examples, we construct an automaton which accepts non-adjacent forms (see also the example on *non-adjacent forms* in the documentation of the module *Finite state machines, automata, transducers*) and then test it by feeding it with several binary digit expansions.

```
sage: NAF = Automaton(
.....:     {'_': [(('_', 0), ('1', 1)), ('1', 1)], '_': [(('_', 0))]},
.....:     initial_states=['_'], final_states=['_', '1'])
sage: [NAF.process(w) for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
.....:                          [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[(True, '_'), (True, '1'), (False, None),
 (True, '1'), (False, None), (False, None)]
```

If we just want a condensed output, we use:

```
sage: [NAF.process(w, full_output=False)
.....:     for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
.....:              [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[True, True, False, True, False, False]
```

It is equivalent to:

```
sage: [NAF(w) for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
.....:                  [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[True, True, False, True, False, False]
```

The following example illustrates the difference between non-existing paths and reaching a non-final state:

```

sage: NAF.process([2])
(False, None)
sage: NAF.add_transition(('_', 's', 2))
Transition from '_' to 's': 2|-
sage: NAF.process([2])
(False, 's')

```

A simple example of a (non-deterministic) multi-tape automaton is the following: It checks whether the two input tapes have the same number of ones:

```

sage: M = Automaton([('=', '=', (1, 1)),
.....:                ('=', '=', (None, 0)),
.....:                ('=', '=', (0, None)),
.....:                ('=', '<', (None, 1)),
.....:                ('<', '<', (None, 1)),
.....:                ('<', '<', (None, 0)),
.....:                ('=', '>', (1, None)),
.....:                ('>', '>', (1, None)),
.....:                ('>', '>', (0, None))],
.....:                initial_states=['='],
.....:                final_states=['='])
sage: M.process([[1, 0, 1], [1, 0]], use_multitape_input=True)
(False, '>')
sage: M.process([[0, 1, 0], [0, 1, 1]], use_multitape_input=True)
(False, '<')
sage: M.process([[1, 1, 0, 1], [0, 0, 1, 0, 1, 1]],
.....:                use_multitape_input=True)
(True, '=')

```

Alternatively, we can use the following (non-deterministic) multi-tape automaton for the same check:

```

sage: N = Automaton([('=', '=', (0, 0)),
.....:                ('=', '<', (None, 1)),
.....:                ('<', '<', (0, None)),
.....:                ('<', '=', (1, None)),
.....:                ('=', '>', (1, None)),
.....:                ('>', '>', (None, 0)),
.....:                ('>', '=', (None, 1))],
.....:                initial_states=['='],
.....:                final_states=['='])
sage: N.process([[1, 0, 1], [1, 0]], use_multitape_input=True)
(False, '>')
sage: N.process([[0, 1, 0], [0, 1, 1]], use_multitape_input=True)
(False, '<')
sage: N.process([[1, 1, 0, 1], [0, 0, 1, 0, 1, 1]],
.....:                use_multitape_input=True)
(True, '=')

```

FiniteStateMachine.process(), *Transducer.process()*, *iter_process()*, *__call__()*, *FSMPProcessIterator*.

shannon_parry_markov_chain()

Compute a time homogeneous Markov chain such that all words of a given length recognized by the original

automaton occur as the output with the same weight; the transition probabilities correspond to the Parry measure.

OUTPUT:

A Markov chain. Its input labels are the transition probabilities, the output labels the labels of the original automaton. In order to obtain equal weight for all words of the same length, an “exit weight” is needed. It is stored in the attribute `color` of the states of the Markov chain. The weights of the words of the same length sum up to one up to an exponentially small error.

The stationary distribution of this Markov chain is saved as the initial probabilities of the states.

The transition probabilities correspond to the Parry measure (see [S1948] and [P1964]).

The automaton is assumed to be deterministic, irreducible and aperiodic. All states must be final.

EXAMPLES:

```
sage: NAF = Automaton([(0, 0, 0), (0, 1, 1), (0, 1, -1),
....:                 (1, 0, 0)], initial_states=[0],
....:                 final_states=[0, 1])
sage: P_NAF = NAF.shannon_parry_markov_chain()
sage: P_NAF.transitions()
[Transition from 0 to 0: 1/2|0,
  Transition from 0 to 1: 1/4|1,
  Transition from 0 to 1: 1/4|-1,
  Transition from 1 to 0: 1|0]
sage: for s in P_NAF.iter_states():
....:     print(s.color)
3/4
3/2
```

The stationary distribution is also computed and saved as the initial probabilities of the returned Markov chain:

```
sage: for s in P_NAF.states():
....:     print("{} {}".format(s, s.initial_probability))
0 2/3
1 1/3
```

The automaton is assumed to be deterministic, irreducible and aperiodic:

```
sage: A = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 1), (1, 1, 0)],
....:                 initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
...
NotImplementedError: Automaton must be strongly connected.
sage: A = Automaton([(0, 0, 0), (0, 1, 0)],
....:                 initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
...
NotImplementedError: Automaton must be deterministic.
sage: A = Automaton([(0, 1, 0), (1, 0, 0)],
....:                 initial_states=[0])
sage: A.shannon_parry_markov_chain()
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
NotImplementedError: Automaton must be aperiodic.
```

All states must be final:

```
sage: A = Automaton([(0, 1, 0), (0, 0, 1), (1, 0, 0)],
....:               initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
...
NotImplementedError: All states must be final.
```

ALGORITHM:

See [HKP2015a], Lemma 4.1.

REFERENCES:

with_output(*word_out_function=None*)

Construct a transducer out of this automaton.

INPUT:

- *word_out_function* – (default: None) a function. It transforms a *transition* to the output word for this transition.

If this is None, then the output word will be equal to the input word of each transition.

OUTPUT:

A transducer.

EXAMPLES:

```
sage: A = Automaton([(0, 0, 'A'), (0, 1, 'B'), (1, 2, 'C')])
sage: T = A.with_output(); T
Transducer with 3 states
sage: T.transitions()
[Transition from 0 to 0: 'A'|'A',
 Transition from 0 to 1: 'B'|'B',
 Transition from 1 to 2: 'C'|'C']
```

This result is in contrast to:

```
sage: Transducer(A).transitions()
[Transition from 0 to 0: 'A'|-,
 Transition from 0 to 1: 'B'|-,
 Transition from 1 to 2: 'C'|-]
```

where no output labels are created.

Here is another example:

```
sage: T2 = A.with_output(lambda t: [c.lower() for c in t.word_in])
sage: T2.transitions()
[Transition from 0 to 0: 'A'|'a',
```

(continues on next page)

(continued from previous page)

```
Transition from 0 to 1: 'B'|'b',
Transition from 1 to 2: 'C'|'c']
```

We can obtain the same result by composing two transducers. As inner transducer of the composition, we use `with_output()` without the optional argument `word_out_function` (which makes the output of each transition equal to its input); as outer transducer we use a `map-transducer` (for converting to lower case). This gives

```
sage: L = transducers.map(lambda x: x.lower(), ['A', 'B', 'C'])
sage: L.composition(A.with_output()).reabeled().transitions()
[Transition from 0 to 0: 'A'|'a',
Transition from 0 to 1: 'B'|'b',
Transition from 1 to 2: 'C'|'c']
```

See also:

`input_projection()`, `output_projection()`, `Transducer`, `transducers.map()`.

`sage.combinat.finite_state_machine.FSMLetterSymbol(letter)`

Return a string associated to the input letter.

INPUT:

- `letter` – the input letter or `None` (representing the empty word).

OUTPUT:

If `letter` is `None` the symbol for the empty word `FSMEmptyWordSymbol` is returned, otherwise the string associated to the letter.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMLetterSymbol
sage: FSMLetterSymbol(0)
'0'
sage: FSMLetterSymbol(None)
'_'
```

```
class sage.combinat.finite_state_machine.FSMProcessIterator(fsm, input_tape=None,
                                                             initial_state=None, initial_states=[],
                                                             use_multitape_input=False,
                                                             check_epsilon_transitions=True,
                                                             write_final_word_out=True,
                                                             format_output=None,
                                                             process_all_prefixes_of_input=False,
                                                             **kwargs)
```

Bases: `sage.structure.sage_object.SageObject`, `collections.abc.Iterator`

This class takes an input, feeds it into a finite state machine (automaton or transducer, in particular), tests whether this was successful and calculates the written output.

INPUT:

- `fsm` – the finite state machine on which the input should be processed.
- `input_tape` – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.

- `initial_state` or `initial_states` – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- `format_output` – a function that translates the written output (which is in form of a list) to something more readable. By default (`None`) identity is used here.
- `check_epsilon_transitions` – (default: `True`) a boolean. If `False`, then epsilon transitions are not taken into consideration during process.
- `write_final_word_out` – (default: `True`) a boolean specifying whether the final output words should be written or not.
- `use_multitape_input` – (default: `False`) a boolean. If `True`, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- `process_all_prefixes_of_input` – (default: `False`) a boolean. If `True`, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

OUTPUT:

An iterator.

In its simplest form, it behaves like an iterator which, in each step, goes from one state to another. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the process iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read. When the process stops, a `StopIteration` exception is thrown.

Warning: Processing an input tape of length n usually takes at least $n + 1$ iterations, since there will be $n + 1$ states visited (in the case the taken transitions have input words consisting of single letters).

An instance of this class is generated when `FiniteStateMachine.process()` or `FiniteStateMachine.iter_process()` of a finite state machine, an automaton, or a transducer is invoked.

When working with multi-tape finite state machines, all input words of transitions are words of k -tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

Warning: Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

The following transducer reads binary words and outputs a word, where blocks of ones are replaced by just a single one. Further only words that end with a zero are accepted.

```
sage: T = Transducer({'A': [('A', 0, 0), ('B', 1, None)],
.....:                  'B': [('B', 1, None), ('A', 0, [1, 0])]}),
.....:                  initial_states=['A'], final_states=['A'])
```

(continues on next page)

(continued from previous page)

```
sage: input = [1, 1, 0, 0, 1, 0, 1, 1, 1, 0]
sage: T.process(input)
(True, 'A', [1, 0, 0, 1, 0, 1, 0])
```

The function `FiniteStateMachine.process()` (internally) uses a `FSMProcessIterator`. We can do that manually, too, and get full access to the iteration process:

```
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: it = FSMProcessIterator(T, input_tape=input)
sage: for current in it:
.....:     print(current)
process (1 branch)
+ at state 'B'
+-- tape at 1, [[]]
process (1 branch)
+ at state 'B'
+-- tape at 2, [[]]
process (1 branch)
+ at state 'A'
+-- tape at 3, [[1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 4, [[1, 0, 0]]
process (1 branch)
+ at state 'B'
+-- tape at 5, [[1, 0, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 6, [[1, 0, 0, 1, 0]]
process (1 branch)
+ at state 'B'
+-- tape at 7, [[1, 0, 0, 1, 0]]
process (1 branch)
+ at state 'B'
+-- tape at 8, [[1, 0, 0, 1, 0]]
process (1 branch)
+ at state 'B'
+-- tape at 9, [[1, 0, 0, 1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 10, [[1, 0, 0, 1, 0, 1, 0]]
process (0 branches)
sage: it.result()
[Branch(accept=True, state='A', output=[1, 0, 0, 1, 0, 1, 0])]
```

```
sage: T = Transducer([(0, 0, 0, 'a'), (0, 1, 0, 'b'),
.....:                (1, 2, 1, 'c'), (2, 0, 0, 'd'),
.....:                (2, 1, None, 'd')],
.....:                initial_states=[0], final_states=[2])
sage: sorted(T.process([0, 0, 1], format_output=lambda o: ''.join(o)))
[(False, 1, 'abcd'), (True, 2, 'abc')]
sage: it = FSMProcessIterator(T, input_tape=[0, 0, 1],
```

(continues on next page)

(continued from previous page)

```

.....:                               format_output=lambda o: ''.join(o)
sage: for current in it:
.....:     print(current)
process (2 branches)
+ at state 0
+-- tape at 1, [['a']]
+ at state 1
+-- tape at 1, [['b']]
process (2 branches)
+ at state 0
+-- tape at 2, [['a', 'a']]
+ at state 1
+-- tape at 2, [['a', 'b']]
process (2 branches)
+ at state 1
+-- tape at 3, [['a', 'b', 'c', 'd']]
+ at state 2
+-- tape at 3, [['a', 'b', 'c']]
process (0 branches)
sage: sorted(it.result())
[Branch(accept=False, state=1, output='abcd'),
 Branch(accept=True, state=2, output='abc')]

```

class Current

Bases: dict

This class stores the branches which have to be processed during iteration and provides a nicer formatting of them.

This class is derived from dict. It is returned by the next-function during iteration.

EXAMPLES:

In the following example you can see the dict directly and then the nicer output provided by this class:

```

sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: inverter = Transducer({'A': [( 'A', 0, 1), ( 'A', 1, 0)]},
.....:     initial_states=['A'], final_states=['A'])
sage: it = FSMProcessIterator(inverter, input_tape=[0, 1])
sage: for current in it:
.....:     print(dict(current))
.....:     print(current)
{((1, 0),): {'A': Branch(tape_cache=tape at 1, outputs=[[1]])}}
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
{((2, 0),): {'A': Branch(tape_cache=tape at 2, outputs=[[1, 0]])}}
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]

```

(continues on next page)

(continued from previous page)

```
{ }
process (0 branches)
```

FinishedBranch = <class 'sage.combinat.finite_state_machine.Branch'>

A named tuple representing the attributes of a branch, once it is fully processed.

next()

Makes one step in processing the input tape.

INPUT:

Nothing.

OUTPUT:

It returns the current status of the iterator (see below). A `StopIteration` exception is thrown when there is/was nothing to do (i.e. all branches ended with previous call of `next()`).

The current status is a dictionary (encapsulated into an instance of `Current`). The keys are positions on the tape. The value corresponding to such a position is again a dictionary, where each entry represents a branch of the process. This dictionary maps the current state of a branch to a pair consisting of a tape cache and a list of output words, which were written during reaching this current state.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:   initial_states=['A'], final_states=['A'])
sage: it = FSMProcessIterator(inverter, input_tape=[0, 1])
sage: next(it)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
sage: next(it)
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
sage: next(it)
process (0 branches)
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

See also:

`FiniteStateMachine.process()`, `Automaton.process()`, `Transducer.process()`,
`FiniteStateMachine.iter_process()`, `FiniteStateMachine.__call__()`,
`FSMProcessIterator`.

preview_word(*track_number=None, length=1, return_word=False*)

Read a word from the input tape.

INPUT:

- `track_number` – an integer or `None`. If `None`, then a tuple of words (one from each track) is returned.
- `length` – (default: 1) the length of the word(s).

- `return_word` – (default: `False`) a boolean. If set, then a word is returned, otherwise a single letter (in which case `length` has to be 1).

OUTPUT:

A single letter or a word.

An exception `StopIteration` is thrown if the tape (at least one track) has reached its end.

Typically, this method is called from a hook-function of a state.

EXAMPLES:

```
sage: inverter = Transducer({'A': [('A', 0, 'one'),
.....:                          ('A', 1, 'zero')]},
.....:   initial_states=['A'], final_states=['A'])
sage: def state_hook(process, state, output):
.....:     print("We are now in state %s." % (state.label(),))
.....:     try:
.....:         w = process.preview_word()
.....:     except RuntimeError:
.....:         raise StopIteration
.....:     print("Next on the tape is a %s." % (w,))
sage: inverter.state('A').hook = state_hook
sage: it = inverter.iter_process(
.....:     input_tape=[0, 1, 1],
.....:     check_epsilon_transitions=False)
sage: for _ in it:
.....:     pass
We are now in state A.
Next on the tape is a 0.
We are now in state A.
Next on the tape is a 1.
We are now in state A.
Next on the tape is a 1.
We are now in state A.
sage: it.result()
[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]
```

result(*format_output=None*)

Return the already finished branches during process.

INPUT:

- `format_output` – a function converting the output from list form to something more readable (default: output the list directly).

OUTPUT:

A list of triples (accepted, state, output).

See also the parameter `format_output` of *FSMProcessIterator*.

EXAMPLES:

```
sage: inverter = Transducer({'A': [('A', 0, 'one'), ('A', 1, 'zero')]},
.....:   initial_states=['A'], final_states=['A'])
sage: it = inverter.iter_process(input_tape=[0, 1, 1])
sage: for _ in it:
```

(continues on next page)

(continued from previous page)

```

.....:     pass
sage: it.result()
[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]
sage: it.result(lambda L: ', '.join(L))
[(True, 'A', 'one, zero, zero')]

```

Using both the parameter `format_output` of *FSMProcessIterator* and the parameter `format_output` of *result()* leads to concatenation of the two functions:

```

sage: it = inverter.iter_process(input_tape=[0, 1, 1],
.....:                          format_output=lambda L: ', '.join(L))
sage: for _ in it:
.....:     pass
sage: it.result()
[Branch(accept=True, state='A', output='one, zero, zero')]
sage: it.result(lambda L: ', '.join(L))
[(True, 'A', 'o, n, e, , , z, e, r, o, , , z, e, r, o')]

```

```

class sage.combinat.finite_state_machine.FSMState(label, word_out=None, is_initial=False,
                                                    is_final=False, final_word_out=None,
                                                    initial_probability=None, hook=None,
                                                    color=None, allow_label_None=False)

```

Bases: `sage.structure.sage_object.SageObject`

Class for a state of a finite state machine.

INPUT:

- `label` – the label of the state.
- `word_out` – (default: `None`) a word that is written when the state is reached.
- `is_initial` – (default: `False`)
- `is_final` – (default: `False`)
- `final_word_out` – (default: `None`) a word that is written when the state is reached as the last state of some input; only for final states.
- `initial_probability` – (default: `None`) The probability of starting in this state if it is a state of a Markov chain.
- `hook` – (default: `None`) A function which is called when the state is reached during processing input. It takes two input parameters: the first is the current state (to allow using the same hook for several states), the second is the current process iterator object (to have full access to everything; e.g. the next letter from the input tape can be read in). It can output the next transition, i.e. the transition to take next. If it returns `None` the process iterator chooses. Moreover, this function can raise a `StopIteration` exception to stop processing of a finite state machine the input immediately. See also the example below.
- `color` – (default: `None`) In order to distinguish states, they can be given an arbitrary “color” (an arbitrary object). This is used in *FiniteStateMachine.equivalence_classes()*: states of different colors are never considered to be equivalent. Note that *Automaton.determinisation()* requires that `color` is hashable.
- `allow_label_None` – (default: `False`) If `True` allows also `None` as label. Note that a state with label `None` is used in *FSMProcessIterator*.

OUTPUT:

A state of a finite state machine.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('state 1', word_out=0, is_initial=True)
sage: A
'state 1'
sage: A.label()
'state 1'
sage: B = FSMState('state 2')
sage: A == B
False
```

We can also define a final output word of a final state which is used if the input of a transducer leads to this state. Such final output words are used in subsequential transducers.

```
sage: C = FSMState('state 3', is_final=True, final_word_out='end')
sage: C.final_word_out
['end']
```

The final output word can be a single letter, None or a list of letters:

```
sage: A = FSMState('A')
sage: A.is_final = True
sage: A.final_word_out = 2
sage: A.final_word_out
[2]
sage: A.final_word_out = [2, 3]
sage: A.final_word_out
[2, 3]
```

Only final states can have a final output word which is not None:

```
sage: B = FSMState('B')
sage: B.final_word_out is None
True
sage: B.final_word_out = 2
Traceback (most recent call last):
...
ValueError: Only final states can have a final output word,
but state B is not final.
```

Setting the `final_word_out` of a final state to `None` is the same as setting it to `[]` and is also the default for a final state:

```
sage: C = FSMState('C', is_final=True)
sage: C.final_word_out
[]
sage: C.final_word_out = None
sage: C.final_word_out
[]
sage: C.final_word_out = []
sage: C.final_word_out
[]
```

It is not allowed to use None as a label:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: FSMState(None)
Traceback (most recent call last):
...
ValueError: Label None reserved for a special state,
choose another label.
```

This can be overridden by:

```
sage: FSMState(None, allow_label_None=True)
None
```

Note that `Automaton.determinisation()` requires that color is hashable:

```
sage: A = Automaton([[0, 0, 0]], initial_states=[0])
sage: A.state(0).color = []
sage: A.determinisation()
Traceback (most recent call last):
...
TypeError: unhashable type: 'list'
sage: A.state(0).color = ()
sage: A.determinisation()
Automaton with 1 state
```

We can use a hook function of a state to stop processing. This is done by raising a `StopIteration` exception. The following code demonstrates this:

```
sage: T = Transducer([(0, 1, 9, 'a'), (1, 2, 9, 'b'),
.....:                (2, 3, 9, 'c'), (3, 4, 9, 'd')],
.....:                initial_states=[0],
.....:                final_states=[4],
.....:                input_alphabet=[9])
sage: def stop(process, state, output):
.....:     raise StopIteration()
sage: T.state(3).hook = stop
sage: T.process([9, 9, 9, 9])
(False, 3, ['a', 'b', 'c'])
```

copy()

Return a (shallow) copy of the state.

INPUT:

Nothing.

OUTPUT:

A new state.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: A.is_initial = True
sage: A.is_final = True
```

(continues on next page)

(continued from previous page)

```

sage: A.final_word_out = [1]
sage: A.color = 'green'
sage: A.initial_probability = 1/2
sage: B = copy(A)
sage: B.fully_equal(A)
True
sage: A.label() is B.label()
True
sage: A.is_initial is B.is_initial
True
sage: A.is_final is B.is_final
True
sage: A.final_word_out is B.final_word_out
True
sage: A.color is B.color
True
sage: A.initial_probability is B.initial_probability
True

```

deepcopy(memo=None)

Return a deep copy of the state.

INPUT:

- memo – (default: None) a dictionary storing already processed elements.

OUTPUT:

A new state.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState((1, 3), color=[1, 2],
.....:             is_final=True, final_word_out=3,
.....:             initial_probability=1/3)
sage: B = deepcopy(A)
sage: B
(1, 3)
sage: B.label() == A.label()
True
sage: B.label is A.label
False
sage: B.color == A.color
True
sage: B.color is A.color
False
sage: B.is_final == A.is_final
True
sage: B.is_final is A.is_final
True
sage: B.final_word_out == A.final_word_out
True
sage: B.final_word_out is A.final_word_out
False

```

(continues on next page)

(continued from previous page)

```
sage: B.initial_probability == A.initial_probability
True
```

final_word_out

The final output word of a final state which is written if the state is reached as the last state of the input of the finite state machine. For a non-final state, the value is None.

final_word_out can be a single letter, a list or None, but for a final-state, it is always saved as a list.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True, final_word_out=2)
sage: A.final_word_out
[2]
sage: A.final_word_out = 3
sage: A.final_word_out
[3]
sage: A.final_word_out = [3, 4]
sage: A.final_word_out
[3, 4]
sage: A.final_word_out = None
sage: A.final_word_out
[]
sage: B = FSMState('B')
sage: B.final_word_out is None
True
```

A non-final state cannot have a final output word:

```
sage: B.final_word_out = [3, 4]
Traceback (most recent call last):
...
ValueError: Only final states can have a final
output word, but state B is not final.
```

fully_equal(*other*, *compare_color=True*)

Check whether two states are fully equal, i.e., including all attributes except hook.

INPUT:

- self – a state.
- other – a state.
- compare_color – If True (default) colors are compared as well, otherwise not.

OUTPUT:

True or False.

Note that usual comparison by == does only compare the labels.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
```

(continues on next page)

(continued from previous page)

```

sage: B = FSMState('A', is_initial=True)
sage: A.fully_equal(B)
False
sage: A == B
True
sage: A.is_initial = True; A.color = 'green'
sage: A.fully_equal(B)
False
sage: A.fully_equal(B, compare_color=False)
True

```

is_final

Describes whether the state is final or not.

True if the state is final and False otherwise.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True, final_word_out=3)
sage: A.is_final
True
sage: A.is_final = False
Traceback (most recent call last):
...
ValueError: State A cannot be non-final, because it has a
final output word. Only final states can have a final output
word.
sage: A.final_word_out = None
sage: A.is_final = False
sage: A.is_final
False

```

label()

Return the label of the state.

INPUT:

Nothing.

OUTPUT:

The label of the state.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('state')
sage: A.label()
'state'

```

relabelled(label, memo=None)

Return a deep copy of the state with a new label.

INPUT:

- label – the label of new state.

- `memo` – (default: `None`) a dictionary storing already processed elements.

OUTPUT:

A new state.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: A.relabeled('B')
'B'
```

class `sage.combinat.finite_state_machine.FSMTransition`(*from_state, to_state, word_in=None, word_out=None, hook=None*)

Bases: `sage.structure.sage_object.SageObject`

Class for a transition of a finite state machine.

INPUT:

- `from_state` – state from which transition starts.
- `to_state` – state in which transition ends.
- `word_in` – the input word of the transitions (when the finite state machine is used as automaton)
- `word_out` – the output word of the transitions (when the finite state machine is used as transducer)

OUTPUT:

A transition of a finite state machine.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: A = FSMState('A')
sage: B = FSMState('B')
sage: S = FSMTransition(A, B, 0, 1)
sage: T = FSMTransition('A', 'B', 0, 1)
sage: T == S
True
sage: U = FSMTransition('A', 'B', 0)
sage: U == T
False
```

copy()

Return a (shallow) copy of the transition.

OUTPUT:

A new transition.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: copy(t)
Transition from 'A' to 'B': 0|-
```

deepcopy(*memo=None*)

Return a deep copy of the transition.

INPUT:

- `memo` – (default: `None`) a dictionary storing already processed elements.

OUTPUT:

A new transition.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: deepcopy(t)
Transition from 'A' to 'B': 0|-
```

from_state = None

State from which the transition starts. Read-only.

to_state = None

State in which the transition ends. Read-only.

word_in = None

Input word of the transition. Read-only.

word_out = None

Output word of the transition. Read-only.

`sage.combinat.finite_state_machine.FSMWordSymbol(word)`

Return a string of word. It may returns the symbol of the empty word `FSMEmptyWordSymbol`.

INPUT:

- `word` – the input word.

OUTPUT:

A string of word.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMWordSymbol
sage: FSMWordSymbol([0, 1, 1])
'0,1,1'
```

class `sage.combinat.finite_state_machine.FiniteStateMachine`(*data=None, initial_states=None, final_states=None, input_alphabet=None, output_alphabet=None, determine_alphabets=None, with_final_word_out=None, store_states_dict=True, on_duplicate_transition=None*)

Bases: `sage.structure.sage_object.SageObject`

Class for a finite state machine.

A finite state machine is a finite set of states connected by transitions.

INPUT:

- `data` – can be any of the following:
 1. a dictionary of dictionaries (of transitions),

2. a dictionary of lists (of states or transitions),
 3. a list (of transitions),
 4. a function (transition function),
 5. an other instance of a finite state machine.
- `initial_states` and `final_states` – the initial and final states of this machine
 - `input_alphabet` and `output_alphabet` – the input and output alphabets of this machine
 - `determine_alphabets` – If `True`, then the function `determine_alphabets()` is called after data was read and processed, if `False`, then not. If it is `None`, then it is decided during the construction of the finite state machine whether `determine_alphabets()` should be called.
 - `with_final_word_out` – If given (not `None`), then the function `with_final_word_out()` (more precisely, its inplace pendant `construct_final_word_out()`) is called with `input_letters=with_final_word_out` at the end of the creation process.
 - `store_states_dict` – If `True`, then additionally the states are stored in an internal dictionary for speed up.
 - `on_duplicate_transition` – A function which is called when a transition is inserted into `self` which already existed (same `from_state`, same `to_state`, same `word_in`, same `word_out`).

This function is assumed to take two arguments, the first being the already existing transition, the second being the new transition (as an *FSMTransition*). The function must return the (possibly modified) original transition.

By default, we have `on_duplicate_transition=None`, which is interpreted as `on_duplicate_transition=duplicate_transition_ignore`, where `duplicate_transition_ignore` is a predefined function ignoring the occurrence. Other such predefined functions are `duplicate_transition_raise_error` and `duplicate_transition_add_input`.

OUTPUT:

A finite state machine.

The object creation of *Automaton* and *Transducer* is the same as the one described here (i.e. just replace the word `FiniteStateMachine` by `Automaton` or `Transducer`).

Each transition of an automaton has an input label. Automata can, for example, be determined (see *Automaton.determinisation()*) and minimized (see *Automaton.minimization()*). Each transition of a transducer has an input and an output label. Transducers can, for example, be simplified (see *Transducer.simplification()*).

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
```

See documentation for more examples.

We illustrate the different input formats:

1. The input-data can be a dictionary of dictionaries, where
 - the keys of the outer dictionary are state-labels (from-states of transitions),
 - the keys of the inner dictionaries are state-labels (to-states of transitions),
 - the values of the inner dictionaries specify the transition more precisely.

The easiest is to use a tuple consisting of an input and an output word:

```
sage: FiniteStateMachine({'a':{'b':(0, 1), 'c':(1, 1)}})
Finite state machine with 3 states
```

Instead of the tuple anything iterable (e.g. a list) can be used as well.

If you want to use the arguments of *FSMTransition* directly, you can use a dictionary:

```
sage: FiniteStateMachine({'a':{'b':{'word_in':0, 'word_out':1},
.....:                          'c':{'word_in':1, 'word_out':1}}})
Finite state machine with 3 states
```

In the case you already have instances of *FSMTransition*, it is possible to use them directly:

```
sage: FiniteStateMachine({'a':{'b':FSMTransition('a', 'b', 0, 1),
.....:                          'c':FSMTransition('a', 'c', 1, 1)}})
Finite state machine with 3 states
```

- The input-data can be a dictionary of lists, where the keys are states or label of states.

The list-elements can be states:

```
sage: a = FSMState('a')
sage: b = FSMState('b')
sage: c = FSMState('c')
sage: FiniteStateMachine({a:[b, c]})
Finite state machine with 3 states
```

Or the list-elements can simply be labels of states:

```
sage: FiniteStateMachine({'a':['b', 'c']})
Finite state machine with 3 states
```

The list-elements can also be transitions:

```
sage: FiniteStateMachine({'a':[FSMTransition('a', 'b', 0, 1),
.....:                          FSMTransition('a', 'c', 1, 1)]})
Finite state machine with 3 states
```

Or they can be tuples of a label, an input word and an output word specifying a transition:

```
sage: FiniteStateMachine({'a':[('b', 0, 1), ('c', 1, 1)]})
Finite state machine with 3 states
```

- The input-data can be a list, where its elements specify transitions:

```
sage: FiniteStateMachine([FSMTransition('a', 'b', 0, 1),
.....:                    FSMTransition('a', 'c', 1, 1)])
Finite state machine with 3 states
```

It is possible to skip *FSMTransition* in the example above:

```
sage: FiniteStateMachine([('a', 'b', 0, 1), ('a', 'c', 1, 1)])
Finite state machine with 3 states
```

The parameters of the transition are given in tuples. Anyhow, anything iterable (e.g. a list) is possible.

You can also name the parameters of the transition. For this purpose you take a dictionary:

```

sage: FiniteStateMachine([{'from_state':'a', 'to_state':'b',
.....:                    'word_in':0, 'word_out':1},
.....:                    {'from_state':'a', 'to_state':'c',
.....:                    'word_in':1, 'word_out':1}])
Finite state machine with 3 states

```

Other arguments, which *FSMTransition* accepts, can be added, too.

4. The input-data can also be function acting as transition function:

This function has two input arguments:

1. a label of a state (from which the transition starts),
2. a letter of the (input-)alphabet (as input-label of the transition).

It returns a tuple with the following entries:

1. a label of a state (to which state the transition goes),
2. a letter of or a word over the (output-)alphabet (as output-label of the transition).

It may also output a list of such tuples if several transitions from the from-state and the input letter exist (this means that the finite state machine is non-deterministic).

If the transition does not exist, the function should raise a *LookupError* or return an empty list.

When constructing a finite state machine in this way, some initial states and an input alphabet have to be specified.

```

sage: def f(state_from, read):
.....:     if int(state_from) + read <= 2:
.....:         state_to = 2*int(state_from)+read
.....:         write = 0
.....:     else:
.....:         state_to = 2*int(state_from) + read - 5
.....:         write = 1
.....:     return (str(state_to), write)
sage: F = FiniteStateMachine(f, input_alphabet=[0, 1],
.....:                       initial_states=['0'],
.....:                       final_states=['0'])
sage: F([1, 0, 1])
(True, '0', [0, 0, 1])

```

5. The input-data can be an other instance of a finite state machine:

```

sage: F = FiniteStateMachine()
sage: G = Transducer(F)
sage: G == F
True

```

The other parameters cannot be specified in that case. If you want to change these, use the attributes *FSMState.is_initial*, *FSMState.is_final*, *input_alphabet*, *output_alphabet*, *on_duplicate_transition* and methods *determine_alphabets()*, *construct_final_word_out()* on the new machine, respectively.

The following examples demonstrate the use of *on_duplicate_transition*:

```
sage: F = FiniteStateMachine([[ 'a', 'a', 1/2], [ 'a', 'a', 1/2]])
sage: F.transitions()
[Transition from 'a' to 'a': 1/2|-]
```

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_
      ↪error
sage: F1 = FiniteStateMachine([[ 'a', 'a', 1/2], [ 'a', 'a', 1/2]],
      .....:                          on_duplicate_transition=duplicate_transition_raise_
      ↪error)
Traceback (most recent call last):
...
ValueError: Attempting to re-insert transition Transition from 'a' to 'a': 1/2|-]
```

Use `duplicate_transition_add_input` to emulate a Markov chain, the input labels are considered as transition probabilities:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: F = FiniteStateMachine([[ 'a', 'a', 1/2], [ 'a', 'a', 1/2]],
      .....:                          on_duplicate_transition=duplicate_transition_add_input)
sage: F.transitions()
[Transition from 'a' to 'a': 1|-]
```

Use `with_final_word_out` to construct final output:

```
sage: T = Transducer([(0, 1, 0, 0), (1, 0, 0, 0)],
      .....:             initial_states=[0],
      .....:             final_states=[0],
      .....:             with_final_word_out=0)
sage: for s in T.iter_final_states():
      .....:     print("{} {}".format(s, s.final_word_out))
0 []
1 [0]
```

`__call__` (*args, **kwargs)

Call either method `composition()` or `process()` (with `full_output=False`). If the input is not finite (`is_finite` of input is `False`), then `iter_process()` (with `iterator_type='simple'`) is called. Moreover, the flag `automatic_output_type` is set (unless `format_output` is specified). See the documentation of these functions for possible parameters.

EXAMPLES:

The following code performs a `composition()`:

```
sage: F = Transducer([( 'A', 'B', 1, 0), ( 'B', 'B', 1, 1),
      .....:             ( 'B', 'B', 0, 0)],
      .....:             initial_states=[ 'A'], final_states=[ 'B'])
sage: G = Transducer([(1, 1, 0, 0), (1, 2, 1, 0),
      .....:             (2, 2, 0, 1), (2, 1, 1, 1)],
      .....:             initial_states=[1], final_states=[1])
sage: H = G(F)
sage: H.states()
[( 'A', 1), ( 'B', 1), ( 'B', 2)]
```

An automaton or transducer can also act on an input (an list or other iterable of letters):

```

sage: binary_inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:                               initial_states=['A'], final_states=['A'])
sage: binary_inverter([0, 1, 0, 0, 1, 1])
[1, 0, 1, 1, 0, 0]

```

We can also let them act on *words*:

```

sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
sage: binary_inverter(W([0, 1, 1, 0, 1, 1]))
word: 100100

```

Infinite words work as well:

```

sage: words.FibonacciWord()
word: 0100101001001010010100100101001001010010...
sage: binary_inverter(words.FibonacciWord())
word: 1011010110110101101011011010110110101101...

```

When only one successful path is found in a non-deterministic transducer, the result of that path is returned.

```

sage: T = Transducer([(0, 1, 0, 1), (0, 2, 0, 2)],
....:                 initial_states=[0], final_states=[1])
sage: T.process([0])
[(False, 2, [2]), (True, 1, [1])]
sage: T([0])
[1]

```

See also:

[*composition\(\)*](#), [*process\(\)*](#), [*iter_process\(\)*](#), [*Automaton.process\(\)*](#), [*Transducer.process\(\)*](#).

accessible_components()

Return a new finite state machine with the accessible states of self and all transitions between those states.

INPUT:

Nothing.

OUTPUT:

A finite state machine with the accessible states of self and all transitions between those states.

A state is accessible if there is a directed path from an initial state to the state. If self has no initial states then a copy of the finite state machine self is returned.

EXAMPLES:

```

sage: F = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 0), (1, 0, 1)],
....:               initial_states=[0])
sage: F.accessible_components()
Automaton with 2 states

```

```

sage: F = Automaton([(0, 0, 1), (0, 0, 1), (1, 1, 0), (1, 0, 1)],
....:               initial_states=[0])
sage: F.accessible_components()
Automaton with 1 state

```

See also:

`coaccessible_components()`

add_from_transition_function(*function*, *initial_states=None*, *explore_existing_states=True*)

Constructs a finite state machine from a transition function.

INPUT:

- *function* may return a tuple (*new_state*, *output_word*) or a list of such tuples.
- *initial_states* – If no initial states are given, the already existing initial states of self are taken.
- If *explore_existing_states* is True (default), then already existing states in self (e.g. already given final states) will also be processed if they are reachable from the initial states.

OUTPUT:

Nothing.

EXAMPLES:

```
sage: F = FiniteStateMachine(initial_states=['A'],
.....:                      input_alphabet=[0, 1])
sage: def f(state, input):
.....:     return [('A', input), ('B', 1-input)]
sage: F.add_from_transition_function(f)
sage: F.transitions()
[Transition from 'A' to 'A': 0|0,
Transition from 'A' to 'B': 0|1,
Transition from 'A' to 'A': 1|1,
Transition from 'A' to 'B': 1|0,
Transition from 'B' to 'A': 0|0,
Transition from 'B' to 'B': 0|1,
Transition from 'B' to 'A': 1|1,
Transition from 'B' to 'B': 1|0]
```

Initial states can also be given as a parameter:

```
sage: F = FiniteStateMachine(input_alphabet=[0, 1])
sage: def f(state, input):
.....:     return [('A', input), ('B', 1-input)]
sage: F.add_from_transition_function(f, initial_states=['A'])
sage: F.initial_states()
['A']
```

Already existing states in the finite state machine (the final states in the example below) are also explored:

```
sage: F = FiniteStateMachine(initial_states=[0],
.....:                      final_states=[1],
.....:                      input_alphabet=[0])
sage: def transition_function(state, letter):
.....:     return 1 - state, []
sage: F.add_from_transition_function(transition_function)
sage: F.transitions()
[Transition from 0 to 1: 0|-,
Transition from 1 to 0: 0|-]
```

If `explore_existing_states=False`, however, this behavior is turned off, i.e., already existing states are not explored:

```
sage: F = FiniteStateMachine(initial_states=[0],
.....:                       final_states=[1],
.....:                       input_alphabet=[0])
sage: def transition_function(state, letter):
.....:     return 1 - state, []
sage: F.add_from_transition_function(transition_function,
.....:                               explore_existing_states=False)
sage: F.transitions()
[Transition from 0 to 1: 0|-]
```

`add_state(state)`

Adds a state to the finite state machine and returns the new state. If the state already exists, that existing state is returned.

INPUT:

- `state` is either an instance of `FSMState` or, otherwise, a label of a state.

OUTPUT:

The new or existing state.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: F = FiniteStateMachine()
sage: A = FSMState('A', is_initial=True)
sage: F.add_state(A)
'A'
```

`add_states(states)`

Adds several states. See `add_state` for more information.

INPUT:

- `states` – a list of states or iterator over states.

OUTPUT:

Nothing.

EXAMPLES:

```
sage: F = FiniteStateMachine()
sage: F.add_states(['A', 'B'])
sage: F.states()
['A', 'B']
```

`add_transition(*args, **kwargs)`

Adds a transition to the finite state machine and returns the new transition.

If the transition already exists, the return value of `self.on_duplicate_transition` is returned. See the documentation of `FiniteStateMachine`.

INPUT:

The following forms are all accepted:

```

sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: A = FSMState('A')
sage: B = FSMState('B')

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(FSMTransition(A, B, 0, 1))
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(A, B, 0, 1)
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(A, B, word_in=0, word_out=1)
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition('A', 'B', {'word_in': 0, 'word_out': 1})
Transition from 'A' to 'B': {'word_in': 0, 'word_out': 1}|-

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(from_state=A, to_state=B,
.....:                    word_in=0, word_out=1)
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition({'from_state': A, 'to_state': B,
.....:                    'word_in': 0, 'word_out': 1})
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition((A, B, 0, 1))
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition([A, B, 0, 1])
Transition from 'A' to 'B': 0|1

```

If the states A and B are not instances of *FSMState*, then it is assumed that they are labels of states.

OUTPUT:

The new transition.

add_transitions_from_function(*function*, *labels_as_input=True*)

Adds one or more transitions if *function*(*state*, *state*) says that there are some.

INPUT:

- *function* – a transition function. Given two states *from_state* and *to_state* (or their labels if *label_as_input* is true), this function shall return a tuple (*word_in*, *word_out*) to add a transition from *from_state* to *to_state* with input and output labels *word_in* and *word_out*, respectively. If no such addition is to be added, the transition function shall return None. The transition function may also return a list of such tuples in order to add multiple transitions between the pair of states.
- *label_as_input* – (default: True)

OUTPUT:

Nothing.

EXAMPLES:

```
sage: F = FiniteStateMachine()
sage: F.add_states(['A', 'B', 'C'])
sage: def f(state1, state2):
....:     if state1 == 'C':
....:         return None
....:     return (0, 1)
sage: F.add_transitions_from_function(f)
sage: len(F.transitions())
6
```

Multiple transitions are also possible:

```
sage: F = FiniteStateMachine()
sage: F.add_states([0, 1])
sage: def f(state1, state2):
....:     if state1 != state2:
....:         return [(0, 1), (1, 0)]
....:     else:
....:         return None
sage: F.add_transitions_from_function(f)
sage: F.transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 0: 1|0]
```

adjacency_matrix(*input=None, entry=None*)

Return the adjacency matrix of the underlying graph.

INPUT:

- **input** – Only transitions with input label **input** are respected.
- **entry** – The function **entry** takes a transition and the return value is written in the matrix as the entry (**transition.from_state, transition.to_state**). The default value (**None**) of **entry** takes the variable **x** to the power of the sum of the output word of the transition.

OUTPUT:

A matrix.

If any label of a state is not an integer, the finite state machine is relabeled at the beginning. If there are more than one transitions between two states, then the different return values of **entry** are added up.

EXAMPLES:

```
sage: B = FiniteStateMachine({0:{0:(0, 0), 'a':(1, 0)},
....:                        'a':{2:(0, 0), 3:(1, 0)},
....:                        2:{0:(1, 1), 4:(0, 0)},
....:                        3:{'a':(0, 1), 2:(1, 1)},
....:                        4:{4:(1, 1), 3:(0, 1)}}),
....:                        initial_states=[0])
```

(continues on next page)

(continued from previous page)

```

sage: B.adjacency_matrix() # optional - sage.
↪symbolic
[1 1 0 0 0]
[0 0 1 1 0]
[x 0 0 0 1]
[0 x x 0 0]
[0 0 0 x x]

```

This is equivalent to:

```

sage: matrix(B) # optional - sage.
↪symbolic
[1 1 0 0 0]
[0 0 1 1 0]
[x 0 0 0 1]
[0 x x 0 0]
[0 0 0 x x]

```

It is also possible to use other entries in the adjacency matrix:

```

sage: B.adjacency_matrix(entry=(lambda transition: 1))
[1 1 0 0 0]
[0 0 1 1 0]
[1 0 0 0 1]
[0 1 1 0 0]
[0 0 0 1 1]
sage: var('t') # optional - sage.
↪symbolic
t
sage: B.adjacency_matrix(1, entry=(lambda transition: # optional - sage.
↪symbolic
.....: exp(I*transition.word_out[0]*t))
[ 0 1 0 0 0]
[ 0 0 0 1 0]
[e^(I*t) 0 0 0 0]
[ 0 0 e^(I*t) 0 0]
[ 0 0 0 0 e^(I*t)]
sage: a = Automaton([(0, 1, 0),
.....: (1, 2, 0),
.....: (2, 0, 1),
.....: (2, 1, 0)],
.....: initial_states=[0],
.....: final_states=[0])
sage: a.adjacency_matrix() # optional - sage.
↪symbolic
[0 1 0]
[0 0 1]
[1 1 0]

```

asymptotic_moments(variable=None)

Return the main terms of expectation and variance of the sum of output labels and its covariance with the sum of input labels.

INPUT:

- **variable** – a symbol denoting the length of the input, by default n .

OUTPUT:

A dictionary consisting of

- **expectation** – $en + O(1)$,
- **variance** – $vn + O(1)$,
- **covariance** – $cn + O(1)$

for suitable constants e , v and c .

Assume that all input and output labels are numbers and that `self` is complete and has only one final component. Assume further that this final component is aperiodic. Furthermore, assume that there is exactly one initial state and that all states are final.

Denote by X_n the sum of output labels written by the finite state machine when reading a random input word of length n over the input alphabet (assuming equidistribution).

Then the expectation of X_n is $en + O(1)$, the variance of X_n is $vn + O(1)$ and the covariance of X_n and the sum of input labels is $cn + O(1)$, cf. [HKW2015], Theorem 3.9.

In the case of non-integer input or output labels, performance degrades significantly. For rational input and output labels, consider rescaling to integers. This limitation comes from the fact that determinants over polynomial rings can be computed much more efficiently than over the symbolic ring. In fact, we compute (parts) of a trivariate generating function where the input and output labels are exponents of some indeterminates, see [HKW2015], Theorem 3.9 for details. If those exponents are integers, we can use a polynomial ring.

EXAMPLES:

1. A trivial example: write the negative of the input:

```
sage: T = Transducer([(0, 0, 0, 0), (0, 0, 1, -1)],
....:                initial_states=[0],
....:                final_states=[0])
sage: T([0, 1, 1])
[0, -1, -1]
sage: moments = T.asymptotic_moments()           # optional -
↪ sage.symbolic
sage: moments['expectation']                    # optional -
↪ sage.symbolic
-1/2*n + Order(1)
sage: moments['variance']                       # optional -
↪ sage.symbolic
1/4*n + Order(1)
sage: moments['covariance']                     # optional -
↪ sage.symbolic
-1/4*n + Order(1)
```

2. For the case of the Hamming weight of the non-adjacent-form (NAF) of integers, cf. the [Wikipedia article Non-adjacent_form](#) and the [example on recognizing NAFs](#), the following agrees with the results in [HP2007].

We first use the transducer to convert the standard binary expansion to the NAF given in [HP2007]. We use the parameter `with_final_word_out` such that we do not have to add sufficiently many trailing zeros:

```

sage: NAF = Transducer([(0, 0, 0, 0),
.....:                 (0, '.1', 1, None),
.....:                 ('.1', 0, 0, [1, 0]),
.....:                 ('.1', 1, 1, [-1, 0]),
.....:                 (1, 1, 1, 0),
.....:                 (1, '.1', 0, None)],
.....:                 initial_states=[0],
.....:                 final_states=[0],
.....:                 with_final_word_out=[0])

```

As an example, we compute the NAF of 27 by this transducer.

```

sage: binary_27 = 27.bits()
sage: binary_27
[1, 1, 0, 1, 1]
sage: NAF_27 = NAF(binary_27)
sage: NAF_27
[-1, 0, -1, 0, 0, 1, 0]
sage: ZZ(NAF_27, base=2)
27

```

Next, we are only interested in the Hamming weight:

```

sage: def weight(state, input):
.....:     if input is None:
.....:         result = 0
.....:     else:
.....:         result = ZZ(input != 0)
.....:     return (0, result)
sage: weight_transducer = Transducer(weight,
.....:                                 input_alphabet=[-1, 0, 1],
.....:                                 initial_states=[0],
.....:                                 final_states=[0])
sage: NAFweight = weight_transducer.composition(NAF)
sage: NAFweight.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
Transition from (0, 0) to ('.1', 0): 1|-,
Transition from ('.1', 0) to (0, 0): 0|1,0,
Transition from ('.1', 0) to (1, 0): 1|1,0,
Transition from (1, 0) to ('.1', 0): 0|-,
Transition from (1, 0) to (1, 0): 1|0]
sage: NAFweight(binary_27)
[1, 0, 1, 0, 0, 1, 0]

```

Now, we actually compute the asymptotic moments:

```

sage: moments = NAFweight.asymptotic_moments() # optional -
↪ sage.symbolic
sage: moments['expectation'] # optional -
↪ sage.symbolic
1/3*n + Order(1)
sage: moments['variance'] # optional -
↪ sage.symbolic

```

(continues on next page)

(continued from previous page)

```

2/27*n + Order(1)
sage: moments['covariance'] # optional -
→ sage.symbolic
Order(1)

```

3. This is Example 3.16 in [HKW2015], where a transducer with variable output labels is given. There, the aim was to choose the output labels of this very simple transducer such that the input and output sum are asymptotically independent, i.e., the constant c vanishes.

```

sage: var('a_1, a_2, a_3, a_4') # optional -
→ sage.symbolic
(a_1, a_2, a_3, a_4)
sage: T = Transducer([[0, 0, 0, a_1], [0, 1, 1, a_3], # optional -
→ sage.symbolic
.....: [1, 0, 0, a_4], [1, 1, 1, a_2]],
.....: initial_states=[0], final_states=[0, 1])
sage: moments = T.asymptotic_moments() # optional -
→ sage.symbolic
verbose 0 (...) Non-integer output weights lead to
significant performance degradation.
sage: moments['expectation'] # optional -
→ sage.symbolic
1/4*(a_1 + a_2 + a_3 + a_4)*n + Order(1)
sage: moments['covariance'] # optional -
→ sage.symbolic
-1/4*(a_1 - a_2)*n + Order(1)

```

Therefore, the asymptotic covariance vanishes if and only if $a_2 = a_1$.

4. This is Example 4.3 in [HKW2015], dealing with the transducer converting the binary expansion of an integer into Gray code (cf. the [Wikipedia article Gray_code](#) and the *example on Gray code*):

```

sage: moments = transducers.GrayCode().asymptotic_moments() # optional -
→ sage.symbolic
sage: moments['expectation'] # optional -
→ sage.symbolic
1/2*n + Order(1)
sage: moments['variance'] # optional -
→ sage.symbolic
1/4*n + Order(1)
sage: moments['covariance'] # optional -
→ sage.symbolic
Order(1)

```

5. This is the first part of Example 4.4 in [HKW2015], counting the number of 10 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```

sage: block10 = transducers.CountSubblockOccurrences(
.....: [1, 0],
.....: input_alphabet=[0, 1])
sage: sorted(block10.transitions())
[Transition from () to (): 0|0,
Transition from () to (1,): 1|0,

```

(continues on next page)

(continued from previous page)

```

Transition from (1,) to (): 0|1,
Transition from (1,) to (1,): 1|0]
sage: moments = block10.asymptotic_moments()           # optional -
→ sage.symbolic
sage: moments['expectation']                          # optional -
→ sage.symbolic
1/4*n + Order(1)
sage: moments['variance']                             # optional -
→ sage.symbolic
1/16*n + Order(1)
sage: moments['covariance']                          # optional -
→ sage.symbolic
Order(1)

```

6. This is the second part of Example 4.4 in [HKW2015], counting the number of 11 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```

sage: block11 = transducers.CountSubblockOccurrences(
.....:     [1, 1],
.....:     input_alphabet=[0, 1])
sage: sorted(block11.transitions())
[Transition from () to (): 0|0,
Transition from () to (1,): 1|0,
Transition from (1,) to (): 0|0,
Transition from (1,) to (1,): 1|1]
sage: var('N')                                       # optional -
→ sage.symbolic
N
sage: moments = block11.asymptotic_moments(N)       # optional -
→ sage.symbolic
sage: moments['expectation']                         # optional -
→ sage.symbolic
1/4*N + Order(1)
sage: moments['variance']                           # optional -
→ sage.symbolic
5/16*N + Order(1)
sage: correlation = (moments['covariance'].coefficient(N) / # optional -
→ sage.symbolic
.....:     (1/2 * sqrt(moments['variance'].coefficient(N))))
sage: correlation                                   # optional -
→ sage.symbolic
2/5*sqrt(5)

```

7. This is Example 4.5 in [HKW2015], counting the number of 01 blocks minus the number of 10 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```

sage: block01 = transducers.CountSubblockOccurrences(
.....:     [0, 1],
.....:     input_alphabet=[0, 1])
sage: product_01x10 = block01.cartesian_product(block10)
sage: block_difference = transducers.sub([0, 1])(product_01x10)
sage: T = block_difference.simplification().relabelled()

```

(continues on next page)

(continued from previous page)

```

sage: T.transitions()
[Transition from 0 to 2: 0|-1,
 Transition from 0 to 0: 1|0,
 Transition from 1 to 2: 0|0,
 Transition from 1 to 0: 1|0,
 Transition from 2 to 2: 0|0,
 Transition from 2 to 0: 1|1]
sage: moments = T.asymptotic_moments()           # optional -
→ sage.symbolic
sage: moments['expectation']                   # optional -
→ sage.symbolic
Order(1)
sage: moments['variance']                       # optional -
→ sage.symbolic
Order(1)
sage: moments['covariance']                     # optional -
→ sage.symbolic
Order(1)

```

8. The finite state machine must have a unique final component:

```

sage: T = Transducer([(0, -1, -1, -1), (0, 1, 1, 1),
.....:                (-1, -1, -1, -1), (-1, -1, 1, -1),
.....:                (1, 1, -1, 1), (1, 1, 1, 1)],
.....:                initial_states=[0],
.....:                final_states=[0, 1, -1])
sage: T.asymptotic_moments()
Traceback (most recent call last):
...
NotImplementedError: asymptotic_moments is only
implemented for finite state machines with one final
component.

```

In this particular example, the first letter of the input decides whether we reach the loop at -1 or the loop at 1 . In the first case, we have $X_n = -n$, while we have $X_n = n$ in the second case. Therefore, the expectation $E(X_n)$ of X_n is $E(X_n) = 0$. We get $(X_n - E(X_n))^2 = n^2$ in all cases, which results in a variance of n^2 .

So this example shows that the variance may be non-linear if there is more than one final component.

ALGORITHM:

See [HKW2015], Theorem 3.9.

REFERENCES:

coaccessible_components()

Return the sub-machine induced by the coaccessible states of this finite state machine.

OUTPUT:

A finite state machine of the same type as this finite state machine.

EXAMPLES:

```

sage: A = automata.ContainsWord([1, 1],
....:   input_alphabet=[0, 1]).complement().minimization().relabelled()
sage: A.transitions()
[Transition from 0 to 0: 0|-,
  Transition from 0 to 0: 1|-,
  Transition from 1 to 2: 0|-,
  Transition from 1 to 0: 1|-,
  Transition from 2 to 2: 0|-,
  Transition from 2 to 1: 1|-]
sage: A.initial_states()
[2]
sage: A.final_states()
[1, 2]
sage: C = A.coaccessible_components()
sage: C.transitions()
[Transition from 1 to 2: 0|-,
  Transition from 2 to 2: 0|-,
  Transition from 2 to 1: 1|-]

```

See also:

[*accessible_components\(\)*](#), [*induced_sub_finite_state_machine\(\)*](#)

completion(*sink=None*)

Return a completion of this finite state machine.

INPUT:

- *sink* – either an instance of [*FSMState*](#) or a label for the sink (default: `None`). If `None`, the least available non-zero integer is used.

OUTPUT:

A [*FiniteStateMachine*](#) of the same type as this finite state machine.

The resulting finite state machine is a complete version of this finite state machine. A finite state machine is considered to be complete if each transition has an input label of length one and for each pair (q, a) where q is a state and a is an element of the input alphabet, there is exactly one transition from q with input label a .

If this finite state machine is already complete, a deep copy is returned. Otherwise, a new non-final state (usually called a sink) is created and transitions to this sink are introduced as appropriate.

EXAMPLES:

```

sage: F = FiniteStateMachine([(0, 0, 0, 0),
....:                       (0, 1, 1, 1),
....:                       (1, 1, 0, 0)])
sage: F.is_complete()
False
sage: G1 = F.completion()
sage: G1.is_complete()
True
sage: G1.transitions()
[Transition from 0 to 0: 0|0,
  Transition from 0 to 1: 1|1,
  Transition from 1 to 1: 0|0,

```

(continues on next page)

(continued from previous page)

```

Transition from 1 to 2: 1|-,
Transition from 2 to 2: 0|-,
Transition from 2 to 2: 1|-]
sage: G2 = F.completion('Sink')
sage: G2.is_complete()
True
sage: G2.transitions()
[Transition from 0 to 0: 0|0,
Transition from 0 to 1: 1|1,
Transition from 1 to 1: 0|0,
Transition from 1 to 'Sink': 1|-,
Transition from 'Sink' to 'Sink': 0|-,
Transition from 'Sink' to 'Sink': 1|-]
sage: F.completion(1)
Traceback (most recent call last):
...
ValueError: The finite state machine already contains a state
'1'.

```

An input alphabet must be given:

```

sage: F = FiniteStateMachine([(0, 0, 0, 0),
.....:                       (0, 1, 1, 1),
.....:                       (1, 1, 0, 0)],
.....:                       determine_alphabets=False)
sage: F.is_complete()
Traceback (most recent call last):
...
ValueError: No input alphabet is given. Try calling
determine_alphabets().

```

Non-deterministic machines are not allowed.

```

sage: F = FiniteStateMachine([(0, 0, 0, 0), (0, 1, 0, 0)])
sage: F.is_complete()
False
sage: F.completion()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
sage: F = FiniteStateMachine([(0, 0, [0, 0], 0)])
sage: F.is_complete()
False
sage: F.completion()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.

```

See also:

is_complete(), *split_transitions()*, *determine_alphabets()*, *is_deterministic()*.

composition(*other*, *algorithm=None*, *only_accessible_components=True*)

Return a new transducer which is the composition of *self* and *other*.

INPUT:

- `other` – a transducer
- `algorithm` – can be one of the following
 - `direct` – The composition is calculated directly.

There can be arbitrarily many initial and final states, but the input and output labels must have length 1.

Warning: The output of `other` is fed into `self`.

- `explorative` – An explorative algorithm is used.
The input alphabet of `self` has to be specified.

Warning: The output of `other` is fed into `self`.

If `algorithm` is `None`, then the algorithm is chosen automatically (at the moment always `direct`, except when there are output words of `other` or input words of `self` of length greater than 1).

OUTPUT:

A new transducer.

The labels of the new finite state machine are pairs of states of the original finite state machines. The color of a new state is the tuple of colors of the constituent states.

EXAMPLES:

```
sage: F = Transducer([('A', 'B', 1, 0), ('B', 'A', 0, 1)],
.....:               initial_states=['A', 'B'], final_states=['B'],
.....:               determine_alphabets=True)
sage: G = Transducer([(1, 1, 1, 0), (1, 2, 0, 1),
.....:               (2, 2, 1, 1), (2, 2, 0, 0)],
.....:               initial_states=[1], final_states=[2],
.....:               determine_alphabets=True)
sage: Hd = F.composition(G, algorithm='direct')
sage: Hd.initial_states()
[(1, 'B'), (1, 'A')]
sage: Hd.transitions()
[Transition from (1, 'B') to (1, 'A'): 1|1,
Transition from (1, 'A') to (2, 'B'): 0|0,
Transition from (2, 'B') to (2, 'A'): 0|1,
Transition from (2, 'A') to (2, 'B'): 1|0]
sage: He = F.composition(G, algorithm='explorative')
sage: He.initial_states()
[(1, 'A'), (1, 'B')]
sage: He.transitions()
[Transition from (1, 'A') to (2, 'B'): 0|0,
Transition from (1, 'B') to (1, 'A'): 1|1,
Transition from (2, 'B') to (2, 'A'): 0|1,
Transition from (2, 'A') to (2, 'B'): 1|0]
```

(continues on next page)

(continued from previous page)

```
sage: Hd == He
True
```

The following example has output of length > 1 , so the explorative algorithm has to be used (and is selected automatically).

```
sage: F = Transducer([(('A', 'B', 1, [1, 0]), ('B', 'B', 1, 1),
.....:                  ('B', 'B', 0, 0))],
.....:                  initial_states=['A'], final_states=['B'])
sage: G = Transducer([(1, 1, 0, 0), (1, 2, 1, 0),
.....:                  (2, 2, 0, 1), (2, 1, 1, 1)],
.....:                  initial_states=[1], final_states=[1])
sage: He = G.composition(F, algorithm='explorative')
sage: He.transitions()
[Transition from ('A', 1) to ('B', 2): 1|0,1,
Transition from ('B', 2) to ('B', 2): 0|1,
Transition from ('B', 2) to ('B', 1): 1|1,
Transition from ('B', 1) to ('B', 1): 0|0,
Transition from ('B', 1) to ('B', 2): 1|0]
sage: Ha = G.composition(F)
sage: Ha == He
True
```

Final output words are also considered:

```
sage: F = Transducer([(('A', 'B', 1, 0), ('B', 'A', 0, 1)),
.....:                  initial_states=['A', 'B'],
.....:                  final_states=['A', 'B'])
sage: F.state('A').final_word_out = 0
sage: F.state('B').final_word_out = 1
sage: G = Transducer([(1, 1, 1, 0), (1, 2, 0, 1),
.....:                  (2, 2, 1, 1), (2, 2, 0, 0)],
.....:                  initial_states=[1], final_states=[2])
sage: G.state(2).final_word_out = 0
sage: Hd = F.composition(G, algorithm='direct')
sage: Hd.final_states()
[(2, 'B')]
sage: He = F.composition(G, algorithm='explorative')
sage: He.final_states()
[(2, 'B')]
```

Note that (2, 'A') is not final, as the final output 0 of state 2 of G cannot be processed in state 'A' of F .

```
sage: [s.final_word_out for s in Hd.final_states()]
[[1, 0]]
sage: [s.final_word_out for s in He.final_states()]
[[1, 0]]
sage: Hd == He
True
```

Here is a non-deterministic example with intermediate output length > 1 .

```

sage: F = Transducer([(1, 1, 1, ['a', 'a']), (1, 2, 1, 'b'),
.....:                (2, 1, 2, 'a'), (2, 2, 2, 'b')],
.....:                initial_states=[1, 2])
sage: G = Transducer([('A', 'A', 'a', 'i'),
.....:                ('A', 'B', 'a', 'l'),
.....:                ('B', 'B', 'b', 'e')],
.....:                initial_states=['A', 'B'])
sage: G(F).transitions()
[Transition from (1, 'A') to (1, 'A'): 1|i', 'i',
Transition from (1, 'A') to (1, 'B'): 1|i', 'l',
Transition from (1, 'B') to (2, 'B'): 1|e',
Transition from (2, 'A') to (1, 'A'): 2|i',
Transition from (2, 'A') to (1, 'B'): 2|l',
Transition from (2, 'B') to (2, 'B'): 2|e']

```

Be aware that after composition, different transitions may share the same output label (same python object):

```

sage: F = Transducer([( 'A', 'B', 0, 0), ('B', 'A', 0, 0)],
.....:                initial_states=['A'],
.....:                final_states=['A'])
sage: F.transitions()[0].word_out is F.transitions()[1].word_out
False
sage: G = Transducer([( 'C', 'C', 0, 1)],
.....:                initial_states=['C'],
.....:                final_states=['C'])
sage: H = G.composition(F)
sage: H.transitions()[0].word_out is H.transitions()[1].word_out
True

```

concatenation(*other*)

Concatenate this finite state machine with another finite state machine.

INPUT:

- *other* – a *FiniteStateMachine*.

OUTPUT:

A *FiniteStateMachine* of the same type as this finite state machine.

Assume that both finite state machines are automata. If \mathcal{L}_1 is the language accepted by this automaton and \mathcal{L}_2 is the language accepted by the other automaton, then the language accepted by the concatenated automaton is $\{w_1w_2 \mid w_1 \in \mathcal{L}_1, w_2 \in \mathcal{L}_2\}$ where w_1w_2 denotes the concatenation of the words w_1 and w_2 .

Assume that both finite state machines are transducers and that this transducer maps words $w_1 \in \mathcal{L}_1$ to words $f_1(w_1)$ and that the other transducer maps words $w_2 \in \mathcal{L}_2$ to words $f_2(w_2)$. Then the concatenated transducer maps words w_1w_2 with $w_1 \in \mathcal{L}_1$ and $w_2 \in \mathcal{L}_2$ to $f_1(w_1)f_2(w_2)$. Here, w_1w_2 and $f_1(w_1)f_2(w_2)$ again denote concatenation of words.

The input alphabet is the union of the input alphabets (if possible) and None otherwise. In the latter case, try calling `determine_alphabets()`.

Instead of `A.concatenation(B)`, the notation `A * B` can be used.

EXAMPLES:

Concatenation of two automata:

```

sage: A = automata.Word([0])
sage: B = automata.Word([1])
sage: C = A.concatenation(B)
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
 Transition from (0, 1) to (1, 0): -|-,
 Transition from (1, 0) to (1, 1): 1|-]
sage: [w
.....: for w in ([0, 0], [0, 1], [1, 0], [1, 1])
.....: if C(w)]
[[0, 1]]
sage: from sage.combinat.finite_state_machine import (
.....:     is_Automaton, is_Transducer)
sage: is_Automaton(C)
True

```

Concatenation of two transducers:

```

sage: A = Transducer([(0, 1, 0, 1), (0, 1, 1, 2)],
.....:                 initial_states=[0],
.....:                 final_states=[1])
sage: B = Transducer([(0, 1, 0, 1), (0, 1, 1, 0)],
.....:                 initial_states=[0],
.....:                 final_states=[1])
sage: C = A.concatenation(B)
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|1,
 Transition from (0, 0) to (0, 1): 1|2,
 Transition from (0, 1) to (1, 0): -|-,
 Transition from (1, 0) to (1, 1): 0|1,
 Transition from (1, 0) to (1, 1): 1|0]
sage: [(w, C(w)) for w in ([0, 0], [0, 1], [1, 0], [1, 1])]
[[([0, 0], [1, 1]),
 ([0, 1], [1, 0]),
 ([1, 0], [2, 1]),
 ([1, 1], [2, 0])]
sage: is_Transducer(C)
True

```

Alternative notation as multiplication:

```

sage: C == A * B
True

```

Final output words are taken into account:

```

sage: A = Transducer([(0, 1, 0, 1)],
.....:                 initial_states=[0],
.....:                 final_states=[1])
sage: A.state(1).final_word_out = 2
sage: B = Transducer([(0, 1, 0, 3)],
.....:                 initial_states=[0],
.....:                 final_states=[1])

```

(continues on next page)

(continued from previous page)

```
sage: B.state(1).final_word_out = 4
sage: C = A * B
sage: C([[0, 0]])
[1, 2, 3, 4]
```

Handling of the input alphabet:

```
sage: A = Automaton([(0, 0, 0)])
sage: B = Automaton([(0, 0, 1)], input_alphabet=[1, 2])
sage: C = Automaton([(0, 0, 2)], determine_alphabets=False)
sage: D = Automaton([(0, 0, [[0, 0]])], input_alphabet=[[0, 0]])
sage: A.input_alphabet
[0]
sage: B.input_alphabet
[1, 2]
sage: C.input_alphabet is None
True
sage: D.input_alphabet
[[0, 0]]
sage: (A * B).input_alphabet
[0, 1, 2]
sage: (A * C).input_alphabet is None
True
sage: (A * D).input_alphabet is None
True
```

See also:

disjoint_union(), *determine_alphabets()*.

construct_final_word_out (*letters*, *allow_non_final=True*)

This is an inplace version of *with_final_word_out()*. See *with_final_word_out()* for documentation and examples.

copy()

Return a (shallow) copy of the finite state machine.

OUTPUT:

A new finite state machine.

deepcopy (*memo=None*)

Return a deep copy of the finite state machine.

INPUT:

- *memo* – (default: None) a dictionary storing already processed elements.

OUTPUT:

A new finite state machine.

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'A', 0, 1), ('A', 'A', 1, 0)])
sage: deepcopy(F)
Finite state machine with 1 state
```

default_format_letter(*x*, *combine_all=False*)

Return a `LatexExpr` built out of the argument *x*.

INPUT:

- *x* – a Sage object
- *combine_all* – boolean (Default: `False`) If *combine_all* is `True` and the input is a tuple, then it does not return a tuple and instead returns a string with all the elements separated by a single space.

OUTPUT:

A `LatexExpr` built from *x*

EXAMPLES:

```
sage: latex(Integer(3)) # indirect doctest
3
sage: latex(1==0)
\mathrm{False}
sage: print(latex([x,2]))
\left[x, 2\right]
```

Check that [trac ticket #11775](#) is fixed:

```
sage: latex((x,2), combine_all=True)
x 2
```

default_format_transition_label(*word*)

Default formatting of words in transition labels for LaTeX output.

INPUT:

word – list of letters

OUTPUT:

String representation of *word* suitable to be typeset in mathematical mode.

- For a non-empty word: Concatenation of the letters, piped through `self.format_letter` and separated by blanks.
- For an empty word: `sage.combinat.finite_state_machine.EmptyWordLaTeX`.

There is also a variant `format_transition_label_reversed()` writing the words in reversed order.

EXAMPLES:

1. Example of a non-empty word:

```
sage: T = Transducer()
sage: print(T.default_format_transition_label(
.....:      ['a', 'alpha', 'a_1', '0', 0, (0, 1)]))
\text{\texttt{a}} \text{\texttt{alpha}}
\text{\texttt{a}\char`_\_1}} 0 0 \left(0, 1\right)
```

2. In the example above, 'a' and 'alpha' should perhaps be symbols:

```
sage: var('a alpha a_1') #_
↪ optional - sage.symbolic
(a, alpha, a_1)
```

(continues on next page)

(continued from previous page)

```
sage: print(T.default_format_transition_label([a, alpha, a_1])) #_
↪optional - sage.symbolic
a \alpha a_{1}
```

3. Example of an empty word:

```
sage: print(T.default_format_transition_label([]))
\varepsilon
```

We can change this by setting `sage.combinat.finite_state_machine.EmptyWordLaTeX`:

```
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
sage: T.default_format_transition_label([])
''
```

Finally, we restore the default value:

```
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

4. This method is the default value for `FiniteStateMachine.format_transition_label`. That can be changed to be any other function:

```
sage: A = Automaton([(0, 1, 0)])
sage: def custom_format_transition_label(word):
....:     return "t"
sage: A.latex_options(format_transition_label=custom_format_transition_
↪label)
sage: print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\node[state] (v1) at (-3.000000, 0.000000) {$1$};
\path[->] (v0) edge node[rotate=360.00, anchor=south] {$t$} (v1);
\end{tikzpicture}
```

`delete_state(s)`

Deletes a state and all transitions coming or going to this state.

INPUT:

- `s` – a label of a state or an `FSMState`.

OUTPUT:

Nothing.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t1 = FSMTransition('A', 'B', 0)
sage: t2 = FSMTransition('B', 'B', 1)
sage: F = FiniteStateMachine([t1, t2])
sage: F.delete_state('A')
sage: F.transitions()
[Transition from 'B' to 'B': 1|-]
```

delete_transition(*t*)

Deletes a transition by removing it from the list of transitions of the state, where the transition starts.

INPUT:

- *t* – a transition.

OUTPUT:

Nothing.

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0), ('B', 'A', 1)])
sage: F.delete_transition(('A', 'B', 0))
sage: F.transitions()
[Transition from 'B' to 'A': 1|-]
```

determine_alphabets(*reset=True*)

Determine the input and output alphabet according to the transitions in this finite state machine.

INPUT:

- *reset* – If *reset* is *True*, then the existing input and output alphabets are erased, otherwise new letters are appended to the existing alphabets.

OUTPUT:

Nothing.

After this operation the input alphabet and the output alphabet of this finite state machine are a list of letters.

Todo: At the moment, the letters of the alphabets need to be hashable.

EXAMPLES:

```
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
.....:                (2, 2, 1, 1), (2, 2, 0, 0)],
.....:                final_states=[1],
.....:                determine_alphabets=False)
sage: T.state(1).final_word_out = [1, 4]
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
sage: T.determine_alphabets()
sage: (T.input_alphabet, T.output_alphabet)
([0, 1, 2], [0, 1, 4])
```

See also:

[*determine_input_alphabet\(\)*](#), [*determine_output_alphabet\(\)*](#).

determine_input_alphabet(*reset=True*)

Determine the input alphabet according to the transitions of this finite state machine.

INPUT:

- *reset* – a boolean (default: *True*). If *True*, then the existing input alphabet is erased, otherwise new letters are appended to the existing alphabet.

OUTPUT:

Nothing.

After this operation the input alphabet of this finite state machine is a list of letters.

Todo: At the moment, the letters of the alphabet need to be hashable.

EXAMPLES:

```
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
.....:                (2, 2, 1, 1), (2, 2, 0, 0)],
.....:                final_states=[1],
.....:                determine_alphabets=False)
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
sage: T.determine_input_alphabet()
sage: (T.input_alphabet, T.output_alphabet)
([0, 1, 2], None)
```

See also:

[*determine_output_alphabet\(\)*](#), [*determine_alphabets\(\)*](#).

determine_output_alphabet(*reset=True*)

Determine the output alphabet according to the transitions of this finite state machine.

INPUT:

- *reset* – a boolean (default: `True`). If `True`, then the existing output alphabet is erased, otherwise new letters are appended to the existing alphabet.

OUTPUT:

Nothing.

After this operation the output alphabet of this finite state machine is a list of letters.

Todo: At the moment, the letters of the alphabet need to be hashable.

EXAMPLES:

```
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
.....:                (2, 2, 1, 1), (2, 2, 0, 0)],
.....:                final_states=[1],
.....:                determine_alphabets=False)
sage: T.state(1).final_word_out = [1, 4]
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
sage: T.determine_output_alphabet()
sage: (T.input_alphabet, T.output_alphabet)
(None, [0, 1, 4])
```

See also:

[*determine_input_alphabet\(\)*](#), [*determine_alphabets\(\)*](#).

digraph(*edge_labels='words_in_out'*)

Return the graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

- **edge_label:** (default: 'words_in_out') can be
 - 'words_in_out' (labels will be strings 'i|o')
 - a function with which takes as input a transition and outputs (returns) the label

OUTPUT:

A `directed graph`.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: T = Transducer()
sage: T.graph()
Looped multi-digraph on 0 vertices
sage: T.add_state(A)
'A'
sage: T.graph()
Looped multi-digraph on 1 vertex
sage: T.add_transition(('A', 'A', 0, 1))
Transition from 'A' to 'A': 0|1
sage: T.graph()
Looped multi-digraph on 1 vertex
```

See also:

`DiGraph`

disjoint_union(*other*)

Return the disjoint union of this and another finite state machine.

INPUT:

- *other* – a *FiniteStateMachine*.

OUTPUT:

A finite state machine of the same type as this finite state machine.

In general, the disjoint union of two finite state machines is non-deterministic. In the case of a automata, the language accepted by the disjoint union is the union of the languages accepted by the constituent automata. In the case of transducer, for each successful path in one of the constituent transducers, there will be one successful path with the same input and output labels in the disjoint union.

The labels of the states of the disjoint union are pairs (i, s) : for each state s of this finite state machine, there is a state $(0, s)$ in the disjoint union; for each state s of the other finite state machine, there is a state $(1, s)$ in the disjoint union.

The input alphabet is the union of the input alphabets (if possible) and `None` otherwise. In the latter case, try calling `determine_alphabets()`.

The disjoint union can also be written as $A + B$ or $A | B$.

EXAMPLES:

```
sage: A = Automaton([(0, 1, 0), (1, 0, 1)],
.....:               initial_states=[0],
.....:               final_states=[0])
```

(continues on next page)

(continued from previous page)

```

sage: A([0, 1, 0, 1])
True
sage: B = Automaton([(0, 1, 0), (1, 2, 0), (2, 0, 1)],
.....:               initial_states=[0],
.....:               final_states=[0])
sage: B([0, 0, 1])
True
sage: C = A.disjoint_union(B)
sage: C
Automaton with 5 states
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
 Transition from (0, 1) to (0, 0): 1|-,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 1) to (1, 2): 0|-,
 Transition from (1, 2) to (1, 0): 1|-]
sage: C([0, 0, 1])
True
sage: C([0, 1, 0, 1])
True
sage: C([1])
False
sage: C.initial_states()
[(0, 0), (1, 0)]

```

Instead of `.disjoint_union`, alternative notations are available:

```

sage: C1 = A + B
sage: C1 == C
True
sage: C2 = A | B
sage: C2 == C
True

```

In general, the disjoint union is not deterministic.:

```

sage: C.is_deterministic()
False
sage: D = C.determinisation().minimization()
sage: D.is_equivalent(Automaton([(0, 0, 0), (0, 0, 1),
.....: (1, 7, 0), (1, 0, 1), (2, 6, 0), (2, 0, 1),
.....: (3, 5, 0), (3, 0, 1), (4, 0, 0), (4, 2, 1),
.....: (5, 0, 0), (5, 3, 1), (6, 4, 0), (6, 0, 1),
.....: (7, 4, 0), (7, 3, 1)],
.....: initial_states=[1],
.....: final_states=[1, 2, 3]))
True

```

Disjoint union of transducers:

```

sage: T1 = Transducer([(0, 0, 0, 1)],
.....:                 initial_states=[0],
.....:                 final_states=[0])

```

(continues on next page)

(continued from previous page)

```

sage: T2 = Transducer([(0, 0, 0, 2)],
.....:                 initial_states=[0],
.....:                 final_states=[0])
sage: T1([0])
[1]
sage: T2([0])
[2]
sage: T = T1.disjoint_union(T2)
sage: T([0])
Traceback (most recent call last):
...
ValueError: Found more than one accepting path.
sage: T.process([0])
[(True, (0, 0), [1]), (True, (1, 0), [2])]

```

Handling of the input alphabet (see [trac ticket #18989](#)):

```

sage: A = Automaton([(0, 0, 0)])
sage: B = Automaton([(0, 0, 1)], input_alphabet=[1, 2])
sage: C = Automaton([(0, 0, 2)], determine_alphabets=False)
sage: D = Automaton([(0, 0, [[0, 0]])], input_alphabet=[[0, 0]])
sage: A.input_alphabet
[0]
sage: B.input_alphabet
[1, 2]
sage: C.input_alphabet is None
True
sage: D.input_alphabet
[[0, 0]]
sage: (A + B).input_alphabet
[0, 1, 2]
sage: (A + C).input_alphabet is None
True
sage: (A + D).input_alphabet is None
True

```

See also:

Automaton.intersection(), *Transducer.intersection()*, *determine_alphabets()*.

empty_copy(*memo=None*, *new_class=None*)

Return an empty deep copy of the finite state machine, i.e., *input_alphabet*, *output_alphabet*, *on_duplicate_transition* are preserved, but states and transitions are not.

INPUT:

- *memo* – a dictionary storing already processed elements.
- *new_class* – a class for the copy. By default (*None*), the class of *self* is used.

OUTPUT:

A new finite state machine.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_
      ↪error
sage: F = FiniteStateMachine([(('A', 'A', 0, 2), ('A', 'A', 1, 3))],
      .....:                   input_alphabet=[0, 1],
      .....:                   output_alphabet=[2, 3],
      .....:                   on_duplicate_transition=duplicate_transition_raise_
      ↪error)
sage: FE = F.empty_copy(); FE
Empty finite state machine
sage: FE.input_alphabet
[0, 1]
sage: FE.output_alphabet
[2, 3]
sage: FE.on_duplicate_transition == duplicate_transition_raise_error
True

```

epsilon_successors(state)

Return the dictionary with states reachable from state without reading anything from an input tape as keys. The values are lists of outputs.

INPUT:

- state – the state whose epsilon successors should be determined.

OUTPUT:

A dictionary mapping states to a list of output words.

The states in the output are the epsilon successors of state. Each word of the list of output words is a word written when taking a path from state to the corresponding state.

EXAMPLES:

```

sage: T = Transducer([(0, 1, None, 'a'), (1, 2, None, 'b')])
sage: T.epsilon_successors(0)
{1: [['a']], 2: [['a', 'b']]}
sage: T.epsilon_successors(1)
{2: [['b']]}
sage: T.epsilon_successors(2)
{}

```

If there is a cycle with only epsilon transitions, then this cycle is only processed once and there is no infinite loop:

```

sage: S = Transducer([(0, 1, None, 'a'), (1, 0, None, 'b')])
sage: S.epsilon_successors(0)
{0: [['a', 'b']], 1: [['a']]}
sage: S.epsilon_successors(1)
{0: [['b']], 1: [['b', 'a']]}

```

equivalence_classes()

Return a list of equivalence classes of states.

OUTPUT:

A list of equivalence classes of states.

Two states a and b are equivalent if and only if there is a bijection φ between paths starting at a and paths starting at b with the following properties: Let p_a be a path from a to a' and p_b a path from b to b' such that $\varphi(p_a) = p_b$, then

- $p_a.word_{in} = p_b.word_{in}$,
- $p_a.word_{out} = p_b.word_{out}$,
- a' and b' have the same output label, and
- a' and b' are both final or both non-final and have the same final output word.

The function `equivalence_classes()` returns a list of the equivalence classes to this equivalence relation.

This is one step of Moore's minimization algorithm.

See also:

`minimization()`

EXAMPLES:

```
sage: fsm = FiniteStateMachine([("A", "B", 0, 1), ("A", "B", 1, 0),
.....:                          ("B", "C", 0, 0), ("B", "C", 1, 1),
.....:                          ("C", "D", 0, 1), ("C", "D", 1, 0),
.....:                          ("D", "A", 0, 0), ("D", "A", 1, 1)])
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
sage: fsm.state("A").is_final = True
sage: sorted(fsm.equivalence_classes())
[['A'], ['B'], ['C'], ['D']]
sage: fsm.state("C").is_final = True
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
sage: fsm.state("A").final_word_out = 1
sage: sorted(fsm.equivalence_classes())
[['A'], ['B'], ['C'], ['D']]
sage: fsm.state("C").final_word_out = 1
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
```

final_components()

Return the final components of a finite state machine as finite state machines.

OUTPUT:

A list of finite state machines, each representing a final component of `self`.

A final component of a transducer T is a strongly connected component C such that there are no transitions of T leaving C .

The final components are the only parts of a transducer which influence the main terms of the asymptotic behaviour of the sum of output labels of a transducer, see [HKP2015] and [HKW2015].

EXAMPLES:

```
sage: T = Transducer([['A', 'B', 0, 0], ['B', 'C', 0, 1],
.....:                  ['C', 'B', 0, 1], ['A', 'D', 1, 0],
.....:                  ['D', 'D', 0, 0], ['D', 'B', 1, 0],
```

(continues on next page)

(continued from previous page)

```

.....:          ['A', 'E', 2, 0], ['E', 'E', 0, 0]])
sage: FC = T.final_components()
sage: sorted(FC[0].transitions())
[Transition from 'B' to 'C': 0|1,
 Transition from 'C' to 'B': 0|1]
sage: FC[1].transitions()
[Transition from 'E' to 'E': 0|0]

```

Another example (cycle of length 2):

```

sage: T = Automaton([[0, 1, 0], [1, 0, 0]])
sage: len(T.final_components()) == 1
True
sage: T.final_components()[0].transitions()
[Transition from 0 to 1: 0|-,
 Transition from 1 to 0: 0|-]

```

final_states()

Return a list of all final states.

OUTPUT:

A list of all final states.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True)
sage: B = FSMState('B', is_initial=True)
sage: C = FSMState('C', is_final=True)
sage: F = FiniteStateMachine([(A, B), (A, C)])
sage: F.final_states()
['A', 'C']

```

format_letter(x, combine_all=False)

Return a `LatexExpr` built out of the argument `x`.

INPUT:

- `x` – a Sage object
- `combine_all` – boolean (Default: `False`) If `combine_all` is `True` and the input is a tuple, then it does not return a tuple and instead returns a string with all the elements separated by a single space.

OUTPUT:

A `LatexExpr` built from `x`

EXAMPLES:

```

sage: latex(Integer(3)) # indirect doctest
3
sage: latex(1==0)
\mathrm{False}
sage: print(latex([x,2]))
\left[x, 2\right]

```

Check that [trac ticket #11775](#) is fixed:

```
sage: latex((x,2), combine_all=True)
x 2
```

format_letter_negative(*letter*)

Format negative numbers as overlined numbers, everything else by standard LaTeX formatting.

INPUT:

letter – anything.

OUTPUT:

Overlined absolute value if *letter* is a negative integer, `latex(letter)` otherwise.

EXAMPLES:

```
sage: A = Automaton([(0, 0, -1)])
sage: list(map(A.format_letter_negative, [-1, 0, 1, 'a', None]))
['\overline{1}', 0, 1, \text{\texttt{a}}, \mathrm{None}]
sage: A.latex_options(format_letter=A.format_letter_negative)
sage: print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\path[->] (v0) edge[loop above] node {$\overline{1}$} ();
\end{tikzpicture}
```

format_transition_label(*word*)

Default formatting of words in transition labels for LaTeX output.

INPUT:

word – list of letters

OUTPUT:

String representation of *word* suitable to be typeset in mathematical mode.

- For a non-empty word: Concatenation of the letters, piped through `self.format_letter` and separated by blanks.
- For an empty word: `sage.combinat.finite_state_machine.EmptyWordLaTeX`.

There is also a variant `format_transition_label_reversed()` writing the words in reversed order.

EXAMPLES:

1. Example of a non-empty word:

```
sage: T = Transducer()
sage: print(T.default_format_transition_label(
.....:    ['a', 'alpha', 'a_1', '0', 0, (0, 1)])
\text{\texttt{a}} \text{\texttt{alpha}}
\text{\texttt{a}\char`\_1}} 0 0 \left(0, 1\right)
```

2. In the example above, 'a' and 'alpha' should perhaps be symbols:

```
sage: var('a alpha a_1') #_
↪ optional - sage.symbolic
(a, alpha, a_1)
```

(continues on next page)

(continued from previous page)

```
sage: print(T.default_format_transition_label([a, alpha, a_1])) #_
↪ optional - sage.symbolic
a \alpha a_{1}
```

3. Example of an empty word:

```
sage: print(T.default_format_transition_label([]))
\varepsilon
```

We can change this by setting `sage.combinat.finite_state_machine.EmptyWordLaTeX`:

```
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
sage: T.default_format_transition_label([])
''
```

Finally, we restore the default value:

```
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

4. This method is the default value for `FiniteStateMachine.format_transition_label`. That can be changed to be any other function:

```
sage: A = Automaton([(0, 1, 0)])
sage: def custom_format_transition_label(word):
....:     return "t"
sage: A.latex_options(format_transition_label=custom_format_transition_
↪ label)
sage: print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\node[state] (v1) at (-3.000000, 0.000000) {$1$};
\path[->] (v0) edge node[rotate=360.00, anchor=south] {$t$} (v1);
\end{tikzpicture}
```

format_transition_label_reversed(*word*)

Format words in transition labels in reversed order.

INPUT:

word – list of letters.

OUTPUT:

String representation of word suitable to be typeset in mathematical mode, letters are written in reversed order.

This is the reversed version of `default_format_transition_label()`.

In digit expansions, digits are frequently processed from the least significant to the most significant position, but it is customary to write the least significant digit at the right-most position. Therefore, the labels have to be reversed.

EXAMPLES:

```
sage: T = Transducer([(0, 0, 0, [1, 2, 3])])
sage: T.format_transition_label_reversed([1, 2, 3])
```

(continues on next page)

(continued from previous page)

```
'3 2 1'
sage: T.latex_options(format_transition_label=T.format_transition_label_
↳reversed)
sage: print(latex(T))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.0000000, 0.0000000) {$0$};
\path[->] (v0) edge[loop above] node {$0\mid 3 2 1$} ();
\end{tikzpicture}
```

graph(*edge_labels*='words_in_out')

Return the graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

- **edge_label**: (default: 'words_in_out') can be
 - 'words_in_out' (labels will be strings 'i|o')
 - a function with which takes as input a transition and outputs (returns) the label

OUTPUT:

A directed graph.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: T = Transducer()
sage: T.graph()
Looped multi-digraph on 0 vertices
sage: T.add_state(A)
'A'
sage: T.graph()
Looped multi-digraph on 1 vertex
sage: T.add_transition(('A', 'A', 0, 1))
Transition from 'A' to 'A': 0|1
sage: T.graph()
Looped multi-digraph on 1 vertex
```

See also:[DiGraph](#)**has_final_state**(*state*)Return whether *state* is one of the final states of the finite state machine.

INPUT:

- *state* can be a *FSMState* or a label.

OUTPUT:

True or False.

EXAMPLES:

```
sage: FiniteStateMachine(final_states=['A']).has_final_state('A')
True
```

has_final_states()

Return whether the finite state machine has a final state.

OUTPUT:

True or False.

EXAMPLES:

```
sage: FiniteStateMachine().has_final_states()
False
```

has_initial_state(*state*)

Return whether *state* is one of the initial states of the finite state machine.

INPUT:

- *state* can be a *FSMState* or a label.

OUTPUT:

True or False.

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'A')], initial_states=['A'])
sage: F.has_initial_state('A')
True
```

has_initial_states()

Return whether the finite state machine has an initial state.

OUTPUT:

True or False.

EXAMPLES:

```
sage: FiniteStateMachine().has_initial_states()
False
```

has_state(*state*)

Return whether *state* is one of the states of the finite state machine.

INPUT:

- *state* can be a *FSMState* or a label of a state.

OUTPUT:

True or False.

EXAMPLES:

```
sage: FiniteStateMachine().has_state('A')
False
```

has_transition(*transition*)

Return whether *transition* is one of the transitions of the finite state machine.

INPUT:

- *transition* has to be a *FSMTransition*.

OUTPUT:

True or False.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'A', 0, 1)
sage: FiniteStateMachine().has_transition(t)
False
sage: FiniteStateMachine().has_transition(('A', 'A', 0, 1))
Traceback (most recent call last):
...
TypeError: Transition is not an instance of FSMTransition.
```

induced_sub_finite_state_machine(states)

Return a sub-finite-state-machine of the finite state machine induced by the given states.

INPUT:

- *states* – a list (or an iterator) of states (either labels or instances of *FSMState*) of the sub-finite-state-machine.

OUTPUT:

A new finite state machine. It consists (of deep copies) of the given states and (deep copies) of all transitions of *self* between these states.

EXAMPLES:

```
sage: FSM = FiniteStateMachine([(0, 1, 0), (0, 2, 0),
.....:                        (1, 2, 0), (2, 0, 0)])
sage: sub_FSM = FSM.induced_sub_finite_state_machine([0, 1])
sage: sub_FSM.states()
[0, 1]
sage: sub_FSM.transitions()
[Transition from 0 to 1: 0|-]
sage: FSM.induced_sub_finite_state_machine([3])
Traceback (most recent call last):
...
ValueError: 3 is not a state of this finite state machine.
```

initial_states()

Return a list of all initial states.

OUTPUT:

A list of all initial states.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_initial=True)
sage: B = FSMState('B')
sage: F = FiniteStateMachine([(A, B, 1, 0)])
sage: F.initial_states()
['A']
```

input_alphabet = None

A list of letters representing the input alphabet of the finite state machine.

It can be set by the parameter `input_alphabet` when initializing a finite state machine, see [FiniteStateMachine](#).

It can also be set by the method `determine_alphabets()`.

See also:

[FiniteStateMachine](#), [determine_alphabets\(\)](#), [output_alphabet](#).

input_projection()

Return an automaton where the output of each transition of self is deleted.

OUTPUT:

An automaton.

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0, 1), ('A', 'A', 1, 1),
.....:                       ('B', 'B', 1, 0)])
sage: G = F.input_projection()
sage: G.transitions()
[Transition from 'A' to 'B': 0|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 1|-]
```

intersection(*other*)

is_Markov_chain(*is_zero=None*)

Checks whether `self` is a Markov chain where the transition probabilities are modeled as input labels.

INPUT:

- `is_zero` – by default (`is_zero=None`), checking for zero is simply done by `is_zero()`. This parameter can be used to provide a more sophisticated check for zero, e.g. in the case of symbolic probabilities, see the examples below.

OUTPUT:

True or False.

`on_duplicate_transition` must be `duplicate_transition_add_input()`, the sum of the input weights of the transitions leaving a state must add up to 1 and the sum of initial probabilities must add up to 1 (or all be None).

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_
      ↪input
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
.....:                [1, 0, 1/2, 0], [1, 1, 1/2, 1]],
.....:                on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
True
```

`on_duplicate_transition` must be `duplicate_transition_add_input()`:

```
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
.....:                [1, 0, 1/2, 0], [1, 1, 1/2, 1]])
sage: F.is_Markov_chain()
False
```

Sum of input labels of the transitions leaving states must be 1:

```
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
.....:                [1, 0, 1/2, 0]],
.....:                on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
False
```

The initial probabilities of all states must be None or they must sum up to 1. The initial probabilities of all states have to be set in the latter case:

```
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
.....:                [1, 0, 1, 0]],
.....:                on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
True
sage: F.state(0).initial_probability = 1/4
sage: F.is_Markov_chain()
False
sage: F.state(1).initial_probability = 7
sage: F.is_Markov_chain()
False
sage: F.state(1).initial_probability = 3/4
sage: F.is_Markov_chain()
True
```

If the probabilities are variables in the symbolic ring, `assume()` will do the trick:

```
sage: var('p q')
↪# optional - sage.symbolic
(p, q)
sage: F = Transducer([(0, 0, p, 1), (0, 0, q, 0)],
↪# optional - sage.symbolic
.....:                on_duplicate_transition=duplicate_transition_add_input)
sage: assume(p + q == 1)
↪# optional - sage.symbolic
sage: (p + q - 1).is_zero()
↪# optional - sage.symbolic
True
sage: F.is_Markov_chain()
↪# optional - sage.symbolic
True
sage: forget()
↪# optional - sage.symbolic
sage: del(p, q)
↪# optional - sage.symbolic
```

If the probabilities are variables in some polynomial ring, the parameter `is_zero` can be used:

```
sage: R.<p, q> = PolynomialRing(QQ)
sage: def is_zero_polynomial(polynomial):
.....:     return polynomial in (p + q - 1)*R
sage: F = Transducer([(0, 0, p, 1), (0, 0, q, 0)],
.....:                on_duplicate_transition=duplicate_transition_add_input)
```

(continues on next page)

(continued from previous page)

```

sage: F.state(0).initial_probability = p + q
sage: F.is_Markov_chain()
False
sage: F.is_Markov_chain(is_zero_polynomial)
True

```

is_complete()

Return whether the finite state machine is complete.

OUTPUT:

True or False

A finite state machine is considered to be complete if each transition has an input label of length one and for each pair (q, a) where q is a state and a is an element of the input alphabet, there is exactly one transition from q with input label a .

EXAMPLES:

```

sage: fsm = FiniteStateMachine([(0, 0, 0, 0),
.....:                        (0, 1, 1, 1),
.....:                        (1, 1, 0, 0)],
.....:                        determine_alphabets=False)
sage: fsm.is_complete()
Traceback (most recent call last):
...
ValueError: No input alphabet is given. Try calling determine_alphabets().
sage: fsm.input_alphabet = [0, 1]
sage: fsm.is_complete()
False
sage: fsm.add_transition((1, 1, 1, 1))
Transition from 1 to 1: 1|1
sage: fsm.is_complete()
True
sage: fsm.add_transition((0, 0, 1, 0))
Transition from 0 to 0: 1|0
sage: fsm.is_complete()
False

```

is_connected()**is_deterministic()**

Return whether the finite finite state machine is deterministic.

OUTPUT:

True or False

A finite state machine is considered to be deterministic if each transition has input label of length one and for each pair (q, a) where q is a state and a is an element of the input alphabet, there is at most one transition from q with input label a . Furthermore, the finite state may not have more than one initial state.

EXAMPLES:

```

sage: fsm = FiniteStateMachine()
sage: fsm.add_transition(('A', 'B', 0, []))
Transition from 'A' to 'B': 0|-

```

(continues on next page)

(continued from previous page)

```

sage: fsm.is_deterministic()
True
sage: fsm.add_transition(('A', 'C', 0, []))
Transition from 'A' to 'C': 0|-
sage: fsm.is_deterministic()
False
sage: fsm.add_transition(('A', 'B', [0,1], []))
Transition from 'A' to 'B': 0,1|-
sage: fsm.is_deterministic()
False

```

Check that [trac ticket #18556](#) is fixed:

```

sage: Automaton().is_deterministic()
True
sage: Automaton(initial_states=[0]).is_deterministic()
True
sage: Automaton(initial_states=[0, 1]).is_deterministic()
False

```

is_monochromatic()

Check whether the colors of all states are equal.

OUTPUT:

True or False

EXAMPLES:

```

sage: G = transducers.GrayCode()
sage: [s.color for s in G.iter_states()]
[None, None, None]
sage: G.is_monochromatic()
True
sage: G.state(1).color = 'blue'
sage: G.is_monochromatic()
False

```

iter_final_states()

Return an iterator of the final states.

OUTPUT:

An iterator over all initial states.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True)
sage: B = FSMState('B', is_initial=True)
sage: C = FSMState('C', is_final=True)
sage: F = FiniteStateMachine([(A, B), (A, C)])
sage: [s.label() for s in F.iter_final_states()]
['A', 'C']

```

iter_initial_states()

Return an iterator of the initial states.

OUTPUT:

An iterator over all initial states.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_initial=True)
sage: B = FSMState('B')
sage: F = FiniteStateMachine([(A, B, 1, 0)])
sage: [s.label() for s in F.iter_initial_states()]
['A']
```

iter_process(*input_tape=None, initial_state=None, process_iterator_class=None, iterator_type=None, automatic_output_type=False, **kwargs*)

This function returns an iterator for processing the input. See [process\(\)](#) (which runs this iterator until the end) for more information.

INPUT:

- *iterator_type* – If *None* (default), then an instance of *FSMProcessIterator* is returned. If this is 'simple' only an iterator over one output is returned (an exception is raised if this is not the case, i.e., if the process has branched).

See [process\(\)](#) for a description of the other parameters.

OUTPUT:

An iterator.

EXAMPLES:

We can use [iter_process\(\)](#) to deal with infinite words:

```
sage: inverter = Transducer({'A': [( 'A', 0, 1), ( 'A', 1, 0)]},
.....:   initial_states=['A'], final_states=['A'])
sage: words.FibonacciWord()
word: 010010100100101001010010010010010010010...
sage: it = inverter.iter_process(
.....:   words.FibonacciWord(), iterator_type='simple')
sage: Words([0,1])(it)
word: 101101011011010110101101011010110101101...
```

This can also be done by:

```
sage: inverter.iter_process(words.FibonacciWord(),
.....:   iterator_type='simple',
.....:   automatic_output_type=True)
word: 101101011011010110101101011010110101101...
```

or even simpler by:

```
sage: inverter(words.FibonacciWord())
word: 101101011011010110101101011010110101101...
```

To see what is going on, we use [iter_process\(\)](#) without arguments:

```

sage: from itertools import islice
sage: it = inverter.iter_process(words.FibonacciWord())
sage: for current in islice(it, 4r):
.....:     print(current)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 3, [[1, 0, 1]]
process (1 branch)
+ at state 'A'
+-- tape at 4, [[1, 0, 1, 1]]

```

The following show the difference between using the 'simple'-option and not using it. With this option, we have

```

sage: it = inverter.iter_process(input_tape=[0, 1, 1],
.....:                          iterator_type='simple')
sage: for i, o in enumerate(it):
.....:     print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 0
step 2: output 0

```

So `iter_process()` is a generator expression which gives a new output letter in each step (and not more). In many cases this is sufficient.

Doing the same without the 'simple'-option does not give the output directly; it has to be extracted first. On the other hand, additional information is presented:

```

sage: it = inverter.iter_process(input_tape=[0, 1, 1])
sage: for current in it:
.....:     print(current)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
process (1 branch)
+ at state 'A'
+-- tape at 3, [[1, 0, 0]]
process (0 branches)
sage: it.result()
[Branch(accept=True, state='A', output=[1, 0, 0])]

```

One can see the growing of the output (the list of lists at the end of each entry).

Even if the transducer has transitions with empty or multiletter output, the simple iterator returns one new output letter in each step:

```

sage: T = Transducer([(0, 0, 0, []),
.....:                (0, 0, 1, [1]),
.....:                (0, 0, 2, [2, 2])],
.....:                initial_states=[0])
sage: it = T.iter_process(input_tape=[0, 1, 2, 0, 1, 2],
.....:                    iterator_type='simple')
sage: for i, o in enumerate(it):
.....:     print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 2
step 2: output 2
step 3: output 1
step 4: output 2
step 5: output 2

```

See also:

FiniteStateMachine.process(), *Automaton.process()*, *Transducer.process()*, *__call__()*, *FSMProcessIterator*.

iter_states()

Return an iterator of the states.

OUTPUT:

An iterator of the states of the finite state machine.

EXAMPLES:

```

sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: [s.label() for s in FSM.iter_states()]
['1', '2']

```

iter_transitions(*from_state=None*)

Return an iterator of all transitions.

INPUT:

- *from_state* – (default: None) If *from_state* is given, then a list of transitions starting there is given.

OUTPUT:

An iterator of all transitions.

EXAMPLES:

```

sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: [(t.from_state.label(), t.to_state.label())
.....:      for t in FSM.iter_transitions('1')]
[('1', '2')]
sage: [(t.from_state.label(), t.to_state.label())
.....:      for t in FSM.iter_transitions('2')]
[('2', '2')]
sage: [(t.from_state.label(), t.to_state.label())
.....:      for t in FSM.iter_transitions()]
[('1', '2'), ('2', '2')]

```

kleene_star()

Compute the Kleene closure of this finite state machine.

OUTPUT:

A *FiniteStateMachine* of the same type as this finite state machine.

Assume that this finite state machine is an automaton recognizing the language \mathcal{L} . Then the Kleene star recognizes the language $\mathcal{L}^* = \{w_1 \dots w_n \mid n \geq 0, w_j \in \mathcal{L} \text{ for all } j\}$.

Assume that this finite state machine is a transducer realizing a function f on some alphabet \mathcal{L} . Then the Kleene star realizes a function g on \mathcal{L}^* with $g(w_1 \dots w_n) = f(w_1) \dots f(w_n)$.

EXAMPLES:

Kleene star of an automaton:

```
sage: A = automata.Word([0, 1])
sage: B = A.kleene_star()
sage: B.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 2 to 0: -|-,
 Transition from 1 to 2: 1|-]
sage: from sage.combinat.finite_state_machine import (
.....:     is_Automaton, is_Transducer)
sage: is_Automaton(B)
True
sage: [w for w in ([], [0, 1], [0, 1, 0], [0, 1, 0, 1], [0, 1, 1, 1])
.....:     if B(w)]
[[],
 [0, 1],
 [0, 1, 0, 1]]
```

Kleene star of a transducer:

```
sage: T = Transducer([(0, 1, 0, 1), (0, 1, 1, 0)],
.....:                 initial_states=[0],
.....:                 final_states=[1])
sage: S = T.kleene_star()
sage: S.transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: -|-]
sage: is_Transducer(S)
True
sage: for w in ([], [0], [1], [0, 0], [0, 1]):
.....:     print("{} {}".format(w, S.process(w)))
[]      (True, 0, [])
[0]     [(True, 0, [1]), (True, 1, [1])]
[1]     [(True, 0, [0]), (True, 1, [0])]
[0, 0]  [(True, 0, [1, 1]), (True, 1, [1, 1])]
[0, 1]  [(True, 0, [1, 0]), (True, 1, [1, 0])]
```

Final output words are taken into account:

```
sage: T = Transducer([(0, 1, 0, 1)],
.....:                 initial_states=[0],
.....:                 final_states=[1])
sage: T.state(1).final_word_out = 2
```

(continues on next page)

(continued from previous page)

```
sage: S = T.kleene_star()
sage: sorted(S.process([0, 0]))
[(True, 0, [1, 2, 1, 2]), (True, 1, [1, 2, 1, 2])]
```

Final output words may lead to undesirable situations if initial states and final states coincide:

```
sage: T = Transducer(initial_states=[0], final_states=[0])
sage: T.state(0).final_word_out = 1
sage: T([])
[1]
sage: S = T.kleene_star()
sage: S([])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input), but
output is written.
```

language(*max_length=None, **kwargs*)

Return all words that can be written by this transducer.

INPUT:

- *max_length* – an integer or *None* (default). Only output words which come from inputs of length at most *max_length* will be considered. If *None*, then this iterates over all possible words without length restrictions.
- *kwargs* – will be passed on to the *process iterator*. See *process()* for a description.

OUTPUT:

An iterator.

EXAMPLES:

```
sage: NAF = Transducer([(0, 0, 0, 0), (0, 1, 1, 0),
.....:                  (1, 0, 0, 1), (1, 2, 1, -1),
.....:                  (2, 1, 0, 0), (2, 2, 1, 0)],
.....:                  initial_states=['I'], final_states=[0],
.....:                  input_alphabet=[0, 1])
sage: sorted(NAF.language(4),
.....:          key=lambda o: (ZZ(o, base=2), len(o)))
[[[], [0], [0, 0], [0, 0, 0],
 [1], [1, 0], [1, 0, 0],
 [0, 1], [0, 1, 0],
 [-1, 0, 1],
 [0, 0, 1],
 [1, 0, 1]]
```

```
sage: iterator = NAF.language()
sage: next(iterator)
[]
sage: next(iterator)
[0]
sage: next(iterator)
```

(continues on next page)

(continued from previous page)

```
[1]
sage: next(iterator)
[0, 0]
sage: next(iterator)
[0, 1]
```

See also:

[*Automaton.language\(\)*](#), [*process\(\)*](#).

latex_options(*coordinates=None, format_state_label=None, format_letter=None, format_transition_label=None, loop_where=None, initial_where=None, accepting_style=None, accepting_distance=None, accepting_where=None, accepting_show_empty=None*)

Set options for LaTeX output via [`latex\(\)`](#) and therefore [`view\(\)`](#).

INPUT:

- **coordinates** – a dictionary or a function mapping labels of states to pairs interpreted as coordinates. If no coordinates are given, states are placed equidistantly on a circle of radius 3. See also [`set_coordinates\(\)`](#).
- **format_state_label** – a function mapping labels of states to a string suitable for typesetting in LaTeX’s mathematics mode. If not given, [`latex\(\)`](#) is used.
- **format_letter** – a function mapping letters of the input and output alphabets to a string suitable for typesetting in LaTeX’s mathematics mode. If not given, [`default_format_transition_label\(\)`](#) uses [`latex\(\)`](#).
- **format_transition_label** – a function mapping words over the input and output alphabets to a string suitable for typesetting in LaTeX’s mathematics mode. If not given, [`default_format_transition_label\(\)`](#) is used.
- **loop_where** – a dictionary or a function mapping labels of initial states to one of 'above', 'left', 'below', 'right'. If not given, 'above' is used.
- **initial_where** – a dictionary or a function mapping labels of initial states to one of 'above', 'left', 'below', 'right'. If not given, TikZ’ default (currently 'left') is used.
- **accepting_style** – one of 'accepting by double' and 'accepting by arrow'. If not given, 'accepting by double' is used unless there are non-empty final output words.
- **accepting_distance** – a string giving a LaTeX length used for the length of the arrow leading from a final state. If not given, TikZ’ default (currently '3ex') is used unless there are non-empty final output words, in which case '7ex' is used.
- **accepting_where** – a dictionary or a function mapping labels of final states to one of 'above', 'left', 'below', 'right'. If not given, TikZ’ default (currently 'right') is used. If the final state has a final output word, it is also possible to give an angle in degrees.
- **accepting_show_empty** – if True the arrow of an empty final output word is labeled as well. Note that this implicitly implies `accepting_style='accepting by arrow'`. If not given, the default False is used.

OUTPUT:

Nothing.

As TikZ (cf. the [Wikipedia article PGF/TikZ](#)) is used to typeset the graphics, the syntax is oriented on TikZ’ syntax.

This is a convenience function collecting all options for LaTeX output. All of its functionality can also be achieved by directly setting the attributes

- `coordinates`, `format_label`, `loop_where`, `initial_where`, and `accepting_where` of *FSMState* (here, `format_label` is a callable without arguments, everything else is a specific value);
- `format_label` of *FSMTransition* (`format_label` is a callable without arguments);
- `format_state_label`, `format_letter`, `format_transition_label`, `accepting_style`, `accepting_distance`, and `accepting_show_empty` of *FiniteStateMachine*.

This function, however, also (somewhat) checks its input and serves to collect documentation on all these options.

The function can be called several times, only those arguments which are not `None` are taken into account. By the same means, it can be combined with directly setting some attributes as outlined above.

EXAMPLES:

See also the section on *LaTeX output* in the introductory examples of this module.

```
sage: T = Transducer(initial_states=[4],
....:   final_states=[0, 3])

sage: view(T) # not tested

```

markov_chain_simplification()

Consider self as Markov chain with probabilities as input labels and simplify it.

INPUT:

Nothing.

OUTPUT:

Simplified version of self.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import duplicate_transition_add
↳input
sage: T = Transducer([[1, 2, 1/4, 0], [1, -2, 1/4, 0], [1, -2, 1/2, 0],

```

(continues on next page)

(continued from previous page)

```

.....:          [2, 2, 1/4, 1], [2, -2, 1/4, 1], [-2, -2, 1/4, 1],
.....:          [-2, 2, 1/4, 1], [2, 3, 1/2, 2], [-2, 3, 1/2, 2]],
.....:          initial_states=[1],
.....:          final_states=[3],
.....:          on_duplicate_transition=duplicate_transition_add_input)
sage: T1 = T.markov_chain_simplification()
sage: sorted(T1.transitions())
[Transition from ((1,)) to ((2, -2,))): 1|0,
  Transition from ((2, -2,)) to ((2, -2,))): 1/2|1,
  Transition from ((2, -2,)) to ((3,))): 1/2|2]

```

merged_transitions()

Merges transitions which have the same `from_state`, `to_state` and `word_out` while adding their `word_in`.

INPUT:

Nothing.

OUTPUT:

A finite state machine with merged transitions. If no mergers occur, return self.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import duplicate_transition_add_
->input
sage: T = Transducer([[1, 2, 1/4, 1], [1, -2, 1/4, 1], [1, -2, 1/2, 1],
.....:          [2, 2, 1/4, 1], [2, -2, 1/4, 1], [-2, -2, 1/4, 1],
.....:          [-2, 2, 1/4, 1], [2, 3, 1/2, 1], [-2, 3, 1/2, 1]],
.....:          on_duplicate_transition=duplicate_transition_add_input)
sage: T1 = T.merged_transitions()
sage: T1 is T
False
sage: sorted(T1.transitions())
[Transition from -2 to -2: 1/4|1,
  Transition from -2 to 2: 1/4|1,
  Transition from -2 to 3: 1/2|1,
  Transition from 1 to 2: 1/4|1,
  Transition from 1 to -2: 3/4|1,
  Transition from 2 to -2: 1/4|1,
  Transition from 2 to 2: 1/4|1,
  Transition from 2 to 3: 1/2|1]

```

Applying the function again does not change the result:

```

sage: T2 = T1.merged_transitions()
sage: T2 is T1
True

```

moments_waiting_time(*test=<class 'bool'>, is_zero=None, expectation_only=False*)

If this finite state machine acts as a Markov chain, return the expectation and variance of the number of steps until first writing True.

INPUT:

- `test` – (default: `bool`) a callable deciding whether an output label is to be considered `True`. By default, the standard conversion to boolean is used.
- `is_zero` – (default: `None`) a callable deciding whether an expression for a probability is zero. By default, checking for zero is simply done by `is_zero()`. This parameter can be used to provide a more sophisticated check for zero, e.g. in the case of symbolic probabilities, see the examples below. This parameter is passed on to `is_Markov_chain()`. This parameter only affects the input of the Markov chain.
- `expectation_only` – (default: `False`) if set, the variance is not computed (in order to save time). By default, the variance is computed.

OUTPUT:

A dictionary (if `expectation_only=False`) consisting of

- `expectation`,
- `variance`.

Otherwise, just the expectation is returned (no dictionary for `expectation_only=True`).

Expectation and variance of the number of steps until first writing `True` (as determined by the parameter `test`).

ALGORITHM:

Relies on a (classical and easy) probabilistic argument, cf. [FGT1992], Eqns. (6) and (7).

For the variance, see [FHP2015], Section 2.

EXAMPLES:

1. The simplest example is to wait for the first 1 in a 0-1-string where both digits appear with probability $1/2$. In fact, the waiting time equals k if and only if the string starts with $0^{k-1}1$. This event occurs with probability 2^{-k} . Therefore, the expected waiting time and the variance are $\sum_{k \geq 1} k2^{-k} = 2$ and $\sum_{k \geq 1} (k-2)^2 2^{-k} = 2$:

```
sage: var('k')
k
sage: sum(k * 2^(-k), k, 1, infinity)
2
sage: sum((k-2)^2 * 2^(-k), k, 1, infinity)
2
```

We now compute the same expectation and variance by using a Markov chain:

```
sage: from sage.combinat.finite_state_machine import (
.....:     duplicate_transition_add_input)
sage: T = Transducer(
.....:     [(0, 0, 1/2, 0), (0, 0, 1/2, 1)],
.....:     on_duplicate_transition=\
.....:         duplicate_transition_add_input,
.....:     initial_states=[0],
.....:     final_states=[0])
sage: T.moments_waiting_time()
{'expectation': 2, 'variance': 2}
sage: T.moments_waiting_time(expectation_only=True)
2
```

In the following, we replace the output `0` by `-1` and demonstrate the use of the parameter `test`:

```
sage: T.delete_transition((0, 0, 1/2, 0))
sage: T.add_transition((0, 0, 1/2, -1))
Transition from 0 to 0: 1/2|-1
sage: T.moments_waiting_time(test=lambda x: x<0)
{'expectation': 2, 'variance': 2}
```

2. Make sure that the transducer is actually a Markov chain. Although this is checked by the code, unexpected behaviour may still occur if the transducer looks like a Markov chain. In the following example, we ‘forget’ to assign probabilities, but due to a coincidence, all ‘probabilities’ add up to one. Nevertheless, 0 is never written, so the expectation is 1.

```
sage: T = Transducer([(0, 0, 0, 0), (0, 0, 1, 1)],
.....:                on_duplicate_transition=\
.....:                duplicate_transition_add_input,
.....:                initial_states=[0],
.....:                final_states=[0])
sage: T.moments_waiting_time()
{'expectation': 1, 'variance': 0}
```

3. If True is never written, the moments are +Infinity:

```
sage: T = Transducer([(0, 0, 1, 0)],
.....:                on_duplicate_transition=\
.....:                duplicate_transition_add_input,
.....:                initial_states=[0],
.....:                final_states=[0])
sage: T.moments_waiting_time()
{'expectation': +Infinity, 'variance': +Infinity}
```

4. Let h and r be positive integers. We consider random strings of letters $1, \dots, r$ where the letter j occurs with probability p_j . Let B be the random variable giving the first position of a block of h consecutive identical letters. Then

$$\mathbb{E}(B) = \frac{1}{\sum_{i=1}^r \frac{1}{p_i^{-1} + \dots + p_i^{-h}}},$$

$$\mathbb{V}(B) = \frac{\sum_{i=1}^r \left(\frac{p_i + p_i^h}{1 - p_i^h} - 2h \frac{p_i^h (1 - p_i)}{(1 - p_i^h)^2} \right)}{\left(\sum_{i=1}^r \frac{1}{p_i^{-1} + \dots + p_i^{-h}} \right)^2}$$

cf. [S1986], p. 62, or [FHP2015], Theorem 1. We now verify this with a transducer approach.

```
sage: def test(h, r):
.....:     R = PolynomialRing(
.....:         QQ,
.....:         names=['p_%d' % j for j in range(r)])
.....:     p = R.gens()
.....:     def is_zero(polynomial):
.....:         return polynomial in (sum(p) - 1) * R
.....:     theory_expectation = 1/(sum(1/sum(p[j]^(-i)
.....:         for i in range(1, h+1))
```

(continues on next page)

(continued from previous page)

```

.....:         for j in range(r))
.....: theory_variance = sum(
.....:     (p[i] + p[i]^h)/(1 - p[i]^h)
.....:     - 2*h*p[i]^h * (1 - p[i])/(1 - p[i]^h)^2
.....:     for i in range(r)
.....:     ) * theory_expectation^2
.....: alphabet = list(range(r))
.....: counters = [
.....:     transducers.CountSubblockOccurrences([j]*h,
.....:         alphabet)
.....:     for j in alphabet]
.....: all_counter = counters[0].cartesian_product(
.....:     counters[1:])
.....: adder = transducers.add(input_alphabet=[0, 1],
.....:     number_of_operands=r)
.....: probabilities = Transducer(
.....:     [(0, 0, p[j], j) for j in alphabet],
.....:     initial_states=[0],
.....:     final_states=[0],
.....:     on_duplicate_transition=\
.....:         duplicate_transition_add_input)
.....: chain = adder(all_counter(probabilities))
.....: result = chain.moments_waiting_time(
.....:     is_zero=is_zero)
.....: return is_zero((result['expectation'] -
.....:     theory_expectation).numerator()) \
.....:     and \
.....:     is_zero((result['variance'] -
.....:     theory_variance).numerator())
sage: test(2, 2)
True
sage: test(2, 3)
True
sage: test(3, 3)
True

```

5. Consider the alphabet $\{0, \dots, r-1\}$, some $1 \leq j \leq r$ and some $h \geq 1$. For some probabilities p_0, \dots, p_{r-1} , we consider infinite words where the letters occur independently with the given probabilities. The random variable B_j is the first position n such that there exist j of the r letters having an h -run. The expectation of B_j is given in [FHP2015], Theorem 2. Here, we verify this result by using transducers:

```

sage: def test(h, r, j):
.....:     R = PolynomialRing(
.....:         QQ,
.....:         names=['p_%d' % i for i in range(r)])
.....:     p = R.gens()
.....:     def is_zero(polynomial):
.....:         return polynomial in (sum(p) - 1) * R
.....:     alphabet = list(range(r))
.....:     counters = [
.....:         transducers.Wait([0, 1])(
.....:             transducers.CountSubblockOccurrences(

```

(continues on next page)

(continued from previous page)

```

.....:         [i]*h,

.....:                     {v[i]: alpha[i]})
.....:             expectation += summand
.....:     return is_zero((result - expectation).\
.....:         numerator())
sage: test(2, 3, 2)
True

```

REFERENCES:

number_of_words (*variable=None, base_ring=None*)

Return the number of successful input words of given length.

INPUT:

- `variable` – a symbol denoting the length of the words, by default n .
- `base_ring` – Ring (default: `QQbar`) in which to compute the eigenvalues.

OUTPUT:

A symbolic expression.

EXAMPLES:

```
sage: NAFpm = Automaton([(0, 0, 0), (0, 1, 1),
.....:                 (0, 1, -1), (1, 0, 0)],
.....:                 initial_states=[0],
.....:                 final_states=[0, 1])
sage: N = NAFpm.number_of_words(); N                               # optional -u
↪sage.symbolic
4/3*2^n - 1/3*(-1)^n
sage: all(len(list(NAFpm.language(s)))                             # optional -u
↪sage.symbolic
.....: - len(list(NAFpm.language(s-1))) == N.subs(n=s)
.....:   for s in srange(1, 6))
True
```

An example with non-rational eigenvalues. By default, eigenvalues are elements of the field of algebraic numbers.

```
sage: NAFp = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 0)],
.....:                 initial_states=[0],
.....:                 final_states=[0, 1])
sage: N = NAFp.number_of_words(); N                               # optional -u
↪sage.symbolic
1.170820393249937?*1.618033988749895?^n
- 0.1708203932499369?*(-0.618033988749895?)^n
sage: all(len(list(NAFp.language(s)))                             # optional -u
↪sage.symbolic
.....: - len(list(NAFp.language(s-1))) == N.subs(n=s)
.....:   for s in srange(1, 6))
True
```

We specify a suitable `base_ring` to obtain a radical expression. To do so, we first compute the characteristic polynomial and then construct a number field generated by its roots.

```
sage: M = NAFp.adjacency_matrix(entry=lambda t: 1)
sage: M.characteristic_polynomial()                               # optional -u
↪sage.symbolic
x^2 - x - 1
sage: R.<phi> = NumberField(x^2-x-1, embedding=1.6)                # optional -u
↪sage.symbolic
sage: N = NAFp.number_of_words(base_ring=R); N                   # optional -u
↪sage.symbolic
1/2*(1/2*sqrt(5) + 1/2)^n*(3*sqrt(1/5) + 1)
- 1/2*(-1/2*sqrt(5) + 1/2)^n*(3*sqrt(1/5) - 1)
sage: all(len(list(NAFp.language(s)))                             # optional -u
↪sage.symbolic
.....: - len(list(NAFp.language(s-1))) == N.subs(n=s)
```

(continues on next page)

(continued from previous page)

```
.....:   for s in xrange(1, 6))
True
```

In this special case, we might also use the constant `golden_ratio`:

```
sage: R.<phi> = NumberField(x^2-x-1, embedding=golden_ratio) # optional -
↪sage.symbolic
sage: N = NAFp.number_of_words(base_ring=R); N # optional -
↪sage.symbolic
1/5*(3*golden_ratio + 1)*golden_ratio^n
- 1/5*(3*golden_ratio - 4)*(-golden_ratio + 1)^n
sage: all(len(list(NAFp.language(s))) # optional -
↪sage.symbolic
.....:   - len(list(NAFp.language(s-1))) == N.subs(n=s)
.....:   for s in xrange(1, 6))
True
```

The adjacency matrix of the following example is a Jordan matrix of size 3 to the eigenvalue 4:

```
sage: J3 = Automaton([(0, 1, -1), (1, 2, -1)],
.....:   initial_states=[0],
.....:   final_states=[0, 1, 2])
sage: for i in range(3):
.....:   for j in range(4):
.....:       new_transition = J3.add_transition(i, i, j)
sage: J3.adjacency_matrix(entry=lambda t: 1)
[4 1 0]
[0 4 1]
[0 0 4]
sage: N = J3.number_of_words(); N # optional -
↪sage.symbolic
1/2*4^(n - 2)*(n - 1)*n + 4^(n - 1)*n + 4^n
sage: all(len(list(J3.language(s))) # optional -
↪sage.symbolic
.....:   - len(list(J3.language(s-1))) == N.subs(n=s)
.....:   for s in xrange(1, 6))
True
```

Here is an automaton without cycles, so with eigenvalue 0.

```
sage: A = Automaton([(j, j+1, 0) for j in range(3)],
.....:   initial_states=[0],
.....:   final_states=list(range(3)))
sage: A.number_of_words() # optional -
↪sage.symbolic
1/2*0^(n - 2)*(n - 1)*n + 0^(n - 1)*n + 0^n
```

`on_duplicate_transition = <function duplicate_transition_ignore>`

Which function to call when a duplicate transition is inserted.

It can be set by the parameter `on_duplicate_transition` when initializing a finite state machine, see [FiniteStateMachine](#).

See also:

FiniteStateMachine, *is_Markov_chain()*, *markov_chain_simplification()*.

output_alphabet = None

A list of letters representing the output alphabet of the finite state machine.

It can be set by the parameter `output_alphabet` when initializing a finite state machine, see *FiniteStateMachine*.

It can also be set by the method *determine_alphabets()*.

See also:

FiniteStateMachine, *determine_alphabets()*, *input_alphabet*.

output_projection()

Return a automaton where the input of each transition of self is deleted and the new input is the original output.

OUTPUT:

An automaton.

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0, 1), ('A', 'A', 1, 1),
.....:                       ('B', 'B', 1, 0)])
sage: G = F.output_projection()
sage: G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]
```

Final output words are also considered correctly:

```
sage: H = Transducer([('A', 'B', 0, 1), ('A', 'A', 1, 1),
.....:                ('B', 'B', 1, 0), ('A', ('final', 0), 0, 0)],
.....:                final_states=['A', 'B'])
sage: H.state('B').final_word_out = 2
sage: J = H.output_projection()
sage: J.states()
['A', 'B', ('final', 0), ('final', 1)]
sage: J.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'A' to ('final', 0): 0|-,
 Transition from 'B' to 'B': 0|-,
 Transition from 'B' to ('final', 1): 2|-]
sage: J.final_states()
['A', ('final', 1)]
```

plot()

Plots a graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

Nothing.

OUTPUT:

A plot of the graph of the finite state machine.

predecessors(*state*, *valid_input=None*)

Lists all predecessors of a state.

INPUT:

- *state* – the state from which the predecessors should be listed.
- *valid_input* – If *valid_input* is a list, then we only consider transitions whose input labels are contained in *valid_input*. *state* has to be a *FSMState* (not a label of a state). If input labels of length larger than 1 are used, then *valid_input* has to be a list of lists.

OUTPUT:

A list of states.

EXAMPLES:

```
sage: A = Transducer([(('I', 'A', 'a', 'b'), ('I', 'B', 'b', 'c'),
.....:                  ('I', 'C', 'c', 'a'), ('A', 'F', 'b', 'a'),
.....:                  ('B', 'F', ['c', 'b'], 'b'), ('C', 'F', 'a', 'c'))],
.....:                  initial_states=['I'], final_states=['F'])
sage: A.predecessors(A.state('A'))
['A', 'I']
sage: A.predecessors(A.state('F'), valid_input=['b', 'a'])
['F', 'C', 'A', 'I']
sage: A.predecessors(A.state('F'), valid_input=[[ 'c', 'b'], 'a'])
['F', 'C', 'B']
```

prepone_output()

For all paths, shift the output of the path from one transition to the earliest possible preceding transition of the path.

INPUT:

Nothing.

OUTPUT:

Nothing.

Apply the following to each state *s* (except initial states) of the finite state machine as often as possible:

If the letter *a* is a prefix of the output label of all transitions from *s* (including the final output of *s*), then remove it from all these labels and append it to all output labels of all transitions leading to *s*.

We assume that the states have no output labels, but final outputs are allowed.

EXAMPLES:

```
sage: A = Transducer([(('A', 'B', 1, 1),
.....:                  ('B', 'B', 0, 0),
.....:                  ('B', 'C', 1, 0))],
.....:                  initial_states=['A'],
.....:                  final_states=['C'])
sage: A.prepone_output()
sage: A.transitions()
[Transition from 'A' to 'B': 1|1,0,
Transition from 'B' to 'B': 0|0,
Transition from 'B' to 'C': 1|-]
```

```

sage: B = Transducer([('A', 'B', 0, 1),
.....:                ('B', 'C', 1, [1, 1]),
.....:                ('B', 'C', 0, 1)],
.....:                initial_states=['A'],
.....:                final_states=['C'])
sage: B.prepone_output()
sage: B.transitions()
[Transition from 'A' to 'B': 0|1,1,
  Transition from 'B' to 'C': 1|1,
  Transition from 'B' to 'C': 0|-]

```

If initial states are not labeled as such, unexpected results may be obtained:

```

sage: C = Transducer([(0,1,0,0)])
sage: C.prepone_output()
verbose 0 (...: finite_state_machine.py, prepone_output)
All transitions leaving state 0 have an output label with
prefix 0. However, there is no inbound transition and it
is not an initial state. This routine (possibly called by
simplification) therefore erased this prefix from all
outbound transitions.
sage: C.transitions()
[Transition from 0 to 1: 0|-]

```

Also the final output of final states can be changed:

```

sage: T = Transducer([('A', 'B', 0, 1),
.....:                ('B', 'C', 1, [1, 1]),
.....:                ('B', 'C', 0, 1)],
.....:                initial_states=['A'],
.....:                final_states=['B'])
sage: T.state('B').final_word_out = [1]
sage: T.prepone_output()
sage: T.transitions()
[Transition from 'A' to 'B': 0|1,1,
  Transition from 'B' to 'C': 1|1,
  Transition from 'B' to 'C': 0|-]
sage: T.state('B').final_word_out
[]

```

```

sage: S = Transducer([('A', 'B', 0, 1),
.....:                ('B', 'C', 1, [1, 1]),
.....:                ('B', 'C', 0, 1)],
.....:                initial_states=['A'],
.....:                final_states=['B'])
sage: S.state('B').final_word_out = [0]
sage: S.prepone_output()
sage: S.transitions()
[Transition from 'A' to 'B': 0|1,
  Transition from 'B' to 'C': 1|1,1,
  Transition from 'B' to 'C': 0|1]
sage: S.state('B').final_word_out
[0]

```

Output labels do not have to be hashable:

```
sage: C = Transducer([(0, 1, 0, []),
.....:                (1, 0, 0, [vector([0, 0]), 0]),
.....:                (1, 1, 1, [vector([0, 0]), 1]),
.....:                (0, 0, 1, 0)],
.....:                determine_alphabets=False,
.....:                initial_states=[0])
sage: C.prepone_output()
sage: sorted(C.transitions())
[Transition from 0 to 1: 0|(0, 0),
Transition from 0 to 0: 1|0,
Transition from 1 to 0: 0|0,
Transition from 1 to 1: 1|1,(0, 0)]
```

process(*args, **kwargs)

Return whether the finite state machine accepts the input, the state where the computation stops and which output is generated.

INPUT:

- **input_tape** – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- **initial_state** or **initial_states** – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- **list_of_outputs** – (default: `None`) a boolean or `None`. If `True`, then the outputs are given in list form (even if we have no or only one single output). If `False`, then the result is never a list (an exception is raised if the result cannot be returned). If `list_of_outputs=None`, the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).
- **only_accepted** – (default: `False`) a boolean. If set, then the first argument in the output is guaranteed to be `True` (if the output is a list, then the first argument of each element will be `True`).
- **always_include_output** – if set (not by default), always include the output. This is inconsequential for a *FiniteStateMachine*, but can be used in derived classes where the output is suppressed by default, cf. *Automaton.process()*.
- **format_output** – a function that translates the written output (which is in form of a list) to something more readable. By default (`None`) identity is used here.
- **check_epsilon_transitions** – (default: `True`) a boolean. If `False`, then epsilon transitions are not taken into consideration during process.
- **write_final_word_out** – (default: `True`) a boolean specifying whether the final output words should be written or not.
- **use_multitape_input** – (default: `False`) a boolean. If `True`, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- **process_all_prefixes_of_input** – (default: `False`) a boolean. If `True`, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

- `process_iterator_class` – (default: `None`) a class inherited from `FSMProcessIterator`. If `None`, then `FSMProcessIterator` is taken. An instance of this class is created and is used during the processing.
- `automatic_output_type` – (default: `False`) a boolean. If set and the input has a parent, then the output will have the same parent. If the input does not have a parent, then the output will be of the same type as the input.

OUTPUT:

A triple (or a list of triples, cf. parameter `list_of_outputs`), where

- the first entry is `True` if the input string is accepted,
- the second gives the reached state after processing the input tape (This is a state with label `None` if the input could not be processed, i.e., if at one point no transition to go on could be found.), and
- the third gives a list of the output labels written during processing (in the case the finite state machine runs as transducer).

Note that in the case the finite state machine is not deterministic, all possible paths are taken into account.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see `__call__()` for a version of `process()` with shortened output.

Internally this function creates and works with an instance of `FSMProcessIterator`. This iterator can also be obtained with `iter_process()`.

If working with multi-tape finite state machines, all input words of transitions are words of k -tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

Warning: Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

```
sage: binary_inverter = FiniteStateMachine({'A': [('A', 0, 1), ('A', 1, 0)]},
.....:                                     initial_states=['A'], final_states=[
->'A'])
sage: binary_inverter.process([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

Alternatively, we can invoke this function by:

```
sage: binary_inverter([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

Below we construct a finite state machine which tests if an input is a non-adjacent form, i.e., no two neighboring letters are both nonzero (see also the example on *non-adjacent forms* in the documentation of the module *Finite state machines, automata, transducers*):

```
sage: NAF = FiniteStateMachine(
.....:     {'_': [(('_', 0), (1, 1)], 1: [(('_', 0)]},
.....:     initial_states=['_'], final_states=['_', 1])
sage: [NAF.process(w)[0] for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
.....:                             [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[True, True, False, True, False, False]
```

Working only with the first component (i.e., returning whether accepted or not) usually corresponds to using the more specialized class *Automaton*.

Non-deterministic finite state machines can be handled as well.

```
sage: T = Transducer([(0, 1, 0, 0), (0, 2, 0, 0)],
.....:     initial_states=[0])
sage: T.process([0])
[(False, 1, [0]), (False, 2, [0])]
```

Here is another non-deterministic finite state machine. Note that we use `format_output` (see *FSMProcessIterator*) to convert the written outputs (all characters) to strings.

```
sage: T = Transducer([(0, 1, [0, 0], 'a'), (0, 2, [0, 0, 1], 'b'),
.....:                 (0, 1, 1, 'c'), (1, 0, [], 'd'),
.....:                 (1, 1, 1, 'e')],
.....:     initial_states=[0], final_states=[0, 1])
sage: T.process([0], format_output=lambda o: ''.join(o))
(False, None, None)
sage: T.process([0, 0], format_output=lambda o: ''.join(o))
[(True, 0, 'ad'), (True, 1, 'a')]
sage: T.process([1], format_output=lambda o: ''.join(o))
[(True, 0, 'cd'), (True, 1, 'c')]
sage: T.process([1, 1], format_output=lambda o: ''.join(o))
[(True, 0, 'cdcd'), (True, 0, 'ced'),
 (True, 1, 'cdc'), (True, 1, 'ce')]
sage: T.process([0, 0, 1], format_output=lambda o: ''.join(o))
[(False, 2, 'b'),
 (True, 0, 'adcd'),
 (True, 0, 'aed'),
 (True, 1, 'adc'),
 (True, 1, 'ae')]
sage: T.process([0, 0, 1], format_output=lambda o: ''.join(o),
.....:     only_accepted=True)
[(True, 0, 'adcd'), (True, 0, 'aed'),
 (True, 1, 'adc'), (True, 1, 'ae')]
```

A simple example of a multi-tape finite state machine is the following: It writes the length of the first tape many letters a and then the length of the second tape many letters b:

```
sage: M = FiniteStateMachine([(0, 0, (1, None), 'a'),
.....:                       (0, 1, [], []),
.....:                       (1, 1, (None, 1), 'b')],
.....:     initial_states=[0],
```

(continues on next page)

(continued from previous page)

```

.....:                               final_states=[1])
sage: M.process([[1, 1], [1]], use_multitape_input=True)
(True, 1, ['a', 'a', 'b'])

```

product_FiniteStateMachine(*other*, *function*, *new_input_alphabet=None*,
only_accessible_components=True, *final_function=None*,
new_class=None)

Return a new finite state machine whose states are d -tuples of states of the original finite state machines.

INPUT:

- *other* – a finite state machine (for $d = 2$) or a list (or iterable) of $d - 1$ finite state machines.
- *function* has to accept d transitions from A_j to B_j for $j \in \{1, \dots, d\}$ and returns a pair (*word_in*, *word_out*) which is the label of the transition $A = (A_1, \dots, A_d)$ to $B = (B_1, \dots, B_d)$. If there is no transition from A to B , then *function* should raise a `LookupError`.
- *new_input_alphabet* (optional) – the new input alphabet as a list.
- *only_accessible_components* – If `True` (default), then the result is piped through *accessible_components()*. If no *new_input_alphabet* is given, it is determined by *determine_alphabets()*.
- *final_function* – A function mapping d final states of the original finite state machines to the final output of the corresponding state in the new finite state machine. By default, the final output is the empty word if both final outputs of the constituent states are empty; otherwise, a `ValueError` is raised.
- *new_class* – Class of the new finite state machine. By default (`None`), the class of `self` is used.

OUTPUT:

A finite state machine whose states are d -tuples of states of the original finite state machines. A state is initial or final if all constituent states are initial or final, respectively.

The labels of the transitions are defined by *function*.

The final output of a final state is determined by calling *final_function* on the constituent states.

The color of a new state is the tuple of colors of the constituent states of *self* and *other*. However, if all constituent states have color `None`, then the state has color `None`, too.

EXAMPLES:

```

sage: F = Automaton([('A', 'B', 1), ('A', 'A', 0), ('B', 'A', 2)],
.....:              initial_states=['A'], final_states=['B'],
.....:              determine_alphabets=True)
sage: G = Automaton([(1, 1, 1)], initial_states=[1], final_states=[1])
sage: def addition(transition1, transition2):
.....:     return (transition1.word_in[0] + transition2.word_in[0],
.....:           None)
sage: H = F.product_FiniteStateMachine(G, addition, [0, 1, 2, 3], only_
↳accessible_components=False)
sage: H.transitions()
[Transition from ('A', 1) to ('B', 1): 2|- ,
Transition from ('A', 1) to ('A', 1): 1|- ,

```

(continues on next page)

(continued from previous page)

```

Transition from ('B', 1) to ('A', 1): 3|-]
sage: [s.color for s in H.iter_states()]
[None, None]
sage: H1 = F.product_FiniteStateMachine(G, addition, [0, 1, 2, 3], only_
↳accessible_components=False)
sage: H1.states()[0].label()[0] is F.states()[0]
True
sage: H1.states()[0].label()[1] is G.states()[0]
True

```

```

sage: F = Automaton([(0,1,1/4), (0,0,3/4), (1,1,3/4), (1,0,1/4)],
.....:               initial_states=[0] )
sage: G = Automaton([(0,0,1), (1,1,3/4), (1,0,1/4)],
.....:               initial_states=[0] )
sage: H = F.product_FiniteStateMachine(
.....:       G, lambda t1,t2: (t1.word_in[0]*t2.word_in[0], None))
sage: H.states()
[(0, 0), (1, 0)]

```

```

sage: F = Automaton([(0,1,1/4), (0,0,3/4), (1,1,3/4), (1,0,1/4)],
.....:               initial_states=[0] )
sage: G = Automaton([(0,0,1), (1,1,3/4), (1,0,1/4)],
.....:               initial_states=[0] )
sage: H = F.product_FiniteStateMachine(G,
.....:               lambda t1,t2: (t1.word_in[0]*t2.word_
↳in[0], None),
.....:               only_accessible_components=False)
sage: H.states()
[(0, 0), (1, 0), (0, 1), (1, 1)]

```

Also final output words are considered according to the function `final_function`:

```

sage: F = Transducer([(0, 1, 0, 1), (1, 1, 1, 1), (1, 1, 0, 1)],
.....:                final_states=[1])
sage: F.state(1).final_word_out = 1
sage: G = Transducer([(0, 0, 0, 1), (0, 0, 1, 0)], final_states=[0])
sage: G.state(0).final_word_out = 1
sage: def minus(t1, t2):
.....:     return (t1.word_in[0] - t2.word_in[0],
.....:            t1.word_out[0] - t2.word_out[0])
sage: H = F.product_FiniteStateMachine(G, minus)
Traceback (most recent call last):
...
ValueError: A final function must be given.
sage: def plus(s1, s2):
.....:     return s1.final_word_out[0] + s2.final_word_out[0]
sage: H = F.product_FiniteStateMachine(G, minus,
.....:               final_function=plus)
sage: H.final_states()
[(1, 0)]
sage: H.final_states()[0].final_word_out
[2]

```

Products of more than two finite state machines are also possible:

```
sage: def plus(s1, s2, s3):
.....:     if s1.word_in == s2.word_in == s3.word_in:
.....:         return (s1.word_in,
.....:                 sum(s.word_out[0] for s in (s1, s2, s3)))
.....:     else:
.....:         raise LookupError
sage: T0 = transducers.CountSubblockOccurrences([0, 0], [0, 1, 2])
sage: T1 = transducers.CountSubblockOccurrences([1, 1], [0, 1, 2])
sage: T2 = transducers.CountSubblockOccurrences([2, 2], [0, 1, 2])
sage: T = T0.product_FiniteStateMachine([T1, T2], plus)
sage: T.transitions()
[Transition from ((, ), (, )) to ((0, ), (, )): 0|0,
 Transition from ((, ), (, )) to ((, ), (1, ), (, )): 1|0,
 Transition from ((, ), (, )) to ((, ), (, ), (2, )): 2|0,
 Transition from ((0, ), (, )) to ((0, ), (, ), (, )): 0|1,
 Transition from ((0, ), (, )) to ((, ), (1, ), (, )): 1|0,
 Transition from ((0, ), (, )) to ((, ), (, ), (2, )): 2|0,
 Transition from ((, ), (1, ), (, )) to ((0, ), (, ), (, )): 0|0,
 Transition from ((, ), (1, ), (, )) to ((, ), (1, ), (, )): 1|1,
 Transition from ((, ), (1, ), (, )) to ((, ), (, ), (2, )): 2|0,
 Transition from ((, ), (, ), (2, )) to ((0, ), (, ), (, )): 0|0,
 Transition from ((, ), (, ), (2, )) to ((, ), (1, ), (, )): 1|0,
 Transition from ((, ), (, ), (2, )) to ((, ), (, ), (2, )): 2|1]
sage: T([0, 0, 1, 1, 2, 2, 0, 1, 2, 2])
[0, 1, 0, 1, 0, 1, 0, 0, 0, 1]
```

other can also be an iterable:

```
sage: T == T0.product_FiniteStateMachine(iter([T1, T2]), plus)
True
```

projection(*what*='input')

Return an Automaton which transition labels are the projection of the transition labels of the input.

INPUT:

- *what* – (default: input) either input or output.

OUTPUT:

An automaton.

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0, 1), ('A', 'A', 1, 1),
.....:                       ('B', 'B', 1, 0)])
sage: G = F.projection(what='output')
sage: G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]
```

quotient(*classes*)

Construct the quotient with respect to the equivalence classes.

INPUT:

- `classes` is a list of equivalence classes of states.

OUTPUT:

A finite state machine.

The labels of the new states are tuples of states of the `self`, corresponding to `classes`.

Assume that c is a class, and a and b are states in c . Then there is a bijection φ between the transitions from a and the transitions from b with the following properties: if $\varphi(t_a) = t_b$, then

- $t_a.word_{in} = t_b.word_{in}$,
- $t_a.word_{out} = t_b.word_{out}$, and
- t_a and t_b lead to some equivalent states a' and b' .

Non-initial states may be merged with initial states, the resulting state is an initial state.

All states in a class must have the same `is_final`, `final_word_out` and `word_out` values.

EXAMPLES:

```
sage: fsm = FiniteStateMachine([("A", "B", 0, 1), ("A", "B", 1, 0),
.....:                          ("B", "C", 0, 0), ("B", "C", 1, 1),
.....:                          ("C", "D", 0, 1), ("C", "D", 1, 0),
.....:                          ("D", "A", 0, 0), ("D", "A", 1, 1)])
sage: fsmq = fsm.quotient([[fsm.state("A"), fsm.state("C")],
.....:                    [fsm.state("B"), fsm.state("D")]])
sage: fsmq.transitions()
[Transition from ('A', 'C')
  to ('B', 'D'): 0|1,
  Transition from ('A', 'C')
  to ('B', 'D'): 1|0,
  Transition from ('B', 'D')
  to ('A', 'C'): 0|0,
  Transition from ('B', 'D')
  to ('A', 'C'): 1|1]
sage: fsmq.relabeled().transitions()
[Transition from 0 to 1: 0|1,
  Transition from 0 to 1: 1|0,
  Transition from 1 to 0: 0|0,
  Transition from 1 to 0: 1|1]
sage: fsmq1 = fsm.quotient(fsm.equivalence_classes())
sage: fsmq1 == fsmq
True
sage: fsm.quotient([[fsm.state("A"), fsm.state("B"), fsm.state("C"), fsm.state(
↪ "D")]])
Traceback (most recent call last):
...
AssertionError: Transitions of state 'A' and 'B' are incompatible.
```

relabeled(*memo=None, labels=None*)

Return a deep copy of the finite state machine, but the states are relabeled.

INPUT:

- `memo` – (default: `None`) a dictionary storing already processed elements.
- `labels` – (default: `None`) a dictionary or callable mapping old labels to new labels. If `None`, then the new labels are integers starting with 0.

OUTPUT:

A new finite state machine.

EXAMPLES:

```
sage: FSM1 = FiniteStateMachine([('A', 'B'), ('B', 'C'), ('C', 'A')])
sage: FSM1.states()
['A', 'B', 'C']
sage: FSM2 = FSM1.relabeled()
sage: FSM2.states()
[0, 1, 2]
sage: FSM3 = FSM1.relabeled(labels={'A': 'a', 'B': 'b', 'C': 'c'})
sage: FSM3.states()
['a', 'b', 'c']
sage: FSM4 = FSM2.relabeled(labels=lambda x: 2*x)
sage: FSM4.states()
[0, 2, 4]
```

remove_epsilon_transitions()

set_coordinates(*coordinates*, *default=True*)

Set coordinates of the states for the LaTeX representation by a dictionary or a function mapping labels to coordinates.

INPUT:

- *coordinates* – a dictionary or a function mapping labels of states to pairs interpreted as coordinates.
- *default* – If True, then states not given by *coordinates* get a default position on a circle of radius 3.

OUTPUT:

Nothing.

EXAMPLES:

```
sage: F = Automaton([[0, 1, 1], [1, 2, 2], [2, 0, 0]])
sage: F.set_coordinates({0: (0, 0), 1: (2, 0), 2: (1, 1)})
sage: F.state(0).coordinates
(0, 0)
```

We can also use a function to determine the coordinates:

```
sage: F = Automaton([[0, 1, 1], [1, 2, 2], [2, 0, 0]])
sage: F.set_coordinates(lambda l: (1, 3/(1+l)))
sage: F.state(2).coordinates
(2, 1)
```

split_transitions()

Return a new transducer, where all transitions in self with input labels consisting of more than one letter are replaced by a path of the corresponding length.

OUTPUT:

A new transducer.

EXAMPLES:

```
sage: A = Transducer([('A', 'B', [1, 2, 3], 0)],
....:               initial_states=['A'], final_states=['B'])
sage: A.split_transitions().states()
[('A', ()), ('B', ()),
 ('A', (1,)), ('A', (1, 2))]
```

state(*state*)

Return the state of the finite state machine.

INPUT:

- *state* – If *state* is not an instance of *FSMState*, then it is assumed that it is the label of a state.

OUTPUT:

The state of the finite state machine corresponding to *state*.

If no state is found, then a *LookupError* is thrown.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: FSM = FiniteStateMachine([(A, 'B'), ('C', A)])
sage: FSM.state('A') == A
True
sage: FSM.state('xyz')
Traceback (most recent call last):
...
LookupError: No state with label xyz found.
```

states()

Return the states of the finite state machine.

OUTPUT:

The states of the finite state machine as list.

EXAMPLES:

```
sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: FSM.states()
['1', '2']
```

transition(*transition*)

Return the transition of the finite state machine.

INPUT:

- *transition* – If *transition* is not an instance of *FSMTransition*, then it is assumed that it is a tuple (*from_state*, *to_state*, *word_in*, *word_out*).

OUTPUT:

The transition of the finite state machine corresponding to *transition*.

If no transition is found, then a *LookupError* is thrown.

EXAMPLES:

```

sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: F = FiniteStateMachine([t])
sage: F.transition(('A', 'B', 0))
Transition from 'A' to 'B': 0|-
sage: id(t) == id(F.transition(('A', 'B', 0)))
True

```

transitions(*from_state=None*)

Return a list of all transitions.

INPUT:

- *from_state* – (default: None) If *from_state* is given, then a list of transitions starting there is given.

OUTPUT:

A list of all transitions.

EXAMPLES:

```

sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: FSM.transitions()
[Transition from '1' to '2': 1|-,
 Transition from '2' to '2': 0|-]

```

transposition(*reverse_output_labels=True*)

Return a new finite state machine, where all transitions of the input finite state machine are reversed.

INPUT:

- *reverse_output_labels* – a boolean (default: True): whether to reverse output labels.

OUTPUT:

A new finite state machine.

EXAMPLES:

```

sage: aut = Automaton([('A', 'A', 0), ('A', 'A', 1), ('A', 'B', 0)],
.....:                 initial_states=['A'], final_states=['B'])
sage: aut.transposition().transitions('B')
[Transition from 'B' to 'A': 0|-]

```

```

sage: aut = Automaton([('1', '1', 1), ('1', '2', 0), ('2', '2', 0)],
.....:                 initial_states=['1'], final_states=['1', '2'])
sage: aut.transposition().initial_states()
['1', '2']

```

```

sage: A = Automaton([(0, 1, [1, 0])],
.....:               initial_states=[0],
.....:               final_states=[1])
sage: A([1, 0])
True
sage: A.transposition()([0, 1])
True

```

```

sage: T = Transducer([(0, 1, [1, 0], [1, 0])],
.....:               initial_states=[0],
.....:               final_states=[1])
sage: T([1, 0])
[1, 0]
sage: T.transposition()([0, 1])
[0, 1]
sage: T.transposition(reverse_output_labels=False)([0, 1])
[1, 0]

```

`with_final_word_out`(*letters*, *allow_non_final=True*)

Constructs a new finite state machine with final output words for all states by implicitly reading trailing letters until a final state is reached.

INPUT:

- *letters* – either an element of the input alphabet or a list of such elements. This is repeated cyclically when needed.
- *allow_non_final* – a boolean (default: `True`) which indicates whether we allow that some states may be non-final in the resulting finite state machine. I.e., if `False` then each state has to have a path to a final state with input label matching *letters*.

OUTPUT:

A finite state machine.

The inplace version of this function is `construct_final_word_out()`.

Suppose for the moment a single element *letter* as input for *letters*. This is equivalent to `letters = [letter]`. We will discuss the general case below.

Let *word_in* be a word over the input alphabet and assume that the original finite state machine transforms *word_in* to *word_out* reaching a possibly non-final state *s*. Let further *k* be the minimum number of letters *letter* such that there is a path from *s* to some final state *f* whose input label consists of *k* copies of *letter* and whose output label is *path_word_out*. Then the state *s* of the resulting finite state machine is a final state with final output `path_word_out + f.final_word_out`. Therefore, the new finite state machine transforms *word_in* to `word_out + path_word_out + f.final_word_out`.

This is e.g. useful for finite state machines operating on digit expansions: there, it is sometimes required to read a sufficient number of trailing zeros (at the most significant positions) in order to reach a final state and to flush all carries. In this case, this method constructs an essentially equivalent finite state machine in the sense that it not longer requires adding sufficiently many trailing zeros. However, it is the responsibility of the user to make sure that if adding trailing zeros to the input anyway, the output is equivalent.

If *letters* consists of more than one letter, then it is assumed that (not necessarily complete) cycles of *letters* are appended as trailing input.

example on Gray code

EXAMPLES:

1. A simple transducer transforming 00 blocks to 01 blocks:

```

sage: T = Transducer([(0, 1, 0, 0), (1, 0, 0, 1)],
.....:               initial_states=[0],
.....:               final_states=[0])
sage: T.process([0, 0, 0])

```

(continues on next page)

(continued from previous page)

```
(False, 1, [0, 1, 0])
sage: T.process([0, 0, 0, 0])
(True, 0, [0, 1, 0, 1])
sage: F = T.with_final_word_out(0)
sage: for f in F.iter_final_states():
.....:     print("{} {}".format(f, f.final_word_out))
0 []
1 [1]
sage: F.process([0, 0, 0])
(True, 1, [0, 1, 0, 1])
sage: F.process([0, 0, 0, 0])
(True, 0, [0, 1, 0, 1])
```

2. A more realistic example: Addition of 1 in binary. We construct a transition function transforming the input to its binary expansion:

```
sage: def binary_transition(carry, input):
.....:     value = carry + input
.....:     if value.mod(2) == 0:
.....:         return (value/2, 0)
.....:     else:
.....:         return ((value-1)/2, 1)
```

Now, we only have to start with a carry of 1 to get the required transducer:

```
sage: T = Transducer(binary_transition,
.....:                 input_alphabet=[0, 1],
.....:                 initial_states=[1],
.....:                 final_states=[0])
```

We test this for the binary expansion of 7:

```
sage: T.process([1, 1, 1])
(False, 1, [0, 0, 0])
```

The final carry 1 has not be flushed yet, we have to add a trailing zero:

```
sage: T.process([1, 1, 1, 0])
(True, 0, [0, 0, 0, 1])
```

We check that with this trailing zero, the transducer performs as advertised:

```
sage: all(ZZ(T(k.bits()+[0]), base=2) == k + 1
.....:     for k in xrange(16))
True
```

However, most of the time, we produce superfluous trailing zeros:

```
sage: T(11.bits()+[0])
[0, 0, 1, 1, 0]
```

We now use this method:

```

sage: F = T.with_final_word_out(0)
sage: for f in F.iter_final_states():
.....:     print("{} {}".format(f, f.final_word_out))
1 [1]
0 []

```

The same tests as above, but we do not have to pad with trailing zeros anymore:

```

sage: F.process([1, 1, 1])
(True, 1, [0, 0, 0, 1])
sage: all(ZZ(F(k.bits())), base=2) == k + 1
.....:     for k in srange(16))
True

```

No more trailing zero in the output:

```

sage: F(11.bits())
[0, 0, 1, 1]
sage: all(F(k.bits())[-1] == 1
.....:     for k in srange(16))
True

```

3. Here is an example, where we allow trailing repeated 10:

```

sage: T = Transducer([(0, 1, 0, 'a'),
.....:                 (1, 2, 1, 'b'),
.....:                 (2, 0, 0, 'c')],
.....:                 initial_states=[0],
.....:                 final_states=[0])
sage: F = T.with_final_word_out([1, 0])
sage: for f in F.iter_final_states():
.....:     print(str(f) + ' ' + ''.join(f.final_word_out))
0
1 bc

```

Trying this with trailing repeated 01 does not produce a final_word_out for state 1, but for state 2:

```

sage: F = T.with_final_word_out([0, 1])
sage: for f in F.iter_final_states():
.....:     print(str(f) + ' ' + ''.join(f.final_word_out))
0
2 c

```

4. Here another example with a more-letter trailing input:

```

sage: T = Transducer([(0, 1, 0, 'a'),
.....:                 (1, 2, 0, 'b'), (1, 2, 1, 'b'),
.....:                 (2, 3, 0, 'c'), (2, 0, 1, 'e'),
.....:                 (3, 1, 0, 'd'), (3, 1, 1, 'd')],
.....:                 initial_states=[0],
.....:                 final_states=[0],
.....:                 with_final_word_out=[0, 0, 1, 1])
sage: for f in T.iter_final_states():
.....:     print(str(f) + ' ' + ''.join(f.final_word_out))

```

                                                    with_final_word_out=None,
                                                    store_states_dict=True,
                                                    on_duplicate_transition=None)

```

Bases: `sage.combinat.finite_state_machine.FiniteStateMachine`

This creates a transducer, which is a finite state machine, whose transitions have input and output labels.

An transducer has additional features like creating a simplified transducer.

See class `FiniteStateMachine` for more information.

EXAMPLES:

We can create a transducer performing the addition of 1 (for numbers given in binary and read from right to left) in the following way:

```

sage: T = Transducer([('C', 'C', 1, 0), ('C', 'N', 0, 1),
.....:                ('N', 'N', 0, 0), ('N', 'N', 1, 1)],
.....:                initial_states=['C'], final_states=['N'])
sage: T
Transducer with 2 states
sage: T([0])
[1]
sage: T([1, 1, 0])
[0, 0, 1]
sage: ZZ(T(15.digits(base=2)+[0]), base=2)
16

```

Note that we have padded the binary input sequence by a 0 so that the transducer can reach its final state.

cartesian_product (*other*, *only_accessible_components=True*)

Return a new transducer which can simultaneously process an input with the machines `self` and `other` where the output labels are d -tuples of the original output labels.

INPUT:

- `other` - a finite state machine (if $d = 2$) or a list (or other iterable) of $d - 1$ finite state machines
- `only_accessible_components` - If True (default), then the result is piped through `accessible_components()`. If no `new_input_alphabet` is given, it is determined by `determine_alphabets()`.

OUTPUT:

A transducer which can simultaneously process an input with `self` and the machine(s) in `other`.

The set of states of the new transducer is the Cartesian product of the set of states of `self` and `other`.

Let (A_j, B_j, a_j, b_j) for $j \in \{1, \dots, d\}$ be transitions in the machines `self` and in `other`. Then there is a transition $((A_1, \dots, A_d), (B_1, \dots, B_d), a, (b_1, \dots, b_d))$ in the new transducer if $a_1 = \dots = a_d =: a$.

EXAMPLES:

```

sage: transducer1 = Transducer([(('A', 'A', 0, 0),
.....:                             ('A', 'A', 1, 1)],
.....:                             initial_states=['A'],
.....:                             final_states=['A'],
.....:                             determine_alphabets=True)
sage: transducer2 = Transducer([(0, 1, 0, ['b', 'c']),
.....:                             (0, 0, 1, 'b'),
.....:                             (1, 1, 0, 'a')],
.....:                             initial_states=[0],
.....:                             final_states=[1],
.....:                             determine_alphabets=True)
sage: result = transducer1.cartesian_product(transducer2)
sage: result
Transducer with 2 states
sage: result.transitions()
[Transition from ('A', 0) to ('A', 1): 0|(0, 'b'),(None, 'c'),
 Transition from ('A', 0) to ('A', 0): 1|(1, 'b'),
 Transition from ('A', 1) to ('A', 1): 0|(0, 'a')]
sage: result([1, 0, 0])
[(1, 'b'), (0, 'b'), (None, 'c'), (0, 'a')]
sage: (transducer1([1, 0, 0]), transducer2([1, 0, 0]))
([1, 0, 0], ['b', 'b', 'c', 'a'])

```

Also final output words are correctly processed:

```

sage: transducer1.state('A').final_word_out = 2
sage: result = transducer1.cartesian_product(transducer2)
sage: result.final_states()[0].final_word_out
[(2, None)]

```

The following transducer counts the number of 11 blocks minus the number of 10 blocks over the alphabet $\{0, 1\}$.

```

sage: count_11 = transducers.CountSubblockOccurrences(
.....:     [1, 1],
.....:     input_alphabet=[0, 1])
sage: count_10 = transducers.CountSubblockOccurrences(
.....:     [1, 0],
.....:     input_alphabet=[0, 1])
sage: count_11x10 = count_11.cartesian_product(count_10)
sage: difference = transducers.sub([0, 1])(count_11x10)
sage: T = difference.simplification().relabelled()
sage: T.initial_states()
[1]
sage: sorted(T.transitions())
[Transition from 0 to 1: 0|-1,
 Transition from 0 to 0: 1|1,
 Transition from 1 to 1: 0|0,
 Transition from 1 to 0: 1|0]
sage: input = [0, 1, 1, 0, 1, 0, 0, 0, 1, 1, 1, 0]
sage: output = [0, 0, 1, -1, 0, -1, 0, 0, 0, 1, 1, -1]
sage: T(input) == output

```

(continues on next page)

(continued from previous page)

```
True
```

If `other` is an automaton, then `cartesian_product()` returns `self` where the input is restricted to the input accepted by `other`.

For example, if the transducer transforms the standard binary expansion into the non-adjacent form and the automaton recognizes the binary expansion without adjacent ones, then the Cartesian product of these two is a transducer which does not change the input (except for changing a to (a, None) and ignoring a leading 0).

```
sage: NAF = Transducer([(0, 1, 0, None),
.....:                 (0, 2, 1, None),
.....:                 (1, 1, 0, 0),
.....:                 (1, 2, 1, 0),
.....:                 (2, 1, 0, 1),
.....:                 (2, 3, 1, -1),
.....:                 (3, 2, 0, 0),
.....:                 (3, 3, 1, 0)],
.....:                 initial_states=[0],
.....:                 final_states=[1],
.....:                 determine_alphabets=True)
sage: aut11 = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 0)],
.....:                  initial_states=[0],
.....:                  final_states=[0, 1],
.....:                  determine_alphabets=True)
sage: res = NAF.cartesian_product(aut11)
sage: res([1, 0, 0, 1, 0, 1, 0])
[(1, None), (0, None), (0, None), (1, None), (0, None), (1, None)]
```

This is obvious because if the standard binary expansion does not have adjacent ones, then it is the same as the non-adjacent form.

Be aware that `cartesian_product()` is not commutative.

```
sage: aut11.cartesian_product(NAF)
Traceback (most recent call last):
...
TypeError: Only an automaton can be intersected with an automaton.
```

The Cartesian product of more than two finite state machines can also be computed:

```
sage: T0 = transducers.CountSubblockOccurrences([0, 0], [0, 1, 2])
sage: T1 = transducers.CountSubblockOccurrences([1, 1], [0, 1, 2])
sage: T2 = transducers.CountSubblockOccurrences([2, 2], [0, 1, 2])
sage: T = T0.cartesian_product([T1, T2])
sage: T.transitions()
[Transition from (( ), ( ), ( )) to ((0, ), ( ), ( )): 0|(0, 0, 0),
Transition from (( ), ( ), ( )) to (( ), (1, ), ( )): 1|(0, 0, 0),
Transition from (( ), ( ), ( )) to (( ), ( ), (2, )): 2|(0, 0, 0),
Transition from ((0, ), ( ), ( )) to ((0, ), ( ), ( )): 0|(1, 0, 0),
Transition from ((0, ), ( ), ( )) to (( ), (1, ), ( )): 1|(0, 0, 0),
Transition from ((0, ), ( ), ( )) to (( ), ( ), (2, )): 2|(0, 0, 0),
Transition from (( ), (1, ), ( )) to ((0, ), ( ), ( )): 0|(0, 0, 0),
Transition from (( ), (1, ), ( )) to (( ), (1, ), ( )): 1|(0, 1, 0),
```

(continues on next page)

(continued from previous page)

```

Transition from ((), (1,), ()) to ((), (), (2,)): 2|(0, 0, 0),
Transition from ((), (), (2,)) to ((0,), (), ()): 0|(0, 0, 0),
Transition from ((), (), (2,)) to ((), (1,), ()): 1|(0, 0, 0),
Transition from ((), (), (2,)) to ((), (), (2,)): 2|(0, 0, 1)]
sage: T([0, 0, 1, 1, 2, 2, 0, 1, 2, 2])
[(0, 0, 0),
 (1, 0, 0),
 (0, 0, 0),
 (0, 1, 0),
 (0, 0, 0),
 (0, 0, 1),
 (0, 0, 0),
 (0, 0, 0),
 (0, 0, 0),
 (0, 0, 0),
 (0, 0, 1)]

```

intersection(*other*, *only_accessible_components=True*)

Return a new transducer which accepts an input if it is accepted by both given finite state machines producing the same output.

INPUT:

- **other** – a transducer
- **only_accessible_components** – If True (default), then the result is piped through `accessible_components()`. If no `new_input_alphabet` is given, it is determined by `determine_alphabets()`.

OUTPUT:

A new transducer which computes the intersection (see below) of the languages of `self` and `other`.

The set of states of the transducer is the Cartesian product of the set of states of both given transducer. There is a transition $((A, B), (C, D), a, b)$ in the new transducer if there are transitions (A, C, a, b) and (B, D, a, b) in the old transducers.

EXAMPLES:

```

sage: transducer1 = Transducer([(1, '2', 1, 0),
.....:                          (2, '2', 1, 0),
.....:                          (2, '2', 0, 1)],
.....:                          initial_states=['1'],
.....:                          final_states=['2'])
sage: transducer2 = Transducer([(1, 'A', 1, 0),
.....:                          (1, 'B', 0, 0),
.....:                          (1, 'B', 0, 1),
.....:                          (1, 'B', 'A', 1, 1)],
.....:                          initial_states=['A'],
.....:                          final_states=['B'])
sage: res = transducer1.intersection(transducer2)
sage: res.transitions()
[Transition from (1, 'A') to (2, 'A'): 1|0,
 Transition from (2, 'A') to (2, 'A'): 1|0]

```

In general, transducers are not closed under intersection. But for transducer which do not have epsilon-transitions, the intersection is well defined (cf. [BaWo2012]). However, in the next example the intersection

of the two transducers is not well defined. The intersection of the languages consists of $(a^n, b^n c^n)$. This set is not recognizable by a *finite* transducer.

```
sage: t1 = Transducer([(0, 0, 'a', 'b'),
.....:                 (0, 1, None, 'c'),
.....:                 (1, 1, None, 'c')],
.....:                 initial_states=[0],
.....:                 final_states=[0, 1])
sage: t2 = Transducer([('A', 'A', None, 'b'),
.....:                 ('A', 'B', 'a', 'c'),
.....:                 ('B', 'B', 'a', 'c')],
.....:                 initial_states=['A'],
.....:                 final_states=['A', 'B'])
sage: t2.intersection(t1)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input or output)
was found.
```

REFERENCES:

`process(*args, **kwargs)`

Return whether the transducer accepts the input, the state where the computation stops and which output is generated.

INPUT:

- `input_tape` – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- `initial_state` or `initial_states` – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- `list_of_outputs` – (default: `None`) a boolean or `None`. If `True`, then the outputs are given in list form (even if we have no or only one single output). If `False`, then the result is never a list (an exception is raised if the result cannot be returned). If `list_of_outputs=None` the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).
- `only_accepted` – (default: `False`) a boolean. If set, then the first argument in the output is guaranteed to be `True` (if the output is a list, then the first argument of each element will be `True`).
- `full_output` – (default: `True`) a boolean. If set, then the full output is given, otherwise only the generated output (the third entry below only). If the input is not accepted, a `ValueError` is raised.
- `always_include_output` – if set (not by default), always include the output. This is inconsequential for a *Transducer*, but can be used in other classes derived from *FiniteStateMachine* where the output is suppressed by default, cf. *Automaton.process()*.
- `format_output` – a function that translates the written output (which is in form of a list) to something more readable. By default (`None`) identity is used here.
- `check_epsilon_transitions` – (default: `True`) a boolean. If `False`, then epsilon transitions are not taken into consideration during process.

- `write_final_word_out` – (default: `True`) a boolean specifying whether the final output words should be written or not.
- `use_multitape_input` – (default: `False`) a boolean. If `True`, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- `process_all_prefixes_of_input` – (default: `False`) a boolean. If `True`, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.
- `process_iterator_class` – (default: `None`) a class inherited from `FSMProcessIterator`. If `None`, then `FSMProcessIterator` is taken. An instance of this class is created and is used during the processing.
- `automatic_output_type` – (default: `False`) a boolean. If set and the input has a parent, then the output will have the same parent. If the input does not have a parent, then the output will be of the same type as the input.

OUTPUT:

The full output is a triple (or a list of triples, cf. parameter `list_of_outputs`), where

- the first entry is `True` if the input string is accepted,
- the second gives the reached state after processing the input tape (This is a state with label `None` if the input could not be processed, i.e., if at one point no transition to go on could be found.), and
- the third gives a list of the output labels written during processing.

If `full_output` is `False`, then only the third entry is returned.

Note that in the case the transducer is not deterministic, all possible paths are taken into account.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see `__call__()` for a version of `process()` with shortened output.

Internally this function creates and works with an instance of `FSMProcessIterator`. This iterator can also be obtained with `iter_process()`.

If working with multi-tape finite state machines, all input words of transitions are words of k -tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

Warning: Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

```
sage: binary_inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
.....:                               initial_states=['A'], final_states=['A'])
sage: binary_inverter.process([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

If we are only interested in the output, we can also use:

```
sage: binary_inverter([0, 1, 0, 0, 1, 1])
[1, 0, 1, 1, 0, 0]
```

This can also be used with words as input:

```
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
sage: w = W([0, 1, 0, 0, 1, 1]); w
word: 010011
sage: binary_inverter(w)
word: 101100
```

In this case it is automatically determined that the output is a word. The call above is equivalent to:

```
sage: binary_inverter.process(w,
.....:                          full_output=False,
.....:                          list_of_outputs=False,
.....:                          automatic_output_type=True)
word: 101100
```

The following transducer transforms 0^n1 to 1^n2 :

```
sage: T = Transducer([(0, 0, 0, 1), (0, 1, 1, 2)])
sage: T.state(0).is_initial = True
sage: T.state(1).is_final = True
```

We can see the different possibilities of the output by:

```
sage: [T.process(w) for w in [[1], [0, 1], [0, 0, 1], [0, 1, 1],
.....:                       [0], [0, 0], [2, 0], [0, 1, 2]]]
[(True, 1, [2]), (True, 1, [1, 2]),
 (True, 1, [1, 1, 2]), (False, None, None),
 (False, 0, [1]), (False, 0, [1, 1]),
 (False, None, None), (False, None, None)]
```

If we just want a condensed output, we use:

```
sage: [T.process(w, full_output=False)
.....:      for w in [[1], [0, 1], [0, 0, 1]]]
[[2], [1, 2], [1, 1, 2]]
sage: T.process([0], full_output=False)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T.process([0, 1, 2], full_output=False)
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: Invalid input sequence.
```

It is equivalent to:

```
sage: [T(w) for w in [[1], [0, 1], [0, 0, 1]]]
[[2], [1, 2], [1, 1, 2]]
sage: T([0])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T([0, 1, 2])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

A cycle with empty input and empty output is correctly processed:

```
sage: T = Transducer([(0, 1, None, None), (1, 0, None, None)],
....:                 initial_states=[0], final_states=[1])
sage: T.process([])
[(False, 0, []), (True, 1, [])]
sage: _ = T.add_transition(-1, 0, 0, 'r')
sage: T.state(-1).is_initial = True
sage: T.state(0).is_initial = False
sage: T.process([0])
[(False, 0, ['r']), (True, 1, ['r'])]
```

If there is a cycle with empty input but non-empty output, the possible outputs would be an infinite set:

```
sage: T = Transducer([(0, 1, None, 'z'), (1, 0, None, None)],
....:                 initial_states=[0], final_states=[1])
sage: T.process([])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input),
but output is written.
```

But if this cycle with empty input and non-empty output is not reached, the correct output is produced:

```
sage: _ = T.add_transition(-1, 0, 0, 'r')
sage: T.state(-1).is_initial = True
sage: T.state(0).is_initial = False
sage: T.process([])
(False, -1, [])
sage: T.process([0])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input),
but output is written.
```

If we set `check_epsilon_transitions=False`, then no transitions with empty input are considered anymore. Thus cycles with empty input are no problem anymore:

```
sage: T.process([0], check_epsilon_transitions=False)
(False, 0, ['r'])
```

A simple example of a multi-tape transducer is the following: It writes the length of the first tape many letters a and then the length of the second tape many letters b:

```
sage: M = Transducer([(0, 0, (1, None), 'a'),
.....:                (0, 1, [], []),
.....:                (1, 1, (None, 1), 'b')],
.....:                initial_states=[0],
.....:                final_states=[1])
sage: M.process([(1, 1), [1]], use_multitape_input=True)
(True, 1, ['a', 'a', 'b'])
```

See also:

FiniteStateMachine.process(), *Automaton.process()*, *iter_process()*, *__call__()*, *FSMProcessIterator*.

simplification()

Return a simplified transducer.

OUTPUT:

A new transducer.

This function simplifies a transducer by Moore's algorithm, first moving common output labels of transitions leaving a state to output labels of transitions entering the state (cf. *prepone_output()*).

The resulting transducer implements the same function as the original transducer.

EXAMPLES:

```
sage: fsm = Transducer([("A", "B", 0, 1), ("A", "B", 1, 0),
.....:                  ("B", "C", 0, 0), ("B", "C", 1, 1),
.....:                  ("C", "D", 0, 1), ("C", "D", 1, 0),
.....:                  ("D", "A", 0, 0), ("D", "A", 1, 1)])
sage: fsms = fsm.simplification()
sage: fsms
Transducer with 2 states
sage: fsms.transitions()
[Transition from ('B', 'D') to ('A', 'C'): 0|0,
 Transition from ('B', 'D') to ('A', 'C'): 1|1,
 Transition from ('A', 'C') to ('B', 'D'): 0|1,
 Transition from ('A', 'C') to ('B', 'D'): 1|0]
sage: fsms.relabeled().transitions()
[Transition from 0 to 1: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 0: 1|0]
```

```
sage: fsm = Transducer([("A", "A", 0, 0),
.....:                  ("A", "B", 1, 1),
.....:                  ("A", "C", 1, -1),
.....:                  ("B", "A", 2, 0),
.....:                  ("C", "A", 2, 0)])
```

(continues on next page)

(continued from previous page)

```

sage: fsm_simplified = fsm.simplification()
sage: fsm_simplified
Transducer with 2 states
sage: fsm_simplified.transitions()
[Transition from ('A',) to ('A',): 0|0,
 Transition from ('A',) to ('B', 'C'): 1|1,0,
 Transition from ('A',) to ('B', 'C'): 1|-1,0,
 Transition from ('B', 'C') to ('A',): 2|-]

```

```

sage: from sage.combinat.finite_state_machine import duplicate_transition_add_
↳input
sage: T = Transducer([('A', 'A', 1/2, 0),
.....:                ('A', 'B', 1/4, 1),
.....:                ('A', 'C', 1/4, 1),
.....:                ('B', 'A', 1, 0),
.....:                ('C', 'A', 1, 0)],
.....:                initial_states=[0],
.....:                final_states=['A', 'B', 'C'],
.....:                on_duplicate_transition=duplicate_transition_add_input)
sage: sorted(T.simplification().transitions())
[Transition from ('A',) to ('A',): 1/2|0,
 Transition from ('A',) to ('B', 'C'): 1/2|1,
 Transition from ('B', 'C') to ('A',): 1|0]

```

Illustrating the use of colors in order to avoid identification of states:

```

sage: T = Transducer( [[0,0,0,0], [0,1,1,1],
.....:                 [1,0,0,0], [1,1,1,1]],
.....:                 initial_states=[0],
.....:                 final_states=[0,1])
sage: sorted(T.simplification().transitions())
[Transition from (0, 1) to (0, 1): 0|0,
 Transition from (0, 1) to (0, 1): 1|1]
sage: T.state(0).color = 0
sage: T.state(0).color = 1
sage: sorted(T.simplification().transitions())
[Transition from (0,) to (0,): 0|0,
 Transition from (0,) to (1,): 1|1,
 Transition from (1,) to (0,): 0|0,
 Transition from (1,) to (1,): 1|1]

```

`sage.combinat.finite_state_machine.duplicate_transition_add_input`(*old_transition*,
new_transition)

Alternative function for handling duplicate transitions in finite state machines. This implementation adds the input label of the new transition to the input label of the old transition. This is intended for the case where a Markov chain is modelled by a finite state machine using the input labels as transition probabilities.

See the documentation of the `on_duplicate_transition` parameter of *FiniteStateMachine*.

INPUT:

- `old_transition` – A transition in a finite state machine.
- `new_transition` – A transition, identical to `old_transition`, which is to be inserted into the finite state machine.

OUTPUT:

A transition whose input weight is the sum of the input weights of `old_transition` and `new_transition`.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_add_input(FSMTransition('a', 'a', 1/2),
....:                               FSMTransition('a', 'a', 1/2))
Transition from 'a' to 'a': 1|-
```

Input labels must be lists of length 1:

```
sage: duplicate_transition_add_input(FSMTransition('a', 'a', [1, 1]),
....:                               FSMTransition('a', 'a', [1, 1]))
Traceback (most recent call last):
...
TypeError: Trying to use duplicate_transition_add_input on
"Transition from 'a' to 'a': 1,1|-" and
"Transition from 'a' to 'a': 1,1|-",
but input words are assumed to be lists of length 1
```

`sage.combinat.finite_state_machine.duplicate_transition_ignore(old_transition, new_transition)`

Default function for handling duplicate transitions in finite state machines. This implementation ignores the occurrence.

See the documentation of the `on_duplicate_transition` parameter of *FiniteStateMachine*.

INPUT:

- `old_transition` – A transition in a finite state machine.
- `new_transition` – A transition, identical to `old_transition`, which is to be inserted into the finite state machine.

OUTPUT:

The same transition, unchanged.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_ignore
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_ignore(FSMTransition(0, 0, 1),
....:                               FSMTransition(0, 0, 1))
Transition from 0 to 0: 1|-
```

`sage.combinat.finite_state_machine.duplicate_transition_raise_error(old_transition, new_transition)`

Alternative function for handling duplicate transitions in finite state machines. This implementation raises a `ValueError`.

See the documentation of the `on_duplicate_transition` parameter of *FiniteStateMachine*.

INPUT:

- `old_transition` – A transition in a finite state machine.
- `new_transition` – A transition, identical to `old_transition`, which is to be inserted into the finite state machine.

OUTPUT:

Nothing. A ValueError is raised.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_
      ↪error
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_raise_error(FSMTransition(0, 0, 1),
      .....:                          FSMTransition(0, 0, 1))
Traceback (most recent call last):
...
ValueError: Attempting to re-insert transition Transition from 0 to 0: 1|-
```

`sage.combinat.finite_state_machine.equal(iterator)`

Checks whether all elements of iterator are equal.

INPUT:

- iterator – an iterator of the elements to check

OUTPUT:

True or False.

This implements <https://stackoverflow.com/a/3844832/1052778>.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import equal
sage: equal([0, 0, 0])
True
sage: equal([0, 1, 0])
False
sage: equal([])
True
sage: equal(iter([None, None]))
True
```

We can test other properties of the elements than the elements themselves. In the following example, we check whether all tuples have the same lengths:

```
sage: equal(len(x) for x in [(1, 2), (2, 3), (3, 1)])
True
sage: equal(len(x) for x in [(1, 2), (1, 2, 3), (3, 1)])
False
```

`sage.combinat.finite_state_machine.full_group_by(l, key=<function <lambda> at 0x7f8749b8cee0>)`

Group iterable `l` by values of `key`.

INPUT:

- iterable `l`
- key function `key`

OUTPUT:

A list of pairs (`k`, `elements`) such that `key(e)=k` for all `e` in `elements`.

This is similar to `itertools.groupby()` except that lists are returned instead of iterables and no prior sorting is required.

We do not require

- that the keys are sortable (in contrast to the approach via `sorted()` and `itertools.groupby()`) and
- that the keys are hashable (in contrast to the implementation proposed in <https://stackoverflow.com/a/15250161>).

However, it is required

- that distinct keys have distinct `str`-representations.

The implementation is inspired by <https://stackoverflow.com/a/15250161>, but non-hashable keys are allowed.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import full_group_by
sage: t = [2/x, 1/x, 2/x] # optional -
      ↪ sage.symbolic
sage: r = full_group_by([0, 1, 2], key=lambda i: t[i]) # optional -
      ↪ sage.symbolic
sage: sorted(r, key=lambda p: p[1]) # optional -
      ↪ sage.symbolic
[(2/x, [0, 2]), (1/x, [1])]
sage: from itertools import groupby # optional -
sage: for k, elements in groupby(sorted([0, 1, 2],
      ↪ sage.symbolic
      .....:         key=lambda i:t[i]),
      .....:         key=lambda i:t[i]):
      .....:     print("{} {}".format(k, list(elements)))
2/x [0]
1/x [1]
2/x [2]
```

Note that the behavior is different from `itertools.groupby()` because neither $1/x < 2/x$ nor $2/x < 1/x$ does hold.

Here, the result `r` has been sorted in order to guarantee a consistent order for the doctest suite.

`sage.combinat.finite_state_machine.is_Automaton(FSM)`

Tests whether or not FSM inherits from *Automaton*.

`sage.combinat.finite_state_machine.is_FSMProcessIterator(PI)`

Tests whether or not PI inherits from *FSMProcessIterator*.

`sage.combinat.finite_state_machine.is_FSMState(S)`

Tests whether or not S inherits from *FSMState*.

`sage.combinat.finite_state_machine.is_FSMTransition(T)`

Tests whether or not T inherits from *FSMTransition*.

`sage.combinat.finite_state_machine.is_FiniteStateMachine(FSM)`

Tests whether or not FSM inherits from *FiniteStateMachine*.

`sage.combinat.finite_state_machine.is_Transducer(FSM)`

Tests whether or not FSM inherits from *Transducer*.

`sage.combinat.finite_state_machine.setup_latex_preamble()`

This function adds the package `tikz` with support for automata to the preamble of Latex so that the finite state machines can be drawn nicely.

See the section on *LaTeX output* in the introductory examples of this module.

`sage.combinat.finite_state_machine.startswith(list_, prefix)`

Determine whether list starts with the given prefix.

INPUT:

- `list_` – list
- `prefix` – list representing the prefix

OUTPUT:

True or False.

Similar to `str.startswith()`.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import startswith
sage: startswith([1, 2, 3], [1, 2])
True
sage: startswith([1], [1, 2])
False
sage: startswith([1, 3, 2], [1, 2])
False
```

`sage.combinat.finite_state_machine.tupleofwords_to_wordoftuples(tupleofwords)`

Transposes a tuple of words over the alphabet to a word of tuples.

INPUT:

- `tupleofwords` – a tuple of a list of letters.

OUTPUT:

A list of tuples.

Missing letters in the words are padded with the letter `None` (from the empty word).

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import (
.....:     tupleofwords_to_wordoftuples)
sage: tupleofwords_to_wordoftuples(
.....:     ([1, 2], [3, 4, 5, 6], [7]))
[(1, 3, 7), (2, 4, None), (None, 5, None), (None, 6, None)]
```

`sage.combinat.finite_state_machine.wordoftuples_to_tupleofwords(wordoftuples)`

Transposes a word of tuples to a tuple of words over the alphabet.

INPUT:

- `wordoftuples` – a list of tuples of letters.

OUTPUT:

A tuple of lists.

Letters `None` (empty word) are removed from each word in the output.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import (
.....:     wordoftuples_to_tupleofwords)
sage: wordoftuples_to_tupleofwords(
.....:     [(1, 2), (1, None), (1, None), (1, 2), (None, 2)])
([1, 1, 1, 1], [2, 2, 2])
```

5.1.106 Common Automata and Transducers (Finite State Machines Generators)

Automata and Transducers in Sage can be built through the `automata` and `transducers` objects, respectively. It contains generators for common finite state machines. For example,

```
sage: I = transducers.Identity([0, 1, 2])
```

generates an identity transducer on the alphabet $\{0, 1, 2\}$.

To construct automata and transducers manually, you can use the classes `Automaton` and `Transducer`, respectively. See *Finite state machines, automata, transducers* for more details and a lot of *examples*.

Automata

<code>AnyLetter()</code>	Return an automaton recognizing any letter.
<code>AnyWord()</code>	Return an automaton recognizing any word.
<code>EmptyWord()</code>	Return an automaton recognizing the empty word.
<code>Word()</code>	Return an automaton recognizing the given word.
<code>ContainsWord()</code>	Return an automaton recognizing words containing the given word.

Transducers

<code>Identity()</code>	Returns a transducer realizing the identity map.
<code>abs()</code>	Returns a transducer realizing absolute value.
<code>map()</code>	Returns a transducer realizing a function.
<code>operator()</code>	Returns a transducer realizing a binary operation.
<code>all()</code>	Returns a transducer realizing logical and.
<code>any()</code>	Returns a transducer realizing logical or.
<code>add()</code>	Returns a transducer realizing addition.
<code>sub()</code>	Returns a transducer realizing subtraction.
<code>CountSubblockOccurrences()</code>	Returns a transducer counting the occurrences of a subblock.
<code>Wait()</code>	Returns a transducer writing <code>False</code> until first (or k-th) true input is read.
<code>weight()</code>	Returns a transducer realizing the Hamming weight.
<code>GrayCode()</code>	Returns a transducer realizing binary Gray code.
<code>Recursion()</code>	Returns a transducer defined by recursions.

Functions and methods

class `sage.combinat.finite_state_machine_generators.AutomatonGenerators`

Bases: object

A collection of constructors for several common automata.

A list of all automata in this database is available via tab completion. Type “automata.” and then hit tab to see which automata are available.

The automata currently in this class include:

- `AnyLetter()`
- `AnyWord()`
- `EmptyWord()`
- `Word()`
- `ContainsWord()`

AnyLetter(*input_alphabet*)

Return an automaton recognizing any letter of the given input alphabet.

INPUT:

- `input_alphabet` – a list, the input alphabet

OUTPUT:

An *Automaton*.

EXAMPLES:

```
sage: A = automata.AnyLetter([0, 1])
sage: A([])
False
sage: A([0])
True
sage: A([1])
True
sage: A([0, 0])
False
```

See also:

`AnyWord()`

AnyWord(*input_alphabet*)

Return an automaton recognizing any word of the given input alphabet.

INPUT:

- *input_alphabet* – a list, the input alphabet

OUTPUT:

An *Automaton*.

EXAMPLES:

```
sage: A = automata.AnyWord([0, 1])
sage: A([0])
True
sage: A([1])
True
sage: A([0, 1])
True
sage: A([0, 2])
False
```

This is equivalent to taking the *kleene_star()* of *AnyLetter()* and minimizing the result. This method immediately gives a minimized version:

```
sage: B = automata.AnyLetter([0, 1]).kleene_star().minimization().relabelled()
sage: B == A
True
```

See also:

AnyLetter(), *Word()*.

ContainsWord(*word*, *input_alphabet*)

Return an automaton recognizing the words containing the given word as a factor.

INPUT:

- *word* – a list (or other iterable) of letters, the word we are looking for.
- *input_alphabet* – a list or other iterable, the input alphabet.

OUTPUT:

An *Automaton*.

EXAMPLES:

```
sage: A = automata.ContainsWord([0, 1, 0, 1, 1],
.....:                          input_alphabet=[0, 1])
sage: A([1, 0, 1, 0, 1, 0, 1, 1, 0, 0])
True
sage: A([1, 0, 1, 0, 1, 0, 1, 0])
False
```

This is equivalent to taking the concatenation of *AnyWord()*, *Word()* and *AnyWord()* and minimizing the result. This method immediately gives a minimized version:

```

sage: B = (automata.AnyWord([0, 1]) *
.....:      automata.Word([0, 1, 0, 1, 1], [0, 1]) *
.....:      automata.AnyWord([0, 1])).minimization()
sage: B.is_equivalent(A)
True

```

See also:

[CountSubblockOccurrences\(\)](#), [AnyWord\(\)](#), [Word\(\)](#).

EmptyWord(*input_alphabet=None*)

Return an automaton recognizing the empty word.

INPUT:

- *input_alphabet* – (default: `None`) an iterable or `None`.

OUTPUT:

An *Automaton*.

EXAMPLES:

```

sage: A = automata.EmptyWord()
sage: A([])
True
sage: A([0])
False

```

See also:

[AnyLetter\(\)](#), [AnyWord\(\)](#).

Word(*word, input_alphabet=None*)

Return an automaton recognizing the given word.

INPUT:

- *word* – an iterable.
- *input_alphabet* – a list or `None`. If `None`, then the letters occurring in the word are used.

OUTPUT:

An *Automaton*.

EXAMPLES:

```

sage: A = automata.Word([0])
sage: A.transitions()
[Transition from 0 to 1: 0|-]
sage: [A(w) for w in ([], [0], [1])]
[False, True, False]
sage: A = automata.Word([0, 1, 0])
sage: A.transitions()
[Transition from 0 to 1: 0|-,
Transition from 1 to 2: 1|-,
Transition from 2 to 3: 0|-]
sage: [A(w) for w in ([], [0], [0, 1], [0, 1, 1], [0, 1, 0])]
[False, False, False, False, True]

```

If the input alphabet is not given, it is derived from the given word.

```
sage: A.input_alphabet
[0, 1]
sage: A = automata.Word([0, 1, 0], input_alphabet=[0, 1, 2])
sage: A.input_alphabet
[0, 1, 2]
```

See also:

AnyWord(), *ContainsWord()*.

class sage.combinat.finite_state_machine_generators.**TransducerGenerators**

Bases: object

A collection of constructors for several common transducers.

A list of all transducers in this database is available via tab completion. Type “transducers.” and then hit tab to see which transducers are available.

The transducers currently in this class include:

- *Identity()*
- *abs()*
- *operator()*
- *all()*
- *any()*
- *add()*
- *sub()*
- *CountSubblockOccurrences()*
- *Wait()*
- *GrayCode()*
- *Recursion()*

CountSubblockOccurrences(*block*, *input_alphabet*)

Returns a transducer counting the number of (possibly overlapping) occurrences of a block in the input.

INPUT:

- *block* – a list (or other iterable) of letters.
- *input_alphabet* – a list or other iterable.

OUTPUT:

A transducer counting (in unary) the number of occurrences of the given block in the input. Overlapping occurrences are counted several times.

Denoting the block by $b_0 \dots b_{k-1}$, the input word by $i_0 \dots i_L$ and the output word by $o_0 \dots o_L$, we have $o_j = 1$ if and only if $i_{j-k+1} \dots i_j = b_0 \dots b_{k-1}$. Otherwise, $o_j = 0$.

EXAMPLES:

1. Counting the number of 10 blocks over the alphabet [0, 1]:

```

sage: T = transducers.CountSubblockOccurrences(
.....:     [1, 0],
.....:     [0, 1])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
  Transition from () to (1,): 1|0,
  Transition from (1,) to (): 0|1,
  Transition from (1,) to (1,): 1|0]
sage: T.input_alphabet
[0, 1]
sage: T.output_alphabet
[0, 1]
sage: T.initial_states()
[()]
sage: T.final_states()
[(), (1,)]

```

Check some sequence:

```

sage: T([0, 1, 0, 1, 1, 0])
[0, 0, 1, 0, 0, 1]

```

2. Counting the number of 11 blocks over the alphabet [0, 1]:

```

sage: T = transducers.CountSubblockOccurrences(
.....:     [1, 1],
.....:     [0, 1])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
  Transition from () to (1,): 1|0,
  Transition from (1,) to (): 0|0,
  Transition from (1,) to (1,): 1|1]

```

Check some sequence:

```

sage: T([0, 1, 0, 1, 1, 0])
[0, 0, 0, 0, 1, 0]

```

3. Counting the number of 1010 blocks over the alphabet [0, 1, 2]:

```

sage: T = transducers.CountSubblockOccurrences(
.....:     [1, 0, 1, 0],
.....:     [0, 1, 2])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
  Transition from () to (1,): 1|0,
  Transition from () to (): 2|0,
  Transition from (1,) to (1, 0): 0|0,
  Transition from (1,) to (1,): 1|0,
  Transition from (1,) to (): 2|0,
  Transition from (1, 0) to (): 0|0,
  Transition from (1, 0) to (1, 0, 1): 1|0,
  Transition from (1, 0) to (): 2|0,

```

(continues on next page)

(continued from previous page)

```

Transition from (1, 0, 1) to (1, 0): 0|1,
Transition from (1, 0, 1) to (1,): 1|0,
Transition from (1, 0, 1) to (): 2|0]
sage: input = [0, 1, 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, 2]
sage: output = [0, 0, 0, 0, 1, 0, 1, 0, 0, 0, 0, 1, 0]
sage: T(input) == output
True

```

See also:[*ContainsWord\(\)*](#)**GrayCode()**

Returns a transducer converting the standard binary expansion to Gray code.

INPUT:

Nothing.

OUTPUT:

A transducer.

Cf. the [Wikipedia article Gray_code](#) for a description of the Gray code.

EXAMPLES:

```

sage: G = transducers.GrayCode()
sage: G
Transducer with 3 states
sage: for v in xrange(10):
.....:     print("{} {}".format(v, G(v.digits(base=2))))
0 []
1 [1]
2 [1, 1]
3 [0, 1]
4 [0, 1, 1]
5 [1, 1, 1]
6 [1, 0, 1]
7 [0, 0, 1]
8 [0, 0, 1, 1]
9 [1, 0, 1, 1]

```

In the example *Gray Code* in the documentation of the *Finite state machines, automata, transducers* module, the Gray code transducer is derived from the algorithm converting the binary expansion to the Gray code. The result is the same as the one given here.

Identity(*input_alphabet*)

Returns the identity transducer realizing the identity map.

INPUT:

- *input_alphabet* – a list or other iterable.

OUTPUT:

A transducer mapping each word over *input_alphabet* to itself.

EXAMPLES:

```

sage: T = transducers.Identity([0, 1])
sage: sorted(T.transitions())
[Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T.input_alphabet
[0, 1]
sage: T.output_alphabet
[0, 1]
sage: T([0, 1, 0, 1, 1])
[0, 1, 0, 1, 1]

```

Recursion(*recursions*, *base*, *function=None*, *var=None*, *input_alphabet=None*, *word_function=None*, *is_zero=None*, *output_rings=[Integer Ring, Rational Field]*)

Return a transducer realizing the given recursion when reading the digit expansion with base *base*.

INPUT:

- *recursions* – list or iterable of equations. Each equation has either the form
 - $f(\text{base}^K * n + r) == f(\text{base}^k * n + s) + t$ for some integers $0 \leq k < K$, r and some t —valid for all n such that the arguments on both sides are non-negative—

or the form

- $f(r) == t$ for some integer r and some t .

Alternatively, an equation may be replaced by a `transducers.RecursionRule` with the attributes K , r , k , s , t as above or a tuple (r, t) . Note that t *must* be a list in this case.

- *base* – base of the digit expansion.
- *function* – symbolic function f occurring in the recursions.
- *var* – symbolic variable.
- *input_alphabet* – (default: `None`) a list of digits to be used as the input alphabet. If `None` and the base is an integer, *input_alphabet* is chosen to be `srange(base.abs())`.
- *word_function* – (default: `None`) a symbolic function. If not `None`, `word_function(arg1, .., argn)` in a symbolic recurrence relation is interpreted as a transition with output `[arg1, ..., argn]`. This could not be entered in a symbolic recurrence relation because lists do not coerce into the `SymbolicRing`.
- *is_zero* – (default: `None`) a callable. The recursion relations are only well-posed if there is no cycle with non-zero output and input consisting of zeros. This parameter is used to determine whether the output of such a cycle is non-zero. By default, the output must evaluate to `False` as a boolean.
- *output_rings* – (default: `[ZZ, QQ]`) a list of rings. The output labels are converted into the first ring of the list in which they are contained. If they are not contained in any ring, they remain in whatever ring they are after parsing the recursions, typically the symbolic ring.

OUTPUT:

A transducer T .

The transducer is constructed such that $T(\text{expansion}) == f(n)$ if *expansion* is the digit expansion of n to the base *base* with the given input alphabet as set of digits. Here, the $+$ on the right hand side of the

recurrence relation is interpreted as the concatenation of words.

The formal equations and initial conditions in the recursion have to be selected such that f is uniquely defined.

EXAMPLES:

- The following example computes the Hamming weight of the ternary expansion of integers.

```
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
.....:     f(3*n + 1) == f(n) + 1,
.....:     f(3*n + 2) == f(n) + 1,
.....:     f(3*n) == f(n),
.....:     f(0) == 0],
.....:     3, f, n)
sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
 Transition from (0, 0) to (0, 0): 1|1,
 Transition from (0, 0) to (0, 0): 2|1]
```

To illustrate what this transducer does, we consider the example of $n = 601$:

```
sage: ternary_expansion = 601.digits(base=3)
sage: ternary_expansion
[1, 2, 0, 1, 1, 2]
sage: weight_sequence = T(ternary_expansion)
sage: weight_sequence
[1, 1, 1, 1, 1]
sage: sum(weight_sequence)
5
```

Note that the digit zero does not show up in the output because the equation $f(3*n) == f(n)$ means that no output is added to $f(n)$.

- The following example computes the Hamming weight of the non-adjacent form, cf. the [Wikipedia article Non-adjacent_form](#).

```
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
.....:     f(4*n + 1) == f(n) + 1,
.....:     f(4*n - 1) == f(n) + 1,
.....:     f(2*n) == f(n),
.....:     f(0) == 0],
.....:     2, f, n)
sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,
 Transition from (1, 1) to (1, 0): 1|1,
```

(continues on next page)

(continued from previous page)

```

Transition from (1, 0) to (1, 1): 0|-,
Transition from (1, 0) to (1, 0): 1|-]
sage: [(s.label(), s.final_word_out)
.....: for s in T.iter_final_states()]
[((0, 0), []),
 ((1, 1), [1]),
 ((1, 0), [1])]

```

As we are interested in the weight only, we also output 1 for numbers congruent to 3 mod 4. The actual expansion is computed in the next example.

Consider the example of $29 = (100\bar{1}01)_2$ (as usual, the digit -1 is denoted by $\bar{1}$ and digits are written from the most significant digit at the left to the least significant digit at the right; for the transducer, we have to give the digits in the reverse order):

```

sage: NAF = [1, 0, -1, 0, 0, 1]
sage: ZZ(NAF, base=2)
29
sage: binary_expansion = 29.digits(base=2)
sage: binary_expansion
[1, 0, 1, 1, 1]
sage: T(binary_expansion)
[1, 1, 1]
sage: sum(T(binary_expansion))
3

```

Indeed, the given non-adjacent form has three non-zero digits.

- The following example computes the non-adjacent form from the binary expansion, cf. the [Wikipedia article Non-adjacent form](#). In contrast to the previous example, we actually compute the expansion, not only the weight.

We have to write the output 0 when converting an even number. This cannot be encoded directly by an equation in the symbolic ring, because $f(2*n) == f(n) + 0$ would be equivalent to $f(2*n) == f(n)$ and an empty output would be written. Therefore, we wrap the output in the symbolic function `w` and use the parameter `word_function` to announce this.

Similarly, we use `w(-1, 0)` to write an output word of length 2 in one iteration. Finally, we write `f(0) == w()` to write an empty word upon completion.

Moreover, there is a cycle with output `[0]` which—from the point of view of this method—is a contradicting recursion. We override this by the parameter `is_zero`.

```

sage: var('n')
n
sage: function('f w')
(f, w)
sage: T = transducers.Recursion([
.....:     f(2*n) == f(n) + w(0),
.....:     f(4*n + 1) == f(n) + w(1, 0),
.....:     f(4*n - 1) == f(n) + w(-1, 0),
.....:     f(0) == w(),
.....:     2, f, n,
.....:     word_function=w,
.....:     is_zero=lambda x: sum(x).is_zero())

```

(continues on next page)

(continued from previous page)

```

sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,0,
 Transition from (1, 1) to (1, 0): 1|-1,0,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]
sage: for s in T.iter_states():
.....:     print("{} {}".format(s, s.final_word_out))
(0, 0) []
(1, 1) [1, 0]
(1, 0) [1, 0]

```

We again consider the example of $n = 29$:

```

sage: T(29.digits(base=2))
[1, 0, -1, 0, 0, 1, 0]

```

The same transducer can also be entered bypassing the symbolic equations:

```

sage: R = transducers.RecursionRule
sage: TR = transducers.Recursion([
.....:     R(K=1, r=0, k=0, s=0, t=[0]),
.....:     R(K=2, r=1, k=0, s=0, t=[1, 0]),
.....:     R(K=2, r=-1, k=0, s=0, t=[-1, 0]),
.....:     (0, [])],
.....:     2,
.....:     is_zero=lambdax: sum(x).is_zero())
sage: TR == T
True

```

- Here is an artificial example where some of the s are negative:

```

sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
.....:     f(2*n + 1) == f(n-1) + 1,
.....:     f(2*n) == f(n),
.....:     f(1) == 1,
.....:     f(0) == 0], 2, f, n)
sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|-,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (-1, 1): 0|1,
 Transition from (1, 1) to (0, 0): 1|1,
 Transition from (-1, 1) to (-1, 2): 0|-,
 Transition from (-1, 1) to (1, 2): 1|-,
 Transition from (-1, 2) to (-1, 1): 0|1,
 Transition from (-1, 2) to (0, 0): 1|1,
 Transition from (1, 2) to (-1, 2): 0|1,
 Transition from (1, 2) to (1, 2): 1|1]

```

(continues on next page)

(continued from previous page)

```
sage: [(s.label(), s.final_word_out)
.....: for s in T.iter_final_states()]
[[((0, 0), []),
  ((1, 1), [1]),
  ((-1, 1), [0]),
  ((-1, 2), [0]),
  ((1, 2), [1])]
```

- Abelian complexity of the paperfolding sequence (cf. [HKP2015], Example 2.8):

```
sage: T = transducers.Recursion([
.....:     f(4*n) == f(2*n),
.....:     f(4*n+2) == f(2*n+1)+1,
.....:     f(16*n+1) == f(8*n+1),
.....:     f(16*n+5) == f(4*n+1)+2,
.....:     f(16*n+11) == f(4*n+3)+2,
.....:     f(16*n+15) == f(2*n+2)+1,
.....:     f(1) == 2, f(0) == 0]
.....:     + [f(16*n+jj) == f(2*n+1)+2 for jj in [3,7,9,13]],
.....:     2, f, n)
sage: T.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
  Transition from (0, 0) to (1, 1): 1|-,
  Transition from (0, 1) to (0, 1): 0|-,
  Transition from (0, 1) to (1, 1): 1|1,
  Transition from (1, 1) to (1, 2): 0|-,
  Transition from (1, 1) to (3, 2): 1|-,
  Transition from (1, 2) to (1, 3): 0|-,
  Transition from (1, 2) to (5, 3): 1|-,
  Transition from (3, 2) to (3, 3): 0|-,
  Transition from (3, 2) to (7, 3): 1|-,
  Transition from (1, 3) to (1, 3): 0|-,
  Transition from (1, 3) to (1, 1): 1|2,
  Transition from (5, 3) to (1, 2): 0|2,
  Transition from (5, 3) to (1, 1): 1|2,
  Transition from (3, 3) to (1, 1): 0|2,
  Transition from (3, 3) to (3, 2): 1|2,
  Transition from (7, 3) to (1, 1): 0|2,
  Transition from (7, 3) to (2, 1): 1|1,
  Transition from (2, 1) to (1, 1): 0|1,
  Transition from (2, 1) to (2, 1): 1|-]
sage: for s in T.iter_states():
.....:     print("{} {}".format(s, s.final_word_out))
(0, 0) []
(0, 1) []
(1, 1) [2]
(1, 2) [2]
(3, 2) [2, 2]
(1, 3) [2]
(5, 3) [2, 2]
(3, 3) [2, 2]
(7, 3) [2, 2]
```

(continues on next page)

(continued from previous page)

```
(2, 1) [1, 2]
sage: list(sum(T(n.bits())) for n in xrange(1, 21))
[2, 3, 4, 3, 4, 5, 4, 3, 4, 5, 6, 5, 4, 5, 4, 3, 4, 5, 6, 5]
```

- We now demonstrate the use of the `output_rings` parameter. If no `output_rings` are specified, the output labels are converted into ZZ:

```
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
.....:     f(2*n + 1) == f(n) + 1,
.....:     f(2*n) == f(n),
.....:     f(0) == 2],
.....:     2, f, n)
sage: for t in T.transitions():
.....:     print([x.parent() for x in t.word_out])
[]
[Integer Ring]
sage: [x.parent() for x in T.states()[0].final_word_out]
[Integer Ring]
```

In contrast, if `output_rings` is set to the empty list, the results are not converted:

```
sage: T = transducers.Recursion([
.....:     f(2*n + 1) == f(n) + 1,
.....:     f(2*n) == f(n),
.....:     f(0) == 2],
.....:     2, f, n, output_rings=[])
sage: for t in T.transitions():
.....:     print([x.parent() for x in t.word_out])
[]
[Symbolic Ring]
sage: [x.parent() for x in T.states()[0].final_word_out]
[Symbolic Ring]
```

Finally, we use a somewhat questionable conversion:

```
sage: T = transducers.Recursion([
.....:     f(2*n + 1) == f(n) + 1,
.....:     f(2*n) == f(n),
.....:     f(0) == 0],
.....:     2, f, n, output_rings=[GF(5)])
sage: for t in T.transitions():
.....:     print([x.parent() for x in t.word_out])
[]
[Finite Field of size 5]
```

Todo: Extend the method to

- non-integral bases,

- higher dimensions.

ALGORITHM:

See [HKP2015], Section 6. However, there are also recursion transitions for states of level $< \kappa$ if the recursion rules allow such a transition. Furthermore, the intermediate step of a non-deterministic transducer is left out by implicitly using recursion transitions. The well-posedness is checked in a truncated version of the recursion digraph.

class RecursionRule

Bases: tuple

K

Alias for field number 0

k

Alias for field number 2

r

Alias for field number 1

s

Alias for field number 3

t

Alias for field number 4

Wait(*input_alphabet*, *threshold=1*)Writes False until reading the *threshold*-th occurrence of a true input letter; then writes True.

INPUT:

- *input_alphabet* – a list or other iterable.
- *threshold* – a positive integer specifying how many occurrences of True inputs are waited for.

OUTPUT:

A transducer writing False until the *threshold*-th true (Python's standard conversion to boolean is used to convert the actual input to boolean) input is read. Subsequently, the transducer writes True.

EXAMPLES:

```
sage: T = transducers.Wait([0, 1])
sage: T([0, 0, 1, 0, 1, 0])
[False, False, True, True, True, True]
sage: T2 = transducers.Wait([0, 1], threshold=2)
sage: T2([0, 0, 1, 0, 1, 0])
[False, False, False, False, True, True]
```

abs(*input_alphabet*)

Returns a transducer which realizes the letter-wise absolute value of an input word over the given input alphabet.

INPUT:

- *input_alphabet* – a list or other iterable.

OUTPUT:

A transducer mapping $i_0 \dots i_k$ to $|i_0| \dots |i_k|$.

EXAMPLES:

The following transducer realizes letter-wise absolute value:

```
sage: T = transducers.abs([-1, 0, 1])
sage: T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([-1, -1, 0, 1])
[1, 1, 0, 1]
```

add(*input_alphabet*, *number_of_operands*=2)

Returns a transducer which realizes addition on pairs over the given input alphabet.

INPUT:

- *input_alphabet* – a list or other iterable.
- *number_of_operands* – (default: 2) it specifies the number of input arguments the operator takes.

OUTPUT:

A transducer mapping an input word $(i_{01}, \dots, i_{0d}) \dots (i_{k1}, \dots, i_{kd})$ to the word $(i_{01} + \dots + i_{0d}) \dots (i_{k1} + \dots + i_{kd})$.

The input alphabet of the generated transducer is the Cartesian product of *number_of_operands* copies of *input_alphabet*.

EXAMPLES:

The following transducer realizes letter-wise addition:

```
sage: T = transducers.add([0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 2]
```

More than two operands can also be handled:

```
sage: T3 = transducers.add([0, 1], number_of_operands=3)
sage: T3.input_alphabet
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1),
 (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1)]
sage: T3([(0, 0, 0), (0, 1, 0), (0, 1, 1), (1, 1, 1)])
[0, 1, 2, 3]
```

all(*input_alphabet*, *number_of_operands*=2)

Returns a transducer which realizes logical and over the given input alphabet.

INPUT:

- *input_alphabet* – a list or other iterable.
- *number_of_operands* – (default: 2) specifies the number of input arguments for the and operation.

OUTPUT:

A transducer mapping an input word $(i_{01}, \dots, i_{0d}) \dots (i_{k1}, \dots, i_{kd})$ to the word $(i_{01} \wedge \dots \wedge i_{0d}) \dots (i_{k1} \wedge \dots \wedge i_{kd})$.

The input alphabet of the generated transducer is the Cartesian product of *number_of_operands* copies of *input_alphabet*.

EXAMPLES:

The following transducer realizes letter-wise logical and:

```
sage: T = transducers.all([False, True])
sage: T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|False,
 Transition from 0 to 0: (True, False)|False,
 Transition from 0 to 0: (True, True)|True]
sage: T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(False, False), (False, True), (True, False), (True, True)])
[False, False, False, True]
```

More than two operands and other input alphabets (with conversion to boolean) are also possible:

```
sage: T3 = transducers.all([0, 1], number_of_operands=3)
sage: T3([(0, 0, 0), (1, 0, 0), (1, 1, 1)])
[False, False, True]
```

any(*input_alphabet*, *number_of_operands*=2)

Returns a transducer which realizes logical or over the given input alphabet.

INPUT:

- *input_alphabet* – a list or other iterable.
- *number_of_operands* – (default: 2) specifies the number of input arguments for the or operation.

OUTPUT:

A transducer mapping an input word $(i_{01}, \dots, i_{0d}) \dots (i_{k1}, \dots, i_{kd})$ to the word $(i_{01} \vee \dots \vee i_{0d}) \dots (i_{k1} \vee \dots \vee i_{kd})$.

The input alphabet of the generated transducer is the Cartesian product of *number_of_operands* copies of *input_alphabet*.

EXAMPLES:

The following transducer realizes letter-wise logical or:

```

sage: T = transducers.any([False, True])
sage: T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|True,
 Transition from 0 to 0: (True, False)|True,
 Transition from 0 to 0: (True, True)|True]
sage: T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(False, False), (False, True), (True, False), (True, True)])
[False, True, True, True]

```

More than two operands and other input alphabets (with conversion to boolean) are also possible:

```

sage: T3 = transducers.any([0, 1], number_of_operands=3)
sage: T3([(0, 0, 0), (1, 0, 0), (1, 1, 1)])
[False, True, True]

```

map(*f*, *input_alphabet*)

Return a transducer which realizes a function on the alphabet.

INPUT:

- *f* – function to realize.
- *input_alphabet* – a list or other iterable.

OUTPUT:

A transducer mapping an input letter x to $f(x)$.

EXAMPLES:

The following binary transducer realizes component-wise absolute value (this transducer is also available as `abs()`):

```

sage: T = transducers.map(abs, [-1, 0, 1])
sage: T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.input_alphabet
[-1, 0, 1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([-1, 1, 0, 1])
[1, 1, 0, 1]

```

See also:

[*Automaton.with_output\(\)*](#).

operator(operator, input_alphabet, number_of_operands=2)

Returns a transducer which realizes an operation on tuples over the given input alphabet.

INPUT:

- **operator** – operator to realize. It is a function which takes **number_of_operands** input arguments (each out of **input_alphabet**).
- **input_alphabet** – a list or other iterable.
- **number_of_operands** – (default: 2) it specifies the number of input arguments the operator takes.

OUTPUT:

A transducer mapping an input letter (i_1, \dots, i_n) to $\text{operator}(i_1, \dots, i_n)$. Here, n equals **number_of_operands**.

The input alphabet of the generated transducer is the Cartesian product of **number_of_operands** copies of **input_alphabet**.

EXAMPLES:

The following binary transducer realizes component-wise addition (this transducer is also available as [add\(\)](#)):

```
sage: import operator
sage: T = transducers.operator(operator.add, [0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 2]
```

Note that for a unary operator the input letters of the new transducer are tuples of length 1:

```
sage: T = transducers.operator(abs,
.....:                        [-1, 0, 1],
.....:                        number_of_operands=1)
sage: T([-1, 1, 0])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T([(-1,), (1,), (0,)])
[1, 1, 0]
```

Compare this with the transducer generated by [map\(\)](#):

```
sage: T = transducers.map(abs,
.....:                    [-1, 0, 1])
sage: T([-1, 1, 0])
[1, 1, 0]
```

In fact, this transducer is also available as `abs()`:

```
sage: T = transducers.abs([-1, 0, 1])
sage: T([-1, 1, 0])
[1, 1, 0]
```

`sub(input_alphabet)`

Returns a transducer which realizes subtraction on pairs over the given input alphabet.

INPUT:

- `input_alphabet` – a list or other iterable.

OUTPUT:

A transducer mapping an input word $(i_0, i'_0) \dots (i_k, i'_k)$ to the word $(i_0 - i'_0) \dots (i_k - i'_k)$.

The input alphabet of the generated transducer is the Cartesian product of two copies of `input_alphabet`.

EXAMPLES:

The following transducer realizes letter-wise subtraction:

```
sage: T = transducers.sub([0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|-1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|0]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, -1, 1, 0]
```

`weight(input_alphabet, zero=0)`

Returns a transducer which realizes the Hamming weight of the input over the given input alphabet.

INPUT:

- `input_alphabet` – a list or other iterable.
- `zero` – the zero symbol in the alphabet used

OUTPUT:

A transducer mapping $i_0 \dots i_k$ to $(i_0 \neq 0) \dots (i_k \neq 0)$.

The Hamming weight is defined as the number of non-zero digits in the input sequence over the alphabet `input_alphabet` (see [Wikipedia article Hamming_weight](#)). The output sequence of the transducer is a unary encoding of the Hamming weight. Thus the sum of the output sequence is the Hamming weight of the input.

EXAMPLES:

```
sage: W = transducers.weight([-1, 0, 2])
sage: W.transitions()
[Transition from 0 to 0: -1|1,
```

(continued from previous page)

```

Transition from 0 to 0: 0|0,
Transition from 0 to 0: 2|1]
sage: unary_weight = W([-1, 0, 0, 2, -1])
sage: unary_weight
[1, 0, 0, 1, 1]
sage: weight = add(unary_weight)
sage: weight
3

```

Also the joint Hamming weight can be computed:

```

sage: v1 = vector([-1, 0])
sage: v0 = vector([0, 0])
sage: W = transducers.weight([v1, v0])
sage: unary_weight = W([v1, v0, v1, v0])
sage: add(unary_weight)
2

```

For the input alphabet $[-1, 0, 1]$ the weight transducer is the same as the absolute value transducer `abs()`:

```

sage: W = transducers.weight([-1, 0, 1])
sage: A = transducers.abs([-1, 0, 1])
sage: W == A
True

```

For other input alphabets, we can specify the zero symbol:

```

sage: W = transducers.weight(['a', 'b'], zero='a')
sage: add(W(['a', 'b', 'b']))
2

```

5.1.107 Free Quasi-symmetric functions

AUTHORS:

- Frédéric Chapoton, Darij Grinberg (2017)

class sage.combinat.fqsym.FQSymBases(*base*)

Bases: `sage.categories.realizations.Category_realization_of_parent`

The category of graded bases of *FQSym* indexed by permutations.

class ElementMethods

Bases: object

omega_involution()

Return the image of the element `self` of *FQSym* under the omega involution.

The ω involution is defined as the linear map $FQSym \rightarrow FQSym$ that sends each basis element F_u of the F-basis of *FQSym* to the basis element $F_{u \circ w_0}$, where w_0 is the longest word (i.e., $w_0(i) = n+1-i$) in the symmetric group S_n that contains u . The ω involution is a graded algebra automorphism and a coalgebra anti-automorphism of *FQSym*. Every permutation $u \in S_n$ satisfies

$$\omega(F_u) = F_{u \circ w_0}, \quad \omega(G_u) = G_{w_0 \circ u},$$

where standard notations for classical bases of $FQSym$ are being used (that is, F for the F-basis, and G for the G-basis). In other words, writing permutations in one-line notation, we have

$$\omega(F_{(u_1, u_2, \dots, u_n)}) = F_{(u_n, u_{n-1}, \dots, u_1)}, \quad \omega(G_{(u_1, u_2, \dots, u_n)}) = G_{(n+1-u_1, n+1-u_2, \dots, n+1-u_n)}.$$

If we also consider the ω involution (`omega_involution()`) of the quasisymmetric functions (by slight abuse of notation), and if we let π be the canonical projection $FQSym \rightarrow QSym$, then $\pi \circ \omega = \omega \circ \pi$.

Additionally, consider the ψ involution (`psi_involution()`) of the noncommutative symmetric functions, and if we let ι be the canonical inclusion $NSym \rightarrow FQSym$, then $\omega \circ \iota = \iota \circ \psi$.

Todo: Duality?

See also:

`psi_involution()`, `star_involution()`

EXAMPLES:

```
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].omega_involution()
F[1, 3, 2]
sage: (3*F[[1]] - 4*F[[ ]] + 5*F[[1,2]]).omega_involution()
-4*F[ ] + 3*F[1] + 5*F[2, 1]
sage: G = FQSym.G()
sage: G[[2,3,1]].omega_involution()
G[2, 1, 3]
sage: M = FQSym.M()
sage: M[[2,3,1]].omega_involution()
-M[1, 2, 3] - M[2, 1, 3] - M[3, 1, 2]
```

The omega involution is an algebra homomorphism:

```
sage: (F[1,2] * F[1]).omega_involution()
F[2, 1, 3] + F[2, 3, 1] + F[3, 2, 1]
sage: F[1,2].omega_involution() * F[1].omega_involution()
F[2, 1, 3] + F[2, 3, 1] + F[3, 2, 1]
```

The omega involution intertwines the antipode and the inverse of the antipode:

```
sage: all( F(I).antipode().omega_involution().antipode()
.....:      == F(I).omega_involution()
.....:      for I in Permutations(4) )
True
```

Testing the $\pi \circ \omega = \omega \circ \pi$ relation noticed above:

```
sage: all( M[I].omega_involution().to_qsym()
.....:      == M[I].to_qsym().omega_involution()
.....:      for I in Permutations(4) )
True
```

Testing the $\omega \circ \iota = \iota \circ \psi$ relation:

```

sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].psi_involution().to_fqsym() == S[I].to_fqsym().omega_
↪involution()
.....:     for I in Compositions(4) )
True

```

Todo: Check further commutative squares.

`psi_involution()`

Return the image of the element `self` of $FQSym$ under the psi involution.

The ψ involution is defined as the linear map $FQSym \rightarrow FQSym$ that sends each basis element F_u of the F-basis of $FQSym$ to the basis element $F_{w_0 \circ u}$, where w_0 is the longest word (i.e., $w_0(i) = n+1-i$) in the symmetric group S_n that contains u . The ψ involution is a graded coalgebra automorphism and an algebra anti-automorphism of $FQSym$. Every permutation $u \in S_n$ satisfies

$$\psi(F_u) = F_{w_0 \circ u}, \quad \psi(G_u) = G_{u \circ w_0},$$

where standard notations for classical bases of $FQSym$ are being used (that is, F for the F-basis, and G for the G-basis). In other words, writing permutations in one-line notation, we have

$$\psi(F_{(u_1, u_2, \dots, u_n)}) = F_{(n+1-u_1, n+1-u_2, \dots, n+1-u_n)}, \quad \psi(G_{(u_1, u_2, \dots, u_n)}) = G_{(u_n, u_{n-1}, \dots, u_1)}.$$

If we also consider the ψ involution (`psi_involution()`) of the quasisymmetric functions (by slight abuse of notation), and if we let π be the canonical projection $FQSym \rightarrow QSym$, then $\pi \circ \psi = \psi \circ \pi$.

Additionally, consider the ω involution (`omega_involution()`) of the noncommutative symmetric functions, and if we let ι be the canonical inclusion $NSym \rightarrow FQSym$, then $\psi \circ \iota = \iota \circ \omega$.

Todo: Duality?

See also:

[omega_involution\(\)](#), [star_involution\(\)](#)

EXAMPLES:

```

sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].psi_involution()
F[2, 1, 3]
sage: (3*F[[1]] - 4*F[[]] + 5*F[[1,2]]).psi_involution()
-4*F[] + 3*F[1] + 5*F[2, 1]
sage: G = FQSym.G()
sage: G[[2,3,1]].psi_involution()
G[1, 3, 2]
sage: M = FQSym.M()
sage: M[[2,3,1]].psi_involution()
-M[1, 2, 3] - M[1, 3, 2] - M[2, 3, 1]

```

The ψ involution intertwines the antipode and the inverse of the antipode:

```
sage: all( F(I).antipode().psi_involution().antipode()
.....:    == F(I).psi_involution()
.....:    for I in Permutations(4) )
True
```

Testing the $\pi \circ \psi = \psi \circ \pi$ relation above:

```
sage: all( M[I].psi_involution().to_qsym()
.....:    == M[I].to_qsym().psi_involution()
.....:    for I in Permutations(4) )
True
```

Testing the $\psi \circ \iota = \iota \circ \omega$ relation:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].omega_involution().to_fqsym() == S[I].to_fqsym().psi_
.....:    ↪involution()
.....:    for I in Compositions(4) )
True
```

Todo: Check further commutative squares.

`star_involution()`

Return the image of the element `self` of $FQSym$ under the star involution.

The star involution is defined as the linear map $FQSym \rightarrow FQSym$ that sends each basis element F_u of the F-basis of $FQSym$ to the basis element $F_{w_0 \circ u \circ w_0}$, where w_0 is the longest word (i.e., $w_0(i) = n + 1 - i$) in the symmetric group S_n that contains u . The star involution is a graded Hopf algebra anti-automorphism of $FQSym$. It is denoted by $f \mapsto f^*$. Every permutation $u \in S_n$ satisfies

$$(F_u)^* = F_{w_0 \circ u \circ w_0}, \quad (G_u)^* = G_{w_0 \circ u \circ w_0}, \quad (\mathcal{M}_u)^* = \mathcal{M}_{w_0 \circ u \circ w_0},$$

where standard notations for classical bases of $FQSym$ are being used (that is, F for the F-basis, G for the G-basis, and \mathcal{M} for the Monomial basis). In other words, writing permutations in one-line notation, we have

$$(F_{(u_1, u_2, \dots, u_n)})^* = F_{(n+1-u_n, n+1-u_{n-1}, \dots, n+1-u_1)}, \quad (G_{(u_1, u_2, \dots, u_n)})^* = G_{(n+1-u_n, n+1-u_{n-1}, \dots, n+1-u_1)},$$

and

$$(\mathcal{M}_{(u_1, u_2, \dots, u_n)})^* = \mathcal{M}_{(n+1-u_n, n+1-u_{n-1}, \dots, n+1-u_1)}.$$

Let us denote the star involution by $(*)$ as well.

If we also denote by $(*)$ the star involution of the quasisymmetric functions (`star_involution()`) and if we let $\pi : FQSym \rightarrow QSym$ be the canonical projection then $\pi \circ (*) = (*) \circ \pi$. Similar for the noncommutative symmetric functions (`star_involution()`) with $\pi : NSym \rightarrow FQSym$ being the canonical inclusion and the word quasisymmetric functions (`star_involution()`) with $\pi : FQSym \rightarrow WQSym$ the canonical inclusion.

Todo: Duality?

See also:

`omega_involution()`, `psi_involution()`

EXAMPLES:

```
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].star_involution()
F[3, 1, 2]
sage: (3*F[[1]] - 4*F[[]] + 5*F[[1,2]]).star_involution()
-4*F[] + 3*F[1] + 5*F[1, 2]
sage: G = FQSym.G()
sage: G[[2,3,1]].star_involution()
G[3, 1, 2]
sage: M = FQSym.M()
sage: M[[2,3,1]].star_involution()
M[3, 1, 2]
```

The star involution commutes with the antipode:

```
sage: all( F(I).antipode().star_involution()
.....:      == F(I).star_involution().antipode()
.....:      for I in Permutations(4) )
True
```

Testing the $\pi \circ (*) = (*) \circ \pi$ relation:

```
sage: all( M[I].star_involution().to_qsym()
.....:      == M[I].to_qsym().star_involution()
.....:      for I in Permutations(4) )
True
```

Similar for *NSym*:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].star_involution().to_fqsym() == S[I].to_fqsym().star_
.....:      ↔involution()
.....:      for I in Compositions(4) )
True
```

Similar for *WQSym*:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: all( F(I).to_wqsym().star_involution()
.....:      == F(I).star_involution().to_wqsym()
.....:      for I in Permutations(4) )
True
```

Todo: Check further commutative squares.

to_qsym()

Return the image of `self` under the canonical projection $FQSym \rightarrow QSym$.

The canonical projection $FQSym \rightarrow QSym$ is a surjective homomorphism of Hopf algebras. It sends a basis element F_w of $FQSym$ to the basis element $F_{\text{Comp } w}$ of the fundamental basis of $QSym$, where $\text{Comp } w$ stands for the descent composition (`sage.combinat.permutation.Permutation.descents_composition()`) of the permutation w .

See also:

[QuasiSymmetricFunctions](#) for a definition of $QSym$.

EXAMPLES:

```
sage: G = algebras.FQSym(QQ).G()
sage: x = G[1, 3, 2]
sage: x.to_qsym()
F[2, 1]
sage: G[2, 3, 1].to_qsym()
F[1, 2]
sage: F = algebras.FQSym(QQ).F()
sage: F[2, 3, 1].to_qsym()
F[2, 1]
sage: (F[2, 3, 1] + F[1, 3, 2] + F[1, 2, 3]).to_qsym()
2*F[2, 1] + F[3]
sage: F2 = algebras.FQSym(GF(2)).F()
sage: F2[2, 3, 1].to_qsym()
F[2, 1]
sage: (F2[2, 3, 1] + F2[1, 3, 2] + F2[1, 2, 3]).to_qsym()
F[3]
```

to_symmetric_group_algebra($n=None$)

Return the element of a symmetric group algebra corresponding to the element `self` of $FQSym$.

INPUT:

- n – integer (default: the maximal degree of `self`); the rank of the target symmetric group algebra

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).G()
sage: x = A([1,3,2,4]) + 5/2 * A([2,3,4,1])
sage: x.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[4, 1, 2, 3]
```

to_wqsym()

Return the image of `self` under the canonical inclusion map $FQSym \rightarrow WQSym$.

The canonical inclusion map $FQSym \rightarrow WQSym$ is an injective homomorphism of Hopf algebras. It sends a basis element G_w of $FQSym$ to the sum of basis elements M_u of $WQSym$, where u ranges over all packed words whose standardization is w .

See also:

[WordQuasiSymmetricFunctions](#) for a definition of $WQSym$.

EXAMPLES:

```
sage: G = algebras.FQSym(QQ).G()
sage: x = G[1, 3, 2]
sage: x.to_wqsym()
M[{1}, {3}, {2}] + M[{1, 3}, {2}]
sage: G[1, 2].to_wqsym()
```

(continues on next page)

(continued from previous page)

```

M[{1}, {2}] + M[{1, 2}]
sage: F = algebras.FQSym(QQ).F()
sage: F[3, 1, 2].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
sage: G[2, 3, 1].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]

```

class ParentMethods

Bases: object

basis(*degree=None*)

The basis elements (optionally: of the specified degree).

OUTPUT: Family

EXAMPLES:

```

sage: FQSym = algebras.FQSym(QQ)
sage: G = FQSym.G()
sage: G.basis()
Lazy family (Term map from Standard permutations to Free Quasi-symmetric_
↪functions over Rational Field in the G basis(i))_{i in Standard_
↪permutations}
sage: G.basis().keys()
Standard permutations
sage: G.basis(degree=3).keys()
Standard permutations of 3
sage: G.basis(degree=3).list()
[G[1, 2, 3], G[1, 3, 2], G[2, 1, 3], G[2, 3, 1], G[3, 1, 2], G[3, 2, 1]]

```

from_symmetric_group_algebra(*x*)Return the element of $FQSym$ corresponding to the element x of a symmetric group algebra.

EXAMPLES:

```

sage: A = algebras.FQSym(QQ).F()
sage: SGA4 = SymmetricGroupAlgebra(QQ, 4)
sage: x = SGA4([1, 3, 2, 4]) + 5/2 * SGA4([1, 2, 4, 3])
sage: A.from_symmetric_group_algebra(x)
5/2 * F[1, 2, 4, 3] + F[1, 3, 2, 4]
sage: A.from_symmetric_group_algebra(SGA4.zero())
0

```

is_commutative()Return whether this $FQSym$ is commutative.

EXAMPLES:

```

sage: F = algebras.FQSym(ZZ).F()
sage: F.is_commutative()
False

```

is_field(*proof=True*)Return whether this $FQSym$ is a field.

EXAMPLES:

```
sage: F = algebras.FQSym(QQ).F()
sage: F.is_field()
False
```

one_basis()

Return the index of the unit.

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: A.one_basis()
[]
```

prec()

Return the \prec product.

On the F-basis of FQSym, this product is determined by $F_x \prec F_y = \sum F_z$, where the sum ranges over all z in the shifted shuffle of x and y with the additional condition that the first letter of the result comes from x .

The usual symbol for this operation is \prec .

See also:

[product\(\)](#), [succ\(\)](#)

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = A([2, 1])
sage: A.prec(x, x)
F[2, 1, 4, 3] + F[2, 4, 1, 3] + F[2, 4, 3, 1]
sage: y = A([2, 1, 3])
sage: A.prec(x, y)
F[2, 1, 4, 3, 5] + F[2, 4, 1, 3, 5] + F[2, 4, 3, 1, 5]
+ F[2, 4, 3, 5, 1]
sage: A.prec(y, x)
F[2, 1, 3, 5, 4] + F[2, 1, 5, 3, 4] + F[2, 1, 5, 4, 3]
+ F[2, 5, 1, 3, 4] + F[2, 5, 1, 4, 3] + F[2, 5, 4, 1, 3]
```

prec_by_coercion(x, y)

Return $x \prec y$, computed using coercion to the F-basis.

See [prec\(\)](#) for the definition of the objects involved.

EXAMPLES:

```
sage: G = algebras.FQSym(ZZ).G()
sage: a = G([1])
sage: b = G([2, 3, 1])
sage: G.prec(a, b) + G.succ(a, b) == a * b # indirect doctest
True
```

some_elements()

Return some elements of the free quasi-symmetric functions.

EXAMPLES:

```

sage: A = algebras.FQSym(QQ)
sage: F = A.F()
sage: F.some_elements()
[F[], F[1], F[1, 2] + F[2, 1], F[] + F[1, 2] + F[2, 1]]
sage: G = A.G()
sage: G.some_elements()
[G[], G[1], G[1, 2] + G[2, 1], G[] + G[1, 2] + G[2, 1]]
sage: M = A.M()
sage: M.some_elements()
[M[], M[1], M[1, 2] + 2*M[2, 1], M[] + M[1, 2] + 2*M[2, 1]]

```

succ()

Return the \succ product.

On the F-basis of FQSym, this product is determined by $F_x \succ F_y = \sum F_z$, where the sum ranges over all z in the shifted shuffle of x and y with the additional condition that the first letter of the result comes from y .

The usual symbol for this operation is \succ .

See also:

[product\(\)](#), [prec\(\)](#)

EXAMPLES:

```

sage: A = algebras.FQSym(QQ).F()
sage: x = A([1])
sage: A.succ(x, x)
F[2, 1]
sage: y = A([3, 1, 2])
sage: A.succ(x, y)
F[4, 1, 2, 3] + F[4, 2, 1, 3] + F[4, 2, 3, 1]
sage: A.succ(y, x)
F[4, 3, 1, 2]

```

succ_by_coercion(x, y)

Return $x \succ y$, computed using coercion to the F-basis.

See [succ\(\)](#) for the definition of the objects involved.

EXAMPLES:

```

sage: G = algebras.FQSym(ZZ).G()
sage: G.succ(G([1]), G([2, 3, 1])) # indirect doctest
G[2, 3, 4, 1] + G[3, 2, 4, 1] + G[4, 2, 3, 1]

```

super_categories()

The super categories of self.

EXAMPLES:

```

sage: from sage.combinat.fqsym import FQSymBases
sage: FQSym = algebras.FQSym(ZZ)
sage: bases = FQSymBases(FQSym)
sage: bases.super_categories()
[Category of realizations of Free Quasi-symmetric functions over Integer Ring,

```

(continues on next page)

(continued from previous page)

Join of Category of realizations of hopf algebras over Integer Ring
 and Category of graded algebras over Integer Ring
 and Category of graded coalgebras over Integer Ring,
 Category of graded connected hopf algebras with basis over Integer Ring]

class sage.combinat.fqsym.FQSymBasis_abstract(*alg*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`

Abstract base class for bases of FQSym.

This must define two attributes:

- `_prefix` – the basis prefix
- `_basis_name` – the name of the basis and must match one of the names that the basis can be constructed from FQSym

an_element()

Return an element of `self`.

EXAMPLES:

```
sage: A = algebras.FQSym(QQ)
sage: F = A.F()
sage: F.an_element()
F[1] + 2*F[1, 2] + 2*F[2, 1]
sage: G = A.G()
sage: G.an_element()
G[1] + 2*G[1, 2] + 2*G[2, 1]
sage: M = A.M()
sage: M.an_element()
M[1] + 2*M[1, 2] + 4*M[2, 1]
```

class sage.combinat.fqsym.FreeQuasisymmetricFunctions(*R*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The free quasi-symmetric functions.

The Hopf algebra $FQSym$ of free quasi-symmetric functions over a commutative ring R is the free R -module with basis indexed by all permutations (i.e., the indexing set is the disjoint union of all symmetric groups). Its product is determined by the shifted shuffles of two permutations, whereas its coproduct is given by splitting a permutation (regarded as a word) into two (at every possible point) and standardizing the two pieces. This Hopf algebra was introduced in [MR]. See [GriRei18] (Chapter 8) for a treatment using modern notations.

In more detail: For each $n \geq 0$, consider the symmetric group S_n . Let S be the disjoint union of the S_n over all $n \geq 0$. Then, $FQSym$ is the free R -module with basis $(F_w)_{w \in S}$. This R -module is graded, with the n -th graded component being spanned by all F_w for $w \in S_n$. A multiplication is defined on $FQSym$ as follows: For any two permutations $u \in S_k$ and $v \in S_l$, we set

$$F_u F_v = \sum F_w,$$

where the sum is over all shuffles of u with $v[k]$. Here, the permutations u and v are regarded as words (by writing them in one-line notation), and $v[k]$ means the word obtained from v by increasing each letter by k (for example, $(1, 4, 2, 3)[5] = (6, 9, 7, 8)$); and the shuffles w are translated back into permutations. This defines an associative multiplication on $FQSym$; its unity is F_e , where e is the identity permutation in S_0 .

In Section 1.3 of [AguSot05], Aguiar and Sottile construct a different basis of $FQSym$. Their basis, called the *monomial basis* and denoted by (\mathcal{M}_u) , is also indexed by permutations. It is connected to the above F-basis by the relation

$$F_u = \sum_v \mathcal{M}_v,$$

where the sum ranges over all permutations v such that each inversion of u is an inversion of v . (An *inversion* of a permutation w means a pair (i, j) of positions satisfying $i < j$ and $w(i) > w(j)$.) The above relation yields a unitriangular change-of-basis matrix, and thus can be used to compute the \mathcal{M}_u by Mobius inversion.

Another classical basis of $FQSym$ is $(G_w)_{w \in \mathcal{S}}$, where $G_w = F_{w^{-1}}$. This is just a relabeling of the basis $(F_w)_{w \in \mathcal{S}}$, but is a more natural choice from some viewpoints.

The algebra $FQSym$ is often identified with (“realized as”) a subring of the ring of all bounded-degree non-commutative power series in countably many indeterminates (i.e., elements in $R\langle\langle x_1, x_2, x_3, \dots \rangle\rangle$ of bounded degree). Namely, consider words over the alphabet $\{1, 2, 3, \dots\}$; every noncommutative power series is an infinite R -linear combination of these words. Consider the R -linear map that sends each G_u to the sum of all words whose standardization (also known as “standard permutation”; see [standard_permutation\(\)](#)) is u . This map is an injective R -algebra homomorphism, and thus embeds $FQSym$ into the latter ring.

As an associative algebra, $FQSym$ has the richer structure of a dendriform algebra. This means that the associative product $*$ is decomposed as a sum of two binary operations

$$xy = x \succ y + x \prec y$$

that satisfy the axioms:

$$(x \succ y) \prec z = x \succ (y \prec z),$$

$$(x \prec y) \prec z = x \prec (yz),$$

$$(xy) \succ z = x \succ (y \succ z).$$

These two binary operations are defined similarly to the (associative) product above: We set

$$F_u \prec F_v = \sum F_w,$$

where the sum is now over all shuffles of u with $v[k]$ whose first letter is taken from u (rather than from $v[k]$). Similarly,

$$F_u \succ F_v = \sum F_w,$$

where the sum is over all remaining shuffles of u with $v[k]$.

Todo: Decide what $1 \prec 1$ and $1 \succ 1$ are.

Note: The usual binary operator $*$ is used for the associative product.

EXAMPLES:

```
sage: F = algebras.FQSym(ZZ).F()
sage: x,y,z = F([1]), F([1,2]), F([1,3,2])
sage: (x * y) * z
F[1, 2, 3, 4, 6, 5] + ...
```

The product of $FQSym$ is associative:

```
sage: x * (y * z) == (x * y) * z
True
```

The associative product decomposes into two parts:

```
sage: x * y == F.prec(x, y) + F.succ(x, y)
True
```

The axioms of a dendriform algebra hold:

```
sage: F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
sage: F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
sage: F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

$FQSym$ is also known as the Malvenuto-Reutenauer algebra:

```
sage: algebras.MalvenutoReutenauer(ZZ)
Free Quasi-symmetric functions over Integer Ring
```

REFERENCES:

- [MR]
- [LR1998]
- [GriRei18]

class `F`(*alg*)

Bases: `sage.combinat.fqsym.FQSymBasis_abstract`

The F-basis of $FQSym$.

This is the basis (F_w) , with w ranging over all permutations. See the documentation of [FreeQuasisymmetricFunctions](#) for details.

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: FQSym.F()
Free Quasi-symmetric functions over Rational Field in the F basis
```

class `Element`

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

to_symmetric_group_algebra(*n=None*)

Return the element of a symmetric group algebra corresponding to the element `self` of $FQSym$.

INPUT:

- `n` – integer (default: the maximal degree of `self`); the rank of the target symmetric group algebra

EXAMPLES:

```

sage: A = algebras.FQSym(QQ).FC()
sage: x = A([1,3,2,4]) + 5/2 * A([1,2,4,3])
sage: x.to_symmetric_group_algebra()
5/2*[1, 2, 4, 3] + [1, 3, 2, 4]
sage: x.to_symmetric_group_algebra(n=7)
5/2*[1, 2, 4, 3, 5, 6, 7] + [1, 3, 2, 4, 5, 6, 7]
sage: a = A.zero().to_symmetric_group_algebra(); a
0
sage: parent(a)
Symmetric group algebra of order 0 over Rational Field

sage: y = A([1,3,2,4]) + 5/2 * A([2,1])
sage: y.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[2, 1, 3, 4]
sage: y.to_symmetric_group_algebra(6)
[1, 3, 2, 4, 5, 6] + 5/2*[2, 1, 3, 4, 5, 6]

```

coproduct_on_basis(x)

Return the coproduct of F_σ for σ a permutation (here, σ is x).

EXAMPLES:

```

sage: A = algebras.FQSym(QQ).FC()
sage: x = A([1])
sage: ascii_art(A.coproduct(A.one())) # indirect doctest
1 # 1

sage: ascii_art(A.coproduct(x)) # indirect doctest
1 # F      + F      # 1
   [1]      [1]

sage: A = algebras.FQSym(QQ).FC()
sage: x, y, z = A([1]), A([2,1]), A([3,2,1])
sage: A.coproduct(z)
F[] # F[3, 2, 1] + F[1] # F[2, 1] + F[2, 1] # F[1]
+ F[3, 2, 1] # F[]

```

degree_on_basis(t)

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the n for which the permutation belongs to S_n).

EXAMPLES:

```

sage: A = algebras.FQSym(QQ).FC()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2

```

prec_product_on_basis(x, y)

Return the \prec product of two permutations.

This is the shifted shuffle of x and y with the additional condition that the first letter of the result comes from x .

The usual symbol for this operation is \prec .

See also:

[*product_on_basis\(\)*](#), [*succ_product_on_basis\(\)*](#)

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1,2])
sage: A.prec_product_on_basis(x, x)
F[1, 2, 3, 4] + F[1, 3, 2, 4] + F[1, 3, 4, 2]
sage: y = Permutation([])
sage: A.prec_product_on_basis(x, y) == A(x)
True
sage: A.prec_product_on_basis(y, x) == 0
True
```

product_on_basis(*x*, *y*)

Return the $*$ associative product of two permutations.

This is the shifted shuffle of *x* and *y*.

See also:

[*succ_product_on_basis\(\)*](#), [*prec_product_on_basis\(\)*](#)

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1])
sage: A.product_on_basis(x, x)
F[1, 2] + F[2, 1]
```

succ_product_on_basis(*x*, *y*)

Return the \succ product of two permutations.

This is the shifted shuffle of *x* and *y* with the additional condition that the first letter of the result comes from *y*.

The usual symbol for this operation is \succ .

See also:

- [*product_on_basis\(\)*](#), [*prec_product_on_basis\(\)*](#)

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1,2])
sage: A.succ_product_on_basis(x, x)
F[3, 1, 2, 4] + F[3, 1, 4, 2] + F[3, 4, 1, 2]
sage: y = Permutation([])
sage: A.succ_product_on_basis(x, y) == 0
True
sage: A.succ_product_on_basis(y, x) == A(x)
True
```

class **G**(*alg*)

Bases: [*sage.combinat.fqsym.FQSymBasis_abstract*](#)

The G-basis of *FQSym*.

This is the basis (G_w) , with w ranging over all permutations. See the documentation of [FreeQuasisymmetricFunctions](#) for details.

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: G = FQSym.G(); G
Free Quasi-symmetric functions over Rational Field in the G basis

sage: G([3, 1, 2]).coproduct()
G[] # G[3, 1, 2] + G[1] # G[2, 1] + G[1, 2] # G[1]
+ G[3, 1, 2] # G[]

sage: G([3, 1, 2]) * G([2, 1])
G[3, 1, 2, 5, 4] + G[4, 1, 2, 5, 3] + G[4, 1, 3, 5, 2]
+ G[4, 2, 3, 5, 1] + G[5, 1, 2, 4, 3] + G[5, 1, 3, 4, 2]
+ G[5, 1, 4, 3, 2] + G[5, 2, 3, 4, 1] + G[5, 2, 4, 3, 1]
+ G[5, 3, 4, 2, 1]
```

degree_on_basis(t)

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the n for which the permutation belongs to S_n).

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).G()
sage: u = Permutation([2, 1])
sage: A.degree_on_basis(u)
2
```

class M(alg)

Bases: [sage.combinat.fqsym.FQSymBasis_abstract](#)

The M-basis of $FQSym$.

This is the Monomial basis (\mathcal{M}_w) , with w ranging over all permutations. See the documentation of [FQSym](#) for details.

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: M = FQSym.M(); M
Free Quasi-symmetric functions over Rational Field in the Monomial basis

sage: M([3, 1, 2]).coproduct()
M[] # M[3, 1, 2] + M[1] # M[1, 2] + M[3, 1, 2] # M[]

sage: M([3, 2, 1]).coproduct()
M[] # M[3, 2, 1] + M[1] # M[2, 1] + M[2, 1] # M[1]
+ M[3, 2, 1] # M[]

sage: M([1, 2]) * M([1])
M[1, 2, 3] + 2*M[1, 3, 2] + M[2, 3, 1] + M[3, 1, 2]
```

class Element

Bases: [sage.modules.with_basis.indexed_element.IndexedFreeModuleElement](#)

star_involution()

Return the image of the element `self` of $FQSym$ under the star involution.

See `FQSymBases.ElementMethods.star_involution()` for a definition of the involution and for examples.

See also:

`omega_involution()`, `psi_involution()`

EXAMPLES:

```
sage: FQSym = algebras.FQSym(ZZ)
sage: M = FQSym.M()
sage: M[[2,3,1]].star_involution()
M[3, 1, 2]
sage: M[[]].star_involution()
M[[]]
```

coproduct_on_basis(x)

Return the coproduct of \mathcal{M}_σ for σ a permutation (here, σ is `x`).

This uses Theorem 3.1 in [AguSot05].

EXAMPLES:

```
sage: M = algebras.FQSym(QQ).M()
sage: x = M([1])
sage: ascii_art(M.coproduct(M.one())) # indirect doctest
1 # 1

sage: ascii_art(M.coproduct(x)) # indirect doctest
1 # M      + M      # 1
      [1]    [1]

sage: M.coproduct(M([2, 1, 3]))
M[] # M[2, 1, 3] + M[2, 1, 3] # M[]
sage: M.coproduct(M([2, 3, 1]))
M[] # M[2, 3, 1] + M[1, 2] # M[1] + M[2, 3, 1] # M[]
sage: M.coproduct(M([3, 2, 1]))
M[] # M[3, 2, 1] + M[1] # M[2, 1] + M[2, 1] # M[1]
+ M[3, 2, 1] # M[]
sage: M.coproduct(M([3, 4, 2, 1]))
M[] # M[3, 4, 2, 1] + M[1, 2] # M[2, 1] + M[2, 3, 1] # M[1]
+ M[3, 4, 2, 1] # M[]
sage: M.coproduct(M([3, 4, 1, 2]))
M[] # M[3, 4, 1, 2] + M[1, 2] # M[1, 2] + M[3, 4, 1, 2] # M[]
```

degree_on_basis(t)

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the n for which the permutation belongs to S_n).

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).M()
sage: u = Permutation([2, 1])
```

(continues on next page)

(continued from previous page)

```
sage: A.degree_on_basis(u)
2
```

a_realization()

Return a particular realization of `self` (the F-basis).

EXAMPLES:

```
sage: FQSym = algebras.FQSym(QQ)
sage: FQSym.a_realization()
Free Quasi-symmetric functions over Rational Field in the F basis
```

5.1.108 Free modules

class `sage.combinat.free_module.CartesianProductWithFlattening`(*flatten*)

Bases: `object`

A class for Cartesian product constructor, with partial flattening

class `sage.combinat.free_module.CombinatorialFreeModule`(*R*, *basis_keys=None*, *element_class=None*, *category=None*, *prefix=None*, *names=None*, ***kwds*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.modules.module.Module`, `sage.structure.indexed_generators.IndexedGenerators`

Class for free modules with a named basis

INPUT:

- *R* - base ring
- *basis_keys* - list, tuple, family, set, etc. defining the indexing set for the basis of this module
- *element_class* - the class of which elements of this module should be instances (optional, default `None`, in which case the elements are instances of `IndexedFreeModuleElement`)
- *category* - the category in which this module lies (optional, default `None`, in which case use the “category of modules with basis” over the base ring *R*); this should be a subcategory of `ModulesWithBasis`

For the options controlling the printing of elements, see `IndexedGenerators`.

Note: These print options may also be accessed and modified using the `print_options()` method, after the module has been defined.

EXAMPLES:

We construct a free module whose basis is indexed by the letters a, b, c:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F
Free module generated by {'a', 'b', 'c'} over Rational Field
```

Its basis is a family, indexed by a, b, c:

```
sage: e = F.basis()
sage: e
Finite family {'a': B['a'], 'b': B['b'], 'c': B['c']}
```

```
sage: [x for x in e]
[B['a'], B['b'], B['c']]
sage: [k for k in e.keys()]
['a', 'b', 'c']
```

Let us construct some elements, and compute with them:

```
sage: e['a']
B['a']
sage: 2*e['a']
2*B['a']
sage: e['a'] + 3*e['b']
B['a'] + 3*B['b']
```

Some uses of `sage.categories.commutative_additive_semigroups.CommutativeAdditiveSemigroups.ParentMethods.summation()` and `sum()`:

```
sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.summation(F.monomial(1), F.monomial(3))
B[1] + B[3]

sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.sum(F.monomial(i) for i in [1,2,3])
B[1] + B[2] + B[3]
```

Note that free modules with a given basis and parameters are unique:

```
sage: F1 = CombinatorialFreeModule(QQ, (1,2,3,4))
sage: F1 is F
True
```

The identity of the constructed free module depends on the order of the basis and on the other parameters, like the prefix. Note that *CombinatorialFreeModule* is a *UniqueRepresentation*. Hence, two combinatorial free modules evaluate equal if and only if they are identical:

```
sage: F1 = CombinatorialFreeModule(QQ, (1,2,3,4))
sage: F1 is F
True
sage: F1 = CombinatorialFreeModule(QQ, [4,3,2,1])
sage: F1 == F
False
sage: F2 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F')
sage: F2 == F
False
```

Because of this, if you create a free module with certain parameters and then modify its prefix or other print options, this affects all modules which were defined using the same parameters.

```

sage: F2.print_options(prefix='x')
sage: F2.prefix()
'x'
sage: F3 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F')
sage: F3 is F2 # F3 was defined just like F2
True
sage: F3.prefix()
'x'
sage: F4 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F', bracket=True)
sage: F4 == F2 # F4 was NOT defined just like F2
False
sage: F4.prefix()
'F'

sage: F2.print_options(prefix='F') #reset for following doctests

```

The constructed module is in the category of modules with basis over the base ring:

```

sage: CombinatorialFreeModule(QQ, Partitions()).category()
Category of vector spaces with basis over Rational Field

```

If furthermore the index set is finite (i.e. in the category `Sets().Finite()`), then the module is declared as being finite dimensional:

```

sage: CombinatorialFreeModule(QQ, [1,2,3,4]).category()
Category of finite dimensional vector spaces with basis over Rational Field
sage: CombinatorialFreeModule(QQ, Partitions(3),
.....:                          category=Algebras(QQ).WithBasis()).category()
Category of finite dimensional algebras with basis over Rational Field

```

See [sage.categories.examples.algebras_with_basis](#) and [sage.categories.examples.hopf_algebras_with_basis](#) for illustrations of the use of the `category` keyword, and see [sage.combinat.root_system.weight_space.WeightSpace](#) for an example of the use of `element_class`.

Customizing print and LaTeX representations of elements:

```

sage: F = CombinatorialFreeModule(QQ, ['a','b'], prefix='x')
sage: original_print_options = F.print_options()
sage: sorted(original_print_options.items())
[('bracket', None),
 ('iterate_key', False),
 ('latex_bracket', False), ('latex_names', None),
 ('latex_prefix', None), ('latex_scalar_mult', None),
 ('names', None), ('prefix', 'x'),
 ('scalar_mult', '*'),
 ('sorting_key', <function ...<lambda> at ...>),
 ('sorting_reverse', False), ('string_quotes', True),
 ('tensor_symbol', None)]

sage: e = F.basis()
sage: e['a'] - 3 * e['b']
x['a'] - 3*x['b']

sage: F.print_options(prefix='x', scalar_mult=' ', bracket='{')

```

(continues on next page)

(continued from previous page)

```

sage: e['a'] - 3 * e['b']
x{'a'} - 3 x{'b'}
sage: latex(e['a'] - 3 * e['b'])
x_{a} - 3 x_{b}

sage: F.print_options(latex_prefix='y')
sage: latex(e['a'] - 3 * e['b'])
y_{a} - 3 y_{b}

sage: F.print_options(sorting_reverse=True)
sage: e['a'] - 3 * e['b']
-3 x{'b'} + x{'a'}
sage: F.print_options(**original_print_options) # reset print options

sage: F = CombinatorialFreeModule(QQ, [(1,2), (3,4)])
sage: e = F.basis()
sage: e[(1,2)] - 3 * e[(3,4)]
B[(1, 2)] - 3*B[(3, 4)]

sage: F.print_options(bracket=['_{' , '}'])
sage: e[(1,2)] - 3 * e[(3,4)]
B_{(1, 2)} - 3*B_{(3, 4)}

sage: F.print_options(prefix='', bracket=False)
sage: e[(1,2)] - 3 * e[(3,4)]
(1, 2) - 3*(3, 4)

```

CartesianProductalias of *CombinatorialFreeModule_CartesianProduct***Element**alias of *sage.modules.with_basis.indexed_element.IndexedFreeModuleElement***Tensor**alias of *CombinatorialFreeModule_Tensor***construction()**

The construction functor and base ring for self.

EXAMPLES:

```

sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'],
↪category=AlgebrasWithBasis(QQ))
sage: F.construction()
(VectorFunctor, Rational Field)

```

dimension()

Return the dimension of the free module (which is given by the number of elements in the basis).

EXAMPLES:

```

sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.dimension()
3
sage: F.basis().cardinality()

```

(continues on next page)

(continued from previous page)

```
3
sage: F.basis().keys().cardinality()
3
```

Rank is available as a synonym:

```
sage: F.rank()
3
```

```
sage: s = SymmetricFunctions(QQ).schur()
sage: s.dimension()
+Infinity
```

`element_class()`

The (default) class for the elements of this parent

Overrides `Parent.element_class()` to force the construction of Python class. This is currently needed to inherit really all the features from categories, and in particular the initialization of `_mul_` in `Magnas.ParentMethods.__init_extra__()`.

EXAMPLES:

```
sage: A = Algebras(QQ).WithBasis().example(); A
An example of an algebra with basis:
the free algebra on the generators ('a', 'b', 'c') over Rational Field

sage: A.element_class.mro()
[<class 'sage.categories.examples.algebras_with_basis.FreeAlgebra_with_category.
↪element_class'>,
 <class 'sage.modules.with_basis.indexed_element.IndexedFreeModuleElement'>,
 ...]
sage: a,b,c = A.algebra_generators()
sage: a * b
B[word: ab]
```

`from_vector(vector, order=None, coerce=True)`

Build an element of `self` from a (sparse) vector.

See also:

`get_order()`, `CombinatorialFreeModule.Element._vector_()`

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: b = QS3.from_vector(vector((2, 0, 0, 0, 0, 4))); b
2*[1, 2, 3] + 4*[3, 2, 1]
sage: a = 2*QS3([1,2,3])+4*QS3([3,2,1])
sage: a == b
True
```

`get_order()`

Return the order of the elements in the basis.

EXAMPLES:

```

sage: QS2 = SymmetricGroupAlgebra(QQ,2)
sage: QS2.get_order() # note: order changed on 2009-03-13
[[2, 1], [1, 2]]

```

get_order_key()

Return a comparison key on the basis indices that is compatible with the current term order.

EXAMPLES:

```

sage: A = FiniteDimensionalAlgebrasWithBasis(QQ).example()
sage: A.set_order(['x', 'y', 'a', 'b'])
sage: Akey = A.get_order_key()
sage: sorted(A.basis().keys(), key=Akey)
['x', 'y', 'a', 'b']
sage: A.set_order(list(reversed(A.basis().keys())))
sage: Akey = A.get_order_key()
sage: sorted(A.basis().keys(), key=Akey)
['b', 'a', 'y', 'x']

```

is_exact()

Return True if elements of `self` have exact representations, which is true of `self` if and only if it is true of `self.basis().keys()` and `self.base_ring()`.

EXAMPLES:

```

sage: GroupAlgebra(GL(3, GF(7))).is_exact()
True
sage: GroupAlgebra(GL(3, GF(7)), RR).is_exact()
False
sage: GroupAlgebra(GL(3, pAdicRing(7))).is_exact() # not implemented correctly,
↪(not my fault)!
False

```

linear_combination(iter_of_elements_coeff, factor_on_left=True)

Return the linear combination $\lambda_1 v_1 + \cdots + \lambda_k v_k$ (resp. the linear combination $v_1 \lambda_1 + \cdots + v_k \lambda_k$) where `iter_of_elements_coeff` iterates through the sequence $((v_1, \lambda_1), \dots, (v_k, \lambda_k))$.

INPUT:

- `iter_of_elements_coeff` – iterator of pairs (element, coeff) with element in `self` and coeff in `self.base_ring()`
- `factor_on_left` – (optional) if True, the coefficients are multiplied from the left if False, the coefficients are multiplied from the right

EXAMPLES:

```

sage: F = CombinatorialFreeModule(QQ, [1,2])
sage: f = F.an_element(); f
2*B[1] + 2*B[2]
sage: F.linear_combination( (f,i) for i in range(5) )
20*B[1] + 20*B[2]

```

monomial()

Return the basis element indexed by `i`.

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.monomial('a')
B['a']
```

F.monomial is in fact (almost) a map:

```
sage: F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'} over
↳Rational Field
```

rank()

Return the dimension of the free module (which is given by the number of elements in the basis).

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.dimension()
3
sage: F.basis().cardinality()
3
sage: F.basis().keys().cardinality()
3
```

Rank is available as a synonym:

```
sage: F.rank()
3
```

```
sage: s = SymmetricFunctions(QQ).schur()
sage: s.dimension()
+Infinity
```

set_order(*order*)

Set the order of the elements of the basis.

If `set_order()` has not been called, then the ordering is the one used in the generation of the elements of self's associated enumerated set.

Warning: Many cached methods depend on this order, in particular for constructing subspaces and quotients. Changing the order after some computations have been cached does not invalidate the cache, and is likely to introduce inconsistencies.

EXAMPLES:

```
sage: QS2 = SymmetricGroupAlgebra(QQ,2)
sage: b = list(QS2.basis().keys())
sage: b.reverse()
sage: QS2.set_order(b)
sage: QS2.get_order()
[[2, 1], [1, 2]]
```

sum(*iter_of_elements*)Return the sum of all elements in *iter_of_elements*.

Overrides method inherited from commutative additive monoid as it is much faster on dicts directly.

INPUT:

- *iter_of_elements* – iterator of elements of *self*

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ,[1,2])
sage: f = F.an_element(); f
2*B[1] + 2*B[2]
sage: F.sum( f for _ in range(5) )
10*B[1] + 10*B[2]
```

sum_of_terms(*terms*, *distinct=False*)Construct a sum of terms of *self*.

INPUT:

- *terms* – a list (or iterable) of pairs (*index*, *coeff*)
- *distinct* – (default: `False`) whether the indices are guaranteed to be distinct

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.sum_of_terms([('a',2), ('c',3)])
2*B['a'] + 3*B['c']
```

If *distinct* is `True`, then the construction is optimized:

```
sage: F.sum_of_terms([('a',2), ('c',3)], distinct = True)
2*B['a'] + 3*B['c']
```

Warning: Use *distinct=True* only if you are sure that the indices are indeed distinct:

```
sage: F.sum_of_terms([('a',2), ('a',3)], distinct = True)
3*B['a']
```

Extreme case:

```
sage: F.sum_of_terms([])
0
```

term(*index*, *coeff=None*)Construct a term in *self*.

INPUT:

- *index* – the index of a basis element
- *coeff* – an element of the coefficient ring (default: one)

EXAMPLES:

```

sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.term('a',3)
3*B['a']
sage: F.term('a')
B['a']

```

Design: should this do coercion on the coefficient ring?

zero()

EXAMPLES:

```

sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.zero()
0

```

class `sage.combinat.free_module.CombinatorialFreeModule_CartesianProduct`(*modules, **options*)
 Bases: `sage.combinat.free_module.CombinatorialFreeModule`

An implementation of Cartesian products of modules with basis

EXAMPLES:

We construct two free modules, assign them short names, and construct their Cartesian product:

```

sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.__custom_name = "F"
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.__custom_name = "G"
sage: H = CombinatorialFreeModule(ZZ, [4,7]); H.__custom_name = "H"
sage: S = cartesian_product([F, G])
sage: S
F (+) G
sage: S.basis()
Lazy family (Term map from Disjoint union of Family ({4, 5}, {4, 6}) to F (+) G(i))_
↪ {i in Disjoint union of Family ({4, 5}, {4, 6})}

```

Note that the indices of the basis elements of F and G intersect non trivially. This is handled by forcing the union to be disjoint:

```

sage: list(S.basis())
[B[(0, 4)], B[(0, 5)], B[(1, 4)], B[(1, 6)]]

```

We now compute the Cartesian product of elements of free modules:

```

sage: f = F.monomial(4) + 2 * F.monomial(5)
sage: g = 2*G.monomial(4) + G.monomial(6)
sage: h = H.monomial(4) + H.monomial(7)
sage: cartesian_product([f,g])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)]
sage: cartesian_product([f,g,h])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)] + B[(2, 4)] + B[(2, 7)]
sage: cartesian_product([f,g,h]).parent()
F (+) G (+) H

```

TODO: choose an appropriate semantic for Cartesian products of Cartesian products (associativity?):

```

sage: S = cartesian_product([cartesian_product([F, G]), H]) # todo: not implemented
F (+) G (+) H

```

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

cartesian_embedding(*i*)

Return the natural embedding morphism of the *i*-th Cartesian factor (summand) of `self` into `self`.

INPUT:

- *i* – an integer

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.__custom_name = "F"
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.__custom_name = "G"
sage: S = cartesian_product([F, G])
sage: phi = S.cartesian_embedding(0)
sage: phi(F.monomial(4) + 2 * F.monomial(5))
B[(0, 4)] + 2*B[(0, 5)]
sage: phi(F.monomial(4) + 2 * F.monomial(6)).parent() == S
True
```

cartesian_factors()

Return the factors of the Cartesian product.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.__custom_name = "F"
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.__custom_name = "G"
sage: S = cartesian_product([F, G])
sage: S.cartesian_factors()
(F, G)
```

cartesian_projection(*i*)

Return the natural projection onto the *i*-th Cartesian factor (summand) of `self`.

INPUT:

- *i* – an integer

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.__custom_name = "F"
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.__custom_name = "G"
sage: S = cartesian_product([F, G])
sage: x = S.monomial((0,4)) + 2 * S.monomial((0,5)) + 3 * S.monomial((1,6))
sage: S.cartesian_projection(0)(x)
B[4] + 2*B[5]
sage: S.cartesian_projection(1)(x)
3*B[6]
sage: S.cartesian_projection(0)(x).parent() == F
True
sage: S.cartesian_projection(1)(x).parent() == G
True
```

summand_embedding(*i*)

Return the natural embedding morphism of the *i*-th Cartesian factor (summand) of `self` into `self`.

INPUT:

- *i* – an integer

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.__custom_name = "F"
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.__custom_name = "G"
sage: S = cartesian_product([F, G])
sage: phi = S.cartesian_embedding(0)
sage: phi(F.monomial(4) + 2 * F.monomial(5))
B[(0, 4)] + 2*B[(0, 5)]
sage: phi(F.monomial(4) + 2 * F.monomial(6)).parent() == S
True
```

summand_projection(*i*)

Return the natural projection onto the *i*-th Cartesian factor (summand) of self.

INPUT:

- *i* – an integer

EXAMPLES:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.__custom_name = "F"
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.__custom_name = "G"
sage: S = cartesian_product([F, G])
sage: x = S.monomial((0,4)) + 2 * S.monomial((0,5)) + 3 * S.monomial((1,6))
sage: S.cartesian_projection(0)(x)
B[4] + 2*B[5]
sage: S.cartesian_projection(1)(x)
3*B[6]
sage: S.cartesian_projection(0)(x).parent() == F
True
sage: S.cartesian_projection(1)(x).parent() == G
True
```

class sage.combinat.free_module.**CombinatorialFreeModule_Tensor**(*modules*, ***options*)

Bases: *sage.combinat.free_module.CombinatorialFreeModule*

Tensor Product of Free Modules

EXAMPLES:

We construct two free modules, assign them short names, and construct their tensor product:

```
sage: F = CombinatorialFreeModule(ZZ, [1,2]); F.__custom_name = "F"
sage: G = CombinatorialFreeModule(ZZ, [3,4]); G.__custom_name = "G"
sage: T = tensor([F, G]); T
F # G

sage: T.category()
Category of tensor products of finite dimensional modules with basis over Integer_
↔ Ring

sage: T.construction() # todo: not implemented
[tensor, ]
```

T is a free module, with same base ring as F and G:

```
sage: T.base_ring()
Integer Ring
```

The basis of T is indexed by tuples of basis indices of F and G:

```
sage: T.basis().keys()
Image of Cartesian product of {1, 2}, {3, 4} by The map <class 'tuple'> from_
↪Cartesian product of {1, 2}, {3, 4}
sage: T.basis().keys().list()
[(1, 3), (1, 4), (2, 3), (2, 4)]
```

FIXME: Should elements of a CartesianProduct be tuples (making them hashable)?

Here are the basis elements themselves:

```
sage: T.basis().cardinality()
4
sage: list(T.basis())
[B[1] # B[3], B[1] # B[4], B[2] # B[3], B[2] # B[4]]
```

The tensor product is associative and flattens sub tensor products:

```
sage: H = CombinatorialFreeModule(ZZ, [5,6]); H.rename("H")
sage: tensor([F, tensor([G, H]])
F # G # H
sage: tensor([tensor([F, G]), H])
F # G # H
sage: tensor([F, G, H])
F # G # H
```

We now compute the tensor product of elements of free modules:

```
sage: f = F.monomial(1) + 2 * F.monomial(2)
sage: g = 2*G.monomial(3) + G.monomial(4)
sage: h = H.monomial(5) + H.monomial(6)
sage: tensor([f, g])
2*B[1] # B[3] + B[1] # B[4] + 4*B[2] # B[3] + 2*B[2] # B[4]
```

Again, the tensor product is associative on elements:

```
sage: tensor([f, tensor([g, h]]) == tensor([f, g, h])
True
sage: tensor([tensor([f, g]), h]) == tensor([f, g, h])
True
```

Note further that the tensor product spaces need not preexist:

```
sage: t = tensor([f, g, h])
sage: t.parent()
F # G # H
```

tensor_constructor(*modules*)
INPUT:

- *modules* – a tuple (F_1, \dots, F_n) of free modules whose tensor product is self

Returns the canonical multilinear morphism from $F_1 \times \cdots \times F_n$ to $F_1 \otimes \cdots \otimes F_n$

EXAMPLES:

```

sage: F = CombinatorialFreeModule(ZZ, [1,2]); F.__custom_name = "F"
sage: G = CombinatorialFreeModule(ZZ, [3,4]); G.__custom_name = "G"
sage: H = CombinatorialFreeModule(ZZ, [5,6]); H.rename("H")

sage: f = F.monomial(1) + 2 * F.monomial(2)
sage: g = 2*G.monomial(3) + G.monomial(4)
sage: h = H.monomial(5) + H.monomial(6)
sage: FG = tensor([F, G ])
sage: phi_fg = FG.tensor_constructor((F, G))
sage: phi_fg(f,g)
2*B[1] # B[3] + B[1] # B[4] + 4*B[2] # B[3] + 2*B[2] # B[4]

sage: FGH = tensor([F, G, H])
sage: phi_fgh = FGH.tensor_constructor((F, G, H))
sage: phi_fgh(f, g, h)
2*B[1] # B[3] # B[5] + 2*B[1] # B[3] # B[6] + B[1] # B[4] # B[5] + B[1] # B[4]
↳ # B[6] + 4*B[2] # B[3] # B[5] + 4*B[2] # B[3] # B[6] + 2*B[2] # B[4] # B[5] +
↳ 2*B[2] # B[4] # B[6]

sage: phi_fg_h = FGH.tensor_constructor((FG, H))
sage: phi_fg_h(phi_fg(f, g), h)
2*B[1] # B[3] # B[5] + 2*B[1] # B[3] # B[6] + B[1] # B[4] # B[5] + B[1] # B[4]
↳ # B[6] + 4*B[2] # B[3] # B[5] + 4*B[2] # B[3] # B[6] + 2*B[2] # B[4] # B[5] +
↳ 2*B[2] # B[4] # B[6]

```

5.1.109 Free Dendriform Algebras

AUTHORS:

Frédéric Chapoton (2017)

class `sage.combinat.free_dendriform_algebra.DendriformFunctor`(vars)

Bases: `sage.categories.pushout.ConstructionFunctor`

A constructor for dendriform algebras.

EXAMPLES:

```

sage: P = algebras.FreeDendriform(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F = P.construction()[0]; F
Dendriform[x,y]

sage: A = GF(5)['a,b']
sage: a, b = A.gens()
sage: F(A)
Free Dendriform algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5

sage: f = A.hom([a+b,a-b],A)
sage: F(f)

```

(continues on next page)

(continued from previous page)

```
Generic endomorphism of Free Dendriform algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5
```

```
sage: F(f)(a * F(A)(x))
(a+b)*B[x[., .]]
```

merge(*other*)

Merge self with another construction functor, or return None.

EXAMPLES:

```
sage: F = sage.combinat.free_dendriform_algebra.DendriformFunctor(['x', 'y'])
sage: G = sage.combinat.free_dendriform_algebra.DendriformFunctor(['t'])
sage: F.merge(G)
Dendriform[x,y,t]
sage: F.merge(F)
Dendriform[x,y]
```

Now some actual use cases:

```
sage: R = algebras.FreeDendriform(ZZ, 'x,y,z')
sage: x,y,z = R.gens()
sage: 1/2 * x
1/2*B[x[., .]]
sage: parent(1/2 * x)
Free Dendriform algebra on 3 generators ['x', 'y', 'z'] over Rational Field

sage: S = algebras.FreeDendriform(QQ, 'zt')
sage: z,t = S.gens()
sage: x + t
B[t[., .]] + B[x[., .]]
sage: parent(x + t)
Free Dendriform algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field
```

class `sage.combinat.free_dendriform_algebra.FreeDendriformAlgebra`(*R*, *names=None*)Bases: `sage.combinat.free_module.CombinatorialFreeModule`

The free dendriform algebra.

Dendriform algebras are associative algebras, where the associative product $*$ is decomposed as a sum of two binary operations

$$x * y = x \succ y + x \prec y$$

that satisfy the axioms:

$$(x \succ y) \prec z = x \succ (y \prec z),$$

$$(x \prec y) \prec z = x \prec (y * z).$$

$$(x * y) \succ z = x \succ (y \succ z).$$

The free Dendriform algebra on a given set E has an explicit description using (planar) binary trees, just as the free associative algebra can be described using words. The underlying vector space has a basis indexed by finite binary trees endowed with a map from their vertices to E . In this basis, the associative product of two

(decorated) binary trees $S * T$ is the sum over all possible ways of identifying (glueing) the rightmost path in S and the leftmost path in T .

The decomposition of the associative product as the sum of two binary operations \succ and \prec is made by separating the terms according to the origin of the root vertex. For $x \succ y$, one keeps the terms where the root vertex comes from y , whereas for $x \prec y$ one keeps the terms where the root vertex comes from x .

The free dendriform algebra can also be considered as the free algebra over the Dendriform operad.

Note: The usual binary operator $*$ is used for the associative product.

EXAMPLES:

```
sage: F = algebras.FreeDendriform(ZZ, 'xyz')
sage: x,y,z = F.gens()
sage: (x * y) * z
B[x[., y[., z[., .]]]] + B[x[., z[y[., .], .]]] + B[y[x[., .], z[., .]]] + B[z[x[., .],
↪y[., .]], .]] + B[z[y[x[., .], .], .]]
```

The free dendriform algebra is associative:

```
sage: x * (y * z) == (x * y) * z
True
```

The associative product decomposes in two parts:

```
sage: x * y == F.prec(x, y) + F.succ(x, y)
True
```

The axioms hold:

```
sage: F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
sage: F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
sage: F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

When there is only one generator, unlabelled trees are used instead:

```
sage: F1 = algebras.FreeDendriform(QQ)
sage: w = F1.gen(0); w
B[[., .]]
sage: w * w * w
B[[., [., [., .]]]] + B[[., [[., .], .]]] + B[[[., .], [., .]]] + B[[[., [., .]], .
↪]] + B[[[[., .], .], .]]
```

REFERENCES:

- [LR1998]

algebra_generators()

Return the generators of this algebra.

These are the binary trees with just one vertex.

EXAMPLES:

```

sage: A = algebras.FreeDendriform(ZZ, 'fgh'); A
Free Dendriform algebra on 3 generators ['f', 'g', 'h']
over Integer Ring
sage: list(A.algebra_generators())
[B[f[., .]], B[g[., .]], B[h[., .]]]

sage: A = algebras.FreeDendriform(QQ, ['x1', 'x2'])
sage: list(A.algebra_generators())
[B[x1[., .]], B[x2[., .]]]

```

an_element()

Return an element of self.

EXAMPLES:

```

sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.an_element()
B[x[., .]] + 2*B[x[., x[., .]]] + 2*B[x[x[., .], .]]

```

change_ring(R)

Return the free dendriform algebra in the same variables over R .

INPUT:

- R – a ring

EXAMPLES:

```

sage: A = algebras.FreeDendriform(ZZ, 'fgh')
sage: A.change_ring(QQ)
Free Dendriform algebra on 3 generators ['f', 'g', 'h'] over
Rational Field

```

construction()

Return a pair (F, R) , where F is a *DendriformFunctor* and R is a ring, such that $F(R)$ returns self.

EXAMPLES:

```

sage: P = algebras.FreeDendriform(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F, R = P.construction()
sage: F
Dendriform[x,y]
sage: R
Integer Ring
sage: F(ZZ) is P
True
sage: F(QQ)
Free Dendriform algebra on 2 generators ['x', 'y'] over Rational Field

```

coproduct_on_basis(x)

Return the coproduct of a binary tree.

EXAMPLES:

```

sage: A = algebras.FreeDendriform(QQ)
sage: x = A.gen(0)
sage: ascii_art(A.coproduct(A.one())) # indirect doctest
1 # 1

sage: ascii_art(A.coproduct(x)) # indirect doctest
1 # B + B # 1
  o   o

sage: A = algebras.FreeDendriform(QQ, 'xyz')
sage: x, y, z = A.gens()
sage: w = A.under(z, A.over(x, y))
sage: A.coproduct(z)
B[.] # B[z[., .]] + B[z[., .]] # B[.]
sage: A.coproduct(w)
B[.] # B[x[z[., .], y[., .]]] + B[x[., .]] # B[z[., y[., .]]] +
B[x[., .]] # B[y[z[., .], .]] + B[x[., y[., .]]] # B[z[., .]] +
B[x[z[., .], .]] # B[y[., .]] + B[x[z[., .], y[., .]] # B[.]

```

degree_on_basis(*t*)

Return the degree of a binary tree in the free Dendriform algebra.

This is the number of vertices.

EXAMPLES:

```

sage: A = algebras.FreeDendriform(QQ, '@')
sage: RT = A.basis().keys()
sage: u = RT([], '@')
sage: A.degree_on_basis(u.over(u))
2

```

gen(*i*)

Return the *i*-th generator of the algebra.

INPUT:

- *i* – an integer

EXAMPLES:

```

sage: F = algebras.FreeDendriform(ZZ, 'xyz')
sage: F.gen(0)
B[x[., .]]

sage: F.gen(4)
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2

```

gens()

Return the generators of `self` (as an algebra).

EXAMPLES:

```
sage: A = algebras.FreeDendriform(ZZ, 'fgh')
sage: A.gens()
(B[[f[., .]], B[g[., .]], B[h[., .]])
```

one_basis()

Return the index of the unit.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ, '@')
sage: A.one_basis()
.
sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.one_basis()
.
```

over()

Return the over product.

The over product x/y is the binary tree obtained by grafting the root of y at the rightmost leaf of x .

The usual symbol for this operation is $/$.

See also:

`product()`, `succ()`, `prec()`, `under()`

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.over(x, x)
B[[., [., .]]]
```

prec()

Return the \prec dendriform product.

This is the sum over all possible ways to identify the rightmost path in x and the leftmost path in y , with the additional condition that the root vertex of the result comes from x .

The usual symbol for this operation is \prec .

See also:

`product()`, `succ()`, `over()`, `under()`

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.prec(x, x)
B[[., [., .]]]
```

prec_product_on_basis(x, y)

Return the \prec dendriform product of two trees.

This is the sum over all possible ways of identifying the rightmost path in x and the leftmost path in y , with the additional condition that the root vertex of the result comes from x .

The usual symbol for this operation is \prec .

See also:

- `product_on_basis()`, `succ_product_on_basis()`

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.prec_product_on_basis(x, x)
B[[., [.], .]]
```

product_on_basis(x, y)

Return the $*$ associative dendriform product of two trees.

This is the sum over all possible ways of identifying the rightmost path in x and the leftmost path in y . Every term corresponds to a shuffle of the vertices on the rightmost path in x and the vertices on the leftmost path in y .

See also:

- `succ_product_on_basis()`, `prec_product_on_basis()`

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.product_on_basis(x, x)
B[[., [.], .]] + B[[[., .], .]]
```

some_elements()

Return some elements of the free dendriform algebra.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: A.some_elements()
[B[.],
 B[[., .]],
 B[[., [.], .]] + B[[[., .], .]],
 B[.] + B[[., [.], .]] + B[[[., .], .]]]
```

With several generators:

```
sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.some_elements()
[B[.],
 B[x[., .]],
 B[x[., x[., .]]] + B[x[x[., .], .]],
 B[.] + B[x[., x[., .]]] + B[x[x[., .], .]]]
```

succ()

Return the \succ dendriform product.

This is the sum over all possible ways of identifying the rightmost path in x and the leftmost path in y , with the additional condition that the root vertex of the result comes from y .

The usual symbol for this operation is \succ .

See also:

`product()`, `prec()`, `over()`, `under()`

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.succ(x, x)
B[[[., .], .]]
```

succ_product_on_basis(x, y)

Return the \succ dendriform product of two trees.

This is the sum over all possible ways to identify the rightmost path in x and the leftmost path in y , with the additional condition that the root vertex of the result comes from y .

The usual symbol for this operation is \succ .

See also:

- `product_on_basis()`, `prec_product_on_basis()`

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.succ_product_on_basis(x, x)
B[[[., .], .]]
```

under()

Return the under product.

The over product $x \setminus y$ is the binary tree obtained by grafting the root of x at the leftmost leaf of y .

The usual symbol for this operation is \setminus .

See also:

`product()`, `succ()`, `prec()`, `over()`

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.under(x, x)
B[[[., .], .]]
```

variable_names()

Return the names of the variables.

EXAMPLES:

```
sage: R = algebras.FreeDendriform(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}
```

5.1.110 Free Pre-Lie Algebras

AUTHORS:

- Florent Hivert, Frédéric Chapoton (2011)

```
class sage.combinat.free_prelie_algebra.FreePreLieAlgebra(R, names=None)
Bases: sage.combinat.free_module.CombinatorialFreeModule
```

The free pre-Lie algebra.

Pre-Lie algebras are non-associative algebras, where the product $*$ satisfies

$$(x * y) * z - x * (y * z) = (x * z) * y - x * (z * y).$$

We use here the convention where the associator

$$(x, y, z) := (x * y) * z - x * (y * z)$$

is symmetric in its two rightmost arguments. This is sometimes called a right pre-Lie algebra.

They have appeared in numerical analysis and deformation theory.

The free Pre-Lie algebra on a given set E has an explicit description using rooted trees, just as the free associative algebra can be described using words. The underlying vector space has a basis indexed by finite rooted trees endowed with a map from their vertices to E . In this basis, the product of two (decorated) rooted trees $S * T$ is the sum over vertices of S of the rooted tree obtained by adding one edge from the root of T to the given vertex of S . The root of these trees is taken to be the root of S . The free pre-Lie algebra can also be considered as the free algebra over the PreLie operad.

Warning: The usual binary operator $*$ can be used for the pre-Lie product. Beware that it but must be parenthesized properly, as the pre-Lie product is not associative. By default, a multiple product will be taken with left parentheses.

EXAMPLES:

```
sage: F = algebras.FreePreLie(ZZ, 'xyz')
sage: x,y,z = F.gens()
sage: (x * y) * z
B[x[y[z[]]]] + B[x[y[], z[]]]
sage: (x * y) * z - x * (y * z) == (x * z) * y - x * (z * y)
True
```

The free pre-Lie algebra is non-associative:

```
sage: x * (y * z) == (x * y) * z
False
```

The default product is with left parentheses:

```
sage: x * y * z == (x * y) * z
True
sage: x * y * z * x == ((x * y) * z) * x
True
```

The NAP product as defined in [Liv2006] is also implemented on the same vector space:

```
sage: N = F.nap_product
sage: N(x*y, z*z)
B[x[y[], z[z[]]]]
```

When None is given as input, unlabelled trees are used instead:

```
sage: F1 = algebras.FreePreLie(QQ, None)
sage: w = F1.gen(0); w
B[[]]
sage: w * w * w * w
B[[[[[[]]]]]] + B[[[[[], []]]] + 3*B[[[[], [[]]]] + B[[[[], [], []]]]
```

However, it is equally possible to use labelled trees instead:

```
sage: F1 = algebras.FreePreLie(QQ, 'q')
sage: w = F1.gen(0); w
B[q[]]
sage: w * w * w * w
B[q[q[q[q[]]]]] + B[q[q[q[], q[]]]] + 3*B[q[q[q[], q[q[]]]] + B[q[q[q[], q[], q[]]]]
```

The set E can be infinite:

```
sage: F = algebras.FreePreLie(QQ, ZZ)
sage: w = F.gen(1); w
B[1[]]
sage: x = F.gen(2); x
B[-1[]]
sage: y = F.gen(3); y
B[2[]]
sage: w*x
B[1[-1[]]]
sage: (w*x)*y
B[1[-1[2[]]]] + B[1[-1[[], 2[]]]]
sage: w*(x*y)
B[1[-1[2[q[]]]]
```

Elements of a free pre-Lie algebra can be lifted to the universal enveloping algebra of the associated Lie algebra. The universal enveloping algebra is the Grossman-Larson Hopf algebra:

```
sage: F = algebras.FreePreLie(QQ, 'abc')
sage: a,b,c = F.gens()
sage: (a*b+b*c).lift()
B[#[a[b[]]]] + B[#[b[c[]]]]
```

Note: Variables names can be None, a list of strings, a string or an integer. When None is given, unlabelled rooted trees are used. When a single string is given, each letter is taken as a variable. See [sage.combinat](#).

`words.alphabet.build_alphabet()`.

Warning: Beware that the underlying combinatorial free module is based either on `RootedTrees` or on `LabelledRootedTrees`, with no restriction on the labellings. This means that all code calling the `basis()` method would not give meaningful results, since `basis()` returns many “chaff” elements that do not belong to the algebra.

REFERENCES:

- [ChLi]
- [Liv2006]

class Element

Bases: `sage.modules.with_basis.indexed_element.IndexedFreeModuleElement`

lift()

Lift element to the Grossman-Larson algebra.

EXAMPLES:

```
sage: F = algebras.FreePreLie(QQ, 'abc')
sage: elt = F.an_element().lift(); elt
B#[a[a[a[a[[]]]]]] + B#[a[a[], a[a[[]]]]]
sage: parent(elt)
Grossman-Larson Hopf algebra on 3 generators ['a', 'b', 'c']
over Rational Field
```

algebra_generators()

Return the generators of this algebra.

These are the rooted trees with just one vertex.

EXAMPLES:

```
sage: A = algebras.FreePreLie(ZZ, 'fgh'); A
Free PreLie algebra on 3 generators ['f', 'g', 'h']
over Integer Ring
sage: list(A.algebra_generators())
[B[f[]], B[g[]], B[h[]]]

sage: A = algebras.FreePreLie(QQ, ['x1', 'x2'])
sage: list(A.algebra_generators())
[B[x1[]], B[x2[]]]
```

an_element()

Return an element of self.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, 'xy')
sage: A.an_element()
B[x[x[x[x[[]]]]]] + B[x[x[], x[x[[]]]]
```

bracket_on_basis(x, y)

Return the Lie bracket of two trees.

This is the commutator $[x, y] = x * y - y * x$ of the pre-Lie product.

See also:

`pre_Lie_product_on_basis()`

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: y = RT([x])
sage: A.bracket_on_basis(x, y)
-B[[[]], [[]]] + B[[[]], [[]]] - B[[[]], [[]]]
```

change_ring(*R*)

Return the free pre-Lie algebra in the same variables over *R*.

INPUT:

- *R* – a ring

EXAMPLES:

```
sage: A = algebras.FreePreLie(ZZ, 'fgh')
sage: A.change_ring(QQ)
Free PreLie algebra on 3 generators ['f', 'g', 'h'] over
Rational Field
```

construction()

Return a pair (*F*, *R*), where *F* is a *PreLieFunctor* and *R* is a ring, such that *F*(*R*) returns self.

EXAMPLES:

```
sage: P = algebras.FreePreLie(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F, R = P.construction()
sage: F
PreLie[x,y]
sage: R
Integer Ring
sage: F(ZZ) is P
True
sage: F(QQ)
Free PreLie algebra on 2 generators ['x', 'y'] over Rational Field
```

degree_on_basis(*t*)

Return the degree of a rooted tree in the free Pre-Lie algebra.

This is the number of vertices.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: A.degree_on_basis(RT([RT([])])
2
```

gen(*i*)

Return the *i*-th generator of the algebra.

INPUT:

- *i* – an integer

EXAMPLES:

```
sage: F = algebras.FreePreLie(ZZ, 'xyz')
sage: F.gen(0)
B[x[]]

sage: F.gen(4)
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

gens()

Return the generators of *self* (as an algebra).

EXAMPLES:

```
sage: A = algebras.FreePreLie(ZZ, 'fgh')
sage: A.gens()
(B[f[]], B[g[]], B[h[]])
```

nap_product()

Return the NAP product.

See also:

[*nap_product_on_basis\(\)*](#)

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = A(RT([RT([])])
sage: A.nap_product(x, x)
B[[[]], [[]]]
```

nap_product_on_basis(*x*, *y*)

Return the NAP product of two trees.

This is the grafting of the root of *y* over the root of *x*. The root of the resulting tree is the root of *x*.

See also:

[*nap_product\(\)*](#)

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.nap_product_on_basis(x, x)
B[[[]], [[]]]
```

pre_Lie_product()

Return the pre-Lie product.

See also:

[pre_Lie_product_on_basis\(\)](#)

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = A(RT([RT([])])
sage: A.pre_Lie_product(x, x)
B[[[[[]]]]] + B[[[]], [[]]]
```

pre_Lie_product_on_basis(x, y)

Return the pre-Lie product of two trees.

This is the sum over all graftings of the root of y over a vertex of x . The root of the resulting trees is the root of x .

See also:

[pre_Lie_product\(\)](#)

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[]], [[]]]
```

product_on_basis(x, y)

Return the pre-Lie product of two trees.

This is the sum over all graftings of the root of y over a vertex of x . The root of the resulting trees is the root of x .

See also:

[pre_Lie_product\(\)](#)

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[]], [[]]]
```

some_elements()

Return some elements of the free pre-Lie algebra.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: A.some_elements()
[B[[[]], B[[[]]]], B[[[[[]]]]] + B[[[]], [[]]], B[[[[[]]]]] + B[[[]], [[]]], B[[[[[]]]]]
```

With several generators:

```

sage: A = algebras.FreePreLie(QQ, 'xy')
sage: A.some_elements()
[B[x[]],
 B[x[x[]]],
 B[x[x[x[x[]]]]] + B[x[x[]], x[x[]]],
 B[x[x[x[]]]] + B[x[x[]], x[]],
 B[x[x[y[]]]] + B[x[x[]], y[]]]

```

variable_names()

Return the names of the variables.

EXAMPLES:

```

sage: R = algebras.FreePreLie(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}

sage: R = algebras.FreePreLie(QQ, None)
sage: R.variable_names()
{'o'}

```

class sage.combinat.free_prelie_algebra.PreLieFunctor(vars)

Bases: `sage.categories.pushout.ConstructionFunctor`

A constructor for pre-Lie algebras.

EXAMPLES:

```

sage: P = algebras.FreePreLie(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F = P.construction()[0]; F
PreLie[x,y]

sage: A = GF(5)['a,b']
sage: a, b = A.gens()
sage: F(A)
Free PreLie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring in
↪a, b over Finite Field of size 5

sage: f = A.hom([a+b,a-b],A)
sage: F(f)
Generic endomorphism of Free PreLie algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5

sage: F(f)(a * F(A)(x))
(a+b)*B[x[]]

```

merge(other)

Merge self with another construction functor, or return None.

EXAMPLES:

```

sage: F = sage.combinat.free_prelie_algebra.PreLieFunctor(['x','y'])
sage: G = sage.combinat.free_prelie_algebra.PreLieFunctor(['t'])
sage: F.merge(G)

```

(continues on next page)

(continued from previous page)

```

PreLie[x,y,t]
sage: F.merge(F)
PreLie[x,y]

```

Now some actual use cases:

```

sage: R = algebras.FreePreLie(ZZ, 'xyz')
sage: x,y,z = R.gens()
sage: 1/2 * x
1/2*B[x[]]
sage: parent(1/2 * x)
Free PreLie algebra on 3 generators ['x', 'y', 'z'] over Rational Field

sage: S = algebras.FreePreLie(QQ, 'zt')
sage: z,t = S.gens()
sage: x + t
B[t[]] + B[x[]]
sage: parent(x + t)
Free PreLie algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field

```

5.1.111 Fully packed loops

AUTHORS:

- Vincent Knight, James Campbell, Kevin Dilks, Emily Gunawan (2015): Initial version
- Vincent Delecroix (2017): cleaning and enhanced plotting function

class `sage.combinat.fully_packed_loop.FullyPackedLoop`(*parent, generator*)

Bases: `sage.structure.element.Element`

A class for fully packed loops.

A fully packed loop is a collection of non-intersecting lattice paths on a square grid such that every vertex is part of some path, and the paths are either closed internal loops or have endpoints corresponding to alternate points on the boundary [Pro2001]. They are known to be in bijection with alternating sign matrices.

See also:

[*AlternatingSignMatrix*](#)

To each fully packed loop, we assign a link pattern, which is the non-crossing matching attained by seeing which points on the boundary are connected by open paths in the fully packed loop.

We can create a fully packed loop using the corresponding alternating sign matrix and also extract the link pattern:

```

sage: A = AlternatingSignMatrix([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.link_pattern()
[(1, 4), (2, 3), (5, 6)]
sage: fpl
      |         |
      |         |
      + -- +   +
      |         |

```

(continues on next page)

(continued from previous page)

```

-- +   |   |
  |   |   |
  +   + -- +
  |   |   |
  |   |   |
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fplb = FullyPackedLoop(B)
sage: fplb.link_pattern()
[(1, 6), (2, 5), (3, 4)]
sage: fplb
  |           |
  |           |
  +   + -- +
  |   |   |
-- +   +   + --
  |   |   |
  + -- +   +
  |   |   |
  |   |   |

```

The class also has a plot method:

```
sage: fpl.plot()
Graphics object consisting of 3 graphics primitives
```

which gives:

Note that we can also create a fully packed loop from a six vertex model configuration:

```

sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: S
  ^   ^   ^
  |   |   |
--> # -> # -> # <--
  ^   ^   |
  |   |   V
--> # -> # <- # <--

```

(continues on next page)

(continued from previous page)

```

      ^   |   |
      |   V   V
--> # <- # <- # <--
      |   |   |
      V   V   V
sage: fpl = FullyPackedLoop(S)
sage: fpl
      |           |
      |           |
      + -- +     +
           |     |
           |     |
-- +     +     + --
      |     |
      |     |
      +     + -- +
      |           |
      |           |

```

Once we have a fully packed loop we can obtain the corresponding alternating sign matrix:

```

sage: fpl.to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]

```

Here are some more examples using bigger ASMs:

```

sage: A = AlternatingSignMatrix([[0,1,0,0],[0,0,1,0],[1,-1,0,1],[0,1,0,0]])
sage: S = SixVertexModel(4, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.link_pattern()
[(1, 2), (3, 6), (4, 5), (7, 8)]
sage: fpl
      |           |
      |           |
      + -- + -- +     + --
           |     |
           |     |
-- +     + -- + -- +
      |     |
      |     |
      +     +     + -- + --
      |     |     |
      |     |     |
-- +     +     + -- +
           |     |
           |     |
sage: m = AlternatingSignMatrix([[0,0,1,0,0,0],
.....:                             [1,0,-1,0,1,0],

```

(continues on next page)

(continued from previous page)

```

.....:          [0,0,0,1,0,0],
.....:          [0,1,0,0,-1,1],
.....:          [0,0,0,0,1,0],
.....:          [0,0,1,0,0,0]])
sage: fpl = FullyPackedLoop(m)
sage: fpl.link_pattern()
[(1, 12), (2, 7), (3, 4), (5, 6), (8, 9), (10, 11)]
sage: fpl

```

```

|           |           |
|           |           |
+ -- +     +     + -- +     + --
|           |           |           |
-- + -- +   +     + -- + -- +
|           |
+ -- +     + -- + -- +     + --
|           |           |           |
-- +     +     + -- +     +     +
|           |           |           |
+ -- +     + -- +     +     + --
|           |           |           |
-- +     + -- + -- +     + -- +
|           |           |           |

```

```

sage: m = AlternatingSignMatrix([[0,1,0,0,0,0,0],
.....:          [1,-1,0,0,1,0,0],
.....:          [0,0,0,1,0,0,0],
.....:          [0,1,0,0,-1,1,0],
.....:          [0,0,0,0,1,0,0],
.....:          [0,0,1,0,-1,0,1],
.....:          [0,0,0,0,1,0,0]])
sage: fpl = FullyPackedLoop(m)
sage: fpl.link_pattern()
[(1, 2), (3, 4), (5, 6), (7, 8), (9, 14), (10, 11), (12, 13)]
sage: fpl

```

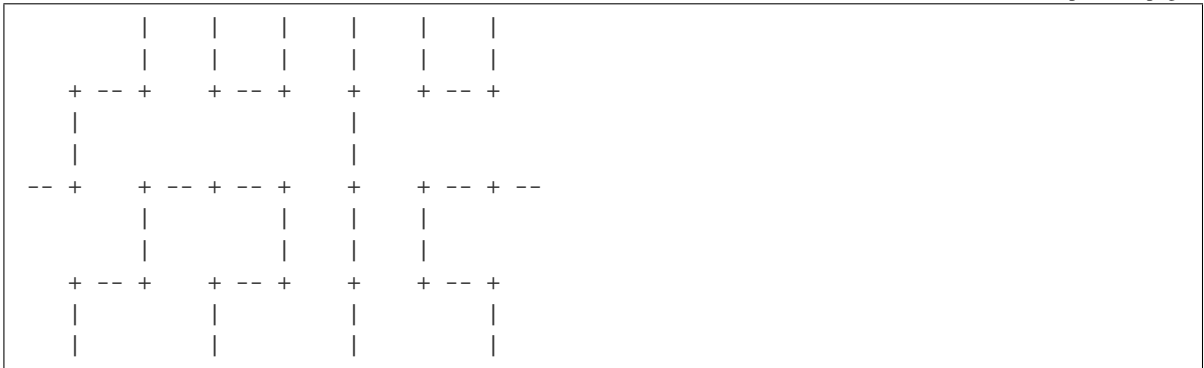

```

|           |           |           |
|           |           |           |
+ -- + -- +     + -- +     + -- +
|           |           |           |
-- + -- + -- +   + -- + -- +     + --
|           |           |           |
+ -- +     + -- + -- +     + -- +
|           |           |           |
|           |           |           |
-- +     +     + -- +     +     + --

```

(continues on next page)

(continued from previous page)

Gyration on an alternating sign matrix/fully packed loop fpl of the link pattern corresponding to fpl:

```

sage: ASMs = AlternatingSignMatrices(3).list()
sage: ncp = FullyPackedLoop(ASMs[1]).link_pattern() # fpl's gyration orbit size is 2
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(5):
.....:         a,b=a%6+1,b%6+1;
.....:         rotated_ncp.append((a,b))
sage: PerfectMatching(ASMs[1].gyration().to_fully_packed_loop().link_pattern()) ==\
.....:     PerfectMatching(rotated_ncp)
True

sage: fpl = FullyPackedLoop(ASMs[0])
sage: ncp = fpl.link_pattern() # fpl's gyration size is 3
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(5):
.....:         a,b=a%6+1,b%6+1;
.....:         rotated_ncp.append((a,b))
sage: PerfectMatching(ASMs[0].gyration().to_fully_packed_loop().link_pattern()) ==\
.....:     PerfectMatching(rotated_ncp)
True

sage: mat = AlternatingSignMatrix([[0,0,1,0,0,0,0],[1,0,-1,0,1,0,0],
.....:     [0,0,1,0,0,0,0],[0,1,-1,0,0,1,0],[0,0,1,0,0,0,0],[0,0,0,1,0,0,0],[0,0,0,0,
↪0,0,1]])
sage: fpl = FullyPackedLoop(mat) # n=7
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(13):
.....:         a,b=a%14+1,b%14+1;
.....:         rotated_ncp.append((a,b))
sage: PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) ==\
.....:     PerfectMatching(rotated_ncp)
True

sage: mat = AlternatingSignMatrix([[0,0,0,1,0,0],[0,0,1,-1,1,0],
.....:     [0,1,0,0,-1,1],[1,0,-1,1,0,0],[0,0,1,0,0,0],[0,0,0,0,1,0]])

```

(continues on next page)

(continued from previous page)

```

sage: fpl = FullyPackedLoop(mat) # n =6
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(11):
.....:         a,b=a%12+1,b%12+1;
.....:         rotated_ncp.append((a,b))
sage: PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) ==\
.....:     PerfectMatching(rotated_ncp)
True

```

More examples:

We can initiate a fully packed loop using an alternating sign matrix:

```

sage: A = AlternatingSignMatrix([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl
  |         |
  |         |
+ -- +     +
  |         |
  |         |
-- +     + + --
  |         |
  |         |
+     + -- +
  |         |
  |         |
sage: FullyPackedLoops(3)(A) == fpl
True

```

We can also input a matrix:

```

sage: FullyPackedLoop([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
  |         |
  |         |
+ -- +     +
  |         |
  |         |
-- +     + + --
  |         |
  |         |
+     + -- +
  |         |
  |         |
sage: FullyPackedLoop([[0, 0, 1], [0, 1, 0], [1, 0, 0]]) ==\
.....: FullyPackedLoops(3)([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
True

```

Otherwise we initiate a fully packed loop using a six vertex model:

```

sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl
  |         |
  |         |
  + -- +   +
      |   |
  -- +   +   + --
      |   |
  +   + -- +
  |         |
  |         |

sage: FullyPackedLoops(3)(S) == FullyPackedLoop(S)
True

sage: fpl.six_vertex_model().to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]

```

We can also input the matrix associated to a six vertex model:

```

sage: SixVertexModel(2)([[3,1],[5,3]])
  ^     ^
  |     |
--> # <- # <--
  |     ^
  v     |
--> # -> # <--
  |     |
  v     v

sage: FullyPackedLoop([[3,1],[5,3]])
  |
  |
  +   + --
  |   |
  |   |
-- +   +
      |
      |

sage: FullyPackedLoops(2)([[3,1],[5,3]]) == FullyPackedLoop([[3,1],[5,3]])
True

```

Note that the matrix corresponding to a six vertex model without the ice boundary condition is not allowed:

```

sage: SixVertexModel(2)([[3,1],[5,5]])
  ^     ^

```

(continues on next page)

(continued from previous page)

```

  |   |
--> # <- # <--
  |   ^
  v   v
--> # -> # -->
  |   |
  v   v

sage: FullyPackedLoop([[3,1],[5,5]])
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

sage: FullyPackedLoops(2)([[3,1],[5,5]])
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

```

Note that if anything else is used to generate the fully packed loop an error will occur:

```

sage: fpl = FullyPackedLoop(5)
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

sage: fpl = FullyPackedLoop((1, 2, 3))
Traceback (most recent call last):
...
ValueError: The alternating sign matrices must be square

sage: SVM = SixVertexModel(3)[0]
sage: FullyPackedLoop(SVM)
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

```

REFERENCES:

- [Pro2001]
- [Str2015]

gyration()

Return the fully packed loop obtained by applying gyration to the alternating sign matrix in bijection with `self`.

Gyration was first defined in [Wie2000] as an action on fully-packed loops.

EXAMPLES:

```

sage: A = AlternatingSignMatrix([[1, 0, 0],[0, 1, 0],[0, 0, 1]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.gyration().to_alternating_sign_matrix()
[0 0 1]
[0 1 0]

```

(continues on next page)

(continued from previous page)

```

[1 0 0]
sage: asm = AlternatingSignMatrix([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: f = FullyPackedLoop(asm)
sage: f.gyration().to_alternating_sign_matrix()
[0 1 0]
[0 0 1]
[1 0 0]

```

link_pattern()

Return a link pattern corresponding to a fully packed loop.

Here we define a link pattern LP to be a partition of the list $[1, \dots, 2k]$ into 2-element sets (such a partition is also known as a perfect matching) such that the following non-crossing condition holds: Let the numbers $1, \dots, 2k$ be written on the perimeter of a circle. For every 2-element set (a, b) of the partition LP , draw an arc linking the two numbers a and b . We say that LP is non-crossing if every arc can be drawn so that no two arcs intersect.

Since every endpoint of a fully packed loop fpl is connected to a different endpoint, there is a natural surjection from the fully packed loops on an $n \times n$ grid onto the link patterns on the list $[1, \dots, 2n]$. The pairs of connected endpoints of a fully packed loop fpl correspond to the 2-element tuples of the corresponding link pattern.

See also:

[PerfectMatching](#)

Note: by convention, we choose the top left vertex to be even. See [Pro2001] and [Str2015].

EXAMPLES:

We can extract the underlying link pattern (a non-crossing partition) from a fully packed loop:

```

sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.link_pattern()
[(1, 2), (3, 6), (4, 5)]

sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(B)
sage: fpl.link_pattern()
[(1, 6), (2, 5), (3, 4)]

```

Gyration on an alternating sign matrix/fully packed loop fpl corresponds to a rotation (i.e. a becomes $a-1 \pmod{2n}$) of the link pattern corresponding to fpl :

```

sage: ASMs = AlternatingSignMatrices(3).list()
sage: ncp = FullyPackedLoop(ASMs[1]).link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(5):
.....:         a,b=a%6+1,b%6+1;
.....:         rotated_ncp.append((a,b))
sage: PerfectMatching(ASMs[1].gyration().to_fully_packed_loop().link_pattern())
↩==\

```

(continues on next page)

(continued from previous page)

```

.....:   PerfectMatching(rotated_ncp)
True

sage: fpl = FullyPackedLoop(ASMs[0])
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(5):
.....:         a,b=a%6+1,b%6+1;
.....:         rotated_ncp.append((a,b))
sage: PerfectMatching(ASMs[0].gyration().to_fully_packed_loop().link_pattern())
↵==\
.....:   PerfectMatching(rotated_ncp)
True

sage: mat = AlternatingSignMatrix([[0,0,1,0,0,0,0],[1,0,-1,0,1,0,0],[0,0,1,0,0,
↵0,0],
.....:   [0,1,-1,0,0,1,0],[0,0,1,0,0,0,0],[0,0,0,1,0,0,0],[0,0,0,0,0,0,1]])
sage: fpl = FullyPackedLoop(mat) # n=7
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(13):
.....:         a,b=a%14+1,b%14+1;
.....:         rotated_ncp.append((a,b))
sage: PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) ==\
.....:   PerfectMatching(rotated_ncp)
True

sage: mat = AlternatingSignMatrix([[0,0,0,1,0,0], [0,0,1,-1,1,0], [0,1,0,0,-1,
↵1], [1,0,-1,1,0,0],
.....:   [0,0,1,0,0,0], [0,0,0,0,1,0]])
sage: fpl = FullyPackedLoop(mat)
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(11):
.....:         a,b=a%12+1,b%12+1;
.....:         rotated_ncp.append((a,b))
sage: PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) ==\
.....:   PerfectMatching(rotated_ncp)
True

```

plot(*link=True, loop=True, loop_fill=False, **options*)

Return a graphical object of the Fully Packed Loop.

Each option can be specified separately for links (the curves that join boundary points) and the loops. In order to do so, you need to prefix its name with either 'link_' or 'loop_'. As an example, setting `color='red'` will color both links and loops in red while setting `link_color='red'` will only apply the color option for the links.

INPUT:

- `link, loop` - (boolean, default True) whether to plot the links or the loops

- `color`, `link_color`, `loop_color` - (optional, a string or a RGB triple)
- `colors`, `link_colors`, `loop_colors` - (optional, list) a list of colors
- `color_map`, `link_color_map`, `loop_color_map` - (string, optional) a name of a matplotlib color map for the link or the loop
- `link_color_randomize` - (boolean, default `False`) when `link_colors` or `link_color_map` is specified it randomizes its order. Setting this option to `True` makes it unlikely to have two neighboring links with the same color.
- `loop_fill` - (boolean, optional) whether to fill the interior of the loops

EXAMPLES:

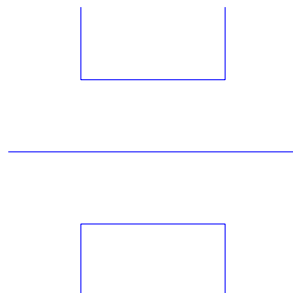

To plot the fully packed loop associated to the following alternating sign matrix

$$\begin{pmatrix} 0 & 1 & 1 \\ 1 & -1 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

simply do:

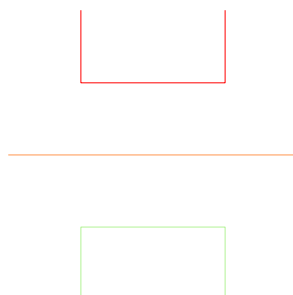

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.plot()
Graphics object consisting of 3 graphics primitives
```

The resulting graphics is as follows

You can also have the three links in different colors with:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.plot(link_color_map='rainbow')
Graphics object consisting of 3 graphics primitives
```

You can plot the 42 fully packed loops of size 4×4 using:

```

sage: G = [fpl.plot(link_color_map='winter', loop_color='black') for fpl in
↳ FullyPackedLoops(4)]
sage: graphics_array(G, 7, 6)
Graphics Array of size 7 x 6

```

Here is an example of a 20×20 fully packed loop:

```

sage: s = "000000000000+000000000000000000+00-0+000000000000+00-00+0-+00000\
..... 0000+-00+00-+00000000+00-0000+0000-+00000000+000-0+0-+000\
..... 000+-000+-00+0000000+-+000+00-+0-000+000+-000+-0+0000000-0+\
..... 0000+0-+0-+00000-+00000+-+0-0+-00+00000000000+-0000+0-00+0000\
..... 000000+0-000+0000000000000000+0000-00+00000000+0000-000+00000\
..... 00+0-00+0000000000000000+-0000+000000-+000000+00-0000+-00+00\
..... 00000000+-0000+00000000000000+0000000000"
sage: a = matrix(20, [{ '0':0, '+':1, '-': -1}[i] for i in s])
sage: fpl = FullyPackedLoop(a)
sage: fpl.plot(loop_fill=True, loop_color_map='rainbow')
Graphics object consisting of 27 graphics primitives

```

six_vertex_model()

Return the underlying six vertex model configuration.

EXAMPLES:

```
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(B)
sage: fpl
```

```
  |           |
  +   +   -- +
  |           |
  -- +   +   +   --
  |           |
  +   -- +   +
  |           |
```

```
sage: fpl.six_vertex_model()
```

```
  ^   ^   ^
  |   |   |
--> # <- # <- # <--
  |   ^   ^
  V   |   |
--> # -> # <- # <--
  |   |   ^
  V   V   |
--> # -> # -> # <--
  |   |   |
  V   V   V
```

`to_alternating_sign_matrix()`

Return the alternating sign matrix corresponding to this class.

See also:

[*AlternatingSignMatrix*](#)

EXAMPLES:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.to_alternating_sign_matrix()
[ 0  1  0]
[ 1 -1  1]
[ 0  1  0]
sage: A = AlternatingSignMatrix([[0,1,0,0],[0,0,1,0],[1,-1,0,1],[0,1,0,0]])
sage: S = SixVertexModel(4, boundary_conditions='ice').from_alternating_sign_
↪matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.to_alternating_sign_matrix()
[ 0  1  0  0]
[ 0  0  1  0]
[ 1 -1  0  1]
[ 0  1  0  0]
```

class sage.combinat.fully_packed_loop.FullyPackedLoops(*n*)

Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresentation

Class of all fully packed loops on an $n \times n$ grid.

They are known to be in bijection with alternating sign matrices.

See also:

[AlternatingSignMatrices](#)

INPUT:

- *n* – the number of row (and column) or grid

EXAMPLES:

This will create an instance to manipulate the fully packed loops of size 3:

```
sage: FPLs = FullyPackedLoops(3)
sage: FPLs
Fully packed loops on a 3x3 grid
sage: FPLs.cardinality()
7
```

When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```
sage: M = FullyPackedLoops(1)
sage: len(M)
1
sage: M = FullyPackedLoops(4)
sage: len(M)
42
sage: all(len(SixVertexModel(n, boundary_conditions='ice'))
.....:      == FullyPackedLoops(n).cardinality() for n in range(1, 7))
True
```

Elementalias of *FullyPackedLoop***cardinality()**Return the cardinality of *self*.The number of fully packed loops on $n \times n$ grid

$$\prod_{k=0}^{n-1} \frac{(3k+1)!}{(n+k)!} = \frac{1!4!7!10! \cdots (3n-2)!}{n!(n+1)!(n+2)!(n+3)! \cdots (2n-1)!}.$$

EXAMPLES:

```
sage: [AlternatingSignMatrices(n).cardinality() for n in range(11)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]
```

size()Return the size of the matrices in *self*.

5.1.112 Gelfand-Tsetlin Patterns

AUTHORS:

- Travis Scrimshaw (2013-15-03): Initial version

REFERENCES:

class `sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPattern`Bases: `sage.structure.list_clone.ClonableArray`

A Gelfand-Tsetlin (sometimes written as Gelfand-Zetlin or Gelfand-Cetlin) pattern. They were originally defined in [GC50].

A Gelfand-Tsetlin pattern is a triangular array:

$$\begin{array}{ccccccc} a_{1,1} & & a_{1,2} & & a_{1,3} & & \cdots & & a_{1,n} \\ & & a_{2,2} & & a_{2,3} & & \cdots & & a_{2,n} \\ & & & & a_{3,3} & & \cdots & & a_{3,n} \\ & & & & & & \ddots & & \\ & & & & & & & & a_{n,n} \end{array}$$

such that $a_{i,j} \geq a_{i+1,j+1} \geq a_{i,j+1}$.Gelfand-Tsetlin patterns are in bijection with semistandard Young tableaux by the following algorithm. Let G be a Gelfand-Tsetlin pattern with $\lambda^{(k)}$ being the $(n-k+1)$ -st row (note that this is a partition). The definition of G implies

$$\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(n)},$$

where $\lambda^{(0)}$ is the empty partition, and each skew shape $\lambda^{(k)}/\lambda^{(k-1)}$ is a horizontal strip. Thus define $T(G)$ by inserting k into the squares of the skew shape $\lambda^{(k)}/\lambda^{(k-1)}$, for $k = 1, \dots, n$.

To each entry in a Gelfand-Tsetlin pattern, one may attach a decoration of a circle or a box (or both or neither). These decorations appear in the study of Weyl group multiple Dirichlet series, and are implemented here following the exposition in [BBF].

Note: We use the “right-hand” rule for determining circled and boxed entries.

Warning: The entries in Sage are 0-based and are thought of as flushed to the left in a matrix. In other words, the coordinates of entries in the Gelfand-Tsetlin patterns are thought of as the matrix:

$$\begin{bmatrix} g_{0,0} & g_{0,1} & g_{0,2} & \cdots & g_{0,n-2} & g_{n-1,n-1} \\ g_{1,0} & g_{1,1} & g_{1,2} & \cdots & g_{1,n-2} & \\ g_{2,0} & g_{2,1} & g_{2,2} & \cdots & & \\ \vdots & \vdots & \vdots & & & \\ g_{n-2,0} & g_{n-2,1} & & & & \\ g_{n-1,0} & & & & & \end{bmatrix}.$$

However, in the discussions, we will be using the **standard** numbering system.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3, 2, 1], [2, 1], [1]]); G
[[3, 2, 1], [2, 1], [1]]
sage: G.pp()
  3   2   1
   2   1
    1
sage: G = GelfandTsetlinPattern([[7, 7, 4, 0], [7, 7, 3], [7, 5], [5]]); G.pp()
  7   7   4   0
   7   7   3
    7   5
     5
sage: G.to_tableau().pp()
  1  1  1  1  1  2  2
  2  2  2  2  2  3  3
  3  3  3  4
```

Tokuyama_coefficient(name='t')

Return the Tokuyama coefficient attached to self.

Following the exposition of [BBF], Tokuyama's formula asserts

$$\sum_G (t+1)^{s(G)} t^{l(G)} z_1^{d_{n+1}} z_2^{d_n - d_{n+1}} \cdots z_{n+1}^{d_1 - d_2} = s_\lambda(z_1, \dots, z_{n+1}) \prod_{i < j} (z_j + tz_i),$$

where the sum is over all strict Gelfand-Tsetlin patterns with fixed top row $\lambda + \rho$, with λ a partition with at most $n + 1$ parts and $\rho = (n, n - 1, \dots, 1, 0)$, and s_λ is a Schur function.

INPUT:

- name – (Default: 't') An alternative name for the variable t .

EXAMPLES:

```
sage: P = GelfandTsetlinPattern([[3, 2, 1], [2, 2], [2]])
sage: P.Tokuyama_coefficient()
0
sage: G = GelfandTsetlinPattern([[3, 2, 1], [3, 1], [2]])
sage: G.Tokuyama_coefficient()
t^2 + t
sage: G = GelfandTsetlinPattern([[2, 1, 0], [1, 1], [1]])
sage: G.Tokuyama_coefficient()
```

(continues on next page)

(continued from previous page)

```

0
sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.Tokuyama_coefficient()
t^8 + 3*t^7 + 3*t^6 + t^5

```

bender_knuth_involution(*i*)

Return the image of `self` under the *i*-th Bender-Knuth involution.

If the triangle `self` has size *n* then this is defined for $0 < i < n$.

The entries of `self` can take values in any ordered ring. Usually, this will be the integers but can also be the rationals or the real numbers.

This implements the construction of the Bender-Knuth involution using toggling due to Berenstein-Kirillov.

This agrees with the Bender-Knuth involution on semistandard tableaux.

EXAMPLES:

```

sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.bender_knuth_involution(2)
[[5, 3, 2, 1, 0], [4, 3, 2, 0], [4, 2, 1], [4, 1], [3]]

sage: G = GelfandTsetlinPattern([[3,2,0],[2.2,0],[2]])
sage: G.bender_knuth_involution(2)
[[3, 2, 0], [2.800000000000000, 2], [2]]

```

boxed_entries()

Return the position of the boxed entries of `self`.

Using the *right-hand* rule, an entry $a_{i,j}$ is boxed if $a_{i,j} = a_{i-1,j-1}$; i.e., $a_{i,j}$ has the same value as its neighbor to the northwest.

EXAMPLES:

```

sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.boxed_entries()
((1, 0),)

```

check()

Check that this is a valid Gelfand-Tsetlin pattern.

EXAMPLES:

```

sage: G = GelfandTsetlinPatterns()
sage: G([[3,2,1],[2,1],[1]]).check()

```

circled_entries()

Return the circled entries of `self`.

Using the *right-hand* rule, an entry $a_{i,j}$ is circled if $a_{i,j} = a_{i-1,j}$; i.e., $a_{i,j}$ has the same value as its neighbor to the northeast.

EXAMPLES:

```

sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.circled_entries()
((1, 1), (2, 0))

```

is_strict()

Return True if `self` is a strict Gelfand-Tsetlin pattern.

A Gelfand-Tsetlin pattern is said to be *strict* if every row is strictly decreasing.

EXAMPLES:

```
sage: GelfandTsetlinPattern([[7, 3, 1], [6, 2], [4]]) .is_strict()
True
sage: GelfandTsetlinPattern([[3, 2, 1], [3, 1], [1]]) .is_strict()
True
sage: GelfandTsetlinPattern([[6, 0, 0], [3, 0], [2]]) .is_strict()
False
```

number_of_boxes()

Return the number of boxed entries. See `boxed_entries()`.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3, 2, 1], [3, 1], [1]])
sage: G.number_of_boxes()
1
```

number_of_circles()

Return the number of boxed entries. See `circled_entries()`.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3, 2, 1], [3, 1], [1]])
sage: G.number_of_circles()
2
```

number_of_special_entries()

Return the number of special entries. See `special_entries()`.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[4, 2, 1], [4, 1], [2]])
sage: G.number_of_special_entries()
1
```

pp()

Pretty print `self`.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns()
sage: G([[3, 2, 1], [2, 1], [1]]) .pp()
  3   2   1
   2   1
    1
```

row_sums()

Return the list of row sums.

For a Gelfand-Tsetlin pattern G , the i -th row sum d_i is

$$d_i = d_i(G) = \sum_{j=i}^n a_{i,j}.$$

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.row_sums()
[11, 9, 7, 5, 3]
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[2]])
sage: G.row_sums()
[6, 4, 2]
```

special_entries()

Return the special entries.

An entry $a_{i,j}$ is special if $a_{i-1,j-1} > a_{i,j} > a_{i-1,j}$, that is to say, the entry is neither boxed nor circled and is **not** in the first row. The name was coined by [Tok88].

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.special_entries()
()
sage: G = GelfandTsetlinPattern([[4,2,1],[4,1],[2]])
sage: G.special_entries()
((2, 0),)
```

to_tableau()

Return `self` as a semistandard Young tableau.

The conversion from a Gelfand-Tsetlin pattern to a semistandard Young tableaux is as follows. Let G be a Gelfand-Tsetlin pattern with $\lambda^{(k)}$ being the $(n - k + 1)$ -st row (note that this is a partition). The definition of G implies

$$\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \dots \subseteq \lambda^{(n)},$$

where $\lambda^{(0)}$ is the empty partition, and each skew shape $\lambda^{(k)}/\lambda^{(k-1)}$ is a horizontal strip. Thus define $T(G)$ by inserting k into the squares of the skew shape $\lambda^{(k)}/\lambda^{(k-1)}$, for $k = 1, \dots, n$.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns()
sage: elt = G([[3,2,1],[2,1],[1]])
sage: T = elt.to_tableau(); T
[[1, 2, 3], [2, 3], [3]]
sage: T.pp()
 1 2 3
 2 3
 3
sage: G(T) == elt
True
```

weight()

Return the weight of `self`.

Define the weight of G to be the content of the tableau to which G corresponds under the bijection between Gelfand-Tsetlin patterns and semistandard tableaux. More precisely,

$$\text{wt}(G) = (d_n, d_{n-1} - d_n, \dots, d_1 - d_2),$$

where the d_i are the row sums.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[2,1,0],[1,0],[1]])
sage: G.weight()
(1, 0, 2)
sage: G = GelfandTsetlinPattern([[4,2,1],[3,1],[2]])
sage: G.weight()
(2, 2, 3)
```

class `sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPatterns(n, k, strict)`

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

Gelfand-Tsetlin patterns.

INPUT:

- `n` – The width or depth of the array, also known as the rank
- `k` – (Default: None) If specified, this is the maximum value that can occur in the patterns
- `top_row` – (Default: None) If specified, this is the fixed top row of all patterns
- `strict` – (Default: False) Set to True if all patterns are strict patterns

Element

alias of `GelfandTsetlinPattern`

random_element()

Return a uniformly random Gelfand-Tsetlin pattern.

EXAMPLES:

```
sage: g = GelfandTsetlinPatterns(4, 5)
sage: x = g.random_element()
sage: x in g
True
sage: len(x)
4
sage: all(y in range(5+1) for z in x for y in z)
True
sage: x.check()
```

```
sage: g = GelfandTsetlinPatterns(4, 5, strict=True)
sage: x = g.random_element()
sage: x in g
True
sage: len(x)
4
sage: all(y in range(5+1) for z in x for y in z)
True
sage: x.check()
sage: x.is_strict()
True
```

class `sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPatternsTopRow(top_row, strict)`

Bases: `sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPatterns`

Gelfand-Tsetlin patterns with a fixed top row.

Tokuyama_formula(name='t')

Return the Tokuyama formula of `self`.

Following the exposition of [BBF], Tokuyama's formula asserts

$$\sum_G (t+1)^{s(G)} t^{l(G)} z_1^{d_{n+1}} z_2^{d_n - d_{n+1}} \dots z_{n+1}^{d_1 - d_2} = s_\lambda(z_1, \dots, z_{n+1}) \prod_{i < j} (z_j + tz_i),$$

where the sum is over all strict Gelfand-Tsetlin patterns with fixed top row $\lambda + \rho$, with λ a partition with at most $n + 1$ parts and $\rho = (n, n - 1, \dots, 1, 0)$, and s_λ is a Schur function.

INPUT:

- name – (Default: 't') An alternative name for the variable t .

EXAMPLES:

```
sage: GT = GelfandTsetlinPatterns(top_row=[2,1,0],strict=True)
sage: GT.Tokuyama_formula()
t^3*x1^2*x2 + t^2*x1*x2^2 + t^2*x1^2*x3 + t^2*x1*x2*x3 + t*x1*x2*x3 + t*x2^2*x3
↪+ t*x1*x3^2 + x2*x3^2
sage: GT = GelfandTsetlinPatterns(top_row=[3,2,1],strict=True)
sage: GT.Tokuyama_formula()
t^3*x1^3*x2^2*x3 + t^2*x1^2*x2^3*x3 + t^2*x1^3*x2*x3^2 + t^2*x1^2*x2^2*x3^2 +
↪t*x1^2*x2^2*x3^2 + t*x1*x2^3*x3^2 + t*x1^2*x2*x3^3 + x1*x2^2*x3^3
sage: GT = GelfandTsetlinPatterns(top_row=[1,1,1],strict=True)
sage: GT.Tokuyama_formula()
0
```

random_element()

Return a uniformly random Gelfand-Tsetlin pattern with specified top row.

EXAMPLES:

```
sage: g = GelfandTsetlinPatterns(top_row = [4, 3, 1, 1])
sage: x = g.random_element()
sage: x in g
True
sage: x[0] == [4, 3, 1, 1]
True
sage: x.check()

sage: g = GelfandTsetlinPatterns(top_row=[4, 3, 2, 1], strict=True)
sage: x = g.random_element()
sage: x in g
True
sage: x[0] == [4, 3, 2, 1]
True
sage: x.is_strict()
True
sage: x.check()
```

top_row()

Return the top row of `self`.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns(top_row=[4,4,3,1])
sage: G.top_row()
(4, 4, 3, 1)
```

5.1.113 Paths in Directed Acyclic Graphs

`sage.combinat.graph_path.GraphPaths(g, source=None, target=None)`
Return the combinatorial class of paths in the directed acyclic graph *g*.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
```

If source and target are not given, then the returned class contains all paths (including trivial paths containing only one vertex).

```
sage: p = GraphPaths(G); p
Paths in Multi-digraph on 5 vertices
sage: p.cardinality()
37
sage: path = p.random_element()
sage: all(G.has_edge(*path[i:i+2]) for i in range(len(path) - 1))
True
```

If the source is specified, then the returned class contains all of the paths starting at the vertex source (including the trivial path).

```
sage: p = GraphPaths(G, source=3); p
Paths in Multi-digraph on 5 vertices starting at 3
sage: p.list()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
```

If the target is specified, then the returned class contains all of the paths ending at the vertex target (including the trivial path).

```
sage: p = GraphPaths(G, target=3); p
Paths in Multi-digraph on 5 vertices ending at 3
sage: p.cardinality()
5
sage: p.list()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
```

If both the target and source are specified, then the returned class contains all of the paths from source to target.

```
sage: p = GraphPaths(G, source=1, target=3); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
sage: p.cardinality()
3
sage: p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]
```

Note that *G* must be a directed acyclic graph.

```

sage: G = DiGraph({1:[2,2,3,5], 2:[3,4], 3:[4], 4:[2,5,7], 5:[6]}, multiedges=True)
sage: GraphPaths(G)
Traceback (most recent call last):
...
TypeError: g must be a directed acyclic graph

```

```

class sage.combinat.graph_path.GraphPaths_all(g)
    Bases: sage.structure.parent.Parent, sage.combinat.graph_path.GraphPaths_common
    EXAMPLES:

```

```

sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.cardinality()
37

```

```

list()
    Return a list of the paths of self.

```

EXAMPLES:

```

sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: len(GraphPaths(G).list())
37

```

```

class sage.combinat.graph_path.GraphPaths_common
    Bases: object

```

```

incoming_edges(v)
    Return a list of v's incoming edges.

```

EXAMPLES:

```

sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.incoming_edges(2)
[(1, 2, None), (1, 2, None)]

```

```

incoming_paths(v)
    Return a list of paths that end at v.

```

EXAMPLES:

```

sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.incoming_paths(2)
[[2], [1, 2], [1, 2]]

```

```

outgoing_edges(v)
    Return a list of v's outgoing edges.

```

EXAMPLES:

```

sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.outgoing_edges(2)
[(2, 3, None), (2, 4, None)]

```

outgoing_paths(*v*)

Return a list of the paths that start at *v*.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.outgoing_paths(3)
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
sage: gp.outgoing_paths(2)
[[2],
 [2, 3],
 [2, 3, 4],
 [2, 3, 4, 5],
 [2, 3, 4, 5],
 [2, 4],
 [2, 4, 5],
 [2, 4, 5]]
```

paths()

Return a list of all the paths of *self*.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: len(gp.paths())
37
```

paths_from_source_to_target(*source*, *target*)

Return a list of paths from *source* to *target*.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.paths_from_source_to_target(2,4)
[[2, 3, 4], [2, 4]]
```

class sage.combinat.graph_path.GraphPaths_s(*g*, *source*)

Bases: [sage.structure.parent.Parent](#), [sage.combinat.graph_path.GraphPaths_common](#)

list()

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G, 4)
sage: p.list()
[[4], [4, 5], [4, 5]]
```

class sage.combinat.graph_path.GraphPaths_st(*g*, *source*, *target*)

Bases: [sage.structure.parent.Parent](#), [sage.combinat.graph_path.GraphPaths_common](#)

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: GraphPaths(G,1,2).cardinality()
```

(continues on next page)

(continued from previous page)

```

 [1, 2, 3, 4]]

```

5.1.114 Gray codes

Functions

`sage.combinat.gray_codes.combinations(n, t)`

Iterator through the switches of the revolving door algorithm.

The revolving door algorithm is a way to generate all combinations of a set (i.e. the subset of given cardinality) in such way that two consecutive subsets differ by one element. At each step, the iterator output a pair (i, j) where the item i has to be removed and j has to be added.

The ground set is always $\{0, 1, \dots, n - 1\}$. Note that n can be infinity in that algorithm.

See [Knu2011] Section 7.2.1.3, “Generating All Combinations”.

INPUT:

- n – (integer or Infinity) – size of the ground set
- t – (integer) – size of the subsets

EXAMPLES:

```
sage: from sage.combinat.gray_codes import combinations
sage: b = [1, 1, 1, 0, 0]
sage: for i,j in combinations(5,3):
.....:     b[i] = 0; b[j] = 1
.....:     print(b)
[1, 0, 1, 1, 0]
[0, 1, 1, 1, 0]
[1, 1, 0, 1, 0]
[1, 0, 0, 1, 1]
[0, 1, 0, 1, 1]
[0, 0, 1, 1, 1]
[1, 0, 1, 0, 1]
[0, 1, 1, 0, 1]
[1, 1, 0, 0, 1]

sage: s = set([0,1])
sage: for i,j in combinations(4,2):
.....:     s.remove(i)
.....:     s.add(j)
.....:     print(sorted(s))
[1, 2]
[0, 2]
[2, 3]
[1, 3]
[0, 3]
```

Note that n can be infinity:

```
sage: c = combinations(Infinity,4)
sage: s = set([0,1,2,3])
sage: for _ in range(10):
.....:     i,j = next(c)
.....:     s.remove(i); s.add(j)
.....:     print(sorted(s))
```

(continues on next page)

(continued from previous page)

```

[0, 1, 3, 4]
[1, 2, 3, 4]
[0, 2, 3, 4]
[0, 1, 2, 4]
[0, 1, 4, 5]
[1, 2, 4, 5]
[0, 2, 4, 5]
[2, 3, 4, 5]
[1, 3, 4, 5]
[0, 3, 4, 5]
sage: for _ in range(1000):
.....:     i,j = next(c)
.....:     s.remove(i); s.add(j)
sage: sorted(s)
[0, 4, 13, 14]

```

`sage.combinat.gray_codes.product(m)`

Iterator over the switch for the iteration of the product $[m_0] \times [m_1] \dots \times [m_k]$.

The iterator return at each step a pair (p, i) which corresponds to the modification to perform to get the next element. More precisely, one has to apply the increment i at the position p . By construction, the increment is either $+1$ or -1 .

This is algorithm H in [Knu2011] Section 7.2.1.1, “Generating All n -Tuples”: loopless reflected mixed-radix Gray generation.

INPUT:

- m – a list or tuple of positive integers that correspond to the size of the sets in the product

EXAMPLES:

```

sage: from sage.combinat.gray_codes import product
sage: l = [0,0,0]
sage: for p,i in product([3,3,3]):
.....:     l[p] += i
.....:     print(l)
[1, 0, 0]
[2, 0, 0]
[2, 1, 0]
[1, 1, 0]
[0, 1, 0]
[0, 2, 0]
[1, 2, 0]
[2, 2, 0]
[2, 2, 1]
[1, 2, 1]
[0, 2, 1]
[0, 1, 1]
[1, 1, 1]
[2, 1, 1]
[2, 0, 1]
[1, 0, 1]
[0, 0, 1]
[0, 0, 2]

```

(continues on next page)

(continued from previous page)

```

[1, 0, 2]
[2, 0, 2]
[2, 1, 2]
[1, 1, 2]
[0, 1, 2]
[0, 2, 2]
[1, 2, 2]
[2, 2, 2]
sage: l = [0,0]
sage: for i,j in product([2,1]):
.....:     l[i] += j
.....:     print(l)
[1, 0]

```

5.1.115 Growth diagrams and dual graded graphs

AUTHORS:

- Martin Rubey (2016-09): Initial version
- Martin Rubey (2017-09): generalize, more rules, improve documentation
- Travis Scrimshaw (2017-09): switch to rule-based framework

Todo:

- provide examples for the P and Q-symbol in the skew case
- implement a method providing a visualization of the growth diagram with all labels, perhaps as LaTeX code
- when shape is given, check that it is compatible with filling or labels
- optimize rules, mainly for *RuleRSK* and *RuleBurge*
- implement backward rules for `GrowthDiagram.rules.Domino`
- implement backward rule from [LLMSSZ2013], [LS2007]
- make semistandard extension generic
- accommodate dual filtered graphs

A guided tour

Growth diagrams, invented by Sergey Fomin [Fom1994], [Fom1995], provide a vast generalization of the Robinson-Schensted-Knuth (RSK) correspondence between matrices with non-negative integer entries and pairs of semistandard Young tableaux of the same shape.

The main fact is that many correspondences similar to RSK can be defined by providing a pair of so-called local rules: a ‘forward’ rule, whose input are three vertices y , t and x of a certain directed graph (in the case of Robinson-Schensted: the directed graph corresponding to Young’s lattice) and an integer (in the case of Robinson-Schensted: 0 or 1), and whose output is a fourth vertex z . This rule should be invertible in the following sense: there is a so-called ‘backward’ rule that recovers the integer and t given y , z and x .

As an example, the growth rules for the classical RSK correspondence are provided by *RuleRSK*. To produce a growth diagram, pass the desired rule and a permutation to *GrowthDiagram*:

```

sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: w = [2,3,6,1,4,5]; G = GrowthDiagram(RuleRSK, w); G
0 0 0 1 0 0
1 0 0 0 0 0
0 1 0 0 0 0
0 0 0 0 1 0
0 0 0 0 0 1
0 0 1 0 0 0

```

The forward rule just mentioned assigns 49 partitions to the corners of each of the 36 cells of this matrix (i.e., 49 the vertices of a $(6 + 1) \times (6 + 1)$ grid graph), with the exception of the corners on the left and top boundary, which are initialized with the empty partition. More precisely, for each cell, the `forward_rule()` computes the partition z labelling the lower right corner, given the content c of a cell and the other three partitions:

```

t --- x
|   c   |
y --- z

```

Warning: Note that a growth diagram is printed with matrix coordinates, the origin being in the top-left corner. Therefore, the growth is from the top left to the bottom right!

The partitions along the boundary opposite of the origin, reading from the bottom left to the top right, are obtained by using the method `out_labels()`:

```

sage: G.out_labels()
[[],
 [1],
 [2],
 [3],
 [3, 1],
 [3, 2],
 [4, 2],
 [4, 1],
 [3, 1],
 [2, 1],
 [1, 1],
 [1],
 []]

```

However, in the case of a rectangular filling, it is more practical to split this sequence of labels in two. Interpreting the sequence of partitions along the right boundary as a standard Young tableau, we then obtain the so-called `P_symbol()`, the partitions along the bottom boundary yield the so-called `Q_symbol()`. These coincide with the output of the classical `RSK()` insertion algorithm:

```

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 3 4 5   1 2 3 6 ]
[ 2 6       , 4 5   ]
sage: ascii_art(RSK(w))
[ 1 3 4 5   1 2 3 6 ]
[ 2 6       , 4 5   ]

```

The filling can be recovered knowing the partitions labelling the corners of the bottom and the right boundary alone,

by repeatedly applying the `backward_rule()`. Therefore, to initialize a `GrowthDiagram`, we can provide these labels instead of the filling:

```
sage: GrowthDiagram(RuleRSK, labels=G.out_labels())
0 0 0 1 0 0
1 0 0 0 0 0
0 1 0 0 0 0
0 0 0 0 1 0
0 0 0 0 0 1
0 0 1 0 0 0
```

Invocation

In general, growth diagrams are defined for 0 – 1-fillings of arbitrary skew shapes. In the case of the Robinson-Schensted-Knuth correspondence, even arbitrary non-negative integers are allowed. In other cases, entries may be either zero or an r -th root of unity - for example, `RuleDomino` insertion is defined for signed permutations, that is, $r = 2$. Traditionally, words and permutations are also used to specify a filling in special cases.

To accommodate all this, the filling may be passed in various ways. The most general possibility is to pass a dictionary of coordinates to (signed) entries, where zeros can be omitted. In this case, when the parameter `shape` is not explicitly specified, it is assumed to be the minimal rectangle containing the origin and all coordinates with non-zero entries.

For example, consider the following generalized permutation:

```
1 2 2 2 4 4
4 2 3 3 2 3
```

that we encode as the dictionary:

```
sage: P = {(1-1,4-1): 1, (2-1,2-1): 1, (2-1,3-1): 2, (4-1,2-1): 1, (4-1,3-1): 1}
```

Note that we are subtracting 1 from all entries because of zero-based indexing, we obtain:

```
sage: GrowthDiagram(RuleRSK, P)
0 0 0 0
0 1 0 1
0 2 0 1
1 0 0 0
```

Alternatively, we could create the same growth diagram using a matrix.

Let us also mention that one can pass the arguments specifying a growth diagram directly to the rule:

```
sage: RuleRSK(P)
0 0 0 0
0 1 0 1
0 2 0 1
1 0 0 0
```

In contrast to the classical insertion algorithms, growth diagrams immediately generalize to fillings whose shape is an arbitrary skew partition:

```
sage: GrowthDiagram(RuleRSK, [3,1,2], shape=SkewPartition([[3,3,2],[1,1]]))
. 1 0
```

(continues on next page)

(continued from previous page)

```
. 0 1
1 0
```

As an important example, consider the Stanley-Sundaram correspondence between oscillating tableaux and (partial) perfect matchings. Perfect matchings of $\{1, \dots, 2r\}$ are in bijection with $0-1$ -fillings of a triangular shape with $2r-1$ rows, such that for each k there is either exactly one non-zero entry in row k or exactly one non-zero entry in column $2r-k$. Explicitly, if (i, j) is a pair in the perfect matching, the entry in column $i-1$ and row $2r-j$ equals 1. For example:

```
sage: m = [[1,5],[3,4],[2,7],[6,8]]
sage: G = RuleRSK({(i-1, 8-j): 1 for i,j in m}, shape=[7,6,5,4,3,2,1]); G
0 0 0 0 0 1 0
0 1 0 0 0 0 0
0 0 0 0 0 0 0
1 0 0 0 0 0 0
0 0 1 0 0 0 0
0 0 0 0 0 0 0
0 0 0 0 0 0 0
```

The partitions labelling the bottom-right corners along the boundary opposite of the origin then form a so-called oscillating tableau - the remaining partitions along the bottom-right boundary are redundant:

```
sage: G.out_labels()[1::2]
[[1], [1, 1], [2, 1], [1, 1], [1], [1, 1], [1]]
```

Another great advantage of growth diagrams is that we immediately have access to a skew version of the correspondence, by providing different initialization for the labels on the side of the origin. We reproduce the original example of Bruce Sagan and Richard Stanley, see also Tom Roby's thesis [Rob1991]:

```
sage: w = {(1-1,4-1): 1, (2-1,2-1): 1, (4-1,3-1): 1}
sage: T = SkewTableau([[None, None], [None, 5], [1]])
sage: U = SkewTableau([[None, None], [None, 3], [5]])
sage: labels = T.to_chain()[::-1] + U.to_chain()[1:]
sage: G = GrowthDiagram(RuleRSK, filling=w, shape=[5,5,5,5,5], labels=labels); G
0 0 0 0 0
0 1 0 0 0
0 0 0 1 0
1 0 0 0 0
0 0 0 0 0
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ . . 2 3 . . 1 4 ]
[ . . . . ]
[ . 4 . 2 ]
[ 1 3 ]
[ 5 , 5 ]
```

Similarly, there is a correspondence for skew oscillating tableau. Let us conclude by reproducing Example 4.2.6 from [Rob1991]. The oscillating tableau, as given, is:

```
sage: o = [[2,1],[2,2],[3,2],[4,2],[4,1],[4,1,1],[3,1,1],[3,1],[3,2],[3,1],[2,1]]
```

From this, we have to construct the list of labels of the corners along the bottom-right boundary. The labels with odd indices are given by the oscillating tableau, the other labels are obtained by taking the smaller of the two neighbouring partitions:

```

sage: l = [o[i//2] if is_even(i) else min(o[(i-1)//2],o[(i+1)//2])
.....:         for i in range(2*len(o)-1)]
sage: la = list(range(len(o)-2, 0, -1))
sage: G = RuleRSK(labels=l[1:-1], shape=la); G
0 0 0 0 0 0 0 1 0
0 1 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0
0 0 1 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0
0 0 0
0 0
0

```

The skew tableaux can now be read off the partitions labelling the left and the top boundary. These can be accessed using the method `in_labels()`:

```

sage: ascii_art(SkewTableau(chain=G.in_labels()[len(o)-2:],
.....:                SkewTableau(chain=G.in_labels()[len(o)-2::-1])))
. 1 . 7
5 4

```

Rules currently available

As mentioned at the beginning, the Robinson-Schensted-Knuth correspondence is just a special case of growth diagrams. In particular, we have implemented the following local rules:

- RSK (*RuleRSK*).
- A variation of RSK originally due to Burge (*RuleBurge*).
- A correspondence producing binary words originally due to Viennot (*RuleBinaryWord*).
- A correspondence producing domino tableaux (*RuleDomino*) originally due to Barbasch and Vogan.
- A correspondence for shifted shapes (*RuleShiftedShapes*), where the original insertion algorithm is due to Sagan and Worley, and Haiman.
- The Sylvester correspondence, producing binary trees (*RuleSylvester*).
- The Young-Fibonacci correspondence (*RuleYoungFibonacci*).
- LLMS insertion (*RuleLLMS*).

Background

At the heart of Fomin's framework is the notion of dual graded graphs. This is a pair of digraphs P, Q (multiple edges being allowed) on the same set of vertices V , that satisfy the following conditions:

- the graphs are graded, that is, there is a function $\rho : V \rightarrow \mathbf{N}$, such that for any edge (v, w) of P and also of Q we have $\rho(w) = \rho(v) + 1$,
- there is a vertex 0 with rank zero, and
- there is a positive integer r such that $DU = UD + rI$ on the free \mathbf{Z} -module $\mathbf{Z}[V]$, where D is the down operator of Q , assigning to each vertex the formal sum of its predecessors, U is the up operator of P , assigning to each vertex the formal sum of its successors, and I is the identity operator.

Note that the condition $DU = UD + rI$ is symmetric with respect to the interchange of the graphs P and Q , because the up operator of a graph is the transpose of its down operator.

For example, taking for both P and Q to be Young's lattice and $r = 1$, we obtain the dual graded graphs for classical Schensted insertion.

Given such a pair of graphs, there is a bijection between the r -colored permutations on k letters and pairs (p, q) , where p is a path in P from zero to a vertex of rank k and q is a path in Q from zero to the same vertex.

It turns out that - in principle - this bijection can always be described by so-called local forward and backward rules, see [Fom1995] for a detailed description. Knowing at least the forward rules, or the backward rules, you can implement your own growth diagram class.

Implementing your own growth diagrams

The class `GrowthDiagram` is written so that it is easy to implement growth diagrams you come across in your research. Moreover, the class tolerates some deviations from Fomin's definitions. For example, although the general Robinson-Schensted-Knuth correspondence between integer matrices and semistandard tableaux is, strictly speaking, not a growth on dual graded graphs, it is supported by our framework.

For illustration, let us implement a growth diagram class with the backward rule only. Suppose that the vertices of the graph are the non-negative integers, the rank is given by the integer itself, and the backward rule is $(y, z, x) \mapsto (\min(x, y), 0)$ if $y = z$ or $x = z$ and $(y, z, x) \mapsto (\min(x, y), 1)$ otherwise.

We first need to import the base class for a rule:

```
sage: from sage.combinat.growth import Rule
```

Next, we implement the backward rule and the rank function and provide the bottom element zero of the graph. For more information, see `Rule`.

```
sage: class RulePascal(Rule):
.....:     zero = 0
.....:     def rank(self, v): return v
.....:     def backward_rule(self, y, z, x):
.....:         return (min(x,y), 0 if y==z or x==z else 1)
```

We can now compute the filling corresponding to a sequence of labels as follows:

```
sage: GrowthDiagram(RulePascal(), labels=[0,1,2,1,2,1,0])
1 0 0
0 0 1
0 1
```

Of course, since we have not provided the forward rule, we cannot compute the labels belonging to a filling:

```
sage: GrowthDiagram(RulePascal(), [3,1,2])
Traceback (most recent call last):
...
AttributeError: 'RulePascal' object has no attribute 'forward_rule'
```

We now re-implement the rule where we provide the dual graded graphs:

```
sage: class RulePascal(Rule):
.....:     zero = 0
.....:     def rank(self, v): return v
```

(continues on next page)

(continued from previous page)

```

.....:     def backward_rule(self, y, z, x):
.....:         return (min(x,y), 0 if y==z or x==z else 1)
.....:     def vertices(self, n): return [n]
.....:     def is_P_edge(self, v, w): return w == v + 1
.....:     def is_Q_edge(self, v, w): return w == v + 1

```

Are they really dual?

```

sage: RulePascal()._check_duality(3)
Traceback (most recent call last):
...
ValueError: D U - U D differs from 1 I for vertex 3:
D U = [3]
U D + 1 I = [3, 3]

```

With our current definition, duality fails - in fact, there are no dual graded graphs on the integers without multiple edges. Consequently, also the backward rule cannot work as `backward_rule` requires additional information (the edge labels as arguments).

Let us thus continue with the example from Section 4.7 of [Fom1995] instead, which defines dual graded graphs with multiple edges on the integers. The color `self.zero_edge`, which defaults to `0` is reserved for degenerate edges, but may be abused for the unique edge if one of the graphs has no multiple edges. For greater clarity in this example we set it to `None`:

```

sage: class RulePascal(Rule):
.....:     zero = 0
.....:     has_multiple_edges = True
.....:     zero_edge = None
.....:     def rank(self, v): return v
.....:     def vertices(self, n): return [n]
.....:     def is_P_edge(self, v, w): return [0] if w == v + 1 else []
.....:     def is_Q_edge(self, v, w): return list(range(w)) if w == v+1 else []

```

We verify these are 1 dual at level 5:

```

sage: RulePascal()._check_duality(5)

```

Finally, let us provide the backward rule. The arguments of the rule are vertices together with the edge labels now, specifying the path from the lower left to the upper right of the cell. The horizontal edges come from Q , whereas the vertical edges come from P .

Thus, the definition in Section 4.7 of [Fom1995] translates as follows:

```

sage: class RulePascal(Rule):
.....:     zero = 0
.....:     has_multiple_edges = True
.....:     zero_edge = None
.....:     def rank(self, v): return v
.....:     def vertices(self, n): return [n]
.....:     def is_P_edge(self, v, w): return [0] if w == v + 1 else []
.....:     def is_Q_edge(self, v, w): return list(range(w)) if w == v+1 else []
.....:     def backward_rule(self, y, g, z, h, x):
.....:         if g is None:
.....:             return (0, x, None, 0)

```

(continues on next page)

(continued from previous page)

```

.....:         if h is None:
.....:             return (None, y, g, 0)
.....:         if g == 0:
.....:             return (None, y, None, 1)
.....:         else:
.....:             return (0, x-1, g-1, 0)

```

The labels are now alternating between vertices and edge-colors:

```

sage: GrowthDiagram(RulePascal(), labels=[0,0,1,0,2,0,1,0,0])
1 0
0 1

sage: GrowthDiagram(RulePascal(), labels=[0,0,1,1,2,0,1,0,0])
0 1
1 0

```

class `sage.combinat.growth.GrowthDiagram`(*rule*, *filling=None*, *shape=None*, *labels=None*)
 Bases: `sage.structure.sage_object.SageObject`

A generalized Schensted growth diagram in the sense of Fomin.

Growth diagrams were introduced by Sergey Fomin [Fom1994], [Fom1995] and provide a vast generalization of the Robinson–Schensted–Knuth (RSK) correspondence between matrices with non-negative integer entries and pairs of semistandard Young tableaux of the same shape.

A growth diagram is based on the notion of *dual graded graphs*, a pair of digraphs P, Q (multiple edges being allowed) on the same set of vertices V , that satisfy the following conditions:

- the graphs are graded, that is, there is a function $\rho : V \rightarrow \mathbf{N}$, such that for any edge (v, w) of P and also of Q we have $\rho(w) = \rho(v) + 1$,
- there is a vertex 0 with rank zero, and
- there is a positive integer r such that $DU = UD + rI$ on the free \mathbf{Z} -module $\mathbf{Z}[V]$, where D is the down operator of Q , assigning to each vertex the formal sum of its predecessors, U is the up operator of P , assigning to each vertex the formal sum of its successors, and I is the identity operator.

Growth diagrams are defined by providing a pair of local rules: a ‘forward’ rule, whose input are three vertices y, t and x of the dual graded graphs and an integer, and whose output is a fourth vertex z . This rule should be invertible in the following sense: there is a so-called ‘backward’ rule that recovers the integer and t given y, z and x .

All implemented growth diagram rules are available by `GrowthDiagram.rules.<tab>`. The current list is:

- [RuleRSK](#) – RSK
- [RuleBurge](#) – a variation of RSK originally due to Burge
- [RuleBinaryWord](#) – a correspondence producing binary words originally due to Viennot
- [RuleDomino](#) – a correspondence producing domino tableaux originally due to Barbasch and Vogan
- [RuleShiftedShapes](#) – a correspondence for shifted shapes, where the original insertion algorithm is due to Sagan and Worley, and Haiman.
- [RuleSylvester](#) – the Sylvester correspondence, producing binary trees
- [RuleYoungFibonacci](#) – the Young-Fibonacci correspondence
- [RuleLLMS](#) – LLMS insertion

INPUT:

- **rule** – *Rule*; the growth diagram rule
- **filling** – (optional) a dictionary whose keys are coordinates and values are integers, a list of lists of integers, or a word with integer values; if a word, then negative letters but without repetitions are allowed and interpreted as coloured permutations
- **shape** – (optional) a (possibly skew) partition
- **labels** – (optional) a list that specifies a path whose length in the half-perimeter of the shape; more details given below

If **filling** is not given, then the growth diagram is determined by applying the backward rule to **labels** decorating the boundary opposite of the origin of the shape. In this case, **labels** are interpreted as labelling the boundary opposite of the origin.

Otherwise, **shape** is inferred from **filling** or **labels** if possible and **labels** is set to `rule.zero` if not specified. Here, **labels** are labelling the boundary on the side of the origin.

For **labels**, if `rule.has_multiple_edges` is `True`, then the elements should be of the form $(v_1, e_1, \dots, e_{n-1}, v_n)$, where n is the half-perimeter of **shape**, and (v_{i-1}, e_i, v_i) is an edge in the dual graded graph for all i . Otherwise, it is a list of n vertices.

Note: Coordinates are of the form (col, row) where the origin is in the upper left, to be consistent with permutation matrices and skew tableaux (in English convention). This is different from Fomin’s convention, who uses a Cartesian coordinate system.

Conventions are chosen such that for permutations, the same growth diagram is constructed when passing the permutation matrix instead.

EXAMPLES:

We create a growth diagram using the forward RSK rule and a permutation:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: pi = Permutation([4, 1, 2, 3])
sage: G = GrowthDiagram(RuleRSK, pi); G
0 1 0 0
0 0 1 0
0 0 0 1
1 0 0 0
sage: G.out_labels()
[[], [1], [1, 1], [2, 1], [3, 1], [3], [2], [1], []]
```

Passing the permutation matrix instead gives the same result:

```
sage: G = GrowthDiagram(RuleRSK, pi.to_matrix())
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 3 1 3 4 ]
[ 4      , 2      ]
```

We give the same example but using a skew shape:

```
sage: shape = SkewPartition([[4,4,4,2],[1,1]])
sage: G = GrowthDiagram(RuleRSK, pi, shape=shape); G
. 1 0 0
```

(continues on next page)

(continued from previous page)

```
. 0 1 0
0 0 0 1
1 0
sage: G.out_labels()
[[], [1], [1, 1], [1], [2], [3], [2], [1], []]
```

We construct a growth diagram using the backwards RSK rule by specifying the labels:

```
sage: GrowthDiagram(RuleRSK, labels=G.out_labels())
0 1 0 0
0 0 1 0
0 0 0 1
1 0
```

P_chain()

Return the labels along the vertical boundary of a rectangular growth diagram.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: G = GrowthDiagram(BinaryWord, [4, 1, 2, 3])
sage: G.P_chain()
[word: , word: 1, word: 11, word: 111, word: 1011]
```

Check that [trac ticket #25631](#) is fixed:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord(filling = {}).P_chain()
[word: ]
```

P_symbol()

Return the labels along the vertical boundary of a rectangular growth diagram as a generalized standard tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 2 1 3 3 ]
[ 2      , 2      ]
```

Q_chain()

Return the labels along the horizontal boundary of a rectangular growth diagram.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: G = GrowthDiagram(BinaryWord, [[0,1,0,0], [0,0,1,0], [0,0,0,1], [1,0,0,
←0]])
sage: G.Q_chain()
[word: , word: 1, word: 10, word: 101, word: 1011]
```

Check that [trac ticket #25631](#) is fixed:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord(filling = {}).Q_chain()
[word: ]
```

Q_symbol()

Return the labels along the horizontal boundary of a rectangular growth diagram as a generalized standard tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[  1  2  2   1  3  3 ]
[  2      ,  2      ]
```

conjugate()

Return the conjugate growth diagram of self.

This is the growth diagram with the filling reflected over the main diagonal.

The sequence of labels along the boundary on the side of the origin is the reversal of the corresponding sequence of the original growth diagram.

When the filling is a permutation, the conjugate filling corresponds to its inverse.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: Gc = G.conjugate()
sage: (Gc.P_symbol(), Gc.Q_symbol()) == (G.Q_symbol(), G.P_symbol())
True
```

filling()

Return the filling of the diagram as a dictionary.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: G.filling()
{(0, 1): 1, (1, 0): 1, (2, 1): 2}
```

half_perimeter()

Return half the perimeter of the shape of the growth diagram.

in_labels()

Return the labels along the boundary on the side of the origin.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, labels=[[2,2],[3,2],[3,3],[3,2]]); G
1 0
sage: G.in_labels()
[[2, 2], [2, 2], [2, 2], [3, 2]]
```

is_rectangular()

Return True if the shape of the growth diagram is rectangular.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [2,3,1]).is_rectangular()
True
sage: GrowthDiagram(RuleRSK, [[1,0,1],[0,1]]).is_rectangular()
False
```

out_labels()

Return the labels along the boundary opposite of the origin.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: G.out_labels()
[[], [1], [1, 1], [3, 1], [1], []]
```

rotate()

Return the growth diagram with the filling rotated by 180 degrees.

The rotated growth diagram is initialized with `labels=None`, that is, all labels along the boundary on the side of the origin are set to `rule.zero`.

For RSK-growth diagrams and rectangular fillings, this corresponds to evacuation of the P - and the Q -symbol.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: Gc = G.rotate()
sage: ascii_art([Gc.P_symbol(), Gc.Q_symbol()])
[ 1 1 1 1 1 2 ]
[ 2      , 3      ]

sage: ascii_art([Tableau(t).evacuation()
.....:             for t in [G.P_symbol(), G.Q_symbol()]])
[ 1 1 1 1 1 2 ]
[ 2      , 3      ]
```

rules

alias of *Rules*

shape()

Return the shape of the growth diagram as a skew partition.

Warning: In the literature the label on the corner opposite of the origin of a rectangular filling is often called the shape of the filling. This method returns the shape of the region instead.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [1]).shape()
[1] / []
```

to_biword()

Return the filling as a biword, if the shape is rectangular.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: P = Tableau([[1,2,2],[2]])
sage: Q = Tableau([[1,3,3],[2]])
sage: bw = RSK_inverse(P, Q); bw
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[::-1]+P.to_chain()[::-1]); G
0 1 0
1 0 2

sage: P = SemistandardTableau([[1, 1, 2], [2]])
sage: Q = SemistandardTableau([[1, 2, 2], [2]])
sage: G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[::-1]+P.to_chain()[::-1]); G
0 2
1 1
sage: G.to_biword()
([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

to_word()

Return the filling as a word, if the shape is rectangular and there is at most one nonzero entry in each column, which must be 1.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: w = [3,3,2,4,1]; G = GrowthDiagram(RuleRSK, w)
sage: G
0 0 0 0 1
0 0 1 0 0
1 1 0 0 0
0 0 0 1 0
sage: G.to_word()
[3, 3, 2, 4, 1]
```

class sage.combinat.growth.Rule

Bases: `sage.structure.unique_representation.UniqueRepresentation`

Generic base class for a rule for a growth diagram.

Subclasses may provide the following attributes:

- `zero` – the zero element of the vertices of the graphs
- `r` – (default: 1) the parameter in the equation $DU - UD = rI$
- `has_multiple_edges` – (default: False) if the dual graded graph has multiple edges and therefore edges are triples consisting of two vertices and a label.

- `zero_edge` – (default: 0) the zero label of the edges of the graphs used for degenerate edges. It is allowed to use this label also for other edges.

Subclasses may provide the following methods:

- `normalize_vertex` – a function that converts its input to a vertex.
- `vertices` – a function that takes a non-negative integer as input and returns the list of vertices on this rank.
- `rank` – the rank function of the dual graded graphs.
- `forward_rule` – a function with input $(y, t, x, \text{content})$ or $(y, e, t, f, x, \text{content})$ if `has_multiple_edges` is `True`. (y, e, t) is an edge in the graph P , (t, f, x) an edge in the graph Q . It should return the fourth vertex z , or, if `has_multiple_edges` is `True`, the path (g, z, h) from y to x .
- `backward_rule` – a function with input (y, z, x) or (y, g, z, h, x) if `has_multiple_edges` is `True`. (y, g, z) is an edge in the graph Q , (z, h, x) an edge in the graph P . It should return the fourth vertex and the content $(t, \text{content})$, or, if `has_multiple_edges` is `True`, the path from y to x and the content as $(e, t, f, \text{content})$.
- `is_P_edge`, `is_Q_edge` – functions that take two vertices as arguments and return `True` or `False`, or, if multiple edges are allowed, the list of edge labels of the edges from the first vertex to the second in the respective graded graph. These are only used for checking user input and providing the dual graded graph, and are therefore not mandatory.

Note that the class `GrowthDiagram` is able to use partially implemented subclasses just fine. Suppose that `MyRule` is such a subclass. Then:

- `GrowthDiagram(MyRule, my_filling)` requires only an implementation of `forward_rule`, `zero` and possibly `has_multiple_edges`.
- `GrowthDiagram(MyRule, labels=my_labels, shape=my_shape)` requires only an implementation of `backward_rule` and possibly `has_multiple_edges`, provided that the labels `my_labels` are given as needed by `backward_rule`.
- `GrowthDiagram(MyRule, labels=my_labels)` additionally needs an implementation of `rank` to deduce the shape.

In particular, this allows to implement rules which do not quite fit Fomin’s notion of dual graded graphs. An example would be Bloom and Saracino’s variant of the RSK correspondence [BS2012], where a backward rule is not available.

Similarly:

- `MyRule.P_graph` only requires an implementation of `vertices`, `is_P_edge` and possibly `has_multiple_edges` is required, mutatis mutandis for `MyRule.Q_graph`.
- `MyRule._check_duality` requires `P_graph` and `Q_graph`.

In particular, this allows to work with dual graded graphs without local rules.

`P_graph(n)`

Return the first n levels of the first dual graded graph.

The non-degenerate edges in the vertical direction come from this graph.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.P_graph(3)
Finite poset containing 8 elements
```

Q_graph(*n*)

Return the first *n* levels of the second dual graded graph.

The non-degenerate edges in the horizontal direction come from this graph.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Q = Domino.Q_graph(3); Q
Finite poset containing 8 elements

sage: Q.upper_covers(Partition([1,1]))
[[1, 1, 1, 1], [3, 1], [2, 2]]
```

normalize_vertex(*v*)

Return *v* as a vertex of the dual graded graph.

This is a default implementation, returning its argument.

EXAMPLES:

```
sage: from sage.combinat.growth import Rule
sage: Rule().normalize_vertex("hello") == "hello"
True
```

class sage.combinat.growth.RuleBinaryWord

Bases: *sage.combinat.growth.Rule*

A rule modelling a Schensted-like correspondence for binary words.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: GrowthDiagram(BinaryWord, [3,1,2])
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are binary words:

```
sage: BinaryWord.vertices(3)
[word: 100, word: 101, word: 110, word: 111]
```

Note that, instead of passing the rule to *GrowthDiagram*, we can also use call the rule to create growth diagrams. For example:

```
sage: BinaryWord([2,4,1,3]).P_chain()
[word: , word: 1, word: 10, word: 101, word: 1101]
sage: BinaryWord([2,4,1,3]).Q_chain()
[word: , word: 1, word: 11, word: 110, word: 1101]
```

The Kleitman Greene invariant is the descent word, encoded by the positions of the zeros:

```
sage: pi = Permutation([4,1,8,3,6,5,2,7,9])
sage: G = BinaryWord(pi); G
0 1 0 0 0 0 0 0 0
0 0 0 0 0 0 1 0 0
```

(continues on next page)

(continued from previous page)

```

0 0 0 1 0 0 0 0 0
1 0 0 0 0 0 0 0 0
0 0 0 0 0 1 0 0 0
0 0 0 0 1 0 0 0 0
0 0 0 0 0 0 0 1 0
0 0 1 0 0 0 0 0 0
0 0 0 0 0 0 0 0 1

```

sage: `pi.descents()`
`[1, 3, 5, 6]`

backward_rule(*y, z, x*)

Return the content and the input shape.

See [Fom1995] Lemma 4.6.1, page 40.

- *y, z, x* – three binary words from a cell in a growth diagram, labelled as:

```

  x
y z

```

OUTPUT:

A pair (*t, content*) consisting of the shape of the fourth word and the content of the cell according to Viennot's bijection [Vie1983].**forward_rule**(*y, t, x, content*)

Return the output shape given three shapes and the content.

See [Fom1995] Lemma 4.6.1, page 40.

INPUT:

- *y, t, x* – three binary words from a cell in a growth diagram, labelled as:

```

t x
y

```

- *content* – 0 or 1; the content of the cell

OUTPUT:

The fourth binary word *z* according to Viennot's bijection [Vie1983].

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
```

```
sage: BinaryWord.forward_rule([], [], [], 1)
word: 1
```

```
sage: BinaryWord.forward_rule([1], [1], [1], 1)
word: 11
```

if $x \neq y$ append last letter of *x* to *y*:

```
sage: BinaryWord.forward_rule([1,0], [1], [1,1], 0)
word: 101
```

if $x == y \neq t$ append 0 to *y*:

```
sage: BinaryWord.forward_rule([1,1], [1], [1,1], 0)
word: 110
```

is_P_edge(v, w)

Return whether (v, w) is a P -edge of self.

(v, w) is an edge if v is obtained from w by deleting a letter.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: v = BinaryWord.vertices(2)[1]; v
word: 11
sage: [w for w in BinaryWord.vertices(3) if BinaryWord.is_P_edge(v, w)]
[word: 101, word: 110, word: 111]
sage: [w for w in BinaryWord.vertices(4) if BinaryWord.is_P_edge(v, w)]
[]
```

is_Q_edge(v, w)

Return whether (v, w) is a Q -edge of self.

(w, v) is an edge if w is obtained from v by appending a letter.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: v = BinaryWord.vertices(2)[0]; v
word: 10
sage: [w for w in BinaryWord.vertices(3) if BinaryWord.is_Q_edge(v, w)]
[word: 100, word: 101]
sage: [w for w in BinaryWord.vertices(4) if BinaryWord.is_Q_edge(v, w)]
[]
```

normalize_vertex(v)

Return v as a binary word.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.normalize_vertex([0,1]).parent()
Finite words over {0, 1}
```

rank(v)

Return the rank of v : number of letters of the word.

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.rank(BinaryWord.vertices(3)[0])
3
```

vertices(n)

Return the vertices of the dual graded graph on level n .

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.vertices(3)
[word: 100, word: 101, word: 110, word: 111]
```

class sage.combinat.growth.RuleBurge

Bases: *sage.combinat.growth.RulePartitions*

A rule modelling Burge insertion.

EXAMPLES:

```
sage: Burge = GrowthDiagram.rules.Burge()
sage: GrowthDiagram(Burge, labels=[[ ], [1,1,1], [2,1,1,1], [2,1,1], [2,1], [1,1], [ ]])
1 1
0 1
1 0
1 0
```

The vertices of the dual graded graph are integer partitions:

```
sage: Burge.vertices(3)
Partitions of the integer 3
```

The local rules implemented provide Burge's correspondence between matrices with non-negative integer entries and pairs of semistandard tableaux, the *P_symbol()* and the *Q_symbol()*. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. For example:

```
sage: m = matrix([[2,0,0,1,0], [1,1,0,0,0], [0,0,0,0,3]])
sage: G = Burge(m); G
2 0 0 1 0
1 1 0 0 0
0 0 0 0 3

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 3 1 2 5 ]
[ 1 3 1 5 ]
[ 1 3 1 5 ]
[ 2 , 4 ]
```

For rectangular fillings, the Kleitman-Greene invariant is the shape of the *P_symbol()*. Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the transpose of the partition (μ_1, \dots, μ_n) , where $\mu_1 + \dots + \mu_i$ is the maximal sum of entries in a collection of i pairwise disjoint sequences of cells with weakly decreasing row indices and weakly increasing column indices.

backward_rule(y, z, x)

Return the content and the input shape.

See [Kra2006] $(B^4_0) - (B^4_2)$. (In the arXiv version of the article there is a typo: in the computation of carry in (B^4_2) , ρ must be replaced by λ).

INPUT:

- y, z, x – three partitions from a cell in a growth diagram, labelled as:

```
x
y z
```

OUTPUT:

A pair $(t, \text{content})$ consisting of the shape of the fourth partition according to the Burge correspondence and the content of the cell.

EXAMPLES:

```
sage: Burge = GrowthDiagram.rules.Burge()
sage: Burge.backward_rule([1,1,1],[2,1,1,1],[2,1,1])
([1, 1], 0)
```

forward_rule($y, t, x, \text{content}$)

Return the output shape given three shapes and the content.

See [Kra2006] $(F^4 0) - (F^4 2)$.

INPUT:

- y, t, x – three from a cell in a growth diagram, labelled as:

```
t x
y
```

- content – a non-negative integer; the content of the cell

OUTPUT:

The fourth partition according to the Burge correspondence.

EXAMPLES:

```
sage: Burge = GrowthDiagram.rules.Burge()
sage: Burge.forward_rule([2,1],[2,1],[2,1],1)
[3, 1]

sage: Burge.forward_rule([1],[],[2],2)
[2, 1, 1, 1]
```

class `sage.combinat.growth.RuleDomino`

Bases: `sage.combinat.growth.Rule`

A rule modelling domino insertion.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: GrowthDiagram(Domino, [[1,0,0],[0,0,1],[0,-1,0]])
1  0  0
0  0  1
0 -1  0
```

The vertices of the dual graded graph are integer partitions whose Ferrers diagram can be tiled with dominoes:

```
sage: Domino.vertices(2)
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

Instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. For example, let us check Figure 3 in [Lam2004]:

```
sage: G = Domino([[0,0,0,-1],[0,0,1,0],[-1,0,0,0],[0,1,0,0]]; G
0 0 0 -1
0 0 1 0
-1 0 0 0
0 1 0 0

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 4 1 2 2 ]
[ 1 2 4 1 3 3 ]
[ 3 3 , 4 4 ]
```

The spin of a domino tableau is half the number of vertical dominoes:

```
sage: def spin(T):
.....:     return sum(2*len(set(row)) - len(row) for row in T)/4
```

According to [Lam2004], the number of negative entries in the signed permutation equals the sum of the spins of the two associated tableaux:

```
sage: pi = [3,-1,2,4,-5]
sage: G = Domino(pi)
sage: list(G.filling().values()).count(-1) == spin(G.P_symbol()) + spin(G.Q_
->symbol())
True
```

Negating all signs transposes all the partitions:

```
sage: G.P_symbol() == Domino([-e for e in pi]).P_symbol().conjugate()
True
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) domino tableau.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: G = Domino([[0,1,0],[0,0,-1],[1,0,0]])
sage: G.P_symbol().pp()
1 1
2 3
2 3
```

Q_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) domino tableau.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: G = Domino([[0,1,0],[0,0,-1],[1,0,0]])
sage: G.P_symbol().pp()
1 1
2 3
2 3
```

forward_rule($y, t, x, content$)

Return the output shape given three shapes and the content.

See [Lam2004] Section 3.1.

INPUT:

- y, t, x – three partitions from a cell in a growth diagram, labelled as:

```
t x
y
```

- $content$ – $-1, 0$ or 1 ; the content of the cell

OUTPUT:

The fourth partition according to domino insertion.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
```

Rule 1:

```
sage: Domino.forward_rule([], [], [], 1)
[2]
```

```
sage: Domino.forward_rule([1,1], [1,1], [1,1], 1)
[3, 1]
```

Rule 2:

```
sage: Domino.forward_rule([1,1], [1,1], [1,1], -1)
[1, 1, 1, 1]
```

Rule 3:

```
sage: Domino.forward_rule([1,1], [1,1], [2,2], 0)
[2, 2]
```

Rule 4:

```
sage: Domino.forward_rule([2,2,2], [2,2], [3,3], 0)
[3, 3, 2]
```

```
sage: Domino.forward_rule([2], [], [1,1], 0)
[2, 2]
```

```
sage: Domino.forward_rule([1,1], [], [2], 0)
[2, 2]
```

```
sage: Domino.forward_rule([2], [], [2], 0)
[2, 2]
```

```
sage: Domino.forward_rule([4], [2], [4], 0)
[4, 2]
```

(continues on next page)

(continued from previous page)

```
sage: Domino.forward_rule([1,1,1,1], [1,1], [1,1,1,1], 0)
[2, 2, 1, 1]

sage: Domino.forward_rule([2,1,1], [2], [4], 0)
[4, 1, 1]
```

is_P_edge(v, w)Return whether (v, w) is a P -edge of self. (v, w) is an edge if v is obtained from w by deleting a domino.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: v = Domino.vertices(2)[1]; ascii_art(v)
***
*

sage: ascii_art([w for w in Domino.vertices(3) if Domino.is_P_edge(v, w)])
[      *** ]
[      *   ]
[ ***** *** * ]
[ *      , *** , * ]

sage: [w for w in Domino.vertices(4) if Domino.is_P_edge(v, w)]
[]
```

is_Q_edge(v, w)Return whether (v, w) is a P -edge of self. (v, w) is an edge if v is obtained from w by deleting a domino.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: v = Domino.vertices(2)[1]; ascii_art(v)
***
*

sage: ascii_art([w for w in Domino.vertices(3) if Domino.is_P_edge(v, w)])
[      *** ]
[      *   ]
[ ***** *** * ]
[ *      , *** , * ]

sage: [w for w in Domino.vertices(4) if Domino.is_P_edge(v, w)]
[]
```

normalize_vertex(v)Return v as a partition.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.normalize_vertex([3,1]).parent()
Partitions
```

rank(v)Return the rank of v .

The rank of a vertex is half the size of the partition, which equals the number of dominoes in any filling.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.rank(Domino.vertices(3)[0])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level *n*.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.vertices(2)
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

zero = []

class sage.combinat.growth.RuleLLMS(*k*)

Bases: *sage.combinat.growth.Rule*

A rule modelling the Schensted correspondence for affine permutations.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: GrowthDiagram(LLMS3, [3,1,2])
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are *Cores*:

```
sage: LLMS3.vertices(4)
3-Cores of length 4
```

Let us check example of Figure 1 in [LS2007]. Note that, instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams:

```
sage: G = LLMS3([4,1,2,6,3,5]); G
0 1 0 0 0 0
0 0 1 0 0 0
0 0 0 0 1 0
1 0 0 0 0 0
0 0 0 0 0 1
0 0 0 1 0 0
```

The *P_symbol()* is a *StrongTableau*:

```
sage: G.P_symbol().pp()
-1 -2 -3 -5
 3  5
-4 -6
 5
 6
```

The *Q_symbol()* is a *WeakTableau*:

```
sage: G.Q_symbol().pp()
1 3 4 5
2 5
3 6
5
6
```

Let us also check Example 6.2 in [LLMSSZ2013]:

```
sage: G = LLMS3([4, 1, 3, 2])
sage: G.P_symbol().pp()
-1 -2 3
-3
-4

sage: G.Q_symbol().pp()
1 3 4
2
3
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a skew *StrongTableau*.

EXAMPLES:

```
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3, 4, 1, 2])
sage: G.P_symbol().pp()
-1 -2
-3 -4
```

Q_symbol(*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew *WeakTableau*.

EXAMPLES:

```
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3, 4, 1, 2])
sage: G.Q_symbol().pp()
1 2
3 4
```

forward_rule(*y, e, t, f, x, content*)

Return the output path given two incident edges and the content.

See [LS2007] Section 3.4 and [LLMSSZ2013] Section 6.3.

INPUT:

- *y, e, t, f, x* – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
t f x
e
y
```

- *content* – 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition g, z, h according to LLMS insertion.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)

sage: Z = LLMS3.zero
sage: LLMS3.forward_rule(Z, None, Z, None, Z, 0)
(None, [], None)

sage: LLMS3.forward_rule(Z, None, Z, None, Z, 1)
(None, [1], 0)

sage: Y = Core([3,1,1], 3)
sage: LLMS3.forward_rule(Y, None, Y, None, Y, 1)
(None, [4, 2, 1, 1], 3)
```

if $x \neq y$:

```
sage: Y = Core([1,1], 3); T = Core([1], 3); X = Core([2], 3)
sage: LLMS3.forward_rule(Y, -1, T, None, X, 0)
(None, [2, 1, 1], -1)

sage: Y = Core([2], 4); T = Core([1], 4); X = Core([1,1], 4)
sage: LLMS4.forward_rule(Y, 1, T, None, X, 0)
(None, [2, 1], 1)

sage: Y = Core([2,1,1], 3); T = Core([2], 3); X = Core([3,1], 3)
sage: LLMS3.forward_rule(Y, -1, T, None, X, 0)
(None, [3, 1, 1], -2)
```

if $x = y \neq t$:

```
sage: Y = Core([1], 3); T = Core([], 3); X = Core([1], 3)
sage: LLMS3.forward_rule(Y, 0, T, None, X, 0)
(None, [1, 1], -1)

sage: Y = Core([1], 4); T = Core([], 4); X = Core([1], 4)
sage: LLMS4.forward_rule(Y, 0, T, None, X, 0)
(None, [1, 1], -1)

sage: Y = Core([2,1], 4); T = Core([1,1], 4); X = Core([2,1], 4)
sage: LLMS4.forward_rule(Y, 1, T, None, X, 0)
(None, [2, 2], 0)
```

is_P_edge(v, w)

Return whether (v, w) is a P -edge of self.

For two k -cores v and w containing v , there are as many edges as there are components in the skew partition w/v . These components are ribbons, and therefore contain a unique cell with maximal content. We index the edge with this content.

EXAMPLES:

```

sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(2)[0]; v
[2]
sage: [(w, LLMS4.is_P_edge(v, w)) for w in LLMS4.vertices(3)]
[[([3], [2]), ([2, 1], [-1]), ([1, 1, 1], [])]
sage: all(LLMS4.is_P_edge(v, w) == [] for w in LLMS4.vertices(4))
True

```

is_Q_edge(v, w)

Return whether (v, w) is a Q-edge of self.

(v, w) is an edge if w is a weak cover of v, see [weak_covers\(\)](#).

EXAMPLES:

```

sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(3)[1]; v
[2, 1]
sage: [w for w in LLMS4.vertices(4) if len(LLMS4.is_Q_edge(v, w)) > 0]
[[2, 2], [3, 1, 1]]
sage: all(LLMS4.is_Q_edge(v, w) == [] for w in LLMS4.vertices(5))
True

```

normalize_vertex(v)

Convert v to a k-core.

EXAMPLES:

```

sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.normalize_vertex([3, 1]).parent()
3-Cores of length 3

```

rank(v)

Return the rank of v: the length of the core.

EXAMPLES:

```

sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.rank(LLMS3.vertices(3)[0])
3

```

vertices(n)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```

sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.vertices(2)
3-Cores of length 2

```

class sage.combinat.growth.RulePartitions

Bases: [sage.combinat.growth.Rule](#)

A rule for growth diagrams on Young's lattice on integer partitions graded by size.

P_symbol(P_chain)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.P_symbol().pp()
1 2 2
2
```

Q_symbol(*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.Q_symbol().pp()
1 3 3
2
```

normalize_vertex(*v*)

Return *v* as a partition.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.normalize_vertex([3,1]).parent()
Partitions
```

rank(*v*)

Return the rank of *v*: the size of the partition.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.rank(RSK.vertices(3)[0])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level *n*.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.vertices(3)
Partitions of the integer 3
```

zero = []

class `sage.combinat.growth.RuleRSK`

Bases: `sage.combinat.growth.RulePartitions`

A rule modelling Robinson-Schensted-Knuth insertion.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [3,2,1,2,3])
0 0 1 0 0
```

(continues on next page)

(continued from previous page)

```
0 1 0 1 0
1 0 0 0 1
```

The vertices of the dual graded graph are integer partitions:

```
sage: RuleRSK.vertices(3)
Partitions of the integer 3
```

The local rules implemented provide the RSK correspondence between matrices with non-negative integer entries and pairs of semistandard tableaux, the *P-symbol()* and the *Q-symbol()*. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. For example:

```
sage: m = matrix([[0,0,0,0,1],[1,1,0,2,0],[0,3,0,0,0]])
sage: G = RuleRSK(m); G
0 0 0 0 1
1 1 0 2 0
0 3 0 0 0

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 2 2 3 1 2 2 2 2 ]
[ 2 3 4 4 ]
[ 3 , 5 ]
```

For rectangular fillings, the Kleitman-Greene invariant is the shape of the *P-symbol()* (or the *Q-symbol()*). Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the partition (μ_1, \dots, μ_n) , where $\mu_1 + \dots + \mu_i$ is the maximal sum of entries in a collection of i pairwise disjoint sequences of cells with weakly increasing coordinates.

For rectangular fillings, we could also use the (faster) implementation provided via *RSK()*. Because of the coordinate conventions in *RSK()*, we have to transpose matrices:

```
sage: [G.P_symbol(), G.Q_symbol()] == RSK(m.transpose())
True

sage: n = 5; l = [(pi, RuleRSK(pi)) for pi in Permutations(n)]
sage: all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True

sage: n = 5; l = [(w, RuleRSK(w)) for w in Words([1,2,3], 5)]
sage: all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True
```

backward_rule(y, z, x)

Return the content and the input shape.

See [Kra2006] $(B^1 0) - (B^1 2)$.

INPUT:

- y, z, x – three partitions from a cell in a growth diagram, labelled as:

```
x
y z
```

OUTPUT:

A pair $(t, \text{content})$ consisting of the shape of the fourth word according to the Robinson-Schensted-Knuth correspondence and the content of the cell.

forward_rule($y, t, x, \text{content}$)

Return the output shape given three shapes and the content.

See [Kra2006] $(F^1_0) - (F^1_2)$.

INPUT:

- y, t, x – three partitions from a cell in a growth diagram, labelled as:

```
t x
y
```

- content – a non-negative integer; the content of the cell

OUTPUT:

The fourth partition according to the Robinson-Schensted-Knuth correspondence.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: RuleRSK.forward_rule([2,1],[2,1],[2,1],1)
[3, 1]

sage: RuleRSK.forward_rule([1],[],[2],2)
[4, 1]
```

class `sage.combinat.growth.RuleShiftedShapes`

Bases: `sage.combinat.growth.Rule`

A class modelling the Schensted correspondence for shifted shapes.

This agrees with Sagan [Sag1987] and Worley's [Wor1984], and Haiman's [Hai1989] insertion algorithms, see Proposition 4.5.2 of [Fom1995].

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: GrowthDiagram(Shifted, [3,1,2])
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are shifted shapes:

```
sage: Shifted.vertices(3)
Partitions of the integer 3 satisfying constraints max_slope=-1
```

Let us check the example just before Corollary 3.2 in [Sag1987]. Note that, instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams:

```
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.P_chain()
[[], 0, [1], 0, [2], 0, [3], 0, [3, 1], 0, [3, 2], 0, [4, 2], 0, [5, 2]]
```

(continues on next page)

(continued from previous page)

```
sage: G.Q_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a shifted tableau.

EXAMPLES:

Check the example just before Corollary 3.2 in [Sag1987]:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.P_symbol().pp()
1 2 3 6 7
  4 5
```

Check the example just before Corollary 8.2 in [SS1990]:

```
sage: T = ShiftedPrimedTableau([[4],[1],[5]], skew=[3,1])
sage: T.pp()
. . . 4
. . 1
. 5
sage: U = ShiftedPrimedTableau([[1],[3.5],[5]], skew=[3,1])
sage: U.pp()
. . . 1
. 4'
. 5
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: labels = [mu if is_even(i) else 0 for i, mu in enumerate(T.to_chain()[::-1])] + U.to_chain()[1:]
sage: G = Shifted({(1,2):1, (2,1):1}, shape=[5,5,5,5,5], labels=labels)
sage: G.P_symbol().pp()
. . . . 2
. . 1 3
. 4 5
```

Q_symbol(*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

EXAMPLES:

Check the example just before Corollary 3.2 in [Sag1987]:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.Q_symbol().pp()
1 2 4' 5 7'
  3 6'
```

Check the example just before Corollary 8.2 in [SS1990]:

```
sage: T = ShiftedPrimedTableau([[4],[1],[5]], skew=[3,1])
sage: T.pp()
. . . 4
```

(continues on next page)

(continued from previous page)

```

. 1
  5
sage: U = ShiftedPrimedTableau([[1],[3.5],[5]], skew=[3,1])
sage: U.pp()
. . . 1
. 4'
  5
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: labels = [mu if is_even(i) else 0 for i, mu in enumerate(T.to_chain()[::-1])] + U.to_chain()[1:]
sage: G = Shifted({(1,2):1, (2,1):1}, shape=[5,5,5,5,5], labels=labels)
sage: G.Q_symbol().pp()
. . . . 2
. . 1 4'
. 3' 5'

```

backward_rule(y, g, z, h, x)

Return the input path and the content given two incident edges.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

- y, g, z, h, x – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```

      x
      h
y g z

```

OUTPUT:

A tuple (e, t, f, content) consisting of the shape t of the fourth word, the colours of the incident edges and the content of the cell according to Sagan - Worley insertion.

EXAMPLES:

```

sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.backward_rule([], 1, [1], 0, [])
(0, [], 0, 1)

sage: Shifted.backward_rule([1], 2, [2], 0, [1])
(0, [1], 0, 1)

```

if x != y:

```

sage: Shifted.backward_rule([3], 1, [3, 1], 0, [2,1])
(0, [2], 1, 0)

sage: Shifted.backward_rule([2,1], 2, [3, 1], 0, [3])
(0, [2], 2, 0)

```

if x == y != t:

```

sage: Shifted.backward_rule([3], 1, [3, 1], 0, [3])
(0, [2], 2, 0)

sage: Shifted.backward_rule([3,1], 2, [3, 2], 0, [3,1])
(0, [2, 1], 2, 0)

sage: Shifted.backward_rule([2,1], 3, [3, 1], 0, [2,1])
(0, [2], 1, 0)

sage: Shifted.backward_rule([3], 3, [4], 0, [3])
(0, [2], 3, 0)

```

forward_rule(*y, e, t, f, x, content*)

Return the output path given two incident edges and the content.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

- *y, e, t, f, x* – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```

t f x
e
y

```

- *content* – 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition *g, z, h* according to Sagan-Worley insertion.

EXAMPLES:

```

sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.forward_rule([], 0, [], 0, [], 1)
(1, [1], 0)

sage: Shifted.forward_rule([1], 0, [1], 0, [1], 1)
(2, [2], 0)

```

if *x* != *y*:

```

sage: Shifted.forward_rule([3], 0, [2], 1, [2,1], 0)
(1, [3, 1], 0)

sage: Shifted.forward_rule([2,1], 0, [2], 2, [3], 0)
(2, [3, 1], 0)

```

if *x* == *y* != *t*:

```

sage: Shifted.forward_rule([3], 0, [2], 2, [3], 0)
(1, [3, 1], 0)

sage: Shifted.forward_rule([3,1], 0, [2,1], 2, [3,1], 0)
(2, [3, 2], 0)

```

(continues on next page)

(continued from previous page)

```
sage: Shifted.forward_rule([2,1], 0, [2], 1, [2,1], 0)
(3, [3, 1], 0)
```

```
sage: Shifted.forward_rule([3], 0, [2], 3, [3], 0)
(3, [4], 0)
```

is_P_edge(v, w)

Return whether (v, w) is a P -edge of self.

(v, w) is an edge if w contains v .

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: v = Shifted.vertices(2)[0]; v
[2]
sage: [w for w in Shifted.vertices(3) if Shifted.is_P_edge(v, w)]
[[3], [2, 1]]
```

is_Q_edge(v, w)

Return whether (v, w) is a Q -edge of self.

(v, w) is an edge if w is obtained from v by adding a cell. It is a black (color 1) edge, if the cell is on the diagonal, otherwise it can be blue or red (color 2 or 3).

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: v = Shifted.vertices(2)[0]; v
[2]
sage: [(w, Shifted.is_Q_edge(v, w)) for w in Shifted.vertices(3)]
[(3, 1), (2, 3), (2, 1), (1, 1)]
sage: all(Shifted.is_Q_edge(v, w) == 1 for w in Shifted.vertices(4))
True
```

normalize_vertex(v)

Return v as a partition.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.normalize_vertex([3,1]).parent()
Partitions
```

rank(v)

Return the rank of v : the size of the shifted partition.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.rank(Shifted.vertices(3)[0])
3
```

vertices(n)

Return the vertices of the dual graded graph on level n .

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.vertices(3)
Partitions of the integer 3 satisfying constraints max_slope=-1
```

```
zero = []
```

class sage.combinat.growth.RuleSylvester

Bases: [sage.combinat.growth.Rule](#)

A rule modelling a Schensted-like correspondence for binary trees.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: GrowthDiagram(Sylvester, [3,1,2])
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are [BinaryTrees](#):

```
sage: Sylvester.vertices(3)
Binary trees of size 3
```

The [P_graph\(\)](#) is also known as the bracket tree, the [Q_graph\(\)](#) is the lattice of finite order ideals of the infinite binary tree, see Example 2.4.6 in [Fom1994].

For a permutation, the [P_symbol\(\)](#) is the binary search tree, the [Q_symbol\(\)](#) is the increasing tree corresponding to the inverse permutation. Note that, instead of passing the rule to [GrowthDiagram](#), we can also call the rule to create growth diagrams. From [Nze2007]:

```
sage: pi = Permutation([3,5,1,4,2,6]); G = Sylvester(pi); G
0 0 1 0 0 0
0 0 0 0 1 0
1 0 0 0 0 0
0 0 0 1 0 0
0 1 0 0 0 0
0 0 0 0 0 1
sage: ascii_art(G.P_symbol())
  __3__
 /      \
1          5
 \        / \
  2      4   6
sage: ascii_art(G.Q_symbol())
  __1__
 /      \
3          2
 \        / \
  5      4   6
sage: all(Sylvester(pi).P_symbol() == pi.binary_search_tree())
.....:   for pi in Permutations(5))
True
```

(continues on next page)

(continued from previous page)

```
sage: all(Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
.....:     for pi in Permutations(5))
True
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the binary search tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).P_symbol())
  _2_
 /   \
1     4
     /
     3
sage: Sylvester(pi).P_symbol() == pi.binary_search_tree()
True
```

We can also do the skew version:

```
sage: B = BinaryTree; E = B(); N = B([])
sage: ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).P_
↪symbol())
  _1_
 /   \
None  3
     /
     2
```

Q_symbol(*Q_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the increasing tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).Q_symbol())
  _1_
 /   \
4     2
     /
     3
sage: Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
True
```

We can also do the skew version:

```

sage: B = BinaryTree; E = B(); N = B([])
sage: ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).Q_
↳symbol())
  _None_
 /       \
3         1
         /
         2

```

backward_rule(*y, z, x*)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

INPUT:

- *y, z, x* – three binary trees from a cell in a growth diagram, labelled as:

```

  x
 y z

```

OUTPUT:

A pair (*t, content*) consisting of the shape of the fourth binary tree *t* and the content of the cell.

EXAMPLES:

```

sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: B = BinaryTree; E = B(); N = B([]); L = B([],None)
sage: R = B([None,[]]); T = B([],[])

sage: ascii_art(Sylvester.backward_rule(E, E, E))
( , 0 )
sage: ascii_art(Sylvester.backward_rule(N, N, N))
( o, 0 )

```

forward_rule(*y, t, x, content*)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

INPUT:

- *y, t, x* – three binary trees from a cell in a growth diagram, labelled as:

```

  t x
 y

```

- *content* – 0 or 1; the content of the cell

OUTPUT:

The fourth binary tree *z*.

EXAMPLES:

```

sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: B = BinaryTree; E = B(); N = B([]); L = B([],None)
sage: R = B([None,[]]); T = B([],[])

```

(continues on next page)

(continued from previous page)

```

sage: ascii_art(Sylvester.forward_rule(E, E, E, 1))
o
sage: ascii_art(Sylvester.forward_rule(N, N, N, 1))
o
 \
  o
sage: ascii_art(Sylvester.forward_rule(L, L, L, 1))
  o
 / \
o   o
sage: ascii_art(Sylvester.forward_rule(R, R, R, 1))
o
 \
  o
   \
    o

```

If $y \neq x$, obtain z from y adding a node such that deleting the right most gives x :

```

sage: ascii_art(Sylvester.forward_rule(R, N, L, 0))
  o
 / \
o   o
sage: ascii_art(Sylvester.forward_rule(L, N, R, 0))
  o
 /
o
 \
  o

```

If $y == x \neq t$, obtain z from x by adding a node as left child to the right most node:

```

sage: ascii_art(Sylvester.forward_rule(N, E, N, 0))
  o
 /
o
sage: ascii_art(Sylvester.forward_rule(T, L, T, 0))
  _o_
 /   \
o     o
   /
  o
sage: ascii_art(Sylvester.forward_rule(L, N, L, 0))
  o
 /
  o
 /
o
sage: ascii_art(Sylvester.forward_rule(R, N, R, 0))
o

```

(continues on next page)

(continued from previous page)

**is_P_edge**(v, w)Return whether (v, w) is a P -edge of self.(v, w) is an edge if v is obtained from w by deleting its right-most node.

EXAMPLES:

```

sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
  o
 /
o

sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_P_edge(v, w)])
[  o ,   o ]
[ / \   / ]
[ o o  o ]
[      / ]
[      o ]

sage: [w for w in Sylvester.vertices(4) if Sylvester.is_P_edge(v, w)]
[]

```

is_Q_edge(v, w)Return whether (v, w) is a Q -edge of self.(v, w) is an edge if v is a sub-tree of w with one node less.

EXAMPLES:

```

sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
  o
 /
o

sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_Q_edge(v, w)])
[  o ,  o,  o ]
[ / \  /  / ]
[ o o o  o ]
[      \ / ]
[      o o ]

sage: [w for w in Sylvester.vertices(4) if Sylvester.is_Q_edge(v, w)]
[]

```

normalize_vertex(v)Return v as a binary tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.normalize_vertex([[[]], [[]]].parent())
Binary trees
```

rank(v)

Return the rank of v : the number of nodes of the tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.rank(Sylvester.vertices(3)[0])
3
```

vertices(n)

Return the vertices of the dual graded graph on level n .

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.vertices(3)
Binary trees of size 3
```

zero = .

class sage.combinat.growth.RuleYoungFibonacci

Bases: [sage.combinat.growth.Rule](#)

A rule modelling a Schensted-like correspondence for Young-Fibonacci-tableaux.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: GrowthDiagram(YF, [3,1,2])
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are Fibonacci words - compositions into parts of size at most two:

```
sage: YF.vertices(4)
[word: 22, word: 211, word: 121, word: 112, word: 1111]
```

Note that, instead of passing the rule to [GrowthDiagram](#), we can also use call the rule to create growth diagrams. For example:

```
sage: G = YF([2, 3, 7, 4, 1, 6, 5]); G
0 0 0 0 1 0 0
1 0 0 0 0 0 0
0 1 0 0 0 0 0
0 0 0 1 0 0 0
0 0 0 0 0 0 1
0 0 0 0 0 1 0
0 0 1 0 0 0 0
```

The Kleitman Greene invariant is: take the last letter and the largest letter of the permutation and remove them. If they coincide write 1, otherwise write 2:

```
sage: G.P_chain()[-1]
word: 21211
```

backward_rule(y, z, x)

Return the content and the input shape.

See [Fom1995] Lemma 4.4.1, page 35.

- y, z, x – three Fibonacci words from a cell in a growth diagram, labelled as:

```
x
y z
```

OUTPUT:

A pair ($t, \text{content}$) consisting of the shape of the fourth word and the content of the cell.

forward_rule($y, t, x, \text{content}$)

Return the output shape given three shapes and the content.

See [Fom1995] Lemma 4.4.1, page 35.

INPUT:

- y, t, x – three Fibonacci words from a cell in a growth diagram, labelled as:

```
t x
y
```

- content – 0 or 1; the content of the cell

OUTPUT:

The fourth Fibonacci word.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()

sage: YF.forward_rule([], [], [], 1)
word: 1

sage: YF.forward_rule([1], [1], [1], 1)
word: 11

sage: YF.forward_rule([1,2], [1], [1,1], 0)
word: 21

sage: YF.forward_rule([1,1], [1], [1,1], 0)
word: 21
```

is_P_edge(v, w)

Return whether (v, w) is a P -edge of `self`.

(v, w) is an edge if v is obtained from w by deleting a 1 or replacing the left-most 2 by a 1.

EXAMPLES:

```

sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: v = YF.vertices(5)[5]; v
word: 1121
sage: [w for w in YF.vertices(6) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
sage: [w for w in YF.vertices(7) if YF.is_P_edge(v, w)]
[]

```

is_Q_edge(v, w)

Return whether (v, w) is a P -edge of self.

(v, w) is an edge if v is obtained from w by deleting a 1 or replacing the left-most 2 by a 1.

EXAMPLES:

```

sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: v = YF.vertices(5)[5]; v
word: 1121
sage: [w for w in YF.vertices(6) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
sage: [w for w in YF.vertices(7) if YF.is_P_edge(v, w)]
[]

```

normalize_vertex(v)

Return v as a word with letters 1 and 2.

EXAMPLES:

```

sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.normalize_vertex([1,2,1]).parent()
Finite words over {1, 2}

```

rank(v)

Return the rank of v : the size of the corresponding composition.

EXAMPLES:

```

sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.rank(YF.vertices(3)[0])
3

```

vertices(n)

Return the vertices of the dual graded graph on level n .

EXAMPLES:

```

sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.vertices(3)
[word: 21, word: 12, word: 111]

```

5.1.116 Grossman-Larson Hopf Algebras

AUTHORS:

- Frédéric Chapoton (2017)

class `sage.combinat.grossman_larson_algebras.GrossmanLarsonAlgebra`(*R*, *names=None*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`

The Grossman-Larson Hopf Algebra.

The Grossman-Larson Hopf Algebras are Hopf algebras with a basis indexed by forests of decorated rooted trees. They are the universal enveloping algebras of free pre-Lie algebras, seen as Lie algebras.

The Grossman-Larson Hopf algebra on a given set E has an explicit description using rooted forests. The underlying vector space has a basis indexed by finite rooted forests endowed with a map from their vertices to E (called the “labeling”). In this basis, the product of two (decorated) rooted forests $S * T$ is a sum over all maps from the set of roots of T to the union of a singleton $\{\#\}$ and the set of vertices of S . Given such a map, one defines a new forest as follows. Starting from the disjoint union of all rooted trees of S and T , one adds an edge from every root of T to its image when this image is not the fake vertex labelled $\#$. The coproduct sends a rooted forest T to the sum of all tensors $T_1 \otimes T_2$ obtained by splitting the connected components of T into two subsets and letting T_1 be the forest formed by the first subset and T_2 the forest formed by the second. This yields a connected graded Hopf algebra (the degree of a forest is its number of vertices).

See [Pana2002] (Section 2) and [GroLar1]. (Note that both references use rooted trees rather than rooted forests, so think of each rooted forest grafted onto a new root. Also, the product is reversed, so they are defining the opposite algebra structure.)

Warning: For technical reasons, instead of using forests as labels for the basis, we use rooted trees. Their root vertex should be considered as a fake vertex. This fake root vertex is labelled '#' when labels are present.

EXAMPLES:

```
sage: G = algebras.GrossmanLarson(QQ, 'xy')
sage: x, y = G.single_vertex_all()
sage: ascii_art(x*y)
```

(continues on next page)

(continued from previous page)

```

B + B
#   #_
|   //
x   x y
|
y

sage: ascii_art(x*x*x)
B + B + 3*B + B
#   #   #_   #_
|   |   //   //
x   x_  x x  x x x
|   //   |
x   x x  x
|
x

```

The Grossman-Larson algebra is associative:

```

sage: z = x * y
sage: x * (y * z) == (x * y) * z
True

```

It is not commutative:

```

sage: x * y == y * x
False

```

When None is given as input, unlabelled forests are used instead; this corresponds to a 1-element set E :

```

sage: G = algebras.GrossmanLarson(QQ, None)
sage: x = G.single_vertex_all()[0]
sage: ascii_art(x*x)
B + B
o   o_
|   //
o   o o
|
o

```

Note: Variables names can be None, a list of strings, a string or an integer. When None is given, unlabelled rooted forests are used. When a single string is given, each letter is taken as a variable. See [sage.combinat.words.alphabet.build_alphabet\(\)](#).

Warning: Beware that the underlying combinatorial free module is based either on RootedTrees or on LabelledRootedTrees, with no restriction on the labellings. This means that all code calling the `basis()` method would not give meaningful results, since `basis()` returns many “chaff” elements that do not belong to the algebra.

REFERENCES:

- [Pana2002]
- [GroLar1]

an_element()

Return an element of self.

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: A.an_element()
B[#[x[]]] + 2*B[#[x[x[]]]] + 2*B[#[x[], x[]]]
```

antipode_on_basis(x)

Return the antipode of a forest.

EXAMPLES:

```
sage: G = algebras.GrossmanLarson(QQ,2)
sage: x, y = G.single_vertex_all()
sage: G.antipode(x) # indirect doctest
-B[#[0[]]]

sage: G.antipode(y*x) # indirect doctest
B[#[0[1[]]]] + B[#[0[], 1[]]]
```

change_ring(R)

Return the Grossman-Larson algebra in the same variables over R .

INPUT:

- R – a ring

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.change_ring(QQ)
Grossman-Larson Hopf algebra on 3 generators ['f', 'g', 'h']
over Rational Field
```

coproduct_on_basis(x)

Return the coproduct of a forest.

EXAMPLES:

```
sage: G = algebras.GrossmanLarson(QQ,2)
sage: x, y = G.single_vertex_all()
sage: ascii_art(G.coproduct(x)) # indirect doctest
1 # B + B # 1
  #   #
  |   |
  0   0

sage: Delta_xy = G.coproduct(y*x)
sage: ascii_art(Delta_xy) # random indirect doctest
1 # B + 1 # B + B # B + B # 1 + B # B + B # 1
  #_   #   #   #   #_   #   #   #
  / /   |   |   |   / /   |   |   |
```

(continues on next page)

(continued from previous page)

0	1		1	0	1	0	1		1	0	1
			0							0	

counit_on_basis(x)

Return the counit on a basis element.

This is zero unless the forest x is empty.

EXAMPLES:

```

sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: RT = A.basis().keys()
sage: x = RT([RT([], 'x')], '#')
sage: A.counit_on_basis(x)
0
sage: A.counit_on_basis(RT([], '#'))
1

```

degree_on_basis(t)

Return the degree of a rooted forest in the Grossman-Larson algebra.

This is the total number of vertices of the forest.

EXAMPLES:

```

sage: A = algebras.GrossmanLarson(QQ, '@')
sage: RT = A.basis().keys()
sage: A.degree_on_basis(RT([RT([])]))
1

```

one_basis()

Return the empty rooted forest.

EXAMPLES:

```

sage: A = algebras.GrossmanLarson(QQ, 'ab')
sage: A.one_basis()
#[]

sage: A = algebras.GrossmanLarson(QQ, None)
sage: A.one_basis()
[]

```

product_on_basis(x, y)Return the product of two forests x and y .This is the sum over all possible ways for the components of the forest y to either fall side-by-side with components of x or be grafted on a vertex of x .

EXAMPLES:

```

sage: A = algebras.GrossmanLarson(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.product_on_basis(x, x)
B[[[]]] + B[[[]], []]

```

Check that the product is the correct one:

```
sage: A = algebras.GrossmanLarson(QQ, 'uv')
sage: RT = A.basis().keys()
sage: Tu = RT([RT([], 'u')], '#')
sage: Tv = RT([RT([], 'v')], '#')
sage: A.product_on_basis(Tu, Tv)
B[#[u[v[]]]] + B[#[u[], v[]]]
```

`single_vertex(i)`

Return the i -th rooted forest with one vertex.

This is the rooted forest with just one vertex, labelled by the i -th element of the label list.

See also:

[`single_vertex_all\(\)`](#).

INPUT:

- i – a nonnegative integer

EXAMPLES:

```
sage: F = algebras.GrossmanLarson(ZZ, 'xyz')
sage: F.single_vertex(0)
B[#[x[]]]

sage: F.single_vertex(4)
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

`single_vertex_all()`

Return the rooted forests with one vertex in self.

They freely generate the Lie algebra of primitive elements as a pre-Lie algebra.

See also:

[`single_vertex\(\)`](#).

EXAMPLES:

```
sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.single_vertex_all()
(B[#[f[]]], B[#[g[]]], B[#[h[]]])

sage: A = algebras.GrossmanLarson(QQ, ['x1', 'x2'])
sage: A.single_vertex_all()
(B[#[x1[]]], B[#[x2[]]])

sage: A = algebras.GrossmanLarson(ZZ, None)
sage: A.single_vertex_all()
(B[[[]]],)
```

`some_elements()`

Return some elements of the Grossman-Larson Hopf algebra.

EXAMPLES:

```

sage: A = algebras.GrossmanLarson(QQ, None)
sage: A.some_elements()
[B[[[]]], B[[[]] + B[[[[]]]] + B[[[]], [[]]],
4*B[[[[]]]] + 4*B[[[]], [[]]]

```

With several generators:

```

sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: A.some_elements()
[B[#[x[]]],
 B[#[]] + B[#[x[x[]]]] + B[#[x[], x[]]],
 B[#[x[x[]]]] + 3*B[#[x[y[]]]] + B[#[x[], x[]]] + 3*B[#[x[], y[]]]

```

variable_names()

Return the names of the variables.

This returns the set E (as a family).

EXAMPLES:

```

sage: R = algebras.GrossmanLarson(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}

sage: R = algebras.GrossmanLarson(QQ, ['a', 'b'])
sage: R.variable_names()
{'a', 'b'}

sage: R = algebras.GrossmanLarson(QQ, 2)
sage: R.variable_names()
{0, 1}

sage: R = algebras.GrossmanLarson(QQ, None)
sage: R.variable_names()
{'o'}

```

5.1.117 Hall Polynomials

`sage.combinat.hall_polynomial.hall_polynomial(nu, mu, la, q=None)`

Return the (classical) Hall polynomial $P_{\mu,\lambda}^\nu$ (where ν , μ and λ are the inputs `nu`, `mu` and `la`).

Let ν, μ, λ be partitions. The Hall polynomial $P_{\mu,\lambda}^\nu(q)$ (in the indeterminate q) is defined as follows: Specialize q to a prime power, and consider the category of \mathbf{F}_q -vector spaces with a distinguished nilpotent endomorphism. The morphisms in this category shall be the linear maps commuting with the distinguished endomorphisms. The *type* of an object in the category will be the Jordan type of the distinguished endomorphism; this is a partition. Now, if N is any fixed object of type ν in this category, then the polynomial $P_{\mu,\lambda}^\nu(q)$ specialized at the prime power q counts the number of subobjects L of N having type λ such that the quotient object N/L has type μ . This determines the values of the polynomial $P_{\mu,\lambda}^\nu$ at infinitely many points (namely, at all prime powers), and hence $P_{\mu,\lambda}^\nu$ is uniquely determined. The degree of this polynomial is at most $n(\nu) - n(\lambda) - n(\mu)$, where $n(\kappa) = \sum_i (i-1)\kappa_i$ for every partition κ . (If this is negative, then the polynomial is zero.)

These are the structure coefficients of the (classical) Hall algebra.

If $|\nu| \neq |\mu| + |\lambda|$, then we have $P_{\mu,\lambda}^\nu = 0$. More generally, if the Littlewood-Richardson coefficient $c_{\mu,\lambda}^\nu$ vanishes, then $P_{\mu,\lambda}^\nu = 0$.

The Hall polynomials satisfy the symmetry property $P_{\mu,\lambda}^\nu = P_{\lambda,\mu}^\nu$.

ALGORITHM:

If $\lambda = (1^r)$ and $|\nu| = |\mu| + |\lambda|$, then we compute $P_{\mu,\lambda}^\nu$ as follows (cf. Example 2.4 in [Sch2006]):

First, write $\nu = (1^{l_1}, 2^{l_2}, \dots, n^{l_n})$, and define a sequence $r = r_0 \geq r_1 \geq \dots \geq r_n$ such that

$$\mu = (1^{l_1 - r_0 + 2r_1 - r_2}, 2^{l_2 - r_1 + 2r_2 - r_3}, \dots, (n-1)^{l_{n-1} - r_{n-2} + 2r_{n-1} - r_n}, n^{l_n - r_{n-1} + r_n}).$$

Thus if $\mu = (1^{m_1}, \dots, n^{m_n})$, we have the following system of equations:

$$\begin{aligned} m_1 &= l_1 - r + 2r_1 - r_2, \\ m_2 &= l_2 - r_1 + 2r_2 - r_3, \\ &\vdots \\ m_{n-1} &= l_{n-1} - r_{n-2} + 2r_{n-1} - r_n, \\ m_n &= l_n - r_{n-1} + r_n \end{aligned}$$

and solving for r_i and back substituting we obtain the equations:

$$\begin{aligned} r_n &= r_{n-1} + m_n - l_n, \\ r_{n-1} &= r_{n-2} + m_{n-1} - l_{n-1} + m_n - l_n, \\ &\vdots \\ r_1 &= r + \sum_{k=1}^n (m_k - l_k), \end{aligned}$$

or in general we have the recursive equation:

$$r_i = r_{i-1} + \sum_{k=i}^n (m_k - l_k).$$

This, combined with the condition that $r_0 = r$, determines the r_i uniquely (recursively). Next we define

$$t = (r_{n-2} - r_{n-1})(l_n - r_{n-1}) + (r_{n-3} - r_{n-2})(l_{n-1} + l_n - r_{n-2}) + \dots + (r_0 - r_1)(l_2 + \dots + l_n - r_1),$$

and with these notations we have

$$P_{\mu,(1^r)}^\nu = q^t \binom{l_n}{r_{n-1}}_q \binom{l_{n-1}}{r_{n-2} - r_{n-1}}_q \cdots \binom{l_1}{r_0 - r_1}_q.$$

To compute $P_{\mu,\lambda}^\nu$ in general, we compute the product $I_\mu I_\lambda$ in the Hall algebra and return the coefficient of I_ν .

EXAMPLES:

```
sage: from sage.combinat.hall_polynomial import hall_polynomial
sage: hall_polynomial([1,1],[1],[1])
q + 1
sage: hall_polynomial([2],[1],[1])
1
sage: hall_polynomial([2,1],[2],[1])
q
sage: hall_polynomial([2,2,1],[2,1],[1,1])
q^2 + q
sage: hall_polynomial([2,2,2,1],[2,2,1],[1,1])
```

(continues on next page)

(continued from previous page)

```

q^4 + q^3 + q^2
sage: hall_polynomial([3,2,2,1], [3,2], [2,1])
q^6 + q^5
sage: hall_polynomial([4,2,1,1], [3,1,1], [2,1])
2*q^3 + q^2 - q - 1
sage: hall_polynomial([4,2], [2,1], [2,1], 0)
1

```

5.1.118 The Hillman-Grassl correspondence

This module implements weak reverse plane partitions and four correspondences on them: the Hillman-Grassl correspondence and its inverse, as well as the Sulzgruber correspondence and its inverse (the Pak correspondence).

Fix a partition λ (see [Partition\(\)](#)). We draw all partitions and tableaux in English notation.

A λ -array will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape* λ (short: λ -rpp) will mean a λ -array whose entries weakly increase along each row and weakly increase along each column. (The name “weak reverse plane partition” comes from Stanley in [EnumComb2] Section 7.22; other authors – such as Pak [Sulzgr2017], or Hillman and Grassl in [HilGra1976] – just call it a reverse plane partition.)

The Hillman-Grassl correspondence is a bijection from the set of λ -arrays to the set of λ -rpps. For its definition, see [hillman_grassl\(\)](#); for its inverse, see [hillman_grassl_inverse\(\)](#).

The Sulzgruber correspondence Φ_λ and the Pak correspondence ξ_λ are two further mutually inverse bijections between the set of λ -arrays and the set of λ -rpps. They appear (sometimes with different definitions, but defining the same maps) in [Pak2002], [Hopkins2017] and [Sulzgr2017]. For their definitions, see [sulzgruber_correspondence\(\)](#) and [pak_correspondence\(\)](#).

EXAMPLES:

We construct a λ -rpp for $\lambda = (3, 3, 1)$ (note that λ needs not be specified explicitly):

```

sage: p = WeakReversePlanePartition([[0, 1, 3], [2, 4, 4], [3]])
sage: p.parent()
Weak Reverse Plane Partitions

```

(This is the example in Section 7.22 of [EnumComb2].)

Next, we apply the inverse of the Hillman-Grassl correspondence to it:

```

sage: HGp = p.hillman_grassl_inverse(); HGp
[[1, 2, 0], [1, 0, 1], [1]]
sage: HGp.parent()
Tableaux

```

This is a λ -array, encoded as a tableau. We can recover our original λ -rpp from it using the Hillman-Grassl correspondence:

```

sage: HGp.hillman_grassl() == p
True

```

We can also apply the Pak correspondence to our rpp:

```
sage: Pp = p.pak_correspondence(); Pp
[[2, 0, 1], [0, 2, 0], [1]]
sage: Pp.parent()
Tableaux
```

This is undone by the Sulzgruber correspondence:

```
sage: Pp.sulzgruber_correspondence() == p
True
```

These four correspondences can also be accessed as standalone functions (*hillman_grassl_inverse()*, *hillman_grassl()*, *pak_correspondence()* and *sulzgruber_correspondence()*) that transform lists of lists into lists of lists; this may be more efficient. For example, the above computation of HGp can also be obtained as follows:

```
sage: from sage.combinat.hillman_grassl import hillman_grassl_inverse
sage: HGp_bare = hillman_grassl_inverse([[0, 1, 3], [2, 4, 4], [3]])
sage: HGp_bare
[[1, 2, 0], [1, 0, 1], [1]]
sage: isinstance(HGp_bare, list)
True
```

- [Hopkins2017]

AUTHORS:

- Darij Grinberg and Tom Roby (2018): Initial implementation

class `sage.combinat.hillman_grassl.WeakReversePlanePartition`(parent, t)

Bases: `sage.combinat.tableau.Tableau`

A weak reverse plane partition (short: rpp).

A weak reverse plane partition is a tableau with nonnegative entries that are weakly increasing in each row and weakly increasing in each column.

EXAMPLES:

```
sage: x = WeakReversePlanePartition([[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3],
→[2]]); x
[[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3], [2]]
sage: x.pp()
0 1 1
0 1 3
1 2 2
1 2 3
2
sage: x.shape()
[3, 3, 3, 3, 1]
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: c = WeakReversePlanePartition([[1, 1], [1, 3], [2]]).conjugate(); c
[[1, 1, 2], [1, 3]]
sage: c.parent()
Weak Reverse Plane Partitions
```

hillman_grassl_inverse()

Return the image of the λ -rpp `self` under the inverse of the Hillman-Grassl correspondence (as a *Tableau*).

Fix a partition λ (see *Partition()*). We draw all partitions and tableaux in English notation.

A λ -array will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape* λ (short: λ -rpp) will mean a λ -array whose entries weakly increase along each row and weakly increase along each column.

The inverse H^{-1} of the Hillman-Grassl correspondence (see (*hillman_grassl()* for the latter) sends a λ -rpp π to a λ -array $H^{-1}(\pi)$ constructed recursively as follows:

- If all entries of π are 0, then $H^{-1}(\pi) = \pi$.
- Otherwise, let s be the index of the leftmost column of π containing a nonzero entry. Write the λ -array M as $(m_{i,j})$.
- Define a sequence $((i_1, j_1), (i_2, j_2), \dots, (i_n, j_n))$ of boxes in the diagram of λ (actually a lattice path made of northward and eastward steps) as follows: Let (i_1, j_1) be the bottommost box in the s -th column of π . If (i_k, j_k) is defined for some $k \geq 1$, then (i_{k+1}, j_{k+1}) is constructed as follows: If q_{i_k-1, j_k} is well-defined and equals q_{i_k, j_k} , then we set $(i_{k+1}, j_{k+1}) = (i_k - 1, j_k)$. Otherwise, we set $(i_{k+1}, j_{k+1}) = (i_k, j_k + 1)$ if this is still a box of λ . Otherwise, the sequence ends here.
- Let π' be the λ -rpp obtained from π by subtracting 1 from the (i_k, j_k) -th entry of π for each $k \in \{1, 2, \dots, n\}$.
- Let N' be the image $H^{-1}(\pi')$ (which is already constructed by recursion). Then, $H^{-1}(\pi)$ is obtained from N' by adding 1 to the (i_n, s) -th entry of N' .

This construction appears in [HilGra1976] Section 6 (where λ -arrays are re-encoded as sequences of “hook number multiplicities”) and [EnumComb2] Section 7.22.

See also:

[hillman_grassl_inverse\(\)](#) for the inverse of the Hillman-Grassl correspondence as a standalone function.

[hillman_grassl\(\)](#) for the inverse map.

EXAMPLES:

```
sage: a = WeakReversePlanePartition([[2, 2, 4], [2, 3, 4], [3, 5]])
sage: a.hillman_grassl_inverse()
[[2, 1, 1], [0, 2, 0], [1, 1]]
sage: b = WeakReversePlanePartition([[1, 1, 2, 2], [1, 1, 2, 2], [2, 2, 3, 3]],
↳ [2, 2, 3, 3]])
sage: B = b.hillman_grassl_inverse(); B
[[1, 0, 1, 0], [0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 0, 1]]
```

(continues on next page)

(continued from previous page)

```
sage: b.parent(), B.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

Applying the inverse of the Hillman-Grassl correspondence to the transpose of a λ -rpp M yields the same result as applying it to M and then transposing the result ([Gans1981] Corollary 3.4):

```
sage: a = WeakReversePlanePartition([[1, 3, 5], [2, 4]])
sage: aic = a.hillman_grassl_inverse().conjugate()
sage: aic == a.conjugate().hillman_grassl_inverse()
True
```

pak_correspondence()

Return the image of the λ -rpp `self` under the Pak correspondence (as a *Tableau*).

See [hillman_grassl](#).

The Pak correspondence is the map ξ_λ from [Sulzgr2017] Section 7, and is the map ξ_λ from [Pak2002] Section 4. It is the inverse of the Sulzgruber correspondence ([sulzgruber_correspondence\(\)](#)). The following description of the Pak correspondence follows [Hopkins2017] (which denotes it by \mathcal{RSK}^{-1}):

Fix a partition λ (see [Partition\(\)](#)). We draw all partitions and tableaux in English notation.

A λ -array will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A *weak reverse plane partition of shape* λ (short: λ -rpp) will mean a λ -array whose entries weakly increase along each row and weakly increase along each column.

We shall also use the following notation: If (u, v) is a cell of λ , and if π is a λ -rpp, then:

- the *lower bound* of π at (u, v) (denoted by $\pi_{<(u,v)}$) is defined to be $\max\{\pi_{u-1,v}, \pi_{u,v-1}\}$ (where $\pi_{0,v}$ and $\pi_{u,0}$ are understood to mean 0).
- the *upper bound* of π at (u, v) (denoted by $\pi_{>(u,v)}$) is defined to be $\min\{\pi_{u+1,v}, \pi_{u,v+1}\}$ (where $\pi_{i,j}$ is understood to mean $+\infty$ if (i, j) is not in λ ; thus, the upper bound at a corner cell is $+\infty$).
- *toggling* π at (u, v) means replacing the entry $\pi_{u,v}$ of π at (u, v) by $\pi_{<(u,v)} + \pi_{>(u,v)} - \pi_{u,v}$ (this is well-defined as long as (u, v) is not a corner of λ).

Note that every λ -rpp π and every cell (u, v) of λ satisfy $\pi_{<(u,v)} \leq \pi_{u,v} \leq \pi_{>(u,v)}$. Note that toggling a λ -rpp (at a cell that is not a corner) always results in a λ -rpp. Also, toggling is an involution).

Note also that the lower bound of π at (u, v) is defined (and finite) even when (u, v) is not a cell of λ , as long as both $(u - 1, v)$ and $(u, v - 1)$ are cells of λ .

The Pak correspondence Φ_λ sends a λ -array $M = (m_{i,j})$ to a λ -rpp $\Phi_\lambda(M)$. It is defined by recursion on λ (that is, we assume that Φ_μ is already defined for every partition μ smaller than λ), and its definition proceeds as follows:

- If $\lambda = \emptyset$, then Φ_λ is the obvious bijection sending the only \emptyset -array to the only \emptyset -rpp.
- Pick any corner $c = (i, j)$ of λ , and let μ be the result of removing this corner c from the partition λ . (The exact choice of c is immaterial.)
- Let M' be what remains of M when the corner cell c is removed.
- Let $\pi' = \Phi_\mu(M')$.
- For each positive integer k such that $(i - k, j - k)$ is a cell of λ , toggle π' at $(i - k, j - k)$. (All these toggling commutes, so the order in which they are made is immaterial.)

- Extend the μ -rpp π' to a λ -rpp π by adding the cell c and writing the number $m_{i,j} - \pi'_{<(i,j)}$ into this cell.
- Set $\Phi_\lambda(M) = \pi$.

See also:

[*pak_correspondence\(\)*](#) for the Pak correspondence as a standalone function.

[*sulzgruber_correspondence\(\)*](#) for the inverse map.

EXAMPLES:

```
sage: a = WeakReversePlanePartition([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
sage: A = a.pak_correspondence(); A
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
sage: a.parent(), A.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

Applying the Pak correspondence to the transpose of a λ -rpp M yields the same result as applying it to M and then transposing the result:

```
sage: a = WeakReversePlanePartition([[1,3,5],[2,4]])
sage: acc = a.pak_correspondence().conjugate()
sage: acc == a.conjugate().pak_correspondence()
True
```

class `sage.combinat.hillman_grassl.WeakReversePlanePartitions`

Bases: [*sage.combinat.tableau.Tableaux*](#)

The set of all weak reverse plane partitions.

Element

alias of [*WeakReversePlanePartition*](#)

an_element()

Returns a particular element of the class.

`sage.combinat.hillman_grassl.hillman_grassl(M)`

Return the image of the λ -array M under the Hillman-Grassl correspondence.

The Hillman-Grassl correspondence is a bijection between the tableaux with nonnegative entries (otherwise arbitrary) and the weak reverse plane partitions with nonnegative entries. This bijection preserves the shape of the tableau. See [*hillman_grassl*](#).

See [*hillman_grassl\(\)*](#) for a description of this map.

See also:

[*hillman_grassl_inverse\(\)*](#)

EXAMPLES:

```
sage: from sage.combinat.hillman_grassl import hillman_grassl
sage: hillman_grassl([[2, 1, 1], [0, 2, 0], [1, 1]])
[[2, 2, 4], [2, 3, 4], [3, 5]]
sage: hillman_grassl([[1, 2, 0], [1, 0, 1], [1]])
[[0, 1, 3], [2, 4, 4], [3]]
sage: hillman_grassl([])
[]
sage: hillman_grassl([[3, 1, 2]])
```

(continues on next page)

(continued from previous page)

```

[[3, 4, 6]]
sage: hillman_grassl([[2, 2, 0], [1, 1, 1], [1]])
[[1, 2, 4], [3, 5, 5], [4]]
sage: hillman_grassl([[1, 1, 1, 1]]*3)
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]

```

`sage.combinat.hillman_grassl.hillman_grassl_inverse(M)`

Return the image of the λ -rpp *M* under the inverse of the Hillman-Grassl correspondence.

See [hillman_grassl](#).

See [hillman_grassl_inverse\(\)](#) for a description of this map.

See also:

[hillman_grassl\(\)](#)

EXAMPLES:

```

sage: from sage.combinat.hillman_grassl import hillman_grassl_inverse
sage: hillman_grassl_inverse([[2, 2, 4], [2, 3, 4], [3, 5]])
[[2, 1, 1], [0, 2, 0], [1, 1]]
sage: hillman_grassl_inverse([[0, 1, 3], [2, 4, 4], [3]])
[[1, 2, 0], [1, 0, 1], [1]]

```

Applying the inverse of the Hillman-Grassl correspondence to the transpose of a λ -rpp *M* yields the same result as applying it to *M* and then transposing the result ([Gans1981] Corollary 3.4):

```

sage: hillman_grassl_inverse([[1, 3, 5], [2, 4]])
[[1, 2, 2], [1, 1]]
sage: hillman_grassl_inverse([[1, 2], [3, 4], [5]])
[[1, 1], [2, 1], [2]]
sage: hillman_grassl_inverse([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
[[1, 2, 0], [0, 1, 1], [1, 0, 1]]
sage: hillman_grassl_inverse([[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]])
[[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1]]

```

`sage.combinat.hillman_grassl.pak_correspondence(M, copy=True)`

Return the image of a λ -rpp *M* under the Pak correspondence.

The Pak correspondence is the map ξ_λ from [Sulzgr2017] Section 7, and is the map ξ_λ from [Pak2002] Section 4. It is the inverse of the Sulzgruber correspondence ([sulzgruber_correspondence\(\)](#)).

See [pak_correspondence\(\)](#) for a description of this map.

INPUT:

- `copy` (default: `True`) – boolean; if set to `False`, the algorithm will mutate the input (but be more efficient)

EXAMPLES:

```

sage: from sage.combinat.hillman_grassl import pak_correspondence
sage: pak_correspondence([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
sage: pak_correspondence([[1, 1, 4], [2, 3, 4], [4, 4, 4]])
[[1, 1, 2], [0, 1, 0], [3, 0, 0]]
sage: pak_correspondence([[0, 2, 3], [1, 3, 3], [2, 4]])

```

(continues on next page)

(continued from previous page)

```

[[1, 0, 2], [0, 2, 0], [1, 1]]
sage: pak_correspondence([[1, 2, 4], [1, 3], [3]])
[[0, 2, 2], [1, 1], [2]]
sage: pak_correspondence([[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]])
[[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1]]

```

The Pak correspondence can actually be extended (by the same definition) to “rpps” of nonnegative reals rather than nonnegative integers. This implementation supports this:

```

sage: pak_correspondence([[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]])
[[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]]

```

`sage.combinat.hillman_grassl.sulzgruber_correspondence(M)`

Return the image of a λ -array M under the Sulzgruber correspondence.

The Sulzgruber correspondence is the map Φ_λ from [Sulzgr2017] Section 7, and is the map ξ_λ^{-1} from [Pak2002] Section 5. It is denoted by \mathcal{RSK} in [Hopkins2017]. It is the inverse of the Pak correspondence (`pak_correspondence()`).

See `sulzgruber_correspondence()` for a description of this map.

EXAMPLES:

```

sage: from sage.combinat.hillman_grassl import sulzgruber_correspondence
sage: sulzgruber_correspondence([[1, 0, 2], [0, 2, 0], [1, 1, 0]])
[[1, 2, 3], [1, 2, 3], [2, 4, 4]]
sage: sulzgruber_correspondence([[1, 1, 2], [0, 1, 0], [3, 0, 0]])
[[1, 1, 4], [2, 3, 4], [4, 4, 4]]
sage: sulzgruber_correspondence([[1, 0, 2], [0, 2, 0], [1, 1]])
[[0, 2, 3], [1, 3, 3], [2, 4]]
sage: sulzgruber_correspondence([[0, 2, 2], [1, 1], [2]])
[[1, 2, 4], [1, 3], [3]]
sage: sulzgruber_correspondence([[1, 1, 1, 1]]*3)
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]

```

The Sulzgruber correspondence can actually be extended (by the same definition) to arrays of nonnegative reals rather than nonnegative integers. This implementation supports this:

```

sage: sulzgruber_correspondence([[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]])
[[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]]

```

`sage.combinat.hillman_grassl.transpose(M)`

Return the transpose of a λ -array.

The transpose of a λ -array $(m_{i,j})$ is the λ^t -array $(m_{j,i})$ (where λ^t is the conjugate of the partition λ).

EXAMPLES:

```

sage: from sage.combinat.hillman_grassl import transpose
sage: transpose([[1, 2, 3], [4, 5]])
[[1, 4], [2, 5], [3]]
sage: transpose([[5, 0, 3], [4, 1, 0], [7]])
[[5, 4, 7], [0, 1], [3, 0]]

```

5.1.119 Enumerated set of lists of integers with constraints: base classes

- *IntegerListsBackend*: base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.
- *Envelope*: a utility class for upper (lower) envelope of a function under constraints.

class sage.combinat.integer_lists.base.**Envelope**

Bases: object

The (currently approximated) upper (lower) envelope of a function under the specified constraints.

INPUT:

- f – a function, list, or tuple; if f is a list, it is considered as the function $f(i)=f[i]$, completed for larger i with $f(i)=\text{max_part}$.
- min_part , max_part , min_slope , max_slope , ... as for *IntegerListsLex* (please consult for details).
- sign – (+1 or -1) multiply the input values with sign and multiply the output with sign . Setting this to -1 can be used to implement a lower envelope.

The *upper envelope* $U(f)$ of f is the (pointwise) largest function which is bounded above by f and satisfies the max_part and max_slope conditions. Furthermore, for $i, i+1 < \text{min_length}$, the upper envelope also satisfies the min_slope condition.

Upon computing $U(f)(i)$, all the previous values for $j \leq i$ are computed and cached; in particular $f(i)$ will be computed at most once for each i .

Todo:

- This class is a good candidate for Cythonization, especially to get the critical path in `__call__` super fast.
 - To get full envelopes, we would want both the min_slope and max_slope conditions to always be satisfied. This is only properly defined for the restriction of f to a finite interval $0, \dots, k$, and depends on k .
 - This is the core “data structure” of *IntegerListsLex*. Improving the lookahead there essentially depends on having functions with a good complexity to compute the area below an envelope; and in particular how it evolves when increasing the length.
-

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
```

Trivial upper and lower envelopes:

```
sage: f = Envelope([3,2,2])
sage: [f(i) for i in range(10)]
[3, 2, 2, inf, inf, inf, inf, inf, inf, inf]
sage: f = Envelope([3,2,2], sign=-1)
sage: [f(i) for i in range(10)]
[3, 2, 2, 0, 0, 0, 0, 0, 0, 0]
```

A more interesting lower envelope:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

Currently, adding `max_slope` has no effect:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

unless `min_length` is large enough:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0, min_
↳length=2)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0, min_
↳length=4)
sage: [f(i) for i in range(10)]
[5, 5, 5, 4, 5, 4, 3, 2, 2, 2]

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0, min_
↳length=5)
sage: [f(i) for i in range(10)]
[5, 5, 5, 5, 5, 4, 3, 2, 2, 2]
```

A non trivial upper envelope:

```
sage: f = Envelope([9,1,5,4], max_part=7, max_slope=2)
sage: [f(i) for i in range(10)]
[7, 1, 3, 4, 6, 7, 7, 7, 7, 7]
```

`adapt(m, j)`

Return this envelope adapted to an additional local constraint.

INPUT:

- `m` – a nonnegative integer (starting value)
- `j` – a nonnegative integer (position)

This method adapts this envelope to the additional local constraint imposed by having a part `m` at position `j`. Namely, this returns a function which computes, for any $i > j$, the minimum of the ceiling function and the value restriction given by the slope conditions.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
sage: f = Envelope(3)
sage: g = f.adapt(1,1)
sage: g is f
True
sage: [g(i) for i in range(10)]
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3]

sage: f = Envelope(3, max_slope=1)
sage: g = f.adapt(1,1)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

Note that, in both cases above, the adapted envelope is only guaranteed to be valid for $i > j!$ This is to leave potential room in the future for sharing similar adapted envelopes:

```
sage: g = f.adapt(0,0)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

sage: g = f.adapt(2,2)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

sage: g = f.adapt(3,3)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

Now with a lower envelope:

```
sage: f = Envelope(1, sign=-1, min_slope=-1)
sage: g = f.adapt(2,2)
sage: [g(i) for i in range(10)]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
sage: g = f.adapt(1,3)
sage: [g(i) for i in range(10)]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
```

`limit()`

Return a bound on the limit of `self`.

OUTPUT: a nonnegative integer or ∞

This returns some upper bound for the accumulation points of this upper envelope. For a lower envelope, a lower bound is returned instead.

In particular this gives a bound for the value of `self` at i for i large enough. Special case: for a lower envelop, and when the limit is ∞ , the envelope is guaranteed to tend to ∞ instead.

When `s=self.limit_start()` is finite, this bound is guaranteed to be valid for $i \geq s$.

Sometimes it's better to have a loose bound that starts early; sometimes the converse holds. At this point which specific bound and starting point is returned is not set in stone, in order to leave room for later optimizations.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit()
inf
sage: Envelope([4,1,5], max_part=2).limit()
2
sage: Envelope([4,1,5], max_slope=0).limit()
1
sage: Envelope(lambda x: 3, max_part=2).limit()
2
```

Lower envelopes:

```

sage: Envelope(lambda x: 3, min_part=2, sign=-1).limit()
2
sage: Envelope([4,1,5], min_slope=0, sign=-1).limit()
5
sage: Envelope([4,1,5], sign=-1).limit()
0

```

See also:

limit_start()

limit_start()

Return from which i on the bound returned by `limit` holds.

See also:

limit() for the precise specifications.

EXAMPLES:

```

sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit_start()
3
sage: Envelope([4,1,5], sign=-1).limit_start()
3

sage: Envelope([4,1,5], max_part=2).limit_start()
3

sage: Envelope(4).limit_start()
0
sage: Envelope(4, sign=-1).limit_start()
0

sage: Envelope(lambda x: 3).limit_start() == Infinity
True
sage: Envelope(lambda x: 3, max_part=2).limit_start() == Infinity
True

sage: Envelope(lambda x: 3, sign=-1, min_part=2).limit_start() == Infinity
True

```

max_part

max_slope

min_slope

sign

class `sage.combinat.integer_lists.base.IntegerListsBackend`

Bases: `object`

Base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.

This base implements the basic operations, including checking for containment using `_contains()`, but not iteration. For iteration, subclass this class and implement an `_iter()` method.

EXAMPLES:

```

sage: from sage.combinat.integer_lists.base import IntegerListsBackend
sage: L = IntegerListsBackend(6, max_slope=-1)
sage: L._contains([3,2,1])
True

```

ceiling
floor
max_length
max_part
max_slope
max_sum
min_length
min_part
min_slope
min_sum

5.1.120 Enumerated set of lists of integers with constraints: front-end

- *IntegerLists*: class which models an enumerated set of lists of integers with certain constraints. This is a Python front-end where all user-accessible functionality should be implemented.

```
class sage.combinat.integer_lists.lists.IntegerList
```

Bases: `sage.structure.list_clone.ClonableArray`

Element class for *IntegerLists*.

check()

Check to make sure this is a valid element in its *IntegerLists* parent.

EXAMPLES:

```

sage: C = IntegerListsLex(4)
sage: C([4]).check()
True
sage: C([5]).check()
False

```

```
class sage.combinat.integer_lists.lists.IntegerLists(*args, **kws)
```

Bases: `sage.structure.parent.Parent`

Enumerated set of lists of integers with constraints.

Currently, this is simply an abstract base class which should not be used by itself. See *IntegerListsLex* for a class which can be used by end users.

IntegerLists is just a Python front-end, acting as a *Parent*, supporting element classes and so on. The attribute `.backend` which is an instance of `sage.combinat.integer_lists.base.IntegerListsBackend` is the Cython back-end which implements all operations such as iteration.

The front-end (i.e. this class) and the back-end are supposed to be orthogonal: there is no imposed correspondence between front-ends and back-ends.

For example, the set of partitions of 5 and the set of weakly decreasing sequences which sum to 5 might be implemented by the same back-end, but they will be presented to the user by a different front-end.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import IntegerLists
sage: L = IntegerLists(5)
sage: L
Integer lists of sum 5 satisfying certain constraints

sage: IntegerListsLex(2, length=3, name="A given name")
A given name
```

Element

alias of *IntegerList*

backend_class

alias of *sage.combinat.integer_lists.base.IntegerListsBackend*

5.1.121 Enumerated set of lists of integers with constraints, in inverse lexicographic order

- *IntegerListsLex*: the enumerated set of lists of nonnegative integers with specified constraints, in inverse lexicographic order.
- *IntegerListsBackend_invlex*: Cython back-end for *IntegerListsLex*.

HISTORY:

This generic tool was originally written by Hivert and Thiery in MuPAD-Combinat in 2000 and ported over to Sage by Mike Hansen in 2007. It was then completely rewritten in 2015 by Gillespie, Schilling, and Thiery, with the help of many, to deal with limitations and lack of robustness w.r.t. input.

class `sage.combinat.integer_lists.invlex.IntegerListsBackend_invlex`

Bases: *sage.combinat.integer_lists.base.IntegerListsBackend*

Cython back-end of an set of lists of integers with specified constraints enumerated in inverse lexicographic order.

check

class `sage.combinat.integer_lists.invlex.IntegerListsLex(*args, **kws)`

Bases: *sage.combinat.integer_lists.lists.IntegerLists*

Lists of nonnegative integers with constraints, in inverse lexicographic order.

An *integer list* is a list l of nonnegative integers, its *parts*. The slope (at position i) is the difference $l[i+1]-l[i]$ between two consecutive parts.

This class allows to construct the set S of all integer lists l satisfying specified bounds on the sum, the length, the slope, and the individual parts, enumerated in *inverse* lexicographic order, that is from largest to smallest in lexicographic order. Note that, to admit such an enumeration, S is almost necessarily finite (see *On finiteness and inverse lexicographic enumeration*).

The main purpose is to provide a generic iteration engine for all the enumerated sets like *Partitions*, *Compositions*, *IntegerVectors*. It can also be used to generate many other combinatorial objects like Dyck paths, Motzkin paths, etc. Mathematically speaking, this is a special case of set of integral points of a polytope (or union thereof, when the length is not fixed).

INPUT:

- `min_sum` – a nonnegative integer (default: 0): a lower bound on `sum(l)`.
- `max_sum` – a nonnegative integer or ∞ (default: ∞): an upper bound on `sum(l)`.
- `n` – a nonnegative integer (optional): if specified, this overrides `min_sum` and `max_sum`.
- `min_length` – a nonnegative integer (default: 0): a lower bound on `len(l)`.
- `max_length` – a nonnegative integer or ∞ (default: ∞): an upper bound on `len(l)`.
- `length` – an integer (optional); overrides `min_length` and `max_length` if specified;
- **`min_part` – a nonnegative integer: a lower bounds on all parts:** `min_part` \leq `l[i]` for $0 \leq i < \text{len}(l)$.
- `floor` – a list of nonnegative integers or a function: lower bounds on the individual parts `l[i]`.
If `floor` is a list of integers, then `floor` \leq `l[i]` for $0 \leq i < \min(\text{len}(l), \text{len}(\text{floor}))$. Similarly, if `floor` is a function, then `floor(i)` \leq `l[i]` for $0 \leq i < \text{len}(l)$.
- `max_part` – a nonnegative integer or ∞ : an upper bound on all parts: `l[i]` \leq `max_part` for $0 \leq i < \text{len}(l)$.
- `ceiling` – upper bounds on the individual parts `l[i]`; this takes the same type of input as `floor`, except that ∞ is allowed in addition to integers, and the default value is ∞ .
- `min_slope` – an integer or $-\infty$ (default: $-\infty$): a lower bound on the slope between consecutive parts: `min_slope` \leq `l[i+1]-l[i]` for $0 \leq i < \text{len}(l)-1$
- `max_slope` – an integer or $+\infty$ (default: $+\infty$): an upper bound on the slope between consecutive parts: `l[i+1]-l[i]` \leq `max_slope` for $0 \leq i < \text{len}(l)-1$
- `category` – a category (default: `FiniteEnumeratedSets`)
- `check` – boolean (default: `True`): whether to display the warnings raised when functions are given as input to `floor` or `ceiling` and the errors raised when there is no proper enumeration.
- `name` – a string or `None` (default: `None`) if set, this will be passed down to `Parent.rename()` to specify the name of `self`. It is recommended to use `rename` method directly because this feature may become deprecated.
- `element_constructor` – a function (or callable) that creates elements of `self` from a list. See also `Parent`.
- `element_class` – a class for the elements of `self` (default: `ClonableArray`). This merely sets the attribute `self.Element`. See the examples for details.

Note: When several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is enumerated (and therefore counted). The others are still considered valid. See the examples below.

This feature is questionable. It is recommended not to rely on it, as it may eventually be discontinued.

EXAMPLES:

We create the enumerated set of all lists of nonnegative integers of length 3 and sum 2:

```
sage: C = IntegerListsLex(2, length=3)
sage: C
Integer lists of sum 2 satisfying certain constraints
sage: C.cardinality()
6
sage: [p for p in C]
```

(continues on next page)

(continued from previous page)

```
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

```
sage: [2, 0, 0] in C
True
sage: [2, 0, 1] in C
False
sage: "a" in C
False
sage: ["a"] in C
False
sage: C.first()
[2, 0, 0]
```

One can specify lower and upper bounds on each part:

```
sage: list(IntegerListsLex(5, length=3, floor=[1,2,0], ceiling=[3,2,3]))
[[3, 2, 0], [2, 2, 1], [1, 2, 2]]
```

When the length is fixed as above, one can also use *IntegerVectors*:

```
sage: IntegerVectors(2,3).list()
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

Using the slope condition, one can generate integer partitions (but see *Partitions*):

```
sage: list(IntegerListsLex(4, max_slope=0))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The following is the list of all partitions of 7 with parts at least 2:

```
sage: list(IntegerListsLex(7, max_slope=0, min_part=2))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

floor and ceiling conditions

Next we list all partitions of 5 of length at most 3 which are bounded below by [2, 1, 1]:

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, floor=[2,1,1]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

Note that [5] is considered valid, because the floor constraints only apply to existing positions in the list. To obtain instead the partitions containing [2, 1, 1], one needs to use `min_length` or `length`:

```
sage: list(IntegerListsLex(5, max_slope=0, length=3, floor=[2,1,1]))
[[3, 1, 1], [2, 2, 1]]
```

Here is the list of all partitions of 5 which are contained in [3, 2, 2]:

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, ceiling=[3,2,2]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

This is the list of all compositions of 4 (but see *Compositions*):

```
sage: list(IntegerListsLex(4, min_part=1))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

This is the list of all integer vectors of sum 4 and length 3:

```
sage: list(IntegerListsLex(4, length=3))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1],
 [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
 [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

For whatever it is worth, the floor and min_part constraints can be combined:

```
sage: L = IntegerListsLex(5, floor=[2,0,2], min_part=1)
sage: L.list()
[[5], [4, 1], [3, 2], [2, 3], [2, 1, 2]]
```

This is achieved by updating the floor upon constructing L:

```
sage: [L.floor(i) for i in range(5)]
[2, 1, 2, 1, 1]
```

Similarly, the ceiling and max_part constraints can be combined:

```
sage: L = IntegerListsLex(4, ceiling=[2,3,1], max_part=2, length=3)
sage: L.list()
[[2, 2, 0], [2, 1, 1], [1, 2, 1]]
sage: [L.ceiling(i) for i in range(5)]
[2, 2, 1, 2, 2]
```

This can be used to generate Motzkin words (see [Wikipedia article Motzkin_number](#)):

```
sage: def motzkin_words(n):
.....:     return IntegerListsLex(length=n+1, min_slope=-1, max_slope=1,
.....:                             ceiling=[0]+[+oo for i in range(n-1)]+[0])
sage: motzkin_words(4).list()
[[0, 1, 2, 1, 0],
 [0, 1, 1, 1, 0],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 0],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 0],
 [0, 0, 0, 1, 0],
 [0, 0, 0, 0, 0]]
sage: [motzkin_words(n).cardinality() for n in range(8)]
[1, 1, 2, 4, 9, 21, 51, 127]
sage: oeis(_) # optional -- internet
0: A001006: Motzkin numbers: number of ways of drawing any number
of nonintersecting chords joining n (labeled) points on a circle.
1: ...
2: ...
```

or Dyck words (see also [DyckWords](#)), through the bijection with paths from $(0, 0)$ to (n, n) with left and up steps that remain below the diagonal:

```

sage: def dyck_words(n):
.....:     return IntegerListsLex(length=n, ceiling=list(range(n+1)), min_slope=0)
sage: [dyck_words(n).cardinality() for n in range(8)]
[1, 1, 2, 5, 14, 42, 132, 429]
sage: dyck_words(3).list()
[[0, 1, 2], [0, 1, 1], [0, 0, 2], [0, 0, 1], [0, 0, 0]]

```

On finiteness and inverse lexicographic enumeration

The set of all lists of integers cannot be enumerated in inverse lexicographic order, since there is no largest list (take $[n]$ for n as large as desired):

```

sage: IntegerListsLex().first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set

```

Here is a variant which could be enumerated in lexicographic order but not in inverse lexicographic order:

```

sage: L = IntegerListsLex(length=2, ceiling=[Infinity, 0], floor=[0, 1])
sage: for l in L: print(l)
Traceback (most recent call last):
...
ValueError: infinite upper bound for values of m

```

Even when the sum is specified, it is not necessarily possible to enumerate *all* elements in inverse lexicographic order. In the following example, the list $[1, 1, 1]$ will never appear in the enumeration:

```

sage: IntegerListsLex(3).first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set

```

If one wants to proceed anyway, one can sign a waiver by setting `check=False` (again, be warned that some valid lists may never appear):

```

sage: L = IntegerListsLex(3, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]

```

In fact, being inverse lexicographically enumerable is almost equivalent to being finite. The only infinity that can occur would be from a tail of numbers 0, 1 as in the previous example, where the 1 moves further and further to the right. If there is any list that is inverse lexicographically smaller than such a configuration, the iterator would not reach it and hence would not be considered iterable. Given that the infinite cases are very specific, at this point only the finite cases are supported (without signing the waiver).

The finiteness detection is not complete yet, so some finite cases may not be supported either, at least not without disabling the checks. Practical examples of such are welcome.

On trailing zeroes, and their caveats

As mentioned above, when several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is listed:

```
sage: L = IntegerListsLex(max_length=4, max_part=1)
sage: L.list()
[[1, 1, 1, 1],
 [1, 1, 1],
 [1, 1, 0, 1],
 [1, 1],
 [1, 0, 1, 1],
 [1, 0, 1],
 [1, 0, 0, 1],
 [1],
 [0, 1, 1, 1],
 [0, 1, 1],
 [0, 1, 0, 1],
 [0, 1],
 [0, 0, 1, 1],
 [0, 0, 1],
 [0, 0, 0, 1],
 []]
```

and counted:

```
sage: L.cardinality()
16
```

Still, the others are considered as elements of L :

```
sage: L = IntegerListsLex(4, min_length=3, max_length=4)
sage: L.list()
[... , [2, 2, 0], ...]

sage: [2, 2, 0] in L      # in L.list()
True
sage: [2, 2, 0, 0] in L  # not in L.list() !
True
sage: [2, 2, 0, 0, 0] in L
False
```

Specifying functions as input for the floor or ceiling

We construct all lists of sum 4 and length 4 such that $l[i] \leq i$:

```
sage: list(IntegerListsLex(4, length=4, ceiling=lambda i: i, check=False))
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]
```

Warning: When passing a function as floor or ceiling, it may become undecidable to detect improper inverse lexicographic enumeration. For example, the following example has a finite enumeration:

```

sage: L = IntegerListsLex(3, floor=lambda i: 1 if i>=2 else 0, check=False)
sage: L.list()
[[3],
 [2, 1],
 [2, 0, 1],
 [1, 2],
 [1, 1, 1],
 [1, 0, 2],
 [1, 0, 1, 1],
 [0, 3],
 [0, 2, 1],
 [0, 1, 2],
 [0, 1, 1, 1],
 [0, 0, 3],
 [0, 0, 2, 1],
 [0, 0, 1, 2],
 [0, 0, 1, 1, 1]]

```

but one cannot decide whether the following has an improper inverse lexicographic enumeration without computing the floor all the way to Infinity:

```

sage: L = IntegerListsLex(3, floor=lambda i: 0, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]

```

Hence a warning is raised when a function is specified as input, unless the waiver is signed by setting `check=False`:

```

sage: L = IntegerListsLex(3, floor=lambda i: 1 if i>=2 else 0)
doctest:...

```

A function has been given as input of the `floor=[...]` or `ceiling=[...]` arguments of `IntegerListsLex`. Please see the documentation for the caveats. If you know what you are doing, you can set `check=False` to skip this warning.

Similarly, the algorithm may need to search forever for a solution when the ceiling is ultimately zero:

```

sage: L = IntegerListsLex(2, ceiling=lambda i:0, check=False)
sage: L.first()          # not tested: will hang forever
sage: L = IntegerListsLex(2, ceiling=lambda i:0 if i<20 else 1, check=False)
sage: it = iter(L)
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1]
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1]
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1]

```

Tip: using disjoint union enumerated sets for additional flexibility

Sometimes, specifying a range for the sum or the length may be too restrictive. One would want instead to specify a list, or iterable L , of acceptable values. This is easy to achieve using a `disjoint union of enumerated sets`. Here we want to accept the values $n = 0, 2, 3$:

```
sage: C = DisjointUnionEnumeratedSets(Family([0,2,3],
.....:      lambda n: IntegerListsLex(n, length=2)))
sage: C
Disjoint union of Finite family
{0: Integer lists of sum 0 satisfying certain constraints,
 2: Integer lists of sum 2 satisfying certain constraints,
 3: Integer lists of sum 3 satisfying certain constraints}
sage: C.list()
[[0, 0],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

The price to pay is that the enumeration order is now *graded lexicographic* instead of lexicographic: first choose the value according to the order specified by L , and use lexicographic order within each value. Here is we reverse L :

```
sage: DisjointUnionEnumeratedSets(Family([3,2,0],
.....:      lambda n: IntegerListsLex(n, length=2))).list()
[[3, 0], [2, 1], [1, 2], [0, 3],
 [2, 0], [1, 1], [0, 2],
 [0, 0]]
```

Note that if a given value appears several times, the corresponding elements will be enumerated several times, which may, or not, be what one wants:

```
sage: DisjointUnionEnumeratedSets(Family([2,2],
.....:      lambda n: IntegerListsLex(n, length=2))).list()
[[2, 0], [1, 1], [0, 2], [2, 0], [1, 1], [0, 2]]
```

Here is a variant where we specify acceptable values for the length:

```
sage: DisjointUnionEnumeratedSets(Family([0,1,3],
.....:      lambda l: IntegerListsLex(2, length=l))).list()
[[2],
 [2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

This technique can also be useful to obtain a proper enumeration on infinite sets by using a graded lexicographic enumeration:

```
sage: C = DisjointUnionEnumeratedSets(Family(NN,
.....:      lambda n: IntegerListsLex(n, length=2)))
sage: C
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
sage: it = iter(C)
sage: [next(it) for i in range(10)]
[[0, 0],
 [1, 0], [0, 1],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

Specifying how to construct elements

This is the list of all monomials of degree 4 which divide the monomial $x^3y^1z^2$ (a monomial being identified with its exponent vector):

```
sage: R.<x,y,z> = QQ[]
sage: m = [3,1,2]
sage: def term(exponents):
.....:     return x^exponents[0] * y^exponents[1] * z^exponents[2]
sage: list( IntegerListsLex(4, length=len(m), ceiling=m, element_constructor=term) )
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

Note the use of the `element_constructor` option to specify how to construct elements from a plain list.

A variant is to specify a class for the elements. With the default element constructor, this class should take as input the parent `self` and a list.

Warning: The protocol for specifying the element class and constructor is subject to changes.

ALGORITHM:

The iteration algorithm uses a depth first search through the prefix tree of the list of integers (see also *Lexicographic generation of lists of integers*). While doing so, it does some lookahead heuristics to attempt to cut dead branches.

In most practical use cases, most dead branches are cut. Then, roughly speaking, the time needed to iterate through all the elements of S is proportional to the number of elements, where the proportion factor is controlled by the length l of the longest element of S . In addition, the memory usage is also controlled by l , which is to say negligible in practice.

Still, there remains much room for efficiency improvements; see [trac ticket #18055](#), [trac ticket #18056](#).

Note: The generation algorithm could in principle be extended to deal with non-constant slope constraints and with negative parts.

TESTS from comments on trac ticket #17979

Comment 191:

```
sage: list(IntegerListsLex(1, min_length=2, min_slope=0, max_slope=0))
[]
```

Comment 240:

```
sage: L = IntegerListsLex(min_length=2, max_part=0)
sage: L.list()
[[0, 0]]
```

Tests on the element constructor feature and mutability

Internally, the iterator works on a single list that is mutated along the way. Therefore, you need to make sure that the `element_constructor` actually **copies** its input. This example shows what can go wrong:

```
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_constructor=lambda
↪x: x)
sage: list(P)
[[], [], []]
```

However, specifying `list()` as constructor solves this problem:

```
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_constructor=list)
sage: list(P)
[[3], [2, 1], [1, 1, 1]]
```

Same, step by step:

```
sage: it = iter(P)
sage: a = next(it); a
[3]
sage: b = next(it); b
[2, 1]
sage: a
[3]
sage: a is b
False
```

Tests from MuPAD-Combinat:

```
sage: IntegerListsLex(7, min_length=2, max_length=6, floor=[0,0,2,0,0,1],
↪ceiling=[3,2,3,2,1,2]).cardinality()
83
sage: IntegerListsLex(7, min_length=2, max_length=6, floor=[0,0,2,0,1,1],
↪ceiling=[3,2,3,2,1,2]).cardinality()
53
sage: IntegerListsLex(5, min_length=2, max_length=6, floor=[0,0,2,0,0,0],
↪ceiling=[2,2,2,2,2,2]).cardinality()
30
sage: IntegerListsLex(5, min_length=2, max_length=6, floor=[0,0,1,1,0,0],
↪ceiling=[2,2,2,2,2,2]).cardinality()
43
sage: IntegerListsLex(0, min_length=0, max_length=7, floor=[1,1,0,0,1,0],
↪ceiling=[4,3,2,3,2,2,1]).first()
[]
sage: IntegerListsLex(0, min_length=1, max_length=7, floor=[0,1,0,0,1,0],
↪ceiling=[4,3,2,3,2,2,1]).first()
[0]
sage: IntegerListsLex(0, min_length=1, max_length=7, floor=[1,1,0,0,1,0],
↪ceiling=[4,3,2,3,2,2,1]).cardinality()
0
```

(continues on next page)

(continued from previous page)

```

sage: IntegerListsLex(2, min_length=0, max_length=7, floor=[1,1,0,0,0,0],
↳ceiling=[4,3,2,3,2,2,1]).first() # Was [1,1], due to slightly different specs
[2]
sage: IntegerListsLex(1, min_length=1, max_length=7, floor=[1,1,0,0,0,0],
↳ceiling=[4,3,2,3,2,2,1]).first()
[1]
sage: IntegerListsLex(1, min_length=2, max_length=7, floor=[1,1,0,0,0,0],
↳ceiling=[4,3,2,3,2,2,1]).cardinality()
0
sage: IntegerListsLex(2, min_length=5, max_length=7, floor=[1,1,0,0,0,0],
↳ceiling=[4,3,2,3,2,2,1]).first()
[1, 1, 0, 0, 0]
sage: IntegerListsLex(2, min_length=5, max_length=7, floor=[1,1,0,0,0,1],
↳ceiling=[4,3,2,3,2,2,1]).first()
[1, 1, 0, 0, 0]
sage: IntegerListsLex(2, min_length=5, max_length=7, floor=[1,1,0,0,1,0],
↳ceiling=[4,3,2,3,2,2,1]).cardinality()
0

sage: IntegerListsLex(4, min_length=3, max_length=6, floor=[2, 1, 2, 1, 1, 1],
↳ceiling=[3, 1, 2, 3, 2, 2]).cardinality()
0
sage: IntegerListsLex(5, min_length=3, max_length=6, floor=[2, 1, 2, 1, 1, 1],
↳ceiling=[3, 1, 2, 3, 2, 2]).first()
[2, 1, 2]
sage: IntegerListsLex(6, min_length=3, max_length=6, floor=[2, 1, 2, 1, 1, 1],
↳ceiling=[3, 1, 2, 3, 2, 2]).first()
[3, 1, 2]
sage: IntegerListsLex(12, min_length=3, max_length=6, floor=[2, 1, 2, 1, 1, 1],
↳ceiling=[3, 1, 2, 3, 2, 2]).first()
[3, 1, 2, 3, 2, 1]
sage: IntegerListsLex(13, min_length=3, max_length=6, floor=[2, 1, 2, 1, 1, 1],
↳ceiling=[3, 1, 2, 3, 2, 2]).first()
[3, 1, 2, 3, 2, 2]
sage: IntegerListsLex(14, min_length=3, max_length=6, floor=[2, 1, 2, 1, 1, 1],
↳ceiling=[3, 1, 2, 3, 2, 2]).cardinality()
0

```

This used to hang (see comment 389 and fix in `Envelope.__init__()`):

```

sage: IntegerListsLex(7, max_part=0, ceiling=lambda i:i, check=False).list()
[]

```

backend_class

alias of `IntegerListsBackend_invlex`

class `sage.combinat.integer_lists.invlex.IntegerListsLexIter(backend)`

Bases: `object`

Iterator class for `IntegerListsLex`.

Let T be the prefix tree of all lists of nonnegative integers that satisfy all constraints except possibly for `min_length` and `min_sum`; let the children of a list be sorted decreasingly according to their last part.

The iterator is based on a depth-first search exploration of a subtree of this tree, trying to cut branches that do not

contain a valid list. Each call of `next` iterates through the nodes of this tree until it finds a valid list to return.

Here are the attributes describing the current state of the iterator, and their invariants:

- `backend` – the `IntegerListsBackend` object this is iterating on;
- `_current_list` – the list corresponding to the current node of the tree;
- `_j` – the index of the last element of `_current_list`: `self._j == len(self._current_list) - 1`;
- `_current_sum` – the sum of the parts of `_current_list`;
- `_search_ranges` – a list of same length as `_current_list`: the range for each part.

Furthermore, we assume that there is no obvious contradiction in the constraints:

- `self.backend.min_length <= self.backend.max_length`;
- `self.backend.min_slope <= self.backend.max_slope` unless `self.backend.min_length <= 1`.

Along this iteration, `next` switches between the following states:

- LOOKAHEAD: determine whether the current list could be a prefix of a valid list;
- PUSH: go deeper into the prefix tree by appending the largest possible part to the current list;
- ME: check whether the current list is valid and if yes return it
- DECREASE: decrease the last part;
- POP: pop the last part of the current list;
- STOP: the iteration is finished.

The attribute `_next_state` contains the next state `next` should enter in.

5.1.122 Counting, generating, and manipulating non-negative integer matrices

Counting, generating, and manipulating non-negative integer matrices with prescribed row sums and column sums.

AUTHORS:

- Franco Saliola

class `sage.combinat.integer_matrices.IntegerMatrices`(*row_sums*, *column_sums*)

Bases: `sage.structure.unique_representation.UniqueRepresentation`, `sage.structure.parent.Parent`

The class of non-negative integer matrices with prescribed row sums and column sums.

An *integer matrix* m with column sums $c := (c_1, \dots, c_k)$ and row sums $l := (l_1, \dots, l_n)$ where $c_1 + \dots + c_k$ is equal to $l_1 + \dots + l_n$, is a $n \times k$ matrix $m = (m_{i,j})$ such that $m_{1,j} + \dots + m_{n,j} = c_j$, for all j and $m_{i,1} + \dots + m_{i,k} = l_i$, for all i .

EXAMPLES:

There are 6 integer matrices with row sums `[3, 2, 2]` and column sums `[2, 5]`:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
sage: IM.list()
[
```

(continues on next page)

(continued from previous page)

```
[2 1] [1 2] [1 2] [0 3] [0 3] [0 3]
[0 2] [1 1] [0 2] [2 0] [1 1] [0 2]
[0 2], [0 2], [1 1], [0 2], [1 1], [2 0]
]
sage: IM.cardinality()
6
```

cardinality()

The number of integer matrices with the prescribed row sums and columns sums.

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IntegerMatrices([2,5], [3,2,2]).cardinality()
6
sage: IntegerMatrices([1,1,1,1,1], [1,1,1,1,1]).cardinality()
120
sage: IntegerMatrices([2,2,2,2], [2,2,2,2]).cardinality()
282
sage: IntegerMatrices([4], [3]).cardinality()
0
sage: len(IntegerMatrices([0,0], [0]).list())
1
```

This method computes the cardinality using symmetric functions. Below are the same examples, but computed by generating the actual matrices:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: len(IntegerMatrices([2,5], [3,2,2]).list())
6
sage: len(IntegerMatrices([1,1,1,1,1], [1,1,1,1,1]).list())
120
sage: len(IntegerMatrices([2,2,2,2], [2,2,2,2]).list())
282
sage: len(IntegerMatrices([4], [3]).list())
0
sage: len(IntegerMatrices([0], [0]).list())
1
```

column_sums()

The column sums of the integer matrices in self.

OUTPUT:

- Composition

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5])
sage: IM.column_sums()
[2, 5]
```

row_sums()

The row sums of the integer matrices in self.

OUTPUT:

- Composition

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5])
sage: IM.row_sums()
[3, 2, 2]
```

to_composition(*x*)

The composition corresponding to the integer matrix.

This is the composition obtained by reading the entries of the matrix from left to right along each row, and reading the rows from top to bottom, ignore zeros.

INPUT:

- *x* – matrix

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
sage: IM.list()
[
 [2 1] [1 2] [1 2] [0 3] [0 3] [0 3]
 [0 2] [1 1] [0 2] [2 0] [1 1] [0 2]
